Instead of going to Italy as he intended, Lessing accepted, in 1770, the office of librarian at Wolfenbüttel, a post which was offered to him by the hereditary prince of Brunswick. In this position he passed his remaining years. For a time he was not unhappy, but by and by he was rendered miserable by his inability to pay the debts which he had contracted in Hamburg. He missed, too, the society of his friends, and his health, which had hitherto been excellent, gradually gave way. In 1775 he travelled for nine months in Italy with Prince Leopold of Brunswick; and in the following year he married Eva König, the widow of a Hamburg merchant, with whom he had been on terms of intimate friendship. She was in every way worthy of Lessing, and their correspondence during his lonely years in Wolfenbüttel forms one of the most attractive elements of his biography. Their happiness in each other was perfect, but it lasted only for a brief period; in 1778 she died in childbed. After her death Lessing found one of his chief sources of consolation in the love of his four step-children, to whom he was tenderly attached.

Meanwhile he had extended his fame by several important writings. Soon after settling in Wolfenbüttel he found in the library an ancient manuscript, which proved to be a treatise of Berengarius of Tours on transubstantiation in reply to Lanfranc. Lessing was thus induced to write an essay on Berengarius, vindicating his character as a serious and consistent thinker. The essay was much admired by the leading theologians of Germany, and it is, on the whole, the ablest and most interesting of his *Rettungen*. In 1771 he published his *Zerstreute Anmerkungen über das Epigramm, und einige der vornehmsten Epigrammatisten*—a work which Herder described as "itself an epigram." Lessing's theory of the origin of the epigram is somewhat fanciful, but no other critic has offered so many pregnant hints as to the laws of epigrammatic verse, or defended with so much force and ingenuity the character of Martial. In 1772 lovers of the drama were delighted by the appearance of *Emilia Galotti*, a tragedy which he had begun many years before in Leipsic. The subject was suggested by the Roman legend of Virginia, but the scene is laid in an Italian court, and the whole play is conceived in accordance with the modern spirit. Its defect is that its tragic conclusion does not seem to be absolutely inevitable, but there is high imaginative power in the character of the prince of Guastalla and in that of Marinelli, his chamberlain, who weaves the intrigue from which Emilia escapes by death. The diction of *Emilia Galotti* is at once refined and vigorous, and there are scenes in which some of the deepest passions of human nature are sounded with perfect art. Having completed *Emilia Galotti*, Lessing occupied himself for some years almost exclusively with the treasures of the Wolfenbüttel library. The results of his researches (some of them of high value) he embodied in a series of volumes, *Zur Geschichte und Literatur*, the first being issued in 1773, the last in the year of his death.

The concluding period of Lessing's life was devoted chiefly to theological controversy. Reimarus, professor of Oriental languages in Hamburg, who commanded general respect as a scholar and thinker, wrote a book entitled *Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes*. The standpoint of Reimarus was that of the English deists, and he investigated, without hesitation, the evidence for the miracles recorded in the Bible. The manuscript of this work, after the author's death in 1767, was entrusted by his daughter, Elise Reimarus, to Lessing, who published extracts from it in his *Zur Geschichte und Literatur*, in 1774–78. These extracts, the authorship of which was not publicly avowed, were known as the "Wolfenbüttel Fragments." They created profound excitement among orthodox theologians, and evoked many replies, in which Lessing was bitterly condemned for having issued writings of so dangerous a tendency. Lessing delighted at all times in the stir of combat, and prepared to offer a full and vigorous defence. His most formidable assailant was Pastor Goeze, of Hamburg, a sincere and earnest theologian, but utterly unscrupulous in his choice of weapons against an opponent. To him, therefore, Lessing addressed his most elaborate answers,—*Eine Parabel*, *Axiomata*, eleven letters with the title *Anti-Goeze*, and two pamphlets in reply to an inquiry by Goeze as to what Lessing meant by Christianity. These papers are not only full of thought and learning; they are written with a grace, vivacity, and energy that make them hardly less interesting to-day than they were to Lessing's contemporaries. He does not undertake to defend the conclusions of Reimarus; his immediate object is to claim the right of free criticism in regard even to the highest subjecte of human thought. The argument on which he chiefly relies is that the Bible cannot be considered necessary to a belief in Christianity, since Christianity was a living and conquering power before the New Testament in its present form was recognized by the church. The true evidence for what is essential in Christianity, he contends, is its adaptation to the wants of human nature; hence the religious spirit is undisturbed by the speculations and researches of the boldest thinkers. The effect of this controversy was to secure wider freedom for writers on theology, and to suggest new problems regarding the growth of Christianity, the formation of the canon, and the essence of religion. On one subject, the origin of the gospels, Lessing poured a flood of fresh light in a treatise, published after his death, presenting "A New Hypothesis concerning the Evangelists, regarded as merely human writers." The Brunswick Government having, in deference to the consistory, confiscated the "Fragments" and ordered Lessing to discontinue the controversy, he resolved, as he wrote to Elise Reimarus, to "try whether they would let him preach undisturbed from his old pulpit, the stage." In *Nathan der Weise*, written in the winter of 1778–79, he gave poetic form to the ideas which he had already developed in prose. Its governing conception is that noble character may be associated with the most diverse creeds, and that there can, therefore, be no good reason why the holders of one set of religious principles should not tolerate those who maintain wholly different doctrines. This element of *Nathan der Weise* receives so much attention from its critics that many of them overlook the high artistic qualities of the work. As a play it has serious imperfections, but as a dramatic poem it is one of the finest creations of the 18th century. The characters possess true vitality, and several passages (including, of course, the famous passage setting forth the parable of the three rings) have both the depth and the spontaneity which are the unmistakable notes of genius. In 1780 appeared *Die Erziehung des Menschengeschlechts*, the first half of which he had published in 1777 with one of the "Fragments." This work, composed of a hundred brief paragraphs, was the last, and is, perhaps, the most suggestive, of Lessing's writings. The doctrine on which its argument is based is that no dogmatic creed can be regarded as final, but that every historical religion has played a great part in the development of the spiritual life of mankind. Lessing also maintains that history reveals a definite law of progress, and that occasional retrogression may be necessary for the advance of the world towards its ultimate goal. These ideas afterwards became familiar, but they offered a striking contrast to the principles both of orthodox and of sceptical writers in Lessing's day, and gave a wholly new direction to religious philosophy. Another work of Lessing's last years, *Ernst und Falk* (a series of five dialogues, of which the first three were published in 1777, the last two in 1780), also indicated in a fascinating style many new points of view. Its nominal subject is freemasonry, but its real aim is to plead for a humane and charitable spirit in opposition to a narrow patriotism, an extravagant respect for rank, and exclusive devotion to any particular church.

Lessing's theological opinions exposed him to much petty persecution, and he was in almost constant straits for money. Nothing, however, broke his manly and generous spirit. To the end he was always ready to help those who appealed to him for aid, and he devoted himself with growing ardour to the search for truth. He formed many new plans of work, but in the course of 1780 it became evident to his friends that he would not be able much longer to continue his labours. His health had been undermined by excessive work and anxiety, and after a short illness he died at Brunswick on the 22d of January 1781.

He was rather above the middle height, and during the greater part of his life maintained an appearance of vigour and elasticity. Luther himself was not of a more fearless and independent character. In an age when men of letters were fond of grouping themselves in sects and coteries, Lessing pursued his own way, unmoved by clamour, and indifferent to popular favour. Yet no man was ever more warmly loved by friends, and he had the satisfaction of knowing that the younger generation of writers looked up to him with confidence and reverence. Jacobi wished for many years to make his acquaintance, but was deterred from addressing him, as he explained to Lessing, by a profound consciousness of the difference between himself and one whom he regarded as "a king among minds." "We lose much, much in him," wrote Goethe after Lessing's death, "more than we think." It may be questioned whether there is any other writer to whom the Germans owe a deeper debt of gratitude. He was succeeded by poets and philosophers who for a time gave Germany the first place in the intellectual life of the world, and it was Lessing, as they themselves acknowledged, who prepared the way for their achievements. Without attaching himself to any particular system of philosophical doctrine, he fought incessantly against error, and in regard to art, poetry, the drama, and religion, suggested ideas which kindled the enthusiasm of aspiring minds, and stimulated their highest energies. While his work was thus effective in its own day, it has lost little of its value for later ages. His great dramas have imaginative qualities which appeal to every generation, and an unfading charm is conferred on his critical and theological writings by the power and classical purity of his style.

The first edition of his collected works appeared, in 30 vols., in 1771–94. A critical edition by Lachmann, in 13 vols., was issued in 1838–40, and this edition was revised, with additions, by Maltzahn in 1853–57. In 1868–77 Lessing's works, edited by several competent scholars, were published in 20 vols. by Hempel, and there is an illustrated edition in 8 vols. (Grote, 1875–76). See *Lessing's Leben*, 1793, by Karl G. Lessing (his brother); Danzel, *G. E. Lessing, sein Leben und seine Werke*, 1850 (completed by Guhrauer, 1853–54); Stahr, *G. E. Lessing, sein Leben und seine Werke*, 1859; H. Duntzer, *Lessing's Leben*, 1882; and in English, J. Sime, *Lessing*, 1877, and H. Zimmern, *Gotthold Ephraim Lessing*, 1878. (J. SI.)

L'ESTRANGE, SIR ROGER (1616-1704), an indefatigable pamphleteer on the royalist and court side during the Restoration epoch, but principally remarkable as the first English man of letters of any distinction who made journalism a profession, was born at Hunstanton in Norfolk, December 17, 1616. In 1644, during the civil war, he headed a conspiracy to seize the town of Lynn for the king, under circumstances which led to his being condemned to death as a spy. The sentence, however, was not executed, and after four years' imprisonment in Newgate he escaped to the Continent. He was excluded from the Act of Indemnity, but in 1653 was pardoned by Cromwell upon his personal solicitation, and lived quietly until the Restoration, when after some delay his services and sufferings were acknowledged by his appointment as licenser of the press. This office was administered by him in th spirit which might be expected from a zealous cavalier. He made himself notorious, not merely by the severity of his literary censorship, but by his vigilance in the suppression of clandestine printing. The inconsistency of this course with his actions and professions when himself opposed to the party in power naturally aggravated the unpopularity inevitably attaching to his office. Few men have been more heartily abused than L'Estrange, and it is undoubtedly true that the rights of free speaking and printing, the indispensable conditions of civil and religious liberty, have seldom had a more determined or more dangerous opponent. At the same time there is no ground for questioning his integrity, and he was probably no more intolerant than any similar official of any Government in that day, inspired by an equal strength of conviction, would have been in his place. The representation of him in Grant's *History of the Newspaper Press* as a mere political hireling is entirely contrary to truth. He was a militant loyalist, who used the pen as he had been wont to use the sword, and proved his zeal for his party by the production of a mass of pamphlet literature, above the ordinary standard of the time in ability, and quite on a par with it in virulence and coarseness. These productions still possess an historical value, but their titles are not worth enumerating here. His memory is more honourably preserved by his connexion as an author with the journalism which as a licenser he laboured to cripple and emasculate. In 1663 he commenced the publication of *The Public Intelligencer and the News*, succeeded in February 1665 by *The London Gazette*, not to be confounded with the official journal still existing, which appeared for the first time at the close of that year, and was at first printed at Oxford. In 1679 he established *The Observator*, a journal specially designed to vindicate the court from the charge of a secret inclination to popery. This line of political controversy, and it may be hoped some natural humanity and good sense as well, obliged him to discredit the Popish Plot, and he manfully resisted the delusion by which many wiser and better men were carried away. The suspicion he thus incurred was increased by the conversion of his daughter to Romanism, but there seems no reason to question the sincerity of his own attachment to the Church of England. In 1687 he gave a further proof of independence by discontinuing *The Observator* from his unwillingness to advocate James II.'s Edict of Toleration, although he had previously gone all lengths in support of the measures of the court. The Revolution cost him his office as licenser, and the remainder of his life was spent in obscurity. He died in 1704. L'Estrange's place is rather in history than in literature. The importance of the part he played as licenser would be more exactly known if it could be more accurately ascertained how much literature he may have been the means of suppressing. The post he held so long was in itself an unmitigated mischief, but at the same time an evil which men of all parties, with the rare exception of men so far in advance of their time as Milton, then deemed necessary; and no obloquy should attach to L'Estrange for having discharged its functions with zeal and efficiency. As a pamphleteer he is but slightly above mediocrity, and he labours under a special imputation of having contributed to corrupt his native language. The same charge is brought against journalists in all ages, and there are obvious reasons why it should be true to a certain extent. The practice of daily writing for the press is undoubtedly one of the numerous forces which tend to wear down and degrade a language, but it also keeps the diction of the cultivated classes in contact with the speech of the people, and prevents the absolute divorce between them which seems to have existed in ancient times. It is to L'Estrange's credit that among the agitations of a busy political life he should have found time for much purely literary work as a translator of Josephus, Cicero, Seneca, Quevedo, and other standard authors. (R. G.)

LESUEUR, JEAN FRANÇOIS (1763–1837), was born near Abbeville in 1763, and studied music under Roze at the college of Amiens. Appointed choirmaster of a church in Paris in 1784, he completed his musical education under Sacchini. In 1786 Lesueur obtained by open competition the musical directorship of Notre-Dame, where he gave successful performances of sacred music with a full orchestra. This place he resigned in 1788; and, after a retirement of five years in a friend's country house, he produced *La Caverne* and two other operas at the theatre Feydeau in Paris. At the foundation of the Paris Conservatoire (1795) Lesueur was appointed one of its inspectors of studies, but was dismissed in 1802, owing to his disagreements with Mehul. On the recommendation of Paisiello, Lesueur succeeded this celebrated composer as *Maestro di cappella* to Napoleon, and produced (1804) his *Ossian* at the Opera. He also composed for the emperor's coronation a mass and a Te Deum. Louis XVIII., who had retained Lesueur in his court, appointed him (1818) professor of composition at the Conservatoire; and at this institution he had, among many other pupils, Hector Berlioz, Ambroise Thomas, Besozzi, and Gounod. He died October 6, 1837. Lesueur composed eight operas and several masses, and other sacred music. All his works are written in a style of rigorous simplicity; and to this may be ascribed their want of popularity at the present time.

LETHE (λήθη, oblivion) is sometimes used as the name of a river in the infernal regions. It seems to have been an idea current in the religion of the mysteries that there were in the lower world two streams, one of memory and one of oblivion. The initiated were taught to distinguish between them, and directions for this purpose written on a gold plate have been found in a tomb at Petilia, buried doubtless with some initiated person. So beside Lebadea, at the oracle of Trophonius, which was counted an entrance to the lower world, the two springs Mnemosyne and Lethe were shown. This thought begins to appear in literature in the end of the 5th century B.C., when Aristophanes (*Frogs*, 186) speaks of the plain of Lethe. Plato (*Rep.*, x.) embodies the idea in one of his finest myths of the future life. It is difficult to find any passage in the earlier writers showing acquaintance with this idea. Hesiod makes Lethe one of the children of Eris, along with Toil, Hunger, Pains, &c.; but his meaning probably is that ingratitude and forgetfulness spring from strife. In the epitaph on Anacreon attributed to Simonides, but reckoned by Bergk spurious, the expression Λήθης δόμοι occurs; but even if the epigram be an early one it is not certain that the words have any mythological sense.

LETRONNE, JEAN ANTOINE (1787–1848), French archæologist, was born at Paris on January 2, 1787. His father, a poor engraver, having chosen the profession of an artist for him, sent him to the studio of David, but his own tastes drew him towards literature, and he became a student in the Collége de France, where it is said he used to exercise his already strongly developed faculty of critical divination by correcting for his own amusement old and bad texts of Greek authors, afterwards comparing the results he had thus obtained with the latest and most approved editions. From 1810 to 1812 he travelled in France, Switzerland, and Italy, and on his return to Paris published an *Essai critique sur la topographie de Syracuse* (1812), designed to elucidate Thucydides; two years later appeared his *Recherches géographiques et critiques* on the *De Mensura Orbis Terræ* of Dicuil, along with a restored text. In 1815 he was appointed by Government to complete the translation of Strabo (1805-1819) which had been begun by Laporte-Dutheil, and in March 1816 he was one of those who were admitted to the Academy of Inscriptions by royal ordinance, having previously contributed a *Mémoire*, "On the Metrical System of the Egyptians," which had been crowned. Further promotion came rapidly; in 1817 he was appointed director of the École des Chartes, in 1819 inspector-general of the university, and in 1831 professor of history in the Collège de France. This chair he exchanged in 1838 for that of archæology, and in 1840 he succeeded Daunou as keeper of the national archives. Meanwhile he had published, among other works, *Considérations générales sur l'évaluation des monnaies grecques et romaines et sur la valeur de l'or et de l'argent avant la découverte de l'Amérique* (1817), *Recherches pour servir à l'histoire d'Égypte pendant la domination des Grecs et des Romains* (1823), and *Sur l'origine Grecque des zodiaques prétendus égyptiens* (1837); by the last-named he finally exploded a fallacy which had up to that time vitiated the chronology of contemporary Egyptologists. His *Diplomes et chartres de l'époque Mérovingienne sur papyrus et sur velin* were published in 1844. The most important work of Letronne is the *Recueil des inscriptions grecques et latines de l'Égypte*, of which the first volume appeared in 1842, and the second in 1848. He died at Paris on December 14, 1848.

LETTRES DE CACHET are really *lettres closes*, that is, letters sealed in such a way that they cannot be opened without breaking the seal, and which were originally always addressed to individuals, in contradistinction to *lettres patentes*, or letters patent, beginning "know all men by these presents." Lettres closes interfering with the administration of justice or the liberty of the subject were forbidden by numerous edicts in the 14th, 15th, and 16th centuries, and the term lettres de cachet, as synonymous with lettres closes, is first found in the ordinance of Orleans in 1560. The convenience of such a means to consign one's enemies to prison was seen by Richelieu and Mazarin, who followed the Guise Government in using them frequently, despite numerous protestations on the part of the parlements, of which the most notable was when in 1648 an ordinance was registered that no man should be kept in prison three days without interrogation. When once Louis XIV. had begun to rule, he made frequent use of lettres de cachet both for state purposes and to control and disorganize his nobility, and he boldly justified their use in an edict of 1705. But the most marked justification is to be found in the circular letter addressed to the parlements of France in reply to protests against arbitrary imprisonment in 1759, in which the king says that "he reserves arbitrary orders—in other words, lettres de cachet —for occasions wherein they may be necessary for the public good and the interests of families." In this remark he distinguishes between the two purposes for which such letters were granted. He first alleges state reasons why he should have power to arrest arbitrarily—a power no one would deny to the executive on occasions of emergency, if used under proper restrictions. Secondly, he says that they are issued in the interest of families, and here he touches the great source of their injustice and unpopularity. It was the custom for the king to sign a number of blank lettres de cachet which his ministers gave away to whoever they pleased. Thus they often fell into hands of people who used them to gratify private hate; fathers obtained them and inserted the names of their sons, wives inserted the names of their husbands, opera dancers those of lovers who had spurned them. The evil grew to such a height that Turgot and Lamoignon de Malesherbes refused to enter the ministry of Louis XVI. unless they might see the contents of the orders they countersigned, and see the causes for which men were to be imprisoned. It is needless to say that when the cahiers of the primary assemblies were prepared, to instruct the deputies to the states-general in the wishes of their constituents, abolition of lettres de cachet was demanded in almost all the cahiers of the noblesse and tiers état. The subject was mentioned in the early debates of the Constituent Assembly, but lettres de cachet were not formally abolished till January 15, 1790, and on March 13 of the same year all imprisoned under them were ordered to be set at liberty. The great authority for the history and injustice of lettres de cachet is Mirabeau's *Enquiries concerning Lettres de Cachet and State Prisons*, written in the dungeon at Vincennes into which his father had thrown him by a lettre de cachet. It is one of the ablest and most eloquent of his works, had an immense circulation, and was translated into English with a dedication to the duke of Norfolk in 1788. See also Mercier's *Tableaux de Paris* (ed. 1783), vol. vii. chap. 588, and numerous stories in Linguet's *Bastille*, and especially in the *Bastille dévoilée* (1790).

LEUCADIA. See SANTA MAURA.

LEUCIPPUS, the founder of Atomism in Greek philosophy, flourished about the middle or latter half of the 5th century B.C. Almost nothing is known of his life. His birthplace is variously given as Elea, Abdera, or Miletus. It is disputed whether he left any writings. Empedocles of Agrigentum and Anaxagoras of Clazomenæ were his contemporaries, while Zeno the Eleatic is said to have been his teacher. As pupil and associate he had Democritus of Abdera, beside whose greater fame his own work has been thrown into the background. Thus Epicurus would not look upon him as a philosopher at all; Lucretius ignored him; and he is barely mentioned by Lange, the modern historian of materialism. But the references of Aristotle, as well as of later authorities, leave no doubt that the leading principles of the Atomic theory are due to him. He eluded the Eleatic criticism of plurality and motion by postulating the reality of that which is not, the empty or space. Empty space and atoms are, he held, the ultimate constituents of all things. The former is infinite in magnitude; the latter are infinite in number, indivisible, and with only quantitative differences amongst one another. Nor is there any such thing as qualitative change; but all growth and decay are merely the compounding and separation of atoms. The atoms are always in activity or motion, and all things happen of necessity. Worlds, infinite in number, are produced by the atoms, variously shaped and of different weight, falling in empty space and giving rise to an eddying motion by their mutual impact. In this way worlds are being for ever produced and again destroyed. In the notices of Leucippus handed down to us there are additional traces of a cosmology, differing slightly from that of Democritus, and of a psychology which identified the soul with spherical atoms, and explained sensation and thought by a change brought about in it mechanically through the entrance of external images. The further development of the Atomic philosophy was the work of Democritus.

LEUK, or LOÈCHE LA VILLE, a village of Switzerland, at the head of a district in the canton of Valais, 15 miles by rail east of Sion, on the right bank of the Rhone. The population has increased from 1220 in 1870 to 1411 in 1880. About 5 miles to the north, in the valley of the Dala, at a height of 4642 feet above the sea, and overshadowed by the immense cliffs of the Gemmi, lie the Baths of Leuk, Leukenbad, or Loèche-les-Bains, a place of only 650 permanent inhabitants, but largely frequented during its brief summer season by French, Swiss, and Italian visitors, attracted by the hot mineral springs. These springs are twenty-two in number, and vary considerably in chemical composition and temperature. The hottest and strongest is the Lorenz spring, the water of which, registering 124° Fahr., has to be allowed to cool over night before it is used. The patients remain for hours up to their necks in the bath, talking, reading, and otherwise amusing themselves in the most sociable style. Most of the hotels are open only from June to September. The little village has several times been destroyed by avalanches (1518, 1719, 1758), and a strong embankment has been erected on the eastern side to protect it from similar catastrophes.

LEUTSCHAU (Hungarian, *Löcse*; Latin, *Leutsovia*; Slovakian, *Levocza*), capital of the Cis-Tisian county of Szepes, Hungary, and until 1876 a royal free town, lies in an elevated position surrounded by mountains, and near the railway from Kassa (Kaschau) to Oderberg, about 120 miles north-east from Budapest, in 49° 1′ N. lat., 20° 35′ E. long. Leutschau is the seat of the county administration, and of a royal court of law, and has many fine old buildings, of which the most interesting is the church of St James, a Gothic structure of the 13th century, with richly carved altar, several monuments, and a celebrated organ erected in 1623, and long reputed the largest in Hungary. The educational establishments comprise a royal upper gymnasium (founded 1520), a state upper real school (1868), a collegiate institute for girls, and a Minorite convent. The soil of the surrounding country is generally stony and sandy, and the climate from October to April severe, but the inhabitants nevertheless succeed in raising barley, wheat, oats, flax, and a large quantity of garden produce, especially beans and pease, which are considered the best in Hungary. Other sources of occupation are mining, foresting, horse, sheep, and cattle breeding, bee-keeping, and the preparation of wax, honey, and mead, for which last the town has long been noted. The number of beehives in 1881 was seven hundred. In December 1881 the population was 6900, mostly Germans and Slovaks by nationality, and Roman Catholics and Lutherans by creed.

Founded by Saxon colonists in 1245, Leutschau had by the early part of the 16th century attained a position of great relative importance. In 1599 a conflagration laid the greater part of the town in ashes, and during the 17th century it suffered repeatedly at the hands of the Transylvanian princes and leaders. In 1849, at the time of the revolutionary war, nearly half the houses were destroyed by fire.

LEVEN, ALEXANDER LESLIE, EARL OF, one of the most distinguished soldiers of his time, was born about the close of the 16th century. He was descended from a younger son of the ancient Scottish family of Balquhain. His father was George Leslie of Balgonie, commander of the castle of Blair, and his mother was Anne, daughter of Stewart of Ballechin. At his first outset in life he acted as a volunteer in Lord Vere's regiment in Holland, fighting with the Dutch against the encroachments of Spain, where he rose to the rank of captain. He then entered the service of Gustavus Adolphus of Sweden, and became field-marshal. In 1628, when the town of Stralsund was besieged by Wallenstein, and reduced almost to the last extremity, the king of Sweden sent Leslie to take the command of the garrison, and he acted with such resolution that he obliged the count to raise the siege. For this service medals were struck in his honour. In 1630 he drove the imperialists out of the island of Rügen, and continued to serve with great distinction in the Swedish armies till the troubles in Scotland brought him home. In 1639 he was invited by the Covenanters to take the command of their army. One of his first exploits was to take the castle of Edinburgh by surprise, without the loss of a man. He commanded the Scottish army at Dunse Law in May of that year, and in 1640 he invaded England, and defeated a party of the king's troops at Newburn, which gave him possession of Newcastle and other towns. At the treaty with the king at Ripon, Leslie was one of the commissioners of the parliament, and Charles was so well pleased with his behaviour that he created him Lord Balgonie and Earl of Leven, by patent dated 1641.

After suppressing an insurrection in Ireland in 1642, he was in 1643 appointed to the command of the Scottish army sent to assist the parliamentary party against King Charles, but after the execution of that prince he warmly espoused the cause of his son, and served as a volunteer against Cromwell at the unfortunate battle of Dunbar in 1650. Next year, however, a gathering at Alyth of Angus royalists, of whom Leslie was one, was surprised and captured by the troops of General Monk, who was then besieging Dundee. The earl with some others was sent to London and confined in the Tower, where he remained incarcerated for some time, till by the intercession of the queen of Sweden he obtained his liberty. After visiting the queen, and thanking her in person for this service, he retired to his seat at Balgonie in Fifeshire and died there at an advanced age in 1661. He is said to have been of a diminutive size, and deformed in person, but prudent, vigilant, and expert in war. He acquired considerable landed property, particularly Inchmartin in the Carse of Gowrie, which he called Inchleslie. His granddaughter married George, earl of Melville; their descendant, the present representative of the title (1882), is twelfth earl of Leven and ninth earl of Melville.

LEVER, CHARLES, novelist, was born at Dublin on the 31st of August 1806 (not 1809 as usually stated), and died at Trieste on the 1st of June 1872. The accounts of the earlier part of his life are, considering the time at which he lived, singularly meagre, confused, and conflicting. His father was an architect, and he entered Trinity College, Dublin, in 1822, taking his degree in 1827. Many of the adventures of college life recorded in *Charles O'Malley* are believed to have actually happened. Later, Lever studied at Göttingen, and obtained a degree there. At some time or other before 1832 (for in this unsatisfactory way most of the facts of this part of his life are recorded) he is said to have visited America, and to have sojourned with the Indians, adopting their dress and mode of life, and going through adventures afterwards utilized in *Con Cregan* and *Arthur O'Leary*. But it is impossible to be certain as to this period; it is only towards the cholera outbreak of 1832 that something like a firm ground offers itself to the biographer. Lever had taken up the profession of medicine, and he was appointed, first to a district of which the headquarters was Kilrush in Galway, where *Harry Lorrequer* was begun, local stories being largely embodied in it, and then to a district in Ulster, around Coleraine and Newtown Limavady, where material was gathered for *Charles O'Malley* and the *Knight of Gwynne*. He married Miss Kate Baker, but even here the mist of uncertainty which envelops him exists, and it is not clear what the real date of the marriage was. After his cholera work was done he proceeded to Brussels. It has been usual to represent him as physician to the embassy, and even Thackeray (who knew him well) has given currency to the description by a quotation in the *Book of Snobs*. But it is certain that Lever was never formally appointed physician to the embassy, though he had letters of introduction to the secretary of the English legation there, and unquestionably practised. *Harry Lorrequer* was completed at Brussels, and it began to be published in 1837. It was followed by *Charles O'Malley* and *Jack Hinton*. All these stories, but especially the first two, were made up to a great extent of experiences through which Lever had gone, or stories which he had heard in Ireland, and of the reminiscences and oddities of English residents at Brussels, where there were then many retired English officers who had gone through the Peninsular and other campaigns of the great war. It is said in particular that Major Monsoon was almost a photograph of a well-known living character at the time, and much the same thing has been asserted of other personages. This piecing together of scraps accounts for the incoherency and absence of plot in the earlier books—defects which were increased by the author's habit of composing them in fragments, and revising them for the press with the utmost carelessness. The abundance and variety of his materials, however, his skill as a *raconteur*, and the fresh and almost boisterous good humour which blew through all his work, made him very popular, and he found a congenial illustrator in H. K. Browne. After a time proposals were made to him to undertake the editorship of the *Dublin University Magazine*, which he accepted, and held the post from 1842 to 1845. During this time his income was considerable, amounting, according to his biographer, to fully three thousand a year. He lived not in Dublin but a little way out of it, and exercised boundless hospitality to visitors. Besides this, he was an inveterate card player, and not on the whole a lucky one, and he was very fond of horses, which he kept in large numbers for himself and all his family. He was indefatigable in novel writing, *Tom Burke*, *The O'Donoghue*, *The Knight of Gwynne*, &c, following those already named. But the work of editing was irksome to him, and for the reasons just named residence in Ireland made it comparatively unprofitable. He therefore resigned his editorship in the year 1845, and went abroad, where he was always more at home than in England or even in Ireland. At first he lived at Carlsruhe, where G. P. R. James was also residing; then he pitched his tent in a castle of Tyrol, which is said to be pretty accurately described in *A Day's Ride*. Afterwards he wandered about, finally settling at Florence. This neighbourhood became specially agreeable to him, uniting as it did abundant society with the possibility of enjoying it without great expense. In November 1858 he received from Lord Derby one of the rare pieces of patronage which have fallen in modern days to the share of Englishmen of letters, by being appointed consul at Spezzia. During this period of wandering or settled life on the Continent, he changed his style of novel writing. His method was, as has been hinted already, always one rather of observation and reproduction than of deliberate creation, and as he had formerly drawn on the humours of Irish life, or the oddities of Wellington's veterans, so now he dealt with those of travelling Britons abroad, and with similar subjects. *The Daltons*, *The Dodd Family Abroad*, *Davenport Dunn*, &c., belong to this time and family for the most part, though some of them rather fall under the earlier class in style and date of composition. *One of Them*, *Barrington*, *The Fortunes of Glencore*, &c., led up to the most singular of all Lever's books, *A Day's Ride, a Life's Romance*. This book, which was published in *All the Year Round*, was said at the time—with what truth it is not easy to say—to have positively lowered the sale of that publication, yet it contains some of Lever's best work, and displays an originality not common with him. The mixture of burlesque and sentiment was, it may be supposed, either uncongenial or incomprehensible to the ordinary reader.

As he grew older, Lever, whose politics had been a rather indefinite Toryism, became more of a party man, and showed this in the papers published in *Blackwood's Magazine*, under the name of "Cornelius O'Dowd," papers of a miscellaneous kind, but often political. He is said to have thought of engaging, or to have been invited to engage, in regular journalism, but wisely declined. In 1867 he was transferred from Spezzia to Trieste, a change pecuniarily advantageous, but involving the loss of the society which he passionately loved. The last years of Lever's life were somewhat clouded. His health had never been good, and he had not lived carefully. His wife, to whom he was much attached, died before him. But he was still active with his pen, and the novels of his last period, if less lively than his earlier ones, are far better written as well as far more regular and careful in construction. Such are *Sir Brooke Fosbrooke*, *That Boy of Norcott's*, *Sir Jasper Carew*, *The Bramleighs of Bishop's Folly*, and his last book, *Lord Kilgobbin*. He died, as has been said, in the summer of 1872. Novels not yet mentioned are *Roland Cashel*, *Luttrell of Arran*, *Tony Butler*, *Maurice Tiernay*, *the Martins of Cro' Martin*, *St Patrick's Eve*, &c.

Lever deserves an honourable place among the secondary novelists of the 19th century, but it is not very probable that any single novel of his will have a long lease of popularity. He is one of the authors who do not take the trouble to learn the mechanism of their art until the heyday of their imaginative force is past. The defects of his earlier works have been already indicated. They are written with almost inconceivable carelessness, the same incidents occurring over and over again, and the chronology being altogether bewildering. This is especially the case with *Charles O'Malley*, which, however, owing to the liveliness of its adventures and the personage of Mickey Free the Irish servant, is still perhaps the most popular of all. With young and uncritical readers this popularity is likely to be maintained until some supplanter in the same kind arises, or until the state of manners and society becomes too obsolete for anything more than historical interest. Then Lever, like all writers whose formal excellence is not sufficient to save them, will be forgotten; for his later work, though almost always amusing and sometimes more, has little abiding interest. The sole authority for Lever's biography is the *Life* by Dr W. J. Fitzgerald (London, 1879). (G. SA.)

LEVERRIER, Urbain Jean Joseph (1811–1877), one of the greatest astronomers of modern times, was born at St Lô in Normandy, March 11, 1811. His father, who held a small post under Government, made great efforts to send him to Paris, where a brilliant examination gained him, in 1831, admittance to the École Polytechnique. The distinction of his career there was rewarded with a free choice amongst the departments of the public service open to pupils of the school. He selected the administration of tobaccos, addressing himself especially to chemical researches under the guidance of Gay-Lussac, and gave striking proof of ability in two papers on the combinations of phosphorus with hydrogen and oxygen, published in *Annales de Chimie et de Physique* (1835 and 1837). His astronomical vocation, like that of Kepler, came from without. The place of teacher of that science at the École Polytechnique falling vacant in 1837, it was offered to and accepted by Leverrier, who, "docile to circumstance," instantly abandoned chemistry, and directed the whole of his powers to celestial mechanics. The first fruits of his arduous labours were contained in two memoirs presented to the Academy, September 16 and October 14, 1839. Pursuing the investigations of Laplace, he demonstrated with greater rigour the stability of the solar system, and calculated the limits within which the eccentricities and inclinations of the planetary orbits vary. This remarkable début excited much attention, and, on the recommendation of Arago, he took in hand the theory of Mercury, producing, in 1843, tables of that planet far superior in accuracy to those hitherto available. The perturbations of the comets discovered, the one by Faye in November 1843, the other by De Vico a year later, were minutely investigated by Leverrier, with the result of disproving the supposed identity of the first with Lexell's lost comet of 1770, and of the other with Tycho's of 1585. On the other hand, he made it appear all but certain that Vico's comet was the same with one seen by Lahire in 1678.

He was once more, by the summons of Arago, recalled to planetary studies, and this time it was to Uranus that his attention was directed. Step by step, with sagacious and patient accuracy, he advanced to the great discovery which has immortalized his name. Carefully sifting all the known causes of disturbance, he showed that one hitherto unknown must be added to their number, and on the 23d of September 1846 the planet Neptune was discerned by Gallè at Berlin, within one degree of the spot indicated by Leverrier. See ASTRONOMY, p. 813.

This memorable achievement was greeted with an outburst of public enthusiasm, and requited with a shower of public distinctions. Academies vied with each other in enrolling Leverrier among their members; the Royal Society awarded him the Copley medal; the king of Denmark sent him the order of the Dannebrog; he was named officer in the Legion of Honour, and preceptor to the Comte de Paris; a chair of astronomy was created for his benefit at the Faculty of Sciences; he was appointed adjunct astronomer to the Bureau of Longitudes. Returned to the Legislative Assembly in 1849 by his native department of Manche, he voted with the anti-republican party, but devoted his principal attention to subjects connected with science and education. After the *coup d'état* he became a senator and inspector-general of superior instruction, sat upon the commission for the reform of the École Polytechnique (1854), and, on January 30, 1854, succeeded Arago as director of the Paris observatory. His official work in the latter capacity would alone have strained the energies of an ordinary man. The institution had fallen into a state of lamentable inefficiency. Leverrier placed it on a totally new footing, freed it from the control of the Bureau of Longitudes, and raised it to its due rank among the observatories of Europe. He did not, however, escape the common lot of reformers. His uncompromising measures and unconciliatory manner of enforcing them raised a storm only appeased by his removal, February 5, 1870. Three years later, on the death of his successor Delaunay, he was reinstated by M. Thiers, but with authority restricted by the supervision of a council. In the midst of these disquietudes, he executed with unflinching resolution a task the gigantic proportions of which cannot be contemplated without amazement. This was nothing less than the complete revision of the planetary theories, together with a laborious comparison of results with the most authentic observations, and the construction of tables representing the movements thus corrected. It required all his indomitable perseverance to carry through to the end a purpose which failing health continually menaced with frustration. He had, however, the happiness of living long enough to perfect his work. Three weeks after he had affixed his signature to the printed sheets of the theory of Neptune he died at Paris, in his sixty-seventh year, September 23, 1877. By his marriage with Mademoiselle Choquet, who survived him little more than a month, he left a son and daughter.

The discovery with which the memory of this great man is popularly identified was only an incident in his career. The elaboration of the scheme of the heavens traced out by Laplace in the *Mécanique Céleste* was its larger aim, for the accomplishment of which forty years of unremitting industry barely sufficed. The work once done, however, may almost be said to have been done for all time, from the extraordinary care with which errors were guarded against, and imperfections in the data allowed for. The organization of the meteorological service in France is entirely due to Leverrier, and the present system of international weather-warnings is the realization of a design which he warmly promoted. He founded the Association Scientifique, and was active in introducing a practical scientific element into public education. His inference of the existence, between Mercury and the sun, of an appreciable quantity of circulating matter (*Comptes Rendus*, 1859, ii. p. 379), though unquestionably sound, has not yet been satisfactorily verified by observation. He was twice, in 1868 and 1876, the recipient of the gold medal of the Royal Astronomical Society, London, and the university of Cambridge conferred upon him, in 1875, the honorary degree of LL.D. All his planetary tables have been adopted by the *Nautical Almanac*, as well as by the *Connaissance des Temps*.

The *Annales de l'Observatoire de Paris*, the publication of which was set on foot by Leverrier, contain, in vols. i.–vi. (*Mémoires*), 1855–61, and x.–xiv., 1874–77, his theories and tables of the several planets. In vol. i. will be found, besides his masterly report on the observatory, a general theory of secular inequalities, in which the development of the disturbing function is carried to a point hitherto unattempted. The memoirs and papers communicated by him to the Academy have been summarized in *Comptes Rendus*, 1839–76, and the more important published in full either separately, or in the *Conn. des Temps* and the *Journal des Mathématiques*. That entitled *Développemens sur différents points de la Théorie des perturbations*, 1841, has been translated in part xviii. of Taylor's *Scientific Memoirs*. For his scientific work see Professor Adams's address, *Monthly Notices*, vol. xxxvi. p. 232, and M. Tisserand's review in *Ann. de l'Obs.*, tom. xv., 1880; for a notice of his life, M. Bertrand's "Éloge Historique," *Mém. de l'Ac. des Sciences*, tom. xli., 2me série. (A. M. C.)

LEVIS, formerly POINTE LEVI or POINT LEVIS, the chief town of a county of the same name in Canada, on the other side of the St Lawrence from Quebec, with which it communicates by a ferry. In the beginning of the present century Pointe Levi was a cluster of white houses, with a church and a number of large mills; it has now become an important station on the Grand Trunk Railway, and in the extent of its river trade is surpassed by only a few places in the Dominion. In 1881 the population was 7597.

LEVITES (לְוִיִּם), or sons of Levi (בְּנֵי לֵוִי), are defined according to the usual methods of Hebrew genealogical history as the descendants of Levi, the third son of Jacob by Leah (Gen. xxix. 34).[1] But in Hebrew genealogies we are not necessarily entitled to look upon the eponymus of a tribe as more than an ideal personality, and, without entering into the large question how far the patriarchal history may be held to furnish exceptions to this rule, it may be observed that the only narrative in which, on a literal interpretation, Levi appears as a person (Gen. xxxiv.) bears internal evidence of the intention of the author to delineate under the form of personification events in the history of the tribes of Levi and Simeon which must have taken place after the sojourn of Israel in Egypt.[2] The same events are alluded to in Gen. xlix. 5–7, where Simeon and Levi are plainly spoken of as communities with a communal assembly (קָהָל). They were allied tribes or brothers; their onslaught on the Shechemites was condemned by the rest of Israel; it took place before the Hebrews had passed from pastoral to settled life (ver. 5, "instruments of violence are their shepherds' staves"); and its results were disastrous to the actors, when their cause was disavowed by their brethren. The Bnê Hamor regained possession of Shechem, as we know from Judges ix., and both the assailing tribes were scattered through Israel, and failed to secure an independent territorial position. The details of this curious portion of the earliest Hebrew history must remain obscure; the narrative in Gen. xxxiv. does not really place them in so clear a light as the briefer reference in Gen. xlix.; for the former chapter has been recast and largely added to by a late writer, who looks upon the action of the brethren in the light of the priestly legislation, and judges it much more favourably than is done in Gen. xlix. In post-canonical Judaism the favourable view of the zeal of Levi and Simeon becomes still more dominant (Judith ix. 2 *sq.*; *B. Jubil.*, chap. xxx.;

[1] In Gen. xxix. 34 the name of Levi is connected with נִלְוָה, "attach oneself to." The form, however, is that of a gentile noun, and it is most probably a *nisbeh* from Leah, as suggested by Wellhausen. See also Stade in *Z. f. ATliche Wissenschaft*, i. 115.

[2] Jacob in verse 30 is not a personal but a collective idea, for he says, "I am a few men," and the capture and total destruction of a considerable city is in the nature of things the work of two tribes rather than of two individuals.

and especially Theodotus, *ap.* Polyhistor, in Müller's *Fragmenta*, iii. 217 *sq.*), and the curse of Jacob on the ferocity of his sons is quite forgotten.[1] In the oldest history, however, the treachery of Levi and Simeon towards a community which had received the right of *connubium* with Israel is represented as a crime, which imperilled the position of the Hebrews and was fatal to the future of the tribes directly involved.

But while the Levites were scattered throughout Israel their name does not disappear from the roll of the tribes. In the Blessing of Moses (Deut. xxxiii.), where Simeon is passed over, Levi still appears, not as a territorial tribe but as the collective name for the priesthood. The priesthood meant is that of the northern kingdom under the dynasty of Jehu, to which the chapter in question belongs; and in fact we know that the priests of the important northern sanctuary of Dan traced their origin to a Levite (Jud. xvii. 9), Jonathan the son of Gershom, the son of Moses (Jud. xviii. 30).[2] That the Judæan priesthood were also known as Levites in the later times of the kingdom appears from the book of Deuteromony, especially from x. 8 *sq.*, xviii. 1 *sq.*; and we learn from Ezek. xliv. 10 *sq.* that the Judæan Levites were not confined to the service of the temple, but included the priests of the local high places abolished by Josiah. Alike in Judah and in the north the priestly prerogative of Levi was traced back to the days of Moses (Deut. x. 8, xxxiii. 8); but in later times at least the Judæan priesthood did not acknowledge the Levitical status of their northern colleagues (1 Kings xii. 31). It must, however, be observed that the prophets Amos and Hosea never speak of the northern priesthood as illegitimate, and Hosea iv. certainly implies the opposite. Presumably it was only after the fall of Samaria, and the introduction of large foreign elements into the population of the north, that the southern priests began to disavow the ministers of the sanctuaries of Samaria, most of whom can no longer have been representatives of the old priesthood as it existed before the northern captivity (2 Kings xvii. 28, comp. Amos vii. 17, Jud. xviii. 30, 2 Kings xxiii. 20, in contrast with verses 8 *sq.*).

In the most developed form of the hierarchical system the ministers of the sanctuary are divided into two grades. All are regarded as Levites by descent, but the mass of the Levites are mere subordinate ministers not entitled to approach the altar or perform any strictly priestly function, and the true priesthood is confined to the descendants of Aaron. In the documents which reveal to us the actual state of the priesthood in the northern and southern kingdoms before the exile, there is no trace of this distinction. Every Levite is a priest, or at least is qualified to become such (Deut. x. 8. xviii. 7). The subordinate and menial offices of the tabernacle are not assigned to members of a holy guild; in Jerusalem at least they were mainly discharged by members of the royal body-guard (the Carians and footmen, 2 Kings xi. 4, *Heb.*), or by bond slaves, the ancestors of the later Nethinim,—in either case by men who might even be uncircumcised foreigners (Ezek. xliv. 7 *sq.*). A Levitical priest was a legitimate priest; when the author of 1 Kings xii. 31 wishes to represent Jeroboam's priests as illegal he contents himself with saying that they were not taken from the sons of Levi. The first historical trace of a modification of this state of things is found in connexion with the suppression of the local high places by Josiah, when their priests were brought to Jerusalem and received their support from the temple offerings, but were not permitted to minister at the altar (2 Kings xxiii. 9). The priests of the temple, the sons of Zadok, were not prepared to concede to their provincial brethren all the privileges which Deut. xviii. had proposed in compensation for the loss of their local ministry. Ezekiel, after the fall of the temple, in planning a scheme of ritual for the new temple, raises this practical exclusion from the altar to the rank of a principle. In the new temple the Levites who had ministered before the local altars shall be punished by exclusion from proper priestly work, and shall fill the subordinate offices of the sanctuary in place of the foreigners who had hitherto occupied them, but shall not be permitted to pollute Jehovah's house in future by their presence (Ezek. xliv. 7 *sq.*). After the exile this principle was actually carried out; priests and Levites are distinguished in the list of the Jews who returned under the decree of Cyrus (Ezra ii.; Neh. vii.); but the former, that is, the descendants of the pre-exilic priests of the royal temple, greatly outnumber the Levites or descendants of the priests of the high places. At this time other classes of temple servants, the singers, the porters, the Nethinim or slaves of the sanctuary, and the children of Solomon's slaves, whose hereditary service would, on Eastern principles, give them a pre-eminence over other slaves of the sanctuary, are also still distinguished from the Levites; but these distinctions lost their significance when the word Levite itself came to mean a subordinate minister. In the time of Nehemiah, Levites and singers, Levites and porters, are very much run into one (Neh. xi., xii., xiii.), and ultimately the absorption of the other classes of subordinate ministers into the hereditary guild of Levites is formally expressed in the shape of genealogies, deriving the singers, and even families whose heathenish and foreign names show them to have originally belonged to the Nethinim, from the ancient stock of Levi.[3]

The new hierarchical system found its legal basis in the Pentateuch, or rather in the so-called priestly legislation, first publicly accepted as an integral part of the Torah under Ezra and Nehemiah. Here the exclusion of the Levites from all share in the proper priesthood of the sons of Aaron is precisely formulated (Num. iii. *sq.*); their service is regulated from the point of view that they are essentially the servants and hereditary serfs of the priests (iii. 9), while, on the other hand, they are recognized as possessing a higher grade of holiness than the mass of the people, and are endowed with the tithes, of which in turn they pay a tithe to the priests (Num. xviii. 21 *sq.*). These regulations as to tithes were enforced by Nehemiah; but the subordinate position of the Levites was hardly consistent with their permanent enjoyment of revenues of such importance, and we learn from the Talmud that they were finally transferred to the priests.[4] Another provision of the law, viz., the assignation to the Levites of certain cities with a definite measure of inalienable pasture ground (Num. xxxv.; Lev. xxv. 34), was apparently never put in force after the exile.

As the priestly legislation carried its ordinances back into the time of Moses (see PENTATEUCH), so the later developments of the Levitical service as they existed in the time of the Chronicler about the close of the 4th century

[1] According to Wellhausen's analysis (*Jahrb. f. D. Theol.*, xxi. 435 *sq.*), the old narrative consisted of Gen. xxxiv. 3, 7*, 11, 12, 19, 25*, 26*, 30, 31, the asterisk denoting that only parts of the verses marked by it are ancient. The latest and most satisfactory discussion is that of Kuenen (*Theol. Tijdsch.*, xiv. 257 *sq.*), in which the opposite view of Dillmann (*Genesis, ad l.*) is fully refuted.

[2] It is generally agreed that Moses (משה) is the true reading. The later Jews corrected the name to Manasseh by inserting the letter נ, but did not venture to do so except above the line (מנשה), so that the reading of the archetype can still be restored.

[3] See the details, and the proof that the later Levites included men whose actual ancestry belonged to other tribes, in Ewald's *Geschichte*, iii. 380; Wellhausen, *Geschichte*, i. 152, 229; Graf in Merx's *Archiv*, i. 231.

[4] See Mishna, *Maaser Sheni*, chap. v. end, and the *Jerusalem Gemara* (iii. 259 of Schwab's translation); *Yebamoth*, f. 86a; Carpzov, *App. ad Godw.*, p. 624; and Hottinger, *De Dec.*, vi. 8. ix. 17.

B.C. are referred by that author to David (1 Chron. xv., xvi., xxiii.) or to Hezekiah (2 Chron. xxix.) and Josiah (2 Chron. xxxv.). The chief point is the development of the musical service of the temple, which has no place in the Pentateuch, but afterwards came to be of the first importance, as we see from the Psalter, and attracted the special attention of Greek observers (Theophrastus, *ap.* Porph., *De Abstin.*, ii. 26).

While it is not difficult to trace the history of the Levites from the time of the Blessing of Moses and Deuteronomy downwards, the links connecting the priestly tribe with the earlier fortunes of the tribe of Levi are hardly to be determined with any certainty.

According to the traditional view the scheme of the Levitical legislation, with its double hierarchy of priests and Levites, is of Mosaic ordinance. But there are many proofs that in the Pentateuch, as we possess it, divergent ordinances, dating from very different ages, are all carried back by means of a legal convention to the time of the wilderness journey. And, if the complete hierarchical theory as it existed after the exile was really the work of Moses, it is inexplicable that all trace of it was so completely lost in the time of the monarchy, that Ezekiel speaks of the degradation of the non-Zadokite Levites as a new thing and as a punishment for their share in the sin of the high places, and that no clear evidence of the existence of a distinction between priests and Levites has been found in any Hebrew writing demonstrably earlier than the exile.[1] It is indeed argued that the narrative of the rebellion of Korah, and the list of Levitical cities in Josh. xxi., imply that the precepts of the post-exile law were practically recognized by Moses and Joshua; but it is certain that the distribution spoken of in Josh. xxi. did not take place at the time of the conquest, because many of the cities named were either not occupied by the Hebrews till long afterwards, or, if conquered, were not held by Levites. The Levitical cities of Joshua are indeed largely identical with ancient holy cities (Hebron, Shechem, Mahanaim, &c.); but in ancient Israel a holy city was one which possessed a noted sanctuary (often of Canaanite origin), not one the inhabitants of which belonged to the holy tribe. These sanctuaries had of course their local priesthoods, which in the time of the monarchy were all called Levitical; and it is only in this sense, not in that of the priestly legislation, that a town like Shechem can ever have been Levitical. So again the narrative of Korah proves on critical examination to be of composite origin; the parts of it which represent Korah as a common Levite in rebellion against the priesthood of Aaron belong to a late date, and the original form of the history knows nothing of the later hierarchical system.[2]

We are thus compelled to give up the idea of carrying back the distinction of Levites and Aaronites in the later sense to the time of Moses, and are excluded from using the priestly parts of the Pentateuch and Joshua as a source for the earliest history of the tribe. It still, however, remains certain that under the monarchy the priestly consecration of Levi was referred to the time of Moses, who was himself a member of the tribe, and in Deut. x. 8 the functions of Levi are specially connected with the Mosaic sanctuary of the ark. Now we know from 1 Sam. ii. 27 *sq.* that the priests of the ark in the period of the Judges claimed descent from the family of Moses; and the case of Micah's Levite shows that a descendant of Moses was regarded as a peculiarly fit priest. The whole evidence conspires to show that from the time of Moses downward his kin had a certain hereditary prerogative in connexion with the worship of Jehovah. In the earliest times the ritual of Jehovah's sanctuary had not attained such a development as to occupy a whole tribe; but if, as appears probable, the mass of the tribe of Levi was almost annihilated in the first age after Moses, the name of Levite might very well continue to be known only in connexion with those of the tribe who traced kin with Moses or remained by the sanctuary. The multiplication of Hebrew holy places was effected partly by syncretism with the Canaanites, partly in other ways that had nothing to do with the Mosaic sanctuary, and so a variety of priestly guilds arose which certainly cannot have been all of Levitical descent. But, as the nation was consolidated and a uniform system of sacred law, referred to Moses as its originator, came to be administered all over the land, in the hands of the ministers of the greater sanctuaries, the various guilds must have been drawn together and have aimed at forming such a united body as we find described in Deut. xxxiii.; and this unity would find a natural expression in the extension of the name of Levites to all priesthoods recognized by the state. If this was the course of things we can hardly suppose that the term came into large use till the Israelites were consolidated under the monarchy, and in fact the integrity of the text in 1 Sam. vi. 15, 2 Sam. xv. 24, as well as 1 Kings viii. 4, is open to question. Up to the time of David and Jeroboam, as appears from the cases of Samuel, Zadok, Eleazar (1 Sam. vii. 1), and the sons of David (2 Sam. viii. 18), as well as from 1 Kings xii. 31, the priesthood was not essentially hereditary; but, like all occupations that required traditional knowledge, it must have tended to become more and more so, so that all priests would appear as Levites by adoption if not by descent. Wellhausen (*Gesch.*, i. 139) has argued from Deut. xxxiii. 9 that the northern priesthood was not an hereditary guild, but involved the surrender of all family connexion; the words, however, are more naturally understood as praise of the judicial impartiality which refused to be influenced by family ties. Our data are too scanty to clear up the details of this interesting piece of history; but it can hardly be doubted that the development of a consolidated and hereditary priestly corporation in all the sanctuaries was closely bound up with the unification of the state and the absorption of tribal organization in the monarchy. The reaction of tribal feeling against the central government, of which there are many traces in the history of Ephraim, has perhaps its counterpart in the opposition to the unified priesthood which is alluded to in Deut. xxxiii. 11.

There have been many attempts on the part of recent writers from the time of Vatke downwards to deny that Levi was one of the original tribes of Israel, but they all break down before the testimony of Gen. xlix. See especially Kuenen's refutation of the theory of Land, *Theol. Tijdsch.*, 1872, p. 628 *sq.*; and for the latest aspects of the whole subject Graf in Merx's *Archiv*, vol. i (1869), "Zur Geschichte des Stammes Levi"; Wellhausen, *Gesch.*, i. p. 123 *sq.*; Stade, *Gesch. d. V. Israels*, p. 152 *sq.* (W. R. S.)

LEVITICUS. See PENTATEUCH.

LEW-CHEW ISLANDS. The Lew-chew, Loochoo, Liu Kiu, or Riu Kiu Islands[3] include, in the wider application of the name, the whole series extending in a north-east and south-west direction from the southern end of Kiushiu in Japan proper to the north-east of Formosa. Within the northern group lies the intersection of 130° E. long. and 30° N. lat.; and in the southern group that of 125° E. long. and 25° N. lat. The islands, however, to the north of 29° are not unfrequently considered, by Europeans as well as Japanese, to belong in part to Japan proper, and in part to constitute the separate group of the Linschotens, Shichi-to, or Cecille Archipelago.

The following, according to Doederlein, are the recognized subdivisions and areas of the whole archipelago:—(1) *The Northern Islands* (attached to Satsuma or Kiushiu Osumi, 398 square miles): Tanega (189 square miles), Make, Yakuno (172 square miles), Take, Yuo or Iwoga, Kuro, Kose or Kowose, and Kuchino-Erabu or Nagarobe; (2) *Shichi-to* (43 square miles): Kuchino, Gaza or Yebi, Naka-no (the largest, 13 square miles), Hira or Fira, Suwase, Akuseki, Takara, and Yoko; (3) *Hokubu-Shoto* (515 square miles): Oshima (302 square miles), Kageruma or Katona (40 square miles), Yoro, Uke or Uru, Kitai, Tokono or Kakirouma (92 square miles), Naka Erabu, and Yoron or Yori; (4) *Chubu-Shoto* (592 square miles): Tori or Iwo, Eheya or Tebeya, Isona, Iye, Awakuni or Agunyeh, Tonashi, Kume, Kerama or Amakirima, and Okinawa (520 square miles); (5) *Nambu-Shoto* or the Meiakoshima Group (315 square miles): Miyako or Ty-pin-san (57 square miles), Misuna and Tarama, Ishigaki or Pat-chung-san (104 square miles), Taketoma or Robertson Island, Ohama or Kubah, Kuro or Baugh, Iriomoto Nishiomoto or Koo-Kien-San, Aragusuku or Chung-chi, Hateruma or Hasyokan, Yonakuni or Kumi.

The area of the Lew-chews proper is thus 1423 square miles, that of the whole chain 1864 square miles. The largest islands are Okinawa (often called Great Lew-chew) and Oshima, the former being also the political centre of the whole archipelago. The Lew-chews consist in the main of crystalline rocks—gneiss, hornblende, and granite—upheaved at a very remote date, and only partially covered by severely weathered sedimentary strata seldom left in their original horizontal position. Coralline limestone is found in great abundance even on the tops of the hills, and the coasts are often fringed by coral reefs. In

[1] The recent defence of the traditional view by S. I. Curtiss (*The Levitical Priests*, 1877) still seeks such evidence in 1 Kings viii. 4. But there are many evidences that the text of this part of Kings has undergone considerable editing at a pretty late date. The LXX. translators did not read the clause which speaks of "priests and Levites," and the Chronicler read "the Levite priests,"—the phrase characteristic of the Deuteronomic identification of priestly and Levitical ministry.

[2] See the latest researches of Kuenen, *Theol. Tijdsch.*, xii. 139 *sq.*, where other recent discussions of the chapter are cited and examined.

[3] See a curious history of the name in Li Ting Yuen's Journal.

Okinawa a soft argillaceous rock occupies a large part of the surface. Though the existence of Sulphur Island with its smoking crater towards the north-west shows that volcanic activity is still going on at no great distance, the main islands at least seem to bear no trace of recent subterranean disturbance. Their surface is very irregular: Okinawa consists for the most part of a succession of rounded swelling hills, 300 to 500 feet in height, broken towards the centre by more precipitous crags, and Oshima may be best described as a cluster of steep mountains reaching in Yowangatake a height of about 2100 feet. Of the many streams a few attain considerable dimensions, and serve to carry the timber from the highlands; and all round the coasts are excellent harbours. The mildness and humidity of climate, which is the natural consequence of the geographical position of the archipelago, is further enhanced by the neighbourhood of the Kuro-Siwo or Pacific gulf-stream. Snow never falls on the tops even of the highest hills; but at the same time even in summer the heat is seldom extreme. Three days seldom pass without rain; sudden downpours are not unfrequent, and wet weather often lasts for several days on end. The boundary between the Palæoarctic and Oriental regions passes to the north of Oshima, which is the northern limit of many southern forms at once of vegetable and animal life both on land and sea. Sago trees and other *Cycadaceæ*, banyans, and pine trees (resembling the cedar of Lebanon) are abundant, and the natives, who succeed well both as farmers and as gardeners, grow wheat, rice, bananas, tarro (*Colocasia*), sweet potatoes, maize, millet, sugar-cane, egg-plants, &c. There is a small but excellent breed of cattle (usually black); and ponies, pigs, goats, and poultry are kept.

Part of the population of the northern Lew-chews is evidently Japanese, but the aboriginal and preponderating element is of quite another type, in some points similar to the Ainos. The striking features, according to Doederlein, are a comparatively narrow face ending in a pointed chin, large European-looking eyes, thin lips, thin and rather convex nose, strongly developed beard, and a luxuriant growth of hair over breast, arms, and legs. The women are (or were, for the practice is forbidden by the Japanese) accustomed to tattoo the back of the hands with a special pattern in a dark blue colour. Though closely allied to Japanese, the native language is a genuinely independent form, containing obsolete words only found in the ancient monuments of Japanese literature, and showing the greatest resemblance to the Satsuma dialect. The use of Japanese and Chinese by the learned has prevented it being used for literary purposes; and the version of the Bible prepared by the missionary Dr Bettelheim (sent out in 1845) is really in Japanese. There was neither printing press nor bookshop in the islands as late as 1876 (see G. W. Aston in *Church Miss. Intell.*, 1879). The lowest class of the population have neither civil rights nor personal freedom; next in order come the peasants, who rent the land from the Government; and above all are the literati or governing class. Rank is indicated by various symbols, particularly by the kind of metal of which the hair-pins are made, and by the colour of the robes and head-dress. Confucianism and Buddhism seem to have had considerable influence on the upper classes at least in Okinawa; in Oshima there is neither temple nor priest, and the people say they pray to no god. The sole objects of worship (if worship it be) are the manes of one's immediate ancestors. To the dead great respect is shown in both islands,—the wealthier people building on the hillsides large and handsome tombs, which from a distance look like dwelling-houses. The body is buried in a coffin in a sitting posture, and after seven years the bones are collected and placed in an urn.

The population of Okinawa was estimated by the American expedition at from 150,000 to 200,000. Doederlein was informed by the officials that Amami Oshima contained 50,000 souls, but thinks 30,000 a more probable conjecture. Besides Napa or Napa-Kiang the capital, and Shui the royal residence, there are some thirty-six towns in Okinawa, with about 6000 inhabitants each; in the other island Nase the chief town (comprising Itsubemura and Kanekumura) has not more than 2000, and only five or six of the other villages exceed 500.

Though Captain Broughton visited Napa in 1797, it was not till the Alceste and Lyra expedition in 1816–17 that detailed information about the Lew-chews was obtained. The people at that time showed a curious mixture of courtesy and shyness. Her British Majesty's ship "Sphinx" visited Okinawa in 1852; and the American expedition under Commodore Perry (1852–54) added very largely to our knowledge of the island, and concluded a treaty of friendship with its Government, securing for the United States the right of using Tamui near Napa as a coaling depôt.

Theen-sun, "Grandson of Heaven," is the mythical founder of the Lew-chew monarchy. Towards the close of the 12th century, his descendants were driven from the throne by a usurper Le-yung; but the old national party soon found a victorious leader in Sun-thien-ong son of Tametomo, a member of the famous Yoritomo family, who, having been expelled from Japan, had come to Lew-chew and married the youngest sister of Ansoo, governor of Oho-prto. The introduction of the arts of reading and writing are assigned to Sun-thien-ong's reign. Chinese invasions of Lew-chew may be traced back to the 6th century, but they did not result in annexation; and it was Hung-woo, the founder of the Ming dynasty, who first in 1395 obtained from the Lew-chew ruler recognition of Chinese supremacy. The earliest notice of intercourse with Japan belongs to the year 1441, when a voluntary gift of copper money (at that time extremely scarce in Japan) was made by the Lew-chewans to the tenno Go-Hanazono; but for a long time afterwards the relations of the two powers continued to be of the friendliest description. In the beginning of the 17th century the Lew-chew minister Yana, anxious to gain favour with the Chinese Government, persuaded his king to break off all connexion with Japan, and when the prince of Satsuma sent to remonstrate against this course of conduct his envoys were maltreated. For this insult the prince exacted signal vengeance. With the permission of his liege lord he invaded the islands with 8000 men, took the capital by storm, and captured the king and carried him off to Kagoshima. A few years later the unfortunate Seang-leng was restored to his throne, but only on condition that he and his successors should receive reinvestiture on the accession of each new shogun, and that each new king of Lew-chew should send an embassy to Yedo. The Lew-chewans nevertheless continued to pay tribute to China, and Chinese commissioners were despatched to attend the installation of their kings. Particular interest in the islands was displayed by the emperor Kang-hi, whose memory is still cherished by the natives as that of a great benefactor; he built them a temple in honour of Confucius, founded a Chinese school, and, when they were in great distress through hurricanes, plague, and famine, contributed liberally for their relief. Su-pao-Koang, from whose report was derived the first information about the islands which found its way to Europe, was Kang-hi's commissioner in the year 1719. When in 1859 the house of Seang became extinct in the direct line, Sho-tai, a descendant of Satto, governor of Urasoyé, was called to the throne. On the establishment of the imperial authority of the mikado he received the title of sovereign prince of Lew-chew; but at the same time his territory was declared first a *han* or feudal dependency and afterwards a *ken* or province of the Japanese monarchy. In 1873, according to a custom with which the lords of Satsuma had not interfered, the people of Lew-chew sent to pay their biennial tribute to China. This was forbidden by the mikado; and it was in vain that they urged—"For five hundred years China has protected us: we regard China as our father, and Japan as our mother." The Japanese Government insisted on its exclusive rights, and undertook to settle the difficulty with China. Its claims were formally recognized by the treaty of Peking in 1874, and the islands are treated as an integral part of the empire.

See Gaubil's extracts from Su-pao-Koang in *Lettres édifiantes*, vol. xxiii.; Klaproth in *Mémoires rel. à l'Asie*, vol. ii.; Hervey de Saint Denys's translation of Ma-twan-lin's *Encyclopædia*; Basil Hall, *Voy. of Dis. to the West Coast of Corea and the Great Loochoo Island*, London, 1818; John M'Leod, *Voy. of H.M.S. LEWES, a market-town and parliamentary borough, and the county town of Sussex, England, is situated on the river Ouse, at the junction of a number of railway lines, 50 miles south of London, and 7 north of Newhaven, which is its port. It occupies the slope of one of the chalk hills, and consists principally of one main street with smaller and narrower ones at right angles. St Michael's church, restored in 1878, is without architectural merit, but possesses some old brasses and monuments; St Anne's church is a very ancient structure in the Early English style; St Thomas at-Cliffe, in the Perpendicular style, was erected in the 15th century; St John's, Southover, is of mixed architecture, but preserves some specimens of Early Norman. There are only slight remains of the old castle, occupying a picturesque situation on the height, and supposed to have been founded by Alfred and rebuilt by William de Warren. In the grounds of the old Cluniac priory of St Pancras, founded in 1078, the leaden coffins of William de Warren and Gundrada were dug up during an excavation in 1845. There is a free grammar school dating from 1512, and among the other public buildings are the county-hall, the prison, and the Fitzroy memorial library. The industries include the manufacture of agricultural implements, brewing, tanning, and iron and brass founding. The population of the urban sanitary district in 1871 was 6010, and in 1881 it was 6017, the population of the parliamentary borough (area 1087 acres) in the same years being 10,753 and 11,199. Lewes was incorporated by royal charter in 1881.

From various discoveries that have been made of Roman coins, and the traces that still remain of old mounds and tumuli, the town is believed to be of very ancient origin. It was a royal demesne of the South Saxon kings. Mints were established at it by Athelstan, which were in operation till the reign of Harold. At the battle of Lewes, May 13, 1264, Simon de Montfort defeated Henry III. From the time of Edward I. until 1868 the town returned two members to parliament, but now it returns only one.

See, besides the histories of Sussex, Horsfield, *History of Lewes*, 2 vols., 1824–27, and several interesting papers in the Sussex *Archæological Collection*.

LEWES, George Henry (1817–1878), a prolific and versatile writer, born in London in 1817, was a grandson of Charles Lee Lewes, a comedian who had a considerable reputation in his day. He was educated in London, Jersey, and Brittany, and began active life by attempting business and afterwards medicine. Later he appears to have had serious thoughts of making the stage his profession. He finally fixed his choice on a literary career. His early writings belong mainly to the lighter departments of letters. He contributed a large number of critical studies to the leading quarterly and other reviews. These discuss a wide variety of subject, and, though often characterized by hasty impulse and imperfect study, betray a singularly acute critical judgment, which has been enlightened by philosophic study. Of these critical writings the most valuable are those on the drama, which were afterwards republished under the title *Actors and Acting* (1875). With this may be taken the volume on *The Spanish Drama* (1846). The combination of wide scholarship, philosophic culture, and practical acquaintance with the theatre gives these essays a high place among the best efforts in English dramatic criticism. In 1845–1846 he published *The Biographical History of Philosophy*, an attempt to depict the life of philosophers as an ever-renewed fruitless labour to attain the unattainable. In 1847–1848 he made two attempts in the field of fiction—*Ranthrope*, and *Rose, Blanche, and Violet*—which, though displaying considerable skill both in plot, construction, and in characterization, have taken no permanent place in literature. The same is to be said of an ingenious attempt to rehabilitate Robespierre (1849). The culmination of the author's work in prose literature is the *Life of Goethe* (1855), probably the best known of his writings. Lewes's many-sidedness of mind, and his combination of scientific with literary tastes, eminently fitted him to appreciate the large nature and the wide-ranging activity of the German poet. The high position this work has taken in Germany itself, notwithstanding the boldness of its criticism and the unpopularity of some of its views (*e.g.*, on the relation of the second to the first part of *Faust*), is a sufficient testimony to its general excellence. From about 1853 Lewes's writings show that he was occupying himself with scientific and more particularly biological work. He may be said to have always manifested a distinctly scientific bent in his writings, and his closer devotion to science was but the following out of early impulses. Considering the author's want of the usual course of technical training, these studies are a remarkable testimony to the penetration of his intellect. The most important of these essays are collected in the volumes *Seaside Studies* (1858), *Physiology of Common Life* (1859), *Studies in Animal Life* (1862), and *Aristotle, a Chapter from the History of Science* (1864). They are much more than popular expositions of accepted scientific truths. They contain able criticisms of authorized ideas, and embody the results of individual research and individual reflexion. He struck out a number of impressive suggestions, some of which have since been accepted by physiologists at home and abroad. Of these the most valuable is that now known as the doctrine of the functional indifference of the nerves—that what are known as the specific energies of the optic, auditory, and other nerves are simply differences in their mode of action due to the differences of the peripheral structures or sense-organs with which they are connected. This idea has since been independently arrived at by Wundt (*Physiologische Psychologie*, 2d ed., p 321). In 1865, on the starting of the *Fortnightly Review*, Lewes became its editor, but he retained the post for less than two years. This date marks the transition from more strictly scientific to philosophic work. He had from early youth cherished a strong liking for philosophic studies; one of his earliest essays was an appreciative account of Hegel's *Æsthetics*. Coming under the influence of positivism as unfolded both in Comte's own works and in J. S. Mill's *System of Logic*, he abandoned all faith in the possibility of metaphysic, and recorded this abandonment in the above-mentioned *History of Philosophy*. Yet he did not at any time give an unqualified adhesion to Comte's teaching, and with wider reading and reflexion his mind moved away further from the positivist's standpoint. In the preface to the third edition of his *History of Philosophy* he avowed a change in this direction, and this movement is still more plainly discernible in subsequent editions of the work. The final outcome of this intellectual progress is given to us in *The Problems of Life and Mind*, which may be regarded as the crowning work of his life. His sudden death in 1878 cut short the work, yet it is complete enough to allow us to judge of the author's matured conceptions on biological, psychological, and metaphysical problems.

The first two volumes on *The Foundations of a Creed* lay down what he regarded as the true principles of philosophizing. He here seeks to effect a *rapprochement* between metaphysic and science. He is still so far a positivist as to pronounce all inquiry into the ultimate nature of things fruitless. What matter, form, spirit are in themselves is a futile question that belongs to the sterile region of "metempirics." But philosophical questions may be so stated as to be susceptible of a precise solution by scientific method. Thus, since the relation of subject to object falls within our experience, it is a proper matter for philosophic investigation. It may be questioned whether Lewes is right in thus identifying the methods of science and philosophy. Philosophy is not a mere extension of scientific knowledge; it is an investigation of the nature and validity of the knowing process itself. In any case Lewes cannot be said to have done much to aid in the settlement of properly philosophical questions. His whole treatment of the question of the relation of subject to object is vitiated by a confusion between the scientific truth that mind and body coexist in the living organism and the philosophic truth that all knowledge of objects implies a knowing subject. In other words, to use Mr Shadworth Hodgson's phrase, he mixes up the question of the *genesis* of mental forms with the question of their *nature* (see *Philosophy of Reflexion*, vol. ii. pp. 40–58). Thus he reaches the "monistic" doctrine that mind and matter are two aspects of the same existence by attending simply to the parallelism between psychical and physical processes given as a fact (or a probable fact) of our experience, and by leaving out of account their relation as subject and object in the cognitive act. His identification of the two as phases of one existence is open to criticism, not only from the point of view of philosophy, but from that of science. In his treatment of such ideas as "sensibility," "sentience," and the like, he does not always show whether he is speaking of physical or of psychical phenomena. Among the other properly philosophic questions discussed in these two volumes the nature of the causal relation is perhaps the one which is handled with most freshness and suggestiveness. The third volume, *The Physical Basis of Mind*, further develops the writer's views on organic activities as a whole. He insists strongly on the radical distinction between organic and inorganic processes, and on the impossibility of ever explaining the former by purely mechanical principles. With respect to the nervous system, he holds that all its parts have one and the same elementary property, namely, sensibility. Thus sensibility belongs as much to the lower centres of the spinal cord as to the brain, contributing in this more elementary form elements to the "subconscious" region of mental life. The higher functions of the nervous system, which make up our conscious mental life, are merely more complex modifications of this fundamental property of nerve substance. Closely related to this doctrine is the view that the nervous organism acts as a whole, that particular mental operations cannot be referred to definitely circumscribed regions of the brain, and that the hypothesis of nervous activity passing in the centre by an isolated pathway from one nerve-cell to another is altogether illusory. By insisting on the complete coincidence between the regions of nerve-action and sentience, and by holding that these are but different aspects of one thing, he is able to attack the doctrine of animal and human automatism, which affirms that feeling or consciousness is merely an incidental concomitant of nerve-action, and in no way essential to the chain of physical events. Lewes's views in psychology, partly opened up in the earlier volumes of the *Problems*, are more fully worked out in the last two volumes (3d series). He discusses the method of psychology with much insight. He claims against Comte and his followers a place for introspection in psychological research. In addition to this subjective method there must be an objective, which consists partly in a reference to nervous conditions, and partly in the employment of sociological and historical data. Biological knowledge, or a consideration of the organic conditions, would only help us to explain mental *functions*, as feeling and thinking; it would not assist us to understand differences of mental *faculty* as manifested in different races and stages of human development. The organic conditions of these differences will probably for ever escape detection. Hence they can be explained only as the products of the social environment. This idea of dealing with mental phenomena in their relation to social and historical conditions is probably Lewes's most important contribution to psychology. Among other points which he emphasizes is the complexity of mental phenomena. Every mental state is regarded as compounded of three factors in different proportions—namely, a process of sensible affection, of logical grouping, and of motor impulse. But Lewes's work in psychology consists less in any definite discoveries than in the inculcation of a sound and just method. His biological training prepared him to view mind as a complex unity, in which the various functions interact one on the other, and of which the highest processes are identical with and evolved out of the lower. Thus the operations of thought, or "the logic of signs," are merely a more complicated form of the elementary operations of sensation and instinct, or "the logic of feeling." The whole of the last volume of the *Problems* may be said to be an illustration of this position. It is a valuable repository of psychological facts, many of them drawn from the more obscure regions of mental life and from abnormal experience, and is throughout suggestive and stimulating. To suggest, and to stimulate the mind, rather than to supply it with any complete system of knowledge, may be said to be Lewes's service in philosophy. The exceptional rapidity and versatility of his intelligence seems to account at once for the freshness in his way of envisaging the subject-matter of philosophy and psychology, and for the want of satisfactory elaboration and of systematic co-ordination. (J. S.)

LEWIS AND HARRIS form together an island of the Outer Hebrides, nearly separated into two parts by the inlets of Loch Reasort and Seaforth,—the northern part, Lewis or the Lews, being in Ross-shire, and the southern part, Harris, in Inverness. The island is situated about 30 miles from the mainland, between 57° 40′ and 58° 32′ N. lat., and 6° and 7° W. long. Its length is 60 miles, the average breadth 15, and the extreme breadth 30. The area is 770 square miles, of which 575 are comprised in Lewis. The greater part of the surface is composed of gneiss rocks, which in Ben More attain a height of 1750 feet, but there is also a large breadth of peat and swamp, with remains of an ancient forest. The coast is much indented by bays. The climate is very moist and unsuitable for tillage. Agriculture is in a backward condition, but much has been done in draining, reclamation, and planting of trees by the late proprietor of Lewis, Sir James Matheson. Barley and potatoes are the principal crops, and a large number of black cattle are reared. Kelp making is also carried on, but one of the chief supports of the inhabitants is fishing, Stornoway being the largest station for the herring fishing in Scotland, and employing over 1000 boats with nearly 4000 men and boys. The town was made a burgh of barony by James VI. It has a commodious harbour with a patent slip suitable for vessels of 1000 tons. On a height overlooking the bay is the beautiful residence of the proprietor of the island. The most remarkable archæological remains in Lewis are the druidical stones of the temple of Callernish. There are also a large number of old obelisks, and at Mealista in Uig the remains of an old monastery. Six miles from Stornoway there is a huge cave covered with stalactites. See HEBRIDES.

LEWIS, SIR GEORGE CORNEWALL, BART. (1806-1863), statesman and man of letters, was born in London on 21st April 1806. His father, Thomas F. Lewis of Harpton Court, Radnorshire, after holding subordinate office in various administrations became a poor-law commissioner. He was made a baronet in 1846. Lewis was educated at Eton, and at Christ Church, Oxford, where in 1828 he took a first-class in classics and a second-class in mathematics. He then entered the Middle Temple, and was called to the bar in 1831. In the year before he had, with John Romilly and John Stuart Mill, attended the celebrated lectures on jurisprudence delivered by John Austin at London University. In 1832 he undertook his first public work as one of the commissioners to inquire into the condition of the poor Irish residents in the United Kingdom.[1] Again, in 1834, Lord Althorp included him in the commission to inquire into the state of church property and church affairs generally in Ireland. To this fact we owe his work on *Local Disturbances in Ireland, and the Irish Church Question* (London, 1836), in which he condemned the existing connexion between church and state, proposed a state provision for the Catholic clergy, and maintained the necessity of an efficient workhouse organization. During this period of apprenticeship to politics Lewis's mind was much occupied with the phenomena of language. Before leaving college he had published some observations on Whately's doctrine of the predicables, and soon afterwards he assisted Thirlwall and Hare in starting the *Philological Museum*. Its successor, the *Classical Museum*, he also supported by occasional contributions. In 1835 he published an *Essay on the Origin and Formation of the Romance Languages* (re-edited in 1862), which, though anticipated by Schlegel, may be taken as the first effective criticism in England of Raynouard's theory of a uniform romance tongue, represented by the poetry of the troubadours. He also set an excellent example to county gentlemen by compiling a glossary of provincial words used in Herefordshire and the adjoining counties. But the most important work of this earlier period was one to which his logical and philological tastes both contributed. The *Remarks on the Use and Abuse of some Political Terms* (London, 1832) may have been suggested by Bentham's *Book of Parliamentary Fallacies*, but it shows all that power of clear sober original thinking which marks his larger and later political works. And yet this original mind did more than most scholars in the humbler walk of useful translation. He translated Boeckh's *Public Economy of Athens* and Müller's *History of Greek Literature*, and he assisted Tufnell in the trans-

[1] See the *Abstract of Final Report of Commissioners of Irish Poor Enquiry*, &c., by G. C. Lewis and N. Senior, 1837.

lation of Müller's *Dorians*. Some time afterwards he edited a text of the *Fables* of Babrius. While his friend Hayward conducted the *Law Magazine*, he wrote in it frequently on such subjects as secondary punishments and the penitentiary system. In 1836, at the request of Lord Glenelg, he accompanied John Austin to Malta, where they spent nearly two years reporting on the condition of the island and framing a new code of laws. One leading object of both commissioners was to associate the Maltese in the responsible government of the dependency. On his return to England Lewis succeeded his father as one of the principal poor-law commissioners. But his literary activity did not cease. In 1841 appeared the *Essay on the Government of Dependencies*, a systematic statement and discussion of the various relations in which colonies may stand towards the mother country. In 1844 Lewis married Lady Maria Theresa Lister, sister of Lord Clarendon, and a lady of literary tastes. Much of their married life was spent in Kent House, Knightsbridge. They had no children. In 1847 Lewis resigned his office. He was then returned for the county of Hereford, and Lord John Russell appointed him secretary to the Board of Control, but a few months afterwards he became under secretary to the Home Office. In this capacity he introduced two important bills, one for the abolition of turnpike trusts and the management of highways by a mixed county board, the other for the purpose of defining and regulating the law of parochial assessment. On the latter subject his evidence before the select committee (Lords) of 1850 is the clearest statement of general results which we have. In that year he succeeded Hayter as financial secretary to the Treasury. About this time, also, appeared his *Essay on the Influence of Authority in Matters of Opinion*. Lewis seems to have thought that authority was too much divided to be of much use in theological matters, while in the world of science he found sufficient authority for declaring that homœopathy, mesmerism, and phrenology were all impostures. On the dissolution of parliament which followed the resignation of Lord John Russell's ministry in 1852, Lewis was defeated for Herefordshire and then for Peterborough. Excluded from parliament he accepted the editorship of the *Edinburgh Review*, which the death of Empson had left vacant. Lord Halifax offered him, in 1853, the governorship of Bombay, but he remained editor until 1855. During this period he did some public work on the Oxford commission, and on the commission to inquire into the government of London. But its chief fruits were the *Treatise on the Methods of Observation and Reasoning in Politics*, and the *Enquiry into the Credibility of the Early Roman History*,[1] in which he vigorously attacks the theory of epic lays and other theories on which Niebuhr's reconstruction of that history had proceeded. In 1855 Lewis succeeded his father in the baronetcy. He was at once elected member for the Radnor boroughs, and Lord Palmerston made him chancellor of the exchequer. The position was difficult, for he had a war loan to contract and heavy additional taxation to impose. But his industry, method, and clear vision carried him safely through. His financial statement of 13th February 1857, and his speech on 12th February 1858 on the bill for the better government of India were most successful efforts. After the change of ministry in 1859 Sir George became home secretary under Lord Palmerston, and in 1861, much against his wish, he succeeded Sidney Herbert (Lord Herbert of Lea) at the War Office. The closing years of his life were marked by increasing intellectual vigour. In 1859 he published an able *Essay on Foreign Jurisdiction and the Extradition of Criminals*, a subject to which the attempt on Napoleon's life, the discussions on the Conspiracy Bill, and the trial of Bernard, had drawn general attention. He advocated the extension of extradition treaties, and condemned the principal idea of *Weltrechtsordnung* which Mohl of Heidelberg had proposed. His two latest works were the *Survey of the Astronomy of the Ancients*, in which, without professing any knowledge of Oriental languages, he applies a sceptical analysis to the ambitious Egyptology of Bunsen; and the *Dialogue on the Best Form of Government*, in which, under the name of Crito, the author points out to the supporters of the various systems that there is no one abstract government which is the best possible for all times and places. An essay on the *Characteristics of Federal, National, Provincial, and Municipal Government* does not seem to have been published. Sir George died in April 1863. A marble bust by Weekes stands in Westminster Abbey. He has two other monuments—the reprint from the *Edinburgh Review* of his long series of papers on the *Administrations of Great Britain* (1864), and his *Letters to various Friends* (1870), edited by his brother, who succeeded him in the baronetcy.

[1] Translated into German by Liebrecht, Hanover. 1858.

Lewis was a man of mild and affectionate disposition, much beloved by a large circle of friends, among whom were Sir E. Head, the Grotes, the Austins, Lord Stanhope, J. S. Mill, Dean Milman, the Duff Gordons. In public life he was distinguished, says Lord Aberdeen, "for candour, moderation, love of truth." He had a passion for the systematic acquirement of knowledge, and a keen and sound critical faculty. Nothing is more remarkable than the practical good sense of his speculative writings. Sometimes he betrayed a slight intellectual impatience; but this was merely the passing irritation of a healthy and modest judgment.

LEWIS, MATTHEW GREGORY (1775–1818), often referred to as "Monk" Lewis, was born in London on July 9, 1775. He was educated for a diplomatic career at Westminster School and at Christ Church, Oxford, spending most of his vacations abroad in the study of modern languages; and in 1794 he proceeded to the Hague as attaché to the British embassy. His stay there lasted only a few months, but was marked by the composition, in ten weeks, of *Ambrosio, or the Monk*, which was published in the summer of the following year. It immediately achieved extensive celebrity; but some passages it contained were of such a nature that about a year after its appearance an injunction to restrain its sale was moved for and a rule *nisi* obtained. Lewis published a second edition from which he had expunged, as he thought, all the objectionable passages, but the work still remains of such a character as almost to justify the severe language in which the author of *English Bards and Scotch Reviewers* addresses—

> "Wonder-working Lewis, Monk or Bard,
> Who fain would'st make Parnassus a churchyard;
> Even Satan's self with thee might dread to dwell,
> And in thy skull discern a deeper hell."

Whatever its demerits, ethical or æsthetic, may have been, *The Monk* did not interfere with the reception of Lewis into the best English society; he was favourably noticed at court, and almost as soon as he came of age he obtained a seat in the House of Commons as member for Hindon, Wilts. After some years, however, during which he never ventured to address the House, he finally withdrew from a parliamentary career. His tastes lay wholly in the direction of literature, and *The Castle Spectre* (1796, a musical drama of no great literary merit, but which enjoyed a long popularity on the stage), *The Minister* (a translation from Schiller's *Kabale u. Liebe*), *Rolla* (1797, a translation from Kotzebue), with numerous other operatic and tragic pieces, appeared in rapid succession. *The Bravo of Venice*, a romance translated from the German, was published in 1804, and has since been reprinted; next to *The Monk* it is the work connected with the name of Lewis which has been most extensively read. By the death of his father he succeeded to a large fortune, and in 1815 embarked for the West Indies to visit his estates; in the course of this tour, which lasted four months, the *Journal of a West Indian Proprietor*, published posthumously in 1833, was written. A second visit to Jamaica was undertaken in 1817, in order that he might become further acquainted with, and able to ameliorate, the condition of the slave population; but the fatigues to which he exposed himself in the tropical climate brought on a fever which terminated fatally on the homeward voyage, May 14, 1818. *The Life and Correspondence of M. G. Lewis*, in two volumes, was published anonymously in 1839; compiled by friendly hands, it makes it sufficiently plain that, whatever may have been the errors of judgment and taste displayed in the writings of his precocious youth, he was nevertheless a man of more than ordinary discretion, good feeling, and generosity.

LEWIS, MERIWETHER (1774-1809), American explorer, was born near Charlottesville, Virginia, August 18, 1774. In 1794 he volunteered with the troops called out to suppress the "whisky insurrection," was commissioned as ensign in the regular army in 1795, and as captain in 1800, and was President Jefferson's private secretary from 1801 to 1803. On Jefferson's recommendation he was appointed by Congress to conduct, in connexion with Captain William Clarke, an expedition to the headwaters of the Missouri river, and thence across the mountains to the Pacific Ocean—the first extended exploration of the north-western portion of the United States. The States had as yet acquired no claim to this region, and the exploration was designed by Jefferson in the interests not only of geographical science but of territorial acquisition. Lewis and Clarke, setting out late in 1803 with twenty-eight men, spent the winter at the mouth of the Missouri. Early in the spring the party embarked in several boats, and during the summer made the difficult ascent of the Missouri as far as 47° 21′ N. lat., where the second winter was passed among the Mandan Indians. In 1805 the ascent of the Missouri was continued as far as the tributary which they named Jefferson river, which was followed to its source in the south-western part of what is now Montana territory. Procuring a guide and horses from the Shoshone Indians, they pushed westward through the mountains, and on October 7 embarked in canoes on a tributary of the Columbia river, the mouth of which they reached on November 15. They had travelled upwards of 4000 miles from their starting point, had encountered various Indian tribes never before seen by whites, had made scientific collections and observations, and were the first explorers to reach the Pacific by crossing the continent north of Mexico. After spending the winter upon the Columbia, they made the return journey across the mountains and down the Missouri, reaching the Mississippi in September 1806. The reports of the Lewis and Clarke expedition attracted great attention at the time, and it has scarcely been exceeded in romantic interest by later explorations in any quarter of the globe. The leaders and men of the exploring party were rewarded with liberal grants of land, and Lewis was made governor of the territory of Missouri. In the unwonted quiet of his new duties his mind, always subject to melancholy, became unbalanced, and, while on his way to Washington, he committed suicide near Nashville, Tennessee, October 11, 1809.

Jefferson wrote a memoir of Lewis, published in 1814 in connexion with Biddle and Allen's *Narrative of the Lewis and Clarke Expedition*. A new edition by M'Vickar was published at New York in 1843.

LEWISTON, a city of the United States, in Androscoggin county, Maine, is situated 36 miles north of Portland, on the left bank of the Androscoggin, and is connected by several bridges with Auburn, a city of 9556 inhabitants, and the capital of the county. As the river at this point breaks over a ledge of mica schist and gneiss, and the natural fall of 40 feet has been raised to 50 feet by a strong granite dam, Lewiston commands an abundant supply of water-power. Cotton and woollen goods (shirtings, sheetings, cassimeres, beavers, tweeds, cloakings), twine, boots and shoes, machinery, &c., are produced to the annual value of \$11,000,000—there being nine considerable manufacturing corporations in the city besides the Franklin Company, which owns the entire water-power. The city hall (1872) is a very fine building; and a public library (over 6000 volumes in 1880) was founded by the corporation in 1861. Bates College, founded by the Free Baptists in 1863-64, and named in honour of Benjamin F. Bates of Boston, possessed in 1880 11 professors, 161 students, and a library of 5537 volumes.

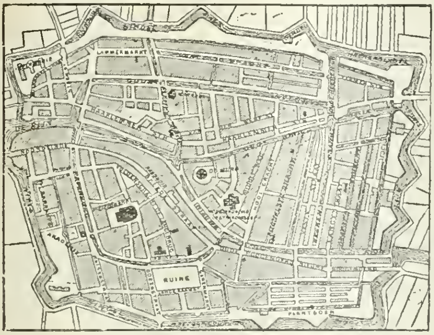
Lewiston dates from 1770. In 1795 it was incorporated as a town, and in 1861 as a city. The population was 3584 in 1850, 7424 in 1860, 13,600 in 1870, and 19,083 in 1880.

LEXINGTON, capital of Fayette county, Kentucky, is situated near the centre of the State, in the midst of a table-land 1100 feet above the sea, known as the Blue Grass region. It stands on a small subtributary of the Kentucky river, 79 miles south of Cincinnati, and 94 miles east by south of Louisville. The population (3584 in 1850, 7424 in 1860, and 13,600 in 1874) in 1880 was 16,656, including about 8000 negroes. Lexington is an important railway junction, has an extensive trade, and manufactures whisky, flour, bagging, ropes, carriages, and machinery. Two railroads, completed in 1882, give access to the mountainous eastern region of the State, from which iron, coal, and timber are obtained in abundance. The surrounding district is characterized at once by beauty and fertility, and the town has been laid out in a spacious and attractive style. It is the seat of the State university (chartered in 1858, originally opened at Harrodsburg in in 1859, and removed to Lexington and incorporated with the Transylvania university in 1865), the State agricultural college, and one of the State lunatic asylums (625 patients). Besides the university library, there is a public library of 15,000 volumes.

Lexington was founded by Colonel Robert Patterson in 1775, and received its name in honour of the first contest in the war of American independence, fought in April of that year at Lexington, Middlesex county, Massachusetts.

Lexington in Kentucky must not be confounded with (1) Lexington, the capital of Lafayette county, Missouri, with a population in 1880 of 3996; or (2) Lexington, capital of Rockbridge county, Virginia, a place of 2771 inhabitants, and the seat of the Washington and Lee university (founded in 1749; professors in 1880, 9; students, 300; library, 15,000 volumes), and of the Virginia military institute, founded in 1839, under the patronage of the State, with 12 professors and 300 students.

LEYDEN, or LEIDEN, a city of the Netherlands, in the province of South Holland, about 20 miles south-west of Amsterdam, and 6 miles inland from the German Ocean. The Old Rhine, on which it is situated, enters at the eastern side by two arms which unite near the middle of the town so as to divide the western half into two nearly equal portions. Though the boundaries, which now include about 467 acres, have been six times extended, the general shape is wonderfully regular, nor is regularity wanting in the interior arrangement of the quiet respectable town with its canals and moats, its broad streets, and lifeless squares. The pensive and even melancholy impression which it seems sometimes to produce on the stranger is easily explained. Leyden is *par excellence* an academic city; the bustle of its great markets for cattle and dairy produce is confined to certain spots, and lasts only for so many hours on so many days, and its industrial activity, considerable though it be, is not sufficient to give that appearance of life and movement which their flourishing local and transit trade makes so generally characteristic of the towns of Holland. The woollen goods (coverlets and broadcloths), the cotton stuffs, the worsted and yarns, the iron and copper wares, and the books and lithographic work which it still produces, are far from maintaining for it the position which it enjoyed when, at the close of the 15th century, its weaving establishments (mainly broadcloth) numbered from three to four hundred, or when, after the expulsion of the Spaniards, Leyden cloth, Leyden baize, and Leyden camlet became familiar terms at home and abroad. Owing to changes of fashion, unwise preservation of old customs and institutions, party spirit, the development of manufactures in other places, these industries had so far declined in the beginning of the 19th century—the total production of all the factories in 1802, for example, did not exceed 1086 pieces of cloth—that the baize manufacture was altogether given up, and the beautiful Say (Worsted) Hall was closed. Although after the revolution of 1813 comparative prosperity was the result of the removal of the French yoke, and more especially of the



Plan of Leyden.

introduction of steam, the times of a Maurice or a Frederick Henry have never returned, and still less the wonderful days of the 15th century. The university is still a flourishing institution, with fifty professors; but other universities have grown up in the Netherlands, and even professors of European reputation can no longer attract from foreign lands the numbers that visited Leyden in the days of Lipsius, Vossius, Heinsius, Gronovius, Hemsterhuis, Ruhuken, Valckenaer, Scaliger, and Boerhaave. As a class the students are remarkably quiet and orderly. Many are destined to a diplomatic career. The university (*Akademie*) was opened in February 1575, and originally located in the convent of St Barbara. In 1581 it was transferred to the convent of the White Nuns, the site of which it still occupies, though the building was destroyed in 1616. Of the institutions connected with the university it is sufficient to mention the library (upwards of 160,000 volumes and 4650 MSS. and 2400 pamphlet portfolios), rich in Oriental and Greek manuscripts and old Dutch travels; the botanic gardens, with splendid collections of East Indian plants; the observatory (1860); the museum of natural history, one of the principal establishments of its kind in Europe; the museum of antiquities, with a specially valuable Egyptian department; the ethnographical museum, of which the nucleus was Von Siebold's Japanese collections; and the national institution for East Indian languages, ethnography, and geography. The Thysian library and the library of the Society of Dutch literature (1766) are both large collections, the former especially rich in legal works and native chronicles; the great school of navigation, and the Remonstrant seminary, transferred from Amsterdam in 1873, deserve special mention, and in general it may be said that there is no city in the Netherlands better supplied than Leyden is with educational and intellectual institutions.

Objects of artistic and antiquarian interest are fewer than might be expected from the position which Leyden holds in the history of painting (Rembrandt, Jan Steen, and Gerard Douw were natives of the town); but such as they are—pieces by Van Finck, Fr. van Mieris, Cornelis Engelbrechtszoon, Lucas of Leyden, and other masters—they have for the most part been collected in the newly founded municipal museum located in the old cloth hall. More interesting is the great collection of portraits of famous professors in the aula of the university. All the gate-houses of the city were still standing about the close of the 17th century; two only, the Zijlpoort and the Morschpoort have been spared. The old town-hall is a quaint 16th century building, and St Pancratius church has some striking features. Near the site of the Rijnsburg gate is the statue of Boerhaave by Stracké. The "Burg," on an artificial mound (perhaps of Roman origin) in the centre of the town, is an old circular wall resting on twenty arches; it forms a favourite promenade, and affords a fine point of view. Towards the south side of the town lies an open space, suggestively called the Ruin, which in 1807 was the scene of a terrible disaster, a powder-ship blowing up and destroying eight hundred houses and killing hundreds of men. In 1623 the population of Leyden was much more than 50,000, and in 1640, it is estimated, reached 100,000. Between 1796 and 1811 it sunk to 30,000. In 1850 it was 35,864; in 1870, 38,943 (9632 Roman Catholics, 396 Jews); and in 1882 about 41,000.

Though Lugdunum Batavorum is used by the learned as the Latin name for Leyden, there is no possibility of identifying the town itself with the Lugdunum of the Romans. It first appears in 11th and 12th century documents as Leythen, Leithen, Leithon, and Leithan. The history of Leyden follows the same general lines as the history of the Netherlands. During the period of the counts the city suffered from the quarrels of one count with another (as when Countess Ada was besieged in the castle by Lewis of Loon in 1203), or of the nobles with the citizens; between 1419 and 1485 it was besieged and captured no less than six times by the "Hooks" or the "Cods." From Floris V. it received the confirmation of its privileges (1266) and of its freedom from toll throughout Holland (1290). During the struggle with Spain Leyden covered itself with glory by the persistence with which it held out against the double siege from 31st October 1573 to 21st March 1574, and from 25th May to 2d October (see Motley, *Rise of the Dutch Republic*, vol. ii.). With the internal troubles of the 17th century it was closely connected. Coolhas, one of the first professors of its university, gave rise about 1578 to a question of heresy which formed in some sort the prelude to the great contest in which his successors Arminius and Gomarus were protagonists. In 1587 Leicester vainly attempted to bring the city over to his side; in 1618 Maurice was there constrained to alter the government; and in 1672 there were violent disturbances in connexion with the elevation of William III. to the stadtholdership. The revolution, excited by the French, took place in 1798; and in 1813 the Rhenish peasants, in revolt against the conscription, marched into the city. In 1836 there was a great inundation caused by the Haarlem Lake. The bicentenary of the university was celebrated with great ceremony in 1874.

See Mieris, *Beschrijving der Stad Leyden*, 1772–84.

LEYDEN, John (1775–1811), was born on the 8th of September 1775, at Denholm on the Teviot, not far from Hawick. Like most Scottish villages, Denholm is commonplace and uninteresting, but Leyden's upbringing was in a wilder part of the country, at the foot of Ruberslaw, whither his father had gone as shepherd to a relation of the family. Though he did not attend school till he was nine years old, long before that he had learnt at home to read, and had devoured all the books he could lay his hands on in the border farm houses and cottages. Naturally his parents thought that a boy so fond of letters was meant for something else than shepherding; and, as the only scholarly office clearly within their horizon was that of a parish minister, they concluded that his gifts pointed in that direction, and with much stinting of their own little comforts sent him to Edinburgh university in 1790. There the uncouth lad, dressed in rough home-spun, with a voice that smacked strongly of the Jed and the Teviot, played his part manfully enough in the class-work, but still better in the "societies" where Brougham, Jeffrey, Sydney Smith, Horner, and other clever young fellows were then chopping logic and cracking jokes. Leyden was a diligent but somewhat miscellaneous student, reading everything apparently, except theology, for which he seems to have had no taste. Accordingly, though he completed his divinity course, and took licence from the presbytery of St Andrews, and preached occasionally, it soon became clear that the pulpit was not his vocation, and that the border shepherds were not to find a second Thomas Boston in John Leyden.

In 1794 Leyden had formed the acquaintance of Dr Robert Anderson, editor of *The British Poets*, and of *The Literary Magazine*, a cultivated but not otherwise remarkable individual, who, however, filled a rather important niche in the Edinburgh of that time. Contributions to his magazine were probably what brought them first together, but more important results followed from their intimacy than either the verses on "Ruberslaw," or "The Descent of Odin," translated from the Norse. For it was Anderson who introduced him to Dr Alexander Murray, and Murray, probably, who led him to the study of Eastern languages, to which that great scholar was so passionately devoted. Soon they became warm friends and generous rivals, though Leyden excelled, perhaps, in the rapid acquisition of new tongues, and acquaintance with their literature, while Murray was the more scientific philologist. Through Anderson also he came to know Richard Heber, by whom he was brought under the notice of Walter Scott, when he was collecting materials for his *Minstrelsy of the Scottish Border*. Leyden was admirably fitted for helping in this kind of work. A borderer himself, an enthusiastic lover of old ballads and folk-lore, he spared no pains to enrich the work that promised to bring fame to his beloved hills and glens. Scott tells us how, on one occasion, Leyden walked 40 miles to get the last two verses of a ballad, and returned at midnight, singing it all the way with his loud, harsh voice, to the wonder and consternation of the poet and his household. Neither Scott nor Leyden, however, studied this folk-lore for proper scientific purposes. They cared only for the picturesque and the poetic in it, and were not very successful in their efforts to restore it to life. Of course, the rough old ballads themselves were a welcome addition to our literature, but Leyden's attempt to make Lord Soulis interesting in a modern ballad was something of a failure, and, though he might have made a Scotch Lorelei out of the mermaid of Corrievreckan, his poem wants the delicate touch of the German, and he does not know where to stop. Scott, however, got valuable assistance from him in his task, and learned to esteem highly the blunt integrity of the man, his literary enthusiasm, and his large attainments.

Leyden was evidently drifting away from the church into the life of a scholar, but as yet he had not found his line there, was indeed only wasting himself on miscellaneous learning. He had compiled a work of four hundred pages on the *Discoveries and Settlements of Europeans in Northern and Western Africa*, suggested by Mungo Park's travels. He had edited for Constable *The Complaint of Scotland*, giving a glossary, and a long preliminary dissertation. He had printed various poems, and nearly finished his *Scenes of Infancy*, a poem in four books, based, no doubt, on border scenes and traditions, but meandering "at its own sweet will" over all the world, and a good way beyond it. There are, here and there, some effective enough lines in this poem, but, in the main, it is of the thin, artificial, big-sounding order, and has no unity of design, so that there is no particular reason why it should not go on for ever. He had also made some translations from Eastern poetry, Persian and Arabic, but they have not somehow the aroma of the East. Clearly, here was a man of great and varied powers which, however, were like to run to waste unless he found a definite field to work in. So, at last, friends got him an appointment in India, at first on the medical staff, for which he qualified by a year of intense hard work; but it was hoped something more fitting would turn up by and by. In 1803, therefore, he sailed for Madras, and took his place in the general hospital there. From that he was soon promoted to be naturalist to the commissioners going to survey Mysore. Ere long, however, his knowledge of the languages and dialects of India procured him an appointment as professor of Hindustani, which he soon after resigned for a judgeship, and that again to be a commissioner in the court of requests, which required a familiarity with several Eastern tongues. Friends who had come from the same border country—Lord Minto, Sir John Malcolm, and others—had done what they could to make his path smooth for him, and his linguistic attainments had been recognized by Colebrooke, the greatest Oriental scholar of the day. But in 1811, having joined Lord Minto in the expedition to Java, on landing there he made his way into a library which was said to contain many Eastern MSS., without having the place aired, and was seized with shivering and sickness, first symptoms of the Batavian fever. The climate of India had never agreed with him, and his constitution had already been shaken by several serious illnesses. He was ill fitted, therefore, to endure the assault of this deadly complaint, and after three days of struggle he died on the 28th of August, in the thirty-sixth year of his age. Cut off thus prematurely, he has left comparatively little fruit of all the bright promise of his youth. As a poet he cannot take high rank, but in his knowledge of Eastern languages he would probably have been no mean rival of Henry Colebrooke, had he been spared a little longer to methodize and perfect his attainments. A genuine and generous nature, with a fine enthusiasm for learning, there were few of Britain's sons in India from whom friends at home looked for better work, and few therefore who were more deeply regretted. (W. C. S.*)

LEYDEN, LUCAS VAN. See LUCAS.

LHASA, often written LASSA, for many centuries the chief city of Tibet. Though the place is of great celebrity, the accounts of it are scanty, and information has to be sifted from authorities differing considerably in age. Till recently the latitude even of Lhasa has been stated with variations extending over $1\frac{1}{2}$ degrees, whilst the longitude has naturally been still more uncertain. The Jesuit Grueber, who was at Lhasa in 1661–62, made the latitude 29° 6′. In the maps of Tibet sent from China by the Jesuits, and engraved on five separate sheets in Du Halde, it is about 29° 40′. D'Anville, in his *Carte Générale du Thibet*, chiefly based on these last, but modified to suit other data, reverted nearly to Grueber's figure; Giorgi in his *Alphabetum Tibetanum* states it at about 30° 30′. Klaproth, stretching every datum to cracking point, to suit his fantasies about the course of the great river of Tibet, made it 30° 45′ lat. (and 91° 50′ long.); our last and highest authority, Pundit Nain Singh, gives (from a mean of twenty observations) 29° 39′ 17″, a result which closely confirms the Jesuit record. The longitude according to the protraction of the same explorer's route is 90° 57′ 13″.[1] The height above the sea, by repeated observation of the boiling point, is stated at 11,700 feet (but the report of Nain Singh, on his second visit, gives 11,910). The city stands near the middle of a tolerably level plain, which is surrounded on all sides by hills, and extends about 13 miles from east to west and about 7 miles from north to south. It lies half a mile to the north of a considerable river called the Kichu Tsanpu, or Tsang-chu, flowing here from east-north-east (called by the Mongols, according to Klaproth, *Galjao-Muren*, or "Turbulent River"), and joining the great Tsanpu (or upper course of the Brahmaputra) some 35 miles to the south-west.

The hills round the city are absolutely barren, and without growth of any kind except an occasional bush of so-called "Tartar furze." There are, however, gardens scattered over the plain round the city, and these are planted with trees of some size (it would seem cedar, willow, and cypress). Four defiles in the encompassing hills, by which the approaches to the city pass, are defended by as many forts. We may quote the description of Huc, which, though a little vague, is vivid, and is the only passage affording anything like a picture of this city, so difficult of access:—

"The sun was about to set as we completed our descent of the innumerable zigzags of the mountain path. Issuing into a wide valley, we beheld on our right Lhasa, the famous metropolis of the Buddhist world. The multitude of aged trees which encircle the city as with a girdle of foliage, the lofty white houses, terminating in flat roofs surrounded by turrets, the numerous temples with their gilt canopies, the Buddhala [*Potala*], crowned by the palace of the Dalai Lama,—all unite to give Lhasa a majestic and imposing appearance."

The meaning of the name *Lhá-Sa* is "God's ground." Formerly it used to be known to the Mongols as *Barontala*, the "right side" or western region; now, according to Huc they call it *Monke Dhot* or *Dehot*, "Eternal Sanctuary."[2] In eastern Turkestan it seems to be best known as *Jo*, a name which properly refers to the great central temple of which we shall speak.

The city is nearly circular in form, and according to Nain Singh less than a mile in diameter. It was walled in the latter part of the 17th century, but the walls were destroyed during the Chinese occupation in 1722. The population has been estimated at 40,000 to 80,000; the last estimate perhaps including the great population of monks and students in the convents near the city.[3]

The chief streets of the city are wide and straight, and in dry weather tolerably clean, but the inferior quarters are unspeakably filthy, and are rife with evil smells and large mangy dogs.[4] Part (much the greater part, according to Nain Singh) of the houses are of clay and sun-dried brick, but those of the richer people of stone and brick. All, however, are frequently white-washed, the doors and windows being framed in bands of red and yellow. In the suburbs there are houses entirely built of the horns of sheep and oxen set in clay mortar. This construction, according to Huc, is very solid and highly picturesque. The houses generally are large, and of three stories at least. The owner of the house, with his family, occupies the upper story, whilst the two lower floors swarm with tenants. Externally the lower part of Tibetan houses generally presents lofty dead walls pierced by a few air-holes only; above these rise tiers of windows with projecting balconies, and over all flat broad-eaved roofs at varying levels. According to Desideri, in the better houses there are often spacious and well-finished apartments, the principal halls, the verandas, and terraces being often paved with a composition of coloured fragments of stone set in a cement of resin, &c., which with much beating and rubbing becomes like a surface of polished porphyry. In every house there is a kind of chapel or shrine, carved and gilt, on which are set images and sacred books, and before them lamps and incense, with the usual offerings of barley, fruits, &c.

Lhasa is not only the nucleus of a cluster of vast monastic establishments, which attract students and aspirants to the (so-called) religious life from all parts of Tibet and Mongolia, and the seat of a quasi papacy, but is also a great place of pilgrimage, so that the streets and public spaces swarm with visitors from every part of the Himalayan plateau, and from all the steppes of Asia between Manchuria and the Balkash Lake, who come to adore the living Buddha, to seek the purgation of their sins and the promise of a happy transmigration, and to carry away with them holy relics, blessed rosaries, and all the miscellaneous trumpery which is set forth to catch the money of idle people in Asia and Europe, whether they are pilgrims or frequenters of mineral waters,[5] whilst as usual a great traffic arises quite apart from the pilgrimage. The city thus swarms with crowds attracted by devotion and the love of gain, and presents an astonishing diversity of language, costume, and physiognomy; though, in regard to the last point, varieties of the broad face and narrow eye greatly predominate. Much of the retail trade of the place is in the hands of the women. Huc's account of the curious practice of the Lhasa women in plastering their faces with a dark-coloured unguent is well known, but it does not rest on his authority alone.

During the month of December especially traders arrive from western China by way of Tatsienlu (Tachindo of the Tibetans), bringing every variety of silk-stuffs, carpets, china-ware, and tea; from Siningfu (commonly in Tibet and Turkestan called *Siling*, Ziling, or Zling, a circumstance that has caused sundry misapprehensions) come silk, gold lace, Russian goods, carpets of a superior kind, semi-precious stones, horse furniture, horses, and a very large breed of fat-tailed sheep; from eastern Tibet musk in large quantities, which eventually finds its way to Europe through Nepal; from Bhutan and Sikkim, rice; from the latter also tobacco; besides a variety of Indian and European goods from Nepal and Darjiling, and *charas* (resinous exudation of hemp) and saffron from Ladak and Kashmir. The merchants, who arrive in December, leave Lhasa in March, before the setting in of the rains renders the rivers impassable.

The tea importation from China is a large matter, on which an interesting paper has been written by Mr E. Baber. The tea is of the coarsest quality, derived from straggling and uncared-for trees, allowed to grow to a height of 10 feet or more, and the coarsest produce of these. This is pressed into bricks or cakes, and carried by porters. The quantity that pays duty at Tatsienlu is about 10,000,000 lb, besides some amount smuggled. No doubt a large part of this comes to Lhasa. Tea is an

[1] This is corrected to the latest value of Madras longitude, viz., 80° 14′ 51″.

[2] The first word of this phrase is certainly the Mongol *mungke*, "eternal." The second is probably a clerical error for *dchot*, which may represent the *Jo* of the next sentence, which is literally (Tib.) "master, lord," and is applied to very sacred images.

[3] Nain Singh says that a census in 1854 gave "9000 women and 6000 men, exclusive of the military and the priests." But these words are subject to too many doubts for precise interpretation.

[4] The Chinese have a proverb as to the three products of Lhasa being dogs, drabs, and lamas.

[5] Among articles sold in the Lhasa bazaars are numerous fossil bones, called by the people "lightning bones," and believed to have healing virtues.

absolute necessary to the Tibetan; he is miserable without it.

The chief industries of Lhasa are the weaving of a great variety of stuffs from the fine Tibetan wool; the making of earthenware (said to be of very good quality), and of the wooden porringers (varying immensely in elaboration and price) of which every Tibetan carries one about with him; also the making of certain fragrant sticks of pastille much valued in China and elsewhere.

It is curious that Tibet, though using coined money, seems never, strictly speaking, to have had a coinage of its own. Till nearly the end of last century the coinage had for a long time been derived from Nepal. That valley prior to the Gorkha domination (1768) was under three native dynasties (at Bhatgaon, Patan, and Khatmandu), and these struck silver mohurs, as they were called, of the nominal value of half a rupee. The coins were at first not struck specially for Tibetan use, but were so afterwards. These latter bore (obverse) a Nepalese emblem surrounded by eight fleurons containing the eight sacred Buddhist jewels, and (reverse) an eight-petalled flower surrounded by eight fleurons containing the names of the eight jewels in Tibetan characters. Ingots of Chinese silver were sent from Lhasa with a small proportion of gold dust, and an equal weight in mohurs was returned, leaving to the Nepal rajahs, between gold-dust and alloy, a good profit. The quality of these coins (weighing about 81 grains Troy) was low, and at last deteriorated so much that the Tibetans deserted the Nepal mints. The Gorkhas, after becoming masters of Nepal, were anxious to renew the profitable traffic in coin, and in this view sent a deputation to Lhasa, with a quantity of coin to be put in circulation. But the Gorkhas were mistrusted, and their coin refused. A coinage was then issued (it would appear once only) in Tibet for domestic use, modelled on an old Khatmandu pattern, and struck by Nepalese artists (see fig. 1). The Gorkhas, however,

in 1788 and following years continued to strike coins of progressively debased quality, which were rude imitations of the old Nepalese mintage (see fig. 2), and to endeavour to force this currency on the Tibetans, eventually making the departure of the latter from old usage a pretext for war and invasion. This brought the intervention of the

Chinese, who drove the Gorkhas out of Tibet (1792), and then began to strike silver coins for Lhasa use, bearing Chinese and Tibetan characters (see fig. 3). For practical use these Tibeto-Chinese coins (of which $2\frac{1}{2} = 1$ rupee, and which are known as *naktang*, *i.e.*, *nagskyang*, "cash"), are cut into aliquot parts by the guidance of the figures on them. Large lumps of Chinese silver, stamped

with the imperial seal, are also used. But of late years there has been an enormous influx of Anglo-Indian rupees, so that these have become practically the currency of the country, even to the frontier of China, and are now counted, instead of being valued as bullion. They are called *Peiling ch'ranka*, or *chanka* (probably Hind. *tankā*), "English (Firinghi?) coins." Those that bear a crowned head of the queen are called *Lama* heads, the crown being taken for a wandering lama's head-gear. This great influx of rupees indicates a very considerable amount of trade with India. And, in spite of the extraordinary difficulties of the road eastward from Lhasa, quantities of trifling European articles find their way even to Tatsienlu on the Chinese frontier. Mr Baber found quarter-rupees very popular as buttons, British army buttons very common, corkscrews offered for sale (though no one knew their use), and tin-plates very common, stamped with the heads of Napoleon III., Mr Gladstone, and other celebrities.

The permanent population embraces, besides Tibetans of the country, settled families of Chinese and Kashmiris in considerable numbers, as well as people from Bhotan and Nepal, from Ladak and even from Patna. The Kashmiris and many of the other foreigners are Mohammedans, and much of the trade is in their hands. Desideri, a century and a half ago, speaks also of Armenians and even "Muscovites." The Chinese have a crowded burial-ground at Lhasa, tended carefully after their manner. The Kashmiris, who are called *Khach'hê*, are an important body, and have their mosque, and a provost, at once civil and religious, who is recognized by the Government. With their turbans, their fine Caucasian features, and their beards, they strikingly contrast with the mass of other nationalities. The Nepalese (called at Lhasa, according to Huc, *Pe-bún*) supply all the mechanics and metal-workers. There are among them excellent gold and silversmiths; and they make the elaborate gilded canopies crowning the temples, which form so notable a feature of Lhasa. Huc describes a striking custom among the native population. Every evening, as light begins to fail, they leave off business, and form groups in the streets; all sit down and begin to chant prayer in a low voice. "The combination of religious music arising from these numerous companies produces an aggregate of vast and solemn harmony, which is exceedingly moving."

In the middle of the city is an open space or *place*, in which markets are held; this is densely thronged in the afternoon and evening. On the north side, overlooking this *place*, is a great building which is the residence of the *Gyalbo*, or so-called king of Tibet. It was built at great cost by the dissolute Lama who was set up by the crafty regent Sangje Gyampo, and put to death by the Calmuck prince Latsan or Jenghiz Khan in 1706–7 (see *infra*); and, as the Lama used to divert himself there with the dances of the ladies of Lhasa, the palace is known as the

Trasi-khang or "dancing house" (so Desideri; the word *trasi* cannot be identified).

Immediately west of the *place* stands the great temple and convent of Labrang (*bLa-brang*, "Lama-house"), regarded as the *umbilicus* and centre of all Tibet, and from which all the main roads are considered to radiate. This is not merely the great metropolitan convent, sanctuary, and church-centre of Tibet, the St Peter's or Lateran of Lamaism, but contains the palace of the government and seat of civil administration. It is believed to have been founded by the Tibetan Constantine, Srong-dsan-gampo, in the 7th century, as the shrine of one of those two very sacred Buddha images which were associated with his conversion, and with the foundation of the civilized monarchy in Tibet. From this image, called *Jo*, or *Jû*, it is known to the Mongols as the *Jo Erdeni* ("the precious Lord") or *Jo Shakyamuni* (to the Chinese as *Ta-shao-sz'*, "house of the great *Jû*"), and hence as *Ju* or *Jo* simply, a name used in eastern Turkestan (as already noticed) and probably in Mongolia, as a synonym of Lhasa. The temple appears to be known also as *Lhasai Chhod-khang*, "offering-house of Lhasa," and among Indian and Nepalese visitors as *Mâchendra Nâth*.[1] The Potala as a sacred centre is modern, whilst the Labrang attaches itself to the whole thread of Tibetan history and religion. On one of the walls of this temple is a picture of the famous "Master of the Law," Hwen T'sang, the travelling doctor of Buddhism (see vol. xii. p. 418), whose journeys have in the revolution of the ages become so familiar to European students, as a mine of information on the geography and history of India during a period so clouded as the 7th century. He is represented with three of his disciples. And before the gate of the Labrang stand several monuments of antiquity, especially that famous obelisk spoken of below, which bears the inscribed record of the treaty of peace concluded in 822 between Thi-de-srong-tsan, king of Tibet, and the emperor Mo-tsung of China. Before this obelisk the apostate from Lamaism, Langdharma, brother and successor of the last-named king, was standing in proud contemplation, when a fanatic recluse, who had been stirred by a vision to avenge his persecuted faith, shot him with an arrow in the forehead.

The main building of the Labrang is three stories high. The entrance, facing eastward, forms a portico supported on six great timber columns, richly carved and gilt, whilst the walls are painted with the history of Sakya. Great folding-doors, covered with reliefs in bronze and iron, lead to the ante-hall, and from this a second gate to the *cella* (so to call it) of the temple. On each side of the gate, two and two, stand colossi of the spirit-kings of the four points of heaven. Within is a great basilica, divided into naves and aisles by many pillars, whilst along each wall, north and south, are chapels or sanctuaries, fourteen to a side.

At the west end steps ascend to a quadrangular choir or chancel, on each side of which also are three chapels, and at the extremity a rectangular apse (if it may be called so), and in it is the altar or graded throne, on which stands the great image of Sakya, seen through a lattice of silver gilt,—the higher shelves or offsets of the altar being beset with small figures in precious metals of *devtas* and saints, and the lower ones with lamps burning josticks, platters holding offerings of butter and meal, flowers modelled from butter, &c. In the choir to the right (*i.e.*, looking from the altar) is the elevated and stepped throne of the Grand Lama, laid with splendid cushions, succeeded by the nearly equal throne of the Teshu Lama of Shigatzé, and then by the seats of other ecclesiastical potentates, reborn and elected, in order; on the left of the Buddha throne, opposite the Grand Lama's, and of equal height, there is said now to be a throne for the emperor of China, then, at a lower level, that of the so-called king of Tibet, whilst the ministers of state follow opposite the inferior lamas.

In a space shut in with silver lattice, on the south side of the chancel-steps, are seen fourteen or fifteen great disks of silver, set with precious stones, on which are embossed fundamental Buddhist symbols, such as their system of cosmogony, the circle of transmigration, the births of Sakya, &c.

The great nave or central aisle of the basilica is truly hypæthral, but on the second and third apparent floors it is encompassed with colonnades or verandas, from which the women and the laity look down upon the lamas engaged in chanting the services or in other functions. The sanctuary or chancel itself towers above the rest of the building, and is crowned with a rectangular canopy or pavilion of gilt metal, which rises to a ridge serrated with fantastic figures. This canopy rests on columns which are also gilt, and from its eaves and angles hang bells that tinkle with every breeze, whilst the pillars beneath the eaves are crowned with a great frieze of bas-reliefs embossed in gilt metal.

This ancient temple contains a vast accumulation from the ages of gold and silver vessels, lamps, reliquaries, and precious bric-a-brac of every kind, which is annually exposed to view in the spring festivities. The daily offices in the Labrang are attended by crowds of worshippers, and a sacred way which leads round it is constantly traversed by devotees who perform the circuit as a work of merit, always in a particular direction.

Besides the convent-cells, halls of study, and magazines of precious lumber, buildings grouped about the Labrang are occupied, as we have said, by the civil administration, *e.g.*, as treasuries, customs office, courts of justice, &c.; and there are also private apartments for the Grand Lama and other high functionaries. No woman is permitted to pass the night within the precinct.

Another great and famous temple is the *Ramo-chhé* ("large pen or fold"), at the north end of the city. This is also regarded as a foundation of Srong-dsan-gampo, and is said to contain the body of his Chinese wife, and the second of the primeval palladia, the image that she brought with her to the Snow-land; whence the Mongols and Chinese call it the temple of the little *Jû*. The lamas of this convent, as well as of that next to be mentioned, are noted for their pretensions to and practice of magical arts, one of the degrading characteristics of the lama forms of Buddhism. The orthodox "yellow" sect indeed profess to distinguish between lawful and unlawful magical formulæ, and to give degrees only in the former. The lamas of Ramo-chhé have also the ill repute of cultivating that species of doctrine which is connected, like their magic, with Tantric mysticism, and which professes to destroy sensual passion by the contemplation of its representations. The walls of the convent are defiled with a series of sculptures of gross obscenity.[2]

Another convent within the city is that of *Moru*, also near the north end, remarkable for its external order and cleanliness, and, though famous like the last as a school of orthodox magic, noted also for the printing-house in the convent garden. Lastly we notice the *Garmakhia*, the inmates of which are sorcerers of the ruder kind, who seem really to represent the rude medicine-men of the superstitions which preceded Buddhism in Tibet. As the vulgar will not dispense with their marvels (knife-swallowing, fire-breathing, cutting off their own heads, and the like), every great orthodox monastery in Tibet keeps one of these conjurors, who does not belong to the fraternity of the house, but lives in a particular part of it, bearing the name of *Choi-chong* (*Ch'hos-skyong*) or "protector of religion," and is allowed to marry. These practitioners of the black art possess no literature, but hand down their mysteries from father to son. Their fantastic equipment, their frantic bearing, and their cries and howls seem to identify them with the grossest Shamanist devil-dancers,—strongly remote in externals from the gentle and cultivated persons in the higher ranks of the Lama Church, of whom we read in Turner or Huc. Other monasteries in or near the city are the *Chumuling* at the north-west corner; the *Tankyaling*

[1] So in Nain Singh's narrative. But the word is properly *Matsyendranâth*, which is the name of a saint adored by the Nepalese Buddhists, and identified with Padmapani, the fourth Dhyâni Bodhisatva of their system (see Hodgson in *Journ. Roy. As. Soc.*, xviii. 394).

[2] It was in this convent that P. Desideri studied the religion of the lamas. "From March to July," he says, "I set myself, I will not say to read, but rather to *devour* the chief books of the *Kaa-n-ghiur*, and to take in a complete knowledge of all that pertains to that false religion."

at the west of the city; the *Kontyaling*, about a mile west of the city, at the foot of a low isolated hill called Chapochi. Three miles south, beyond the river, is the *Chochuling*. These four convents are known as "The Four Ling."

Leaving the city by the side of the Ramoch'hé, we see on our left the famous Potala with its many edifices crowning and seeming to grow out of a rocky hill, which rises like an island from the plain. It forms altogether a majestic mountain of building. At the south base of the rock is a large space inclosed by walls and gates, with great porticoes on the inner side. This swarms with lamas, its nooks with beggars basking in the sun. A series of tolerably easy staircases, broken by intervals of gentle ascent, leads to the summit of the rock. The whole width of this is occupied by the palace. The central part of this group of buildings rises in a vast quadrangular mass, in four stories, to a great height, terminating in a gilt canopy similar, it would seem, to that on the Labrang. Here on the lofty terrace is the Grand Lama's hall of audience, and from this great height he looks down upon the crowds of his votaries far below, thronging the plain, and streaming to kneel before the sacred hill. The monastic buildings attached to the palace temple are said to contain cells for ten thousand monks. Other palatial buildings, towers, chapels, *chodtens* (chaityas), pavilions, gleaming with gold and silver, Buddhas and other idols, cluster round and crown the three peaks of Potala. The palace itself is said to be painted externally with red and white stripes. The walls and ceilings of all the chief apartments and temples are covered with rich silks. We give an engraving of it (fig. 4), extracted from a Chinese view of Lhasa, published by Klaproth in the work quoted

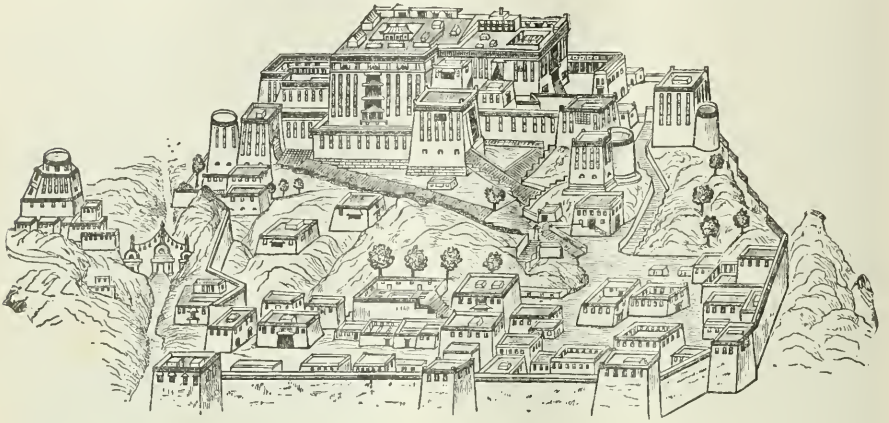

Fig. 4.—Potala, the Palace-Temple of the Grand Lama.

at the end. The Potala has every appearance of having been drawn from the reality. Two avenues bordered with trees of considerable size lead from the city to the foot of Potala. "You see there constantly," says Huc, "a great number of foreign pilgrims, passing between their fingers the beads of their long Buddhist rosaries, with lamas of the court splendidly attired, and mounted on richly caparisoned horses. There reigns in the neighbourhood of the Potala great and incessant movement; but for the most part everybody is grave and silent; religious thoughts appear to occupy the minds of all." It would seem that between the palace and the city runs a stream which is crossed by a bridge called "The Bridge of Glazed Tiles."

On the north side of the rock a wide and easy road descends winding. By this, which has a parapet along the edge, it is lawful to ride. Not far from the base is a garden-palace in the middle of a lake which is surrounded by trees and shrubberies. This palace, called *Lu-khang*, is described by Desideri as of attractive style, and circular in form, with a *loggia* or portico running all round, and adorned with paintings. Here the dissolute Lama who built it, at the end of the 17th century, used to give himself up to dissipation with the women of Lhasa. Several other villas or gardens of the Tibetan pope are mentioned; in one of them the Panch'hen-Rinpoch'he (or Teshu Lama) is received when he visits Lhasa, and the two living Buddhas drink tea together there. It is in the numerous gardens round the town that those large trees grow of which Huc speaks as giving Lhasa such a green girdle of foliage. There is no natural wood.

No country in the world—not even Spain or Italy in the last century—has so abounded in convents and monks as Tibet. The district of Lhasa alone is said to contain thirty great convents, besides many smaller establishments, and a notice of Lhasa would be incomplete without some mention at least of the great monastic establishments which stand within a few miles of the city, and constitute an essential element in its existence. These are not single masses of building like the great convents of Europe. The temple (*Lha-khang*) is the focus of the whole. Round this are gathered numerous houses detached from one another, though not far apart, and generally three stories in height. In each of these are various apartments, each assigned to a monk of some authority and dignity, with several younger members or novices under his immediate direction. Each house has a little garden, and a quantity of vases in which plants are grown. Library, storehouse, hostel, occupy other buildings, and a varying multitude of the peculiar Buddhist objects of adoration which we know as *dagobas* or *chaityas*, as well as of masts with sacred flags and streamers. The whole is usually enclosed in a lofty and solid wall. These establishments have undoubtedly a vast population, though we can hardly accept specific figures, in which indeed authorities do not agree. Huc says the inmates of each of the three great convents which we are about to name amounted to

15,000; Nain Singh states them at 7700, 5500, and 3300 respectively; the former numbers seem excessive, the latter artificial; but no doubt the real numbers are large. In the Labrang they show a copper kettle holding more than one hundred buckets, which was used to make tea for the lamas who took part in the daily temple service.

The three great convents in the vicinity, all claiming to be foundations of Tsongkhapa, the mediæval reformer and organizer of the modern orthodox Lama Church, are the following:—

1. *Bre-bung* (written *Bras-sPungs*, "the Rice-Heap," so called from the shape of the hill on which it stands), called by Nain Singh *Debang*, is 5 or 6 miles from Lhasa, west of the city, at the entrance to the plain from the side of Shigatzé and Nepal. In the middle of the convent buildings rises a kind of pavilion, brilliant with colour and gilding, which is reserved for the Dalai Lama, when he visits Brebung once a year, and expounds to the inmates. The place is greatly frequented by the Mongol students who come to Lhasa to graduate, and is known in the country as the Mongol convent.

2. *Sera* ("The Golden") is 2 or 3 miles from the city on the acclivity of the hills which border the valley on the north, and close to the road by which pilgrims enter from Mongolia. The hill is planted with holly and cypress, and from a distance the crowd of buildings and temples, rising in amphitheatre against a background of trees, forms a pleasing picture. In the recesses of the hill, high above the convent, are scattered cells of lamas adopting the solitary life. There are three great temples rising in many stories, the walls of which are entirely covered with gilding, whence the convent's name. In the chief of these temples is preserved the famous *Dorjé* of Buddha, *i.e.*, the *Vajra* or Thunderbolt (of Indra properly), or Adamant, the symbol of the strong and indestructible, which the priest grasps and manipulates in various ways during prayer. From this *dorjé*, according to one etymology at least, comes the name of the Himalayan sanatarium *Dorjiling* or Darjeeling. The emblem is a bronze instrument, shaped much like a dumb-bell with pointed ends, and it is said by Koeppen to have been one of the later lama borrowings from Sivaism. The original is carried solemnly in procession to Labrang during the New Year's festival. In Sera P. Desideri found shelter during the capture of the city by the Dzungar Khan in 1717, spoken of below.

The hill adjoining Sera is believed to be rich in silver ore, but it is not allowed to be worked. On the summit is a spring, and a holy place of the Lhasa Mohammedans, who resort thither. Near the convent there is said to be gold, which is worked by the monks. "Should they . . . discover a nugget of large size, it is immediately replaced in the earth, under the impression that the large nuggets . . . germinate in time, producing the small lumps which they are privileged to search for" (Nain Singh).

3. *Galdan.*—This great convent is 10 or 12 miles east of Lhasa, on the other side of the Kichu Tsangpo river. It is the oldest monastery of the "Yellow" sect, having been founded by Tsongkhapa, and having had him for its first superior. Here his body is said to be preserved with miraculous circumstances, and here are other relics of him, such as the impression of his hands and feet in hard butter.

Samayé (*bSam-yas*) is another famous convent intimately connected with Lhasa, but it lies some 36 miles south-east on the left bank of the great Tsangpo. It was founded by Padma Sambhava (*Ur-ghien* of the Tibetans), the apostle who came from Udayâna in the 8th century as the great reviver of Buddhism, and was at the head of the old Red sect. It is visited by the Dalai Lama once a year. It is surrounded by a very high circular stone wall, 1½ miles in circumference, with gates facing the four points of the compass. On this wall Nain Singh, who was here on his last journey (1874), counted 1030 *chaityas* of brick. One very large temple (*Lha-khang*) occupies the centre, and round it are four smaller but still very large temples. Many of the idols are of pure gold, and the wealth is very great. The interiors of the temples are covered with beautiful writing in enormous Nagari characters, which the vulgar believe to be the writing of Sakya himself.

Lhasa Festivities.—The greatest of these is at the new year. This lasts fifteen days, and is a kind of lama carnival, in which masks and mummings, wherein the Tibetans take especial delight, play a great part. The celebration commences at midnight, with shouts and clangour of bells, gongs, chank-shells, drums, and all the noisy repertory of Tibetan music; whilst friends exchange early visits and administer coarse sweetmeats and buttered tea. On the 2d day the Dalai Lama gives a grand banquet, at which the Chinese and native authorities are present, whilst in the public spaces, and in front of the great convents, all sorts of shows and jugglers' performances go on. Next day a regular Tibetan exhibition takes place. A long cable, twisted of leather thongs, is stretched from a high point in the battlements of Potala slanting down to the plain, where it is strongly moored. Two men slide from top to bottom of this huge hypothenuse, sometimes lying on the chest (which is protected by a breast-plate of strong leather), spreading their arms as if to swim, and descending with the rapidity of an arrow-flight. Occasionally fatal accidents occur in this performance, which is called "the dance of the gods"; but the survivors are rewarded by the court, and the Grand Lama himself is always a witness of it. This practice occurs more or less over the Himalayan plateau, and is known in the neighbourhood of the Ganges as *Barat.* It is employed as a kind of expiatory rite in cases of pestilence and the like. And exactly the same performance is described as having been exhibited in St Paul's Churchyard before King Edward VI., and again before Philip of Spain, as well as, about 1750, at Hertford and other places in England (see Strutt's *Sports.* &c., 2d ed., p. 198).

The most remarkable celebration of the new year's festivities is the great jubilee of the *Monlam* (*sMon-lam*, "prayer"), instituted by Tsongkhapa himself in 1409. Lamas from all parts of Tibet, but chiefly from the great convents in the neighbourhood, flock to Lhasa, and every road leading thither is thronged with troops of monks on foot or horseback, on yaks or donkeys, and carrying with them their breviaries and their cooking-pots. They descend like swarms of bees upon the city, and those who cannot find lodging bivouac in the streets and squares, or pitch their little black tents in the plain. The festival lasts six days, during which there reigns a kind of saturnalia, and the town is abandoned to these crowds of monks. Unspeakable confusion and disorder reign, whilst gangs of lamas parade the streets, shouting, singing, and coming to blows. The object of this great disorderly gathering is, however, supposed to be devotional. Vast processions take place, with mystic offerings and lama-music, to the Labrang and Moru convents; the Grand Lama himself assists at the festival, and from an elevated throne beside the Labrang receives the offerings of the multitude, and bestows his benediction.

On the 15th of the first month multitudes of torches are kept ablaze, which lighten up the city to a great distance, whilst the interior of the Labrang is illuminated throughout the night by innumerable lanterns shedding light on coloured figures in bas-relief, framed in arabesques of animals, birds, and flowers, and representing the history of Buddha, and other subjects, all modelled in butter. The figures are executed on a large scale, and, as described by Huc, who witnessed the festival at Kunbum on the frontier of China, with extraordinary truth and skill. These singular works of art occupy some months in preparation, and on the morrow are thrown away. On other days horse-races take place from Sera to Potala, and foot-races from Potala to the city. On the 27th of the month the holy *Dorjé* is carried in solemn procession from Sera to the Labrang, and to the presence of the Lama at Potala.

Of other great annual feasts, one, in the fourth month, is assigned to the conception of Sakya, but appears to connect itself with the old nature-feast of the entering of spring, and to be more or less identical with the *Hûlî* of India. A second, the consecration of the waters, in September-October, appears, on the confines of India, to be associated with the Dasehra.

On the 30th day of the second month there comes off a strange ceremony, akin to that of the scapegoat (which is not unknown in India). It is called the driving out of the demon. A man is hired to perform the part of demon (or victim rather), a part which sometimes ends fatally. He is fantastically dressed, his face mottled with white and black, and is then brought forth from the Labrang to engage in quasi-theological controversy with one who represents the Grand Lama. This ends in their throwing dice against each other (as it were for the weal or woe of Lhasa). If the demon were to win the omen would be appalling; so this is effectually barred by false dice. The victim is then marched outside the city, followed by the troops, and by the whole populace, hooting, shouting, and firing volleys after him. Once he is driven off, the people return, and he is carried off to the Samayé convent. Should he die shortly after, this is auspicious; if not, he is kept in ward at Samayé for a twelvemonth.

Nain Singh, whose habitual accuracy is attested by many facts, mentions a strange practice of comparatively recent origin, according to which the civil power in the city is put up to auction for the first twenty-three days of the new year. The purchaser, who must be a member of the Brebung monastery, and is termed the *Jalno*, is a kind of lord of misrule, who exercises arbitrary authority during that time for his own benefit, levying taxes and capricious fines upon the citizens.

Climate, &c.—Pundit Nain Singh, who lived at Lhasa continuously from 26th January to 21st April (1866), made indoor observations of the thermometer from 9th to 23d February hourly, with the exception of eight hours of sleep (11 P.M. to 7 A.M.); and the extreme variation in the record is from 26° (February 2d, 11 A.M.) to 45°·75 (February 22d, 2 P.M.). He also mentions that the river (Kichu Tsangpo) which flows by Lhasa was frozen in December,—the great river (Brahmaputra) being open and passed by boats. Water kept in the warmest part of a house froze, and burst the vessels holding it. It is not easy to draw very precise conclusions from these facts, but they perhaps indicate a somewhat less severe winter than that of Ladak, where the true air temperature is reckoned by Captain H. Strachey to range between zero and 30° Fahr. In other respects the Pundit's account of the climate does not differ materially from those we possess of western Tibet. He says, besides, that strong and high winds are very prevalent, especially during March and April; but snow fell only twice in the three months of his stay, and not deeper than 3 inches. The fall on the surrounding hills was somewhat heavier, but apparently it did not lie, for in general hardly any snow was to be seen from the city. Should the snowfall in Lhasa ever exceed a foot, it is regarded as an evil omen. What little Desideri says is to like effect. The cold, he says, was never hurtful to health, and he had often spent the night (in winter apparently) under the open sky, without suffering. Lightning, which occurs only in connexion with the summer rains, is never known to strike houses or to kill.

It begins to be warm in May, and the sun's power rapidly grows most oppressive. There is a distinct rainy season at Shigatze (July to September), and this appears to extend to Lhasa, though the information is not very precise. Nain Singh was told that earthquakes are unknown in the Lhasa province. Cholera is said to be unknown; but dysentery is often violent, and rapidly fatal. Cough and chest diseases are not prevalent, nor are skin diseases common, in spite of the filthy habits of the people. The most dreaded of all diseases is smallpox. Inoculation is habitually used. Ophthalmia is very prevalent and severe.

History.—The seat of the princes whose family raised Tibet to a position among the powers of Asia was originally on the Yarlung river, in the extreme east of the region now occupied by Tibetan tribes. It was transplanted to Lhasa in the 7th century by the king Srong-dsan-gampo, conqueror, civilizer, and proselytizer, the founder of Buddhism in Tibet, the introducer of the Indian alphabet. On the three-peaked crag now occupied by the palace-monastery of the Great Lama this king is said to have established his fortress, whilst he founded in the plain below temples to receive the sacred images, brought respectively from Nepal and from China, by the brides to whom his own conversion is attributed.

Tibet endured as a conquering power some two centuries, and the more famous among the descendants of the founder added to the city. Thsi-rong-de-tsan (who reigned 740–786) is said to have erected a great temple-palace of which the basement followed the Tibetan style, the middle story the Chinese, and the upper story the Indian—a combination which would aptly symbolize the elements that have moulded the culture of Lhasa, such as it is. His son, the last of the great orthodox kings, in the next century, is said to have summoned artists from Nepal and India, and among many splendid foundations to have erected a sanctuary (at Samayé) of vast height, which had nine stories, the three lower of stone, the three middle of brick, the three uppermost of timber. With this king the glory of Tibet and of ancient Lhasa reached its zenith, and in 822 an obelisk recording his treaty on equal terms with the Great T'ang emperor of China was erected in the city. There followed dark days for Lhasa and the Buddhist Church in the accession of this king's brother Langdharma, who has been called the Julian of the Lamas. This king rejected the doctrine, persecuted and scattered its ministers, and threw down its temples, convents, and images. It was more than a century before Buddhism recovered its hold, and its convents were rehabilitated over Tibet. The country was then split into an infinity of petty states, many of them ruled from the convents by warlike ecclesiastics; but, though the old monarchy never recovered, Lhasa seems to have maintained some supremacy, and probably never lost its claim to be the chief city of that congeries of principalities, with a common faith and a common language, which was called Tibet.

The Arab geographers of the 10th century speak of Tibet, but it is without real knowledge, and none speak of any city that we can identify with Lhasa. The first passage in any Western author in which such identification can be probably traced occurs in the narrative of Friar Odorico of Pordenone (*c.* 1330). This remarkable traveller's route from Europe to India, and thence by sea to China, can be traced satisfactorily, but of his journey homeward through Asia the indications are very fragmentary. He speaks, however, on this return journey of the realm of Tibet, which lay on the confines of India proper:—"The folk of that country dwell in tents made of black felt. But the chief and royal city is all built with walls of black and white, and all its streets are very well paved. In this city no one shall dare to shed the blood of any, whether man or beast, for the reverence they bear a certain idol that is there worshipped. In that city dwelleth the *Abassi*, *i.e.*, in their tongue the pope, who is the head of all the idolators, and who has the disposal of all their benefices such as they are after their manner."

We know that Kublai Khan had constituted a young prince of the Lama Church, Mati Dhwaja, as head of that body, and tributary ruler of Tibet, but besides this all is obscure for a century. This passage of Odoric shows that such authority continued under Kublai's descendants, and that some foreshadow of the position since occupied by the Dalai Lama already existed. But it was not till a century after Odoric that the strange heredity of the dynasty of the Dalai Lamas of Lhasa actually began. And in the first two centuries of its existence the residence of these pontiffs was rather at Brebúng or Sera than at Lhasa itself, though the latter was the centre of devout resort. A great event for Lhasa was the conversion, or reconversion, of the Mongols to Lamaism (*c.* 1577), which made the city the focus of sanctity and pilgrimage to so vast a tract of Asia. It was in the middle of the 17th century that Lhasa became the residence of the Dalai Lama. A native prince, known as the Tsanpo, with his seat at Shigatzé, had made himself master of southern Tibet, and threatened to absorb the whole. The fifth Dalai Lama, Navang Lobsang, called in the aid of a Calmuck prince, Gushi Khan, from the neighbourhood of the Koko-nur, who defeated and slew the Tsanpo and made over full dominion in Tibet to the Lama (1643). The latter now first established his court, and built his palace, on the rock-site of the fortress of the ancient monarchy, which apparently had fallen into ruin, and to this he gave the name of *Potala.*[1]

In the time of this Dalai Lama, Lhasa was visited for the first time by European travellers. In 1624 Antonio d'Andrada, a Portuguese Jesuit, had penetrated to Tibet through the Gangetic Himalaya, and returned the following year with a coadjutor. But the place which he reached was *Caparangue* in the kingdom of *Cogue*, as he calls it, *i.e.*, Chaprang in the province of Gugé on the Tibetan Sutlej, and he never got nearer Lhasa. In June 1661 the Jesuit

[1] This name is absurdly explained by Abbé Huc as *Buddha-la* = "hill of Buddha." This is not even a possible etymology, for, whilst the actual term *Buddha* seems never to be used untranslated in Tibet, one may discern from Huc's own book that *la* means, not "a hill," but "a pass" over mountains. The name seems to be really taken from the classical traditions of the Buddhists. *Potala*, "the harbour" (the *Pattala* of the Greeks, the modern Hyderabad on the Indus), was in legend the royal seat, for more than a hundred generations, of the Sakya progenitors of Gautama Buddha (see Csoma de Körös in *Journ. As. Soc. Bengal*, ii. 390.

fathers, Albert D'Orville and John Grueber, started from Peking, and, by the way of Siningfu and the Koko-nur, reached Lhasa, where they stayed a month, and then went on through Nepal to India. The extracts from Grueber's narrative, given by Athanasius Kircher in his *China Illustrata* (Amst., 1667), are accompanied by a drawing of Potala which, though meagre, appears to be genuine, and is the only European representation in existence of that Tibetan Vatican.

The founder of Potala died in 1682, and his death was followed by events which brought on a time of trouble. He had appointed as "regent" or civil administrator (*Tisri*, or *Deba*), one supposed to be his own natural son. This remarkable personage, Sangje Gyamtso, of great ambition and accomplishment, still renowned in Tibet as the author of some of the most valued works of the native literature, concealed the death of his master, asserting that the latter had retired, in mystic meditation or trance, to the upper chambers of the palace. The government continued to be carried on in the Lama's name by the regent, who leagued with Galdan Khan of Dzungaria against the Chinese (Manchu) power. It was not till the great emperor Kang-hi was marching on Tibet that the death of the Lama, sixteen years before, was admitted. A solemn funeral was then performed, at which 108,000 lamas assisted, and a new incarnation was set up in the person of a youth of fifteen. This young man was the scandal of the Lamaite Church in every kind of evil living and debauchery. But it was under him and the regent Sangje Gyamtso that the Potala palace attained its present scale of grandeur, and that most of the other great buildings of Lhasa were extended and embellished. In 1705–6 a Calmuck prince, Latsan Khan, great grandson of Gushi Khan, taking the renowned name of Jenghiz Khan, made himself master of Tibet, and put to death both the crafty regent and the dissolute lama whom he had set up. The Dzungarians crossed the northern desert in 1717, and stormed Lhasa, but were in turn driven out by the army of Kang-hi in 1720, and from that time the Chinese power, though, as elsewhere, it has been at times severely shaken, has never quite lost its hold of Tibet.

It was in the midst of these troubled times (1708) that a Capuchin mission entered Lhasa. It was unfortunate in the death of its successive heads, and from about 1712 it was abandoned for several years, but after an interval the Capuchins reappeared, twelve in number, reaching Lhasa by Nepal in 1720. Nothing almost was heard of them till the head of the mission, P. Orazio della Penna, appeared at Rome in 1735 to report that nine were dead, and to ask reinforcement. He returned with nine more, carrying presents to the Grand Lama and the so-called "king of Tibet." In 1742 he reported his safe arrival, and that the presents were well received. Called to Nepal, where there was a branch of the mission, he died there in 1747. We possess some of the results collected by this mission in an excellent short treatise on Tibet by P. Orazio himself, as well as in the extraordinary hodge-podge of crude philology, rubbish, and valuable facts (like fossils imbedded in a bank of mud), the *Alphabetum Tibetanum* of the Augustine monk Ant. Giorgi (*Rome*, 1762). The mission seems to have been expelled from Tibet in 1754, and found refuge for a time in Nepal. Some fifty volumes, the relics of the mission library, were in 1847 recovered from Lhasa by Mr Bryan Hodgson, through the courtesy of the Grand Lama himself, and were transmitted as an offering to Pope Pius IX., then in the first bloom of reputation.

In 1716, moreover, two Jesuits, P. Ipolito Desideri of Pistoia, and P. Freyre, a Portuguese, reached Lhasa by way of Kashmir, Ladak, and the enormous journey from Ladak by the holy lakes and the valley of the Tsanpu. Desideri remained at Lhasa till April 1721, witnessing the capture of Lhasa successively by Dzungar and Chinese. Of the moderation of the latter, and their abstinence from all outrage or plunder, he speaks highly. His departure was due to controversies between the Jesuits and Capuchins at Rome, which caused an order to be issued for his retirement from Tibet. An interesting letter from him, dated April 10, 1716, is printed in the *Lettres Édifiantes*, Rec. xv., but a large MS. volume of his observations during his residence in Tibet is still unpublished. The next European visitor was Samuel Van de Putte of Flushing, an LL.D. of Leyden, whose thirst for travel carried him through India to Lhasa, where he is said to have resided a long time, to have acquired the language, and to have become intimate with some of the lamas. After travelling from Lhasa to Peking with a lama mission he returned, again by Lhasa, to India, and was an eye-witness of the sack of Delhi by Nadir Shah in 1737. Unhappily he ordered his papers to be burnt after his death, and the knowledge that such a traveller must have accumulated died with him. We pass on to 1811–12 when the first (and last) English visit to Lhasa occurred. The traveller was Thomas Manning, a Cambridge man of Caius College, who had been long devoted to Chinese studies, the "friend M." of Charles Lamb, from whom "Elia" professes to have got that translation of a Chinese MS. which furnished the immortal dissertation on roast pig. After residing some years at Canton, Manning went to Calcutta, bent on reaching the interior of China through Tibet, since from the seaboard it was sealed. He actually did reach Lhasa, stayed there about five months, and had several interviews with the Dalai Lama, but was compelled to return to India. He never published anything regarding his journey, and the very fact of its occurrence was known to few, when his narrative was printed, through the praiseworthy zeal of Mr C. Markham, in 1876. The man had given the reins to his own eccentricities till he seemed to have lost all power of seriousness, and the account, though containing some passages of great interest, is most disappointing.

The next travellers to reach Lhasa were Huc and Gabet, French Lazarist priests, who travelled from China the route followed by Grueber and by Van de Putte, *via* Siningfu, and reached Lhasa 29th January 1846. On the 15th of March they were sent off under escort by the rugged road to Sz'-chuen. Huc's book, *Souvenirs d'un Voyage*, &c., is probably still well known, and deserves to be so, for it is one of the most delightful among books of travel. Huc was indeed, not only without science, perhaps without accurate knowledge of any kind, but also without that geographical sense which sometimes enables a traveller to bring back valuable contributions to geographical knowledge though unable to make instrumental observations. He was, however, amazingly clever as a narrator and sketcher of character; and, in this his first work, his ambition to shine had not gained the upper hand as it did fatally in later works. It was Ke-shen, a well-known Chinese statesman, disgraced for making peace with the English at Canton in 1841, and who was then on a special deputation to Lhasa, who ostensibly expelled them. The Tibetan regent, with his enlightened and kindly spirit, is painted by Huc in most attractive colours, and Mr Markham expresses strongly the opinion that the native authorities were most willing to receive strangers, whilst the jealousy that excluded them was Chinese only. Recent experiences of attempts to enter Tibet contradict this view. The lamas, whose rule seems to have become more and more grasping and oppressive, appear to be sensible that their system would easily fall to pieces, and are violently opposed to the passage of Europeans across the Tibetan frontier.

Our latest narrative of a visit to Lhasa is that of the late Pundit Nain Singh, trained as an explorer in the Indian survey department. He reached the city in the course of two most remarkable journeys. In the first, after an ineffectual attempt by Nepal, he travelled by the Manasarowar Lake, and the road thence eastward, parallel to the course of the Tsanpu, reaching Lhasa 10th January 1866, and leaving it 21st April 1867. On the second journey (1874) he started from Ladak, crossing the vast and elevated plateau by the Tengri-nor and other great lakes, and again reaching Lhasa 18th November. Between these two journeys Lhasa had also been visited by another native explorer in 1872.[1] Nain Singh, by his extraordinary surveys, and by repeated observations of latitude on his first visit, has fixed for us the position of Lhasa. But he also has given an account of his journeys, and of his residence there, which, though brief, is full of intelligence and interest, and appears to be thoroughly trustworthy. This enterprising and deserving man was, on the completion of his journey in 1875, rewarded by the Indian Government with a pension and grant of land, and afterwards received the gold medal of the Roy. Geog. Soc. and the Companionship of the Star of India. He died early in 1882.

Baber, printed in *Suppt. to Gazette of India*, November 8, 1879; "The Silver Coinage of Tibet," by M. Terrien de la Couperie, in *Numism. Chron.*, 3d ser., vol. i. (H. Y.)

L'HÔPITAL, or L'Hospital, Michel de (*c.* 1505–1573), chancellor of France from 1560 to 1568, was born near Aigueperse in Auvergne (now Puy-de-Dôme) about the year 1505. His father, who was physician and comptroller of accounts to the constable Charles de Bourbon, sent him to study at Toulouse, whence at the age of eighteen he was driven by the evil fortunes of the family patron, after suffering arrest and imprisonment, to Padua, in which university he studied law and letters for about six years. On the completion of his studies he joined his father at Bologna, and afterwards, the constable having died, went to Rome in the suite of Charles V. For some time he held the position of auditor of the rota at Rome, but in 1534, encouraged by the fair promises of Cardinal de

[1] See Walker's *Report* for 1873–74.

Grammont, he returned to France. The death of his patron soon afterwards seriously impaired his prospects; but after he had entered himself of the Parisian bar, his marriage, in 1537, to a daughter of the lieutenant-criminel procured for him the post of counsellor to the parliament of Paris. This office he held until 1547, when he was sent by Henry II. on a mission to Bologna, where the council of Trent was at that time sitting; after sixteen months of wearisome inactivity there, he was by his own desire recalled at the close of 1548. L'Hôpital now for some time held the position of "chancellor" in the household of the princess Margaret, duchess of Berri, and in 1554 he was made superintendent of the royal finances. In 1559 he accompanied his mistress, now duchess of Savoy, to Nice, where, on the following year, tidings reached him that he had been chosen to succeed Olivier in the chancellorship of France. One of his first acts after entering on the duties of his office (in July 1560) was to cause the parliament of Paris to register the edict of Romorantin, of which he is sometimes, but erroneously it would seem, said to have been the author. Designed as it was to protect so-called heretics from the secret and summary methods of the Inquisition, it certainly had his sympathy and approval. In accordance with the consistent policy of inclusion and toleration by which the whole of his official life was characterized, he induced the council to call the Assembly of Notables, which met at Fontainebleau in August 1660 and agreed that the States General should be summoned, all proceedings against heretics being meanwhile suppressed, pending the reformation of the church by a general or national council. The States General met in December; the edict of Orleans (July 1561) followed, and finally, after the colloquy of Poissy, that of January 1562, the most liberal (except that of Nantes) ever obtained by the Protestants of France. Its terms, however, were not carried out, and during the war which was the inevitable result of the massacre of Vassy in May, L'Hôpital, whose dismissal had been for some time urged by the papal legate Hippolytus of Este, found it necessary to retire to his estate at Vignay near Étampes, whence he did not return until after the pacification of Amboise (March 19, 1563). It was by his advice that Charles IX. was declared of age (August 17, 1563) at Rouen, a measure which really increased the power of Catherine de' Medici; and it was under his influence also that the parliament of Paris in 1564 refused to sanction the publication of the acts of the council of Trent; on account of their inconsistency with the Gallican liberties. In 1564–66 he accompanied the young king on an extended tour through France; and in 1566 he was instrumental in the promulgation of an important edict for reform of abuses in the administration of justice. The renewal of the religious war in September 1567, however, was at once a symptom and a cause of diminished influence to L'Hôpital, and in February 1568 he obtained his letters of discharge, which were registered by the parliament on May 11, his titles, honours, and emoluments being reserved to him during the remainder of his life. Henceforward he lived a life of unbroken literary seclusion at Vignay, his only subsequent public appearance being by means of a "mémoire" which he addressed to the king in 1570 under the title *Le but de la guerre et de la paix, ou Discours du chancelier L'Hospital pour exhorter Charles IX. à donner la paix à ses subjects.* Though not exempt from considerable danger, he passed in safety through the troubles of the St Bartholomew, but did not long survive them. His death took place either at Vignay or at Bélesbat (Courdimanche, Étampes) on March 13, 1573.

After his death Pibrac, assisted by De Thou and Scévole de Sainte-Marthe, collected a volume of the *Poemata* of L'Hôpital, and in 1585 his grandson published *Epistolarum seu Sermonum libri sex.* The complete *Œuvres de l'Hôpital* were published for the first time by Dufey (5 vols. 8vo, Paris, 1824–25). They include his "Harangues" and "Remoustrances," the *Epistles*, the *Mémoire* to Charles IX., a *Traité de la Reformation de la Justice*, and the will of L'Hôpital. Haag (*France Prot.*, vii. p. 83) gives the titles of several MSS. still unpublished. Villemain wrote a *Vie de L'Hôpital*, which has recently been reprinted (1874), and there are monographs also by Taillandier (1861) and by Dupré-Lasal (1875).

LIAU-YANG, or Leaou-Yang, a city of China, formerly the chief town of the province of Liau-tung or Shing-king (southern Manchuria), and still a place of considerable mark, 35 miles south of Moukden. It is situated in a rich cotton district, and carries on no small trade. The walls include an area about 2½ miles long by 2 miles broad, and there are pretty extensive suburbs; but a good deal even of the enclosed area is under cultivation. The population is estimated at 80,000.

LIBANIUS, a Sophist, was the most distinguished Greek writer of the 4th century A.D. He was born at Antioch beween 314 and 316. He studied at Athens, and spent most of his earlier manhood in Constantinople and Nicomedia. His private classes at Constantinople were much more popular than those of the public professors; and their jealousy found means of having him expelled from Constantinople in 346 on the charge of studying magic. He was recalled from Nicomedia after five years. Ill health obliged him to retire to Antioch, where he spent the later part of his life. Though a pagan by religion, he enjoyed the favour of the Christian emperors. When Julian restored paganism as the state religion, Libanius showed no intolerance. Among his pupils he numbered St John Chrysostom and St Basil. His works, consisting chiefly of orations, declamations on set topics, and letters, are very voluminous, and have not yet been published in one single edition. He devoted much time to the study of the classical Greek writers, on whom his style is modelled with considerable success.

The best edition of the orations and declamations is Reiske's, of the letters Wolf's. See Westermann, *Gesch. d. Griech. Beredtsamkeit*; Bernhardy's and other histories of Greek literature; Förster, *Zur Schriftstellerei des Libanios*, and articles in *Hermes*, vols. ix. and x.

LIBAU (*Leepaja* of the Letts), a port of Russia, on the Baltic Sea, in the government of Courland and district of Grobin, 143 miles by rail south-west of Riga. It is situated at the northern extremity of a narrow sandy peninsula which separates Lake Libau (12 miles long and 2 miles wide) from the Baltic Sea. The town is well built of stone, with good gardens, and has a gymnasium and more than twenty different schools, cigar manufactories, machine works, and a small wharf. The sea throwing up a good deal of amber, many inhabitants are engaged in the fabrication of small articles of that substance. The harbour of Libau was 2 miles south of the town until a canal was dug through the peninsula in 1697; but this canal is liable to be silted up, and the depth at the bar is only 9 feet, or even 6 feet during south-west winds, so that larger ships must lie in the open roadstead. Libau being the most southern Baltic port in Russia has the advantage of freezing only for a few weeks during the winter. Since being brought, in 1872, into railway connexion with Moscow, Orel, and Kharkoff, it has become an important Russian port, and competes with the northern ports of Prussia, the exports already exceeding by 100,000 tons those from Königsberg. In 1879 the port of Libau was visited by 1976 ships, and the export of corn, flax, hempseed, and linseed has reached 28,212,600 roubles (about £2,822,000), against 1,980,000 roubles and 367 ships in 1872. The merchants carry on an active trade in grain and flax, making their purchases directly in southern Russia; their warehouses are numerous, spacious, and well built. The yearly fair has some importance for the neighbouring districts. The town is also a watering-place, yearly visited by several hundreds of persons. Population in 1881, 27,900; with military and railway servants, 30,000.

The port of Libau, *Lyra portus*, is mentioned as early as 1263; it then belonged to the Livonian order. In 1418 it was burnt by Lithuanians, and in 1560 it was mortgaged by the grandmaster of the order to the Prussian duke Albert. It was annexed to Russia in 1795.

LIBEL AND SLANDER are the terms employed in English law to denote injurious attacks upon a man's reputation or character by words written or spoken, or by equivalent signs. In most early systems of law we find verbal injuries treated as a criminal or quasi-criminal offence, the essence of the injury lying not in pecuniary loss, which may be compensated by damages, but in the personal insult which must be atoned for,—a vindictive penalty coming in the place of personal revenge. By the law of the XII. Tables, the composition of scurrilous songs and gross noisy public affronts were punished by death. Minor offences of the same class seem to have found their place under the general conception of *injuria*, which included ultimately every form of direct personal aggression which involved contumely or insult. In the later Roman jurisprudence, which has, on this point, exercised considerable influence over modern systems of law, we find verbal injuries dealt with in the edict under two heads. The first comprehended defamatory and injurious statements which were made in a public manner (*convicium contra bonos mores*). In this case the essence of the offence lay in the unwarrantable public proclamation, in the contumely which was offered to a man before his fellow-citizens. In such a case the truth of the statements was no justification for the unnecessarily public and insulting manner in which they had been made. The second head included defamatory statements which were made in private, and in this case the offence lay in the imputation itself, not in the manner of its publication. The truth was therefore a sufficient defence, for no man had a right to demand legal protection for a false reputation. Even belief in the truth was enough, because it took away the intention which was essential to the notion of *injuria*. The law thus aimed at giving sufficient scope for the discussion of a man's character, while at the same time it protected him from needless insult and pain. The remedy for verbal injuries was long confined to a civil action for a money penalty, which was estimated according to the gravity of the case, and which, although vindictive in its character, doubtless included practically the element of compensation. But a new remedy was introduced with the extension of the criminal law, under which many kinds of defamation were punished with great severity. We find at the same time increased importance attached to the publication of defamatory books and writings, the *libri* or *libelli famosi*, from which we derive our modern use of the word libel; and under the later emperors the latter term came to be specially applied to anonymous accusations or pasquils, the dissemination of which was regarded as peculiarly dangerous, and visited with very severe punishment, whether the matter contained in them were true or false.

The earlier history of the English law of defamation is somewhat obscure. Civil actions for damages seem to have been tolerably frequent so far back as the reign of Edward I. There was no distinction drawn between words written and spoken. When no pecuniary penalty was involved such cases fell within the old jurisdiction of the ecclesiastical courts, which was only finally abolished during the present reign. It seems, to say the least, uncertain whether any generally applicable criminal process was in use. The crime of *scandalum magnatum*, spreading false reports about the magnates of the realm, was established by statutes, but the first fully reported case in which libel is affirmed generally to be punishable at common law is one tried in the Star Chamber in the reign of James I. In that case no English authorities are cited except a previous case of the same nature before the same tribunal; the law and terminology appear to be taken directly from Roman sources, with the insertion that libels tended to a breach of the peace; and it seems probable that that not very scrupulous tribunal had simply found it convenient to adopt the very stringent Roman provisions regarding the *libelli famosi* without paying any regard to the Roman limitations. From that time we find both the criminal and civil remedies in full operation, and will now consider how the law stands with regard to each at the present time.

Civil Law.—The first important distinction we encounter is that between slander and libel, between the oral and written promulgation of defamatory statements. In the former case the remedy is limited. The law will not take notice of every kind of abusive or defamatory language. It must be shown either that the plaintiff has suffered actual damage as a direct consequence of the slander, or that the imputation is of such a nature that we are entitled to infer damage as a necessary consequence. The special damage on which an action is founded for slanderous words must be of the nature of pecuniary loss. Loss of reputation or of position in society, or even illness, however clearly it may be traced to the slander, is insufficient. When we cannot prove special damage, the action for slander is only allowed upon certain strictly defined grounds. These are the imputation of a crime or misdemeanour which is punishable corporeally, *e.g.*, by imprisonment; the imputation of a contagious or infectious disease; statements which tend to the disherison of an apparent heir (other cases of slander of title when the party is in possession requiring the allegation of special damage); and lastly, slanders directed against a man's professional or business character, which tend directly to prejudice him in his trade, profession, or means of livelihood. In the latter case the words must either be directly aimed at a man in his business or official character, or they must be such as necessarily to imply unfitness for his particular office or occupation. Thus words which merely reflect generally upon the moral character of a tradesman or professional man are not actionable, but they are actionable if directed against his dealings in the course of his trade or profession. But, in the case of a merchant or trader, an allegation which affects his credit generally is enough, and in the same way it has been held that statements are actionable which affect the ability or moral characters of persons who hold offices, or exercise occupation which require a high degree of ability, or infer peculiar confidence. In every case the plaintiff must have been at the time of the slander in the actual exercise of the occupation or enjoyment of the office with reference to which the slander is supposed to have affected him.

The action for libel is not restricted in the same way as that for slander. Originally, as we have seen, there appears to have been no essential distinction between them, but the establishment of libel as a criminal offence had probably considerable influence, and it soon became settled that written defamatory statements, or pictures and other signs which bore a defamatory meaning, implied greater malice and deliberation, and were generally fraught with greater injury than those which were merely made by word of mouth. The result has been that the action for libel is not limited to special grounds, or by the necessity of proving special damage. It may be founded on any statement which disparages a man's private or professional character, or which tends to hold him up to hatred, contempt, or ridicule. In one of the leading cases, for example, the plaintiff obtained damages because it was said of him that he was a hypocrite, and had used the cloak of religion for unworthy purposes. In another case a charge of ingratitude was held sufficient. In civil cases the libel must be published by being brought by the defendant under the notice of a third party, and it has even been held that it is sufficient if this has been done by gross carelessness, without deliberate intention to publish. Every person is liable to an action who is concerned in the publication of a libel, whether he be the author, printer, or publisher; and the extent and manner of the publication, although not affecting the ground of the action, is a material element in estimating the damages.

It is not necessary that the defamatory character of the words or writing complained of should be apparent on their face. They may be couched in the form of an insinuation, or may derive their sting from a reference to circumstances understood by the persons to whom they are addressed. In such a case the plaintiff must make the injurious sense clear by an averment called an innuendo, and it is for the jury to say whether the words bore the meaning thus ascribed to them.

In all civil actions for slander and libel the falsity of the injurious statements is an essential element, so that the defendant is always entitled to justify his statements by their truth; but when the statements are in themselves defamatory, their falsity is presumed, and the burden of proving their truth is laid upon the defendant. There are however, a large class of false defamatory statements, commonly called privileged, which are not actionable on account of the particular circumstances in which they are made. The general theory of law with regard to these cases is this. It is assumed that in every case of defamation intention is a necessary element; but in the ordinary case, when a statement is false and defamatory, the law presumes that it has been made or published with an evil intent, and will not allow this presumption to be rebutted by evidence or submitted as matter of fact to a jury. But there are certain circumstances in which the natural presumption is quite the other way. There are certain natural and proper occasions on which statements may be made which are in themselves defamatory, and which may be false, but which naturally suggest that the statements may have been made from a perfectly proper motive and with entire belief in their truth. In the cases of this kind which are recognized by law, the presumption is reversed. It lies with the plaintiff to show that the defendant was actuated by what is called *express malice*, by an intention to do harm, and in this case the question is not one of legal inference for the court, but a matter of fact to be decided by the jury. Although, however, the theory of the law seems to rest entirely upon natural presumption of intention, it is pretty clear that in determining the limits of privilege the courts have been almost wholly guided by considerations of public or general expediency.

In some cases the privilege is absolute, so that we cannot have an action for defamation even although we prove express malice. Thus no action of this kind can be maintained for statements made in the course of judicial proceedings if they are in any sense relevant to the matter in hand. In the same way no statements or publications are actionable which are made in the ordinary course of parliamentary proceedings. Papers published under the authority of parliament are protected by a special Act, 3 & 4 Vict. c. 9, which was passed after a decree of the law courts adverse to the privilege claimed. The reports of judicial and parliamentary proceedings stand in a somewhat different position, which has only been attained after a long and interesting conflict. The general rule now is that all reports of parliamentary or judicial proceedings are privileged in so far as they are honest and impartial. Even *ex parte* proceedings, in so far as they take place in public, now fall within the same rule. But if the report is garbled, or if part of it only is published, the party who is injured in consequence is entitled to maintain an action, and to have the question of malice submitted to a jury. Comments on subjects of public interest, on the proceedings of courts or public bodies, on publications, exhibitions, and on persons who have in any way chosen to invite the public attention, fall within a similar rule. The public interest demands that on all these subjects a fair latitude for discussion should be permitted; the critic is entitled to the utmost liberty so long as he expresses nothing more than his honest opinion of the subject before him, but if it can be proved that he has used false and defamatory language out of malice, and especially if he has travelled beyond the facts which are properly before the public, he is no longer protected by his privilege. In private life a large number of statements are privileged so long as they remain matters of strictly private communication. It is difficult to define the limits of private privilege without extensive reference to concrete cases; but generally it may be said that it includes all communications which are made in performance of a duty not merely legal but moral or social, answers to *bona fide* inquiries, communications made by persons in confidential relations regarding matters in which one or both are interested, and even statements made within proper limits by persons in the *bona fide* prosecution of their own interest. Common examples of this kind of privilege are to be found in answer to inquiries as to the character of servants or the solvency of a trader, warnings to a friend, communications between persons who are jointly interested in some matters of business. But in every case we must be careful not to exceed the limits of publication required by the occasion, or otherwise the privilege is lost. Thus defamatory statements may be privileged when made to a meeting of shareholders, but not when published to others who have no immediate concern in the business.

In a few instances in which an action cannot be maintained even by the averment of malice, the plaintiff may maintain an action by averring not only malice but also want of reasonable and probable cause. The most common instances of this kind are malicious charges made in the ordinary course of justice and malicious prosecutions. In such cases it would be contrary to public policy to punish or prevent every charge which was made from a purely malicious motive, but there is no reason for protecting accusations which are not only malicious, but destitute of all reasonable probability.

Criminal Law.—Publications which are blasphemous, immoral, or seditious are frequently termed libels, and are punishable both at common law and by various statutes. The matter, however, which constitutes the offence in these publications lies beyond our present scope. Libels upon individuals may be prosecuted by criminal information or indictment, but there can be no criminal prosecution for slander. So far as concerns the definition of libel, and its limitation by the necessity of proving in certain cases express malice, there is no substantial difference between the rules which apply to criminal prosecutions and to civil actions, with the one important exception (now considerably modified) that the falsity of a libel is not in criminal law an essential element of the offence. If the matter alleged were in itself defamatory, the court would not permit inquiry into its truth. The sweeping application of this rule seems chiefly due to the indiscriminate use, in earlier cases, of a rule in Roman law which was only applicable to certain modes of publication, but has been supported by various reasons of general policy, and especially by the view that one main reason for punishing a libel was its tendency to provoke a breach of the peace. The same view has occasioned a difference in the publication required in civil and criminal actions. It is enough in criminal law that the libel has been published to the party against whom it is directed, if it is averred that it is intended or calculated to produce a breach of the peace. Important alterations, however, have been introduced into this branch of the law by 6 & 7 Vict. c. 96. By that Act any person who maliciously publishes a defamatory libel may be punished by fine or imprisonment or both, the imprisonment not to exceed one year. Any person maliciously publishing a defamatory libel, knowing the same to be false, is liable to fine and imprisonment for two years. In every case the truth of the matters charged may be inquired into if it be pleaded, but the truth does not amount to a defence unless it is also proved that the publication was for the public benefit; and if, after such plea, the defendant is convicted, it is competent to the court to consider whether the guilt of the defendant is mitigated or aggravated by the plea, and the evidence given in relation to it. By the same Act a defendant is protected from publication of libels without his knowledge, authority, or consent, if the publication did not arise from the want of due care and caution on his part. The court are further authorized to award costs to the defendant in any information or indictment at the instance of a private prosecutor.

An important dispute about the powers of the jury in cases of libel arose during last century in connexion with some well known trials for seditious libels. The point is familiar to readers of Macaulay in connexion with the trial of the seven bishops, but the cases in which it was brought most prominently forward, and which led to its final settlement, were those against Woodfall (the printer of *Junius*), Wilkes, and others, and especially the case against Shipley, the dean of St Asaph (21 St. Tr. 925), in which the question was fought by Mr Erskine with extraordinary energy and ability. The controversy turned upon the question whether the jury were to be strictly confined to matters of fact which required to be proved by evidence, or whether in every case they were entitled to form their own opinion upon the libellous character of the publication and the intention of the author. There could be no doubt of course that the jury, if they pleased, had it in their power to return a general verdict of guilty or not guilty, but both in theory and practice they were subject in law to the directions of the court, and had to be informed by it as to what they were to take into consideration in determining upon their verdict (see JURY). There is no difficulty about the general application of this principle in criminal trials. In a case of murder, for example, the judge directs the jury that if they are satisfied the accused did so and so they ought to find him guilty. He directs them, not merely as to the definition of the crime, but as to the particular facts which fall within that definition. If the crime is one which is inferred by law from certain facts, they are only concerned with these facts, and must accept the construction which is put upon them by law. Applying these principles to the case of libel, juries were directed that it was for the court to determine whether the publication fell within the definition of libel, and whether the case was one in which malice was to be inferred by construction of law. If the case were one in which malice was inferred by law, the only facts left to the jury were the fact of publication and the meaning averred by innuendoes; they could not go into the question of intention, unless the case were one of privilege, in which express malice had to be proved. In general principle, therefore, the decisions of the court were in accordance with the ordinary principles of criminal law. But there were undoubtedly some peculiarities in the case of libel. The sense of words, the inferences to be drawn from them, and the effect which they produce are not so easily defined as gross matters of fact. They seem to belong to those cases in which the impression made upon a jury is more to be trusted than the decision of a judge. And further, owing to the mode of procedure, the defendant was often punished before the question of law was determined. But nevertheless the question would scarcely have been raised had the libels related merely to private matters. The real ground of dispute was the liberty to be accorded to political discussion. Had the judges taken as wide a view of privilege in discussing matters of public interest as they do now, the question could scarcely have arisen; for Erskine's whole contention really amounted to this, that the jury were entitled to take into consideration the good or bad intent of the authors, which is precisely the question which would now be put before them in any matter which concerned the public. But at that time the notion of a special privilege attaching to political discussion had scarcely arisen, or was at least confined within very narrow limits, and the cause of free political discussion seemed to be more safely entrusted to juries than to courts. The question was finally settled by Mr Fox's Libel Act (32 Geo. III. c. 60), by which the jury were entitled to give a general verdict on the whole matter put in issue.

Scotch Law.—In Scotch law there were originally three remedies for defamation. It might be prosecuted by or with the concurrence of the lord advocate before the Court of Justiciary; or, secondly, a criminal remedy might be obtained in the commissary (ecclesiastical) courts, which originally dealt with the defender by public retractation, or penance, but subsequently made use of fines payable to their own procurator or to the party injured, these latter being regarded as solatium to his feelings; or, lastly, an action of damages was competent before the Court of Session, which was strictly civil in its character, and aimed at the reparation of patrimonial loss. The first remedy has fallen into disuse; the second and third (the commissary courts being now abolished) became mixed up together, and are represented by the present action for damages or solatium. Originally the action before the Court of Session was strictly for damages—founded, not upon the *animus injuriandi*, but upon culpa, and could be defended by proving the truth of the statements. But in time the Court of Session began to assume the original jurisdiction of the commissary courts, and entertained actions for solatium in which the *animus injuriandi* was a necessary element, and to which, as in Roman law, the truth was not necessarily a defence. Ultimately the two actions got very much confused. We find continual disputes as to the necessity for the *animus injuriandi* and the applicability of the plea of *veritas convicii*, which arose from the fact that the courts were not always conscious that they were dealing with two actions, to one of which these notions were applicable, and to the other not. On the introduction of the jury court, presided over by an English lawyer, it was quite natural that he, finding no very clear distinction maintained between damage and solatium, applied the English plea of truth as a justification to every case, and retained the *animus injuriandi* both in ordinary cases and cases of privilege in the same shape as the English conception of malice. The leading and almost only differences between the English and Scotch law now are that the latter makes no essential distinction between oral and written defamation, that it practically gives an action for every case of defamation oral or written upon which in England a civil action might be maintained for libel, and that it possesses no criminal remedy. In consequence of the latter defect and the indiscriminate application of the plea of veritas to every case both of damages and solatium, there appears to be at present no remedy in Scotland even for the widest and most needless publication of offensive statements if only they are true.

American Law.—In this as in so many other departments the American law scarcely if at all differs from that of England. In so far indeed as the common law is concerned, they may be said to be substantially identical. The principal statutes which have altered the English criminal law, such as Mr Fox's Act, and 6 & 7 Vict. c. 96, are also represented by equivalent legislation in most American States. (A. GI.)

LIBER AND LIBERA, among the Romans, were a pair of deities, male and female, in whose worship two very different phases exist side by side. In the country feast of the vintage, and the city festival of March 17th called

Liberalia, we find purely Italian ceremonial unaffected by Greek religion. The country festival was a great merry-making, where the first-fruits of the new must were offered to the gods. It was full of unbridled rejoicing, and characterized by the grossest symbolism, in honour of the fertility of nature. It is usual to refer the name Liber to the free unrestrained character of his worship. In the city festival, growing civilization had impressed a new character on the primitive religion, and connected it with the framework of society. At this time the youths laid aside the boy's *toga prætexta* and assumed the man's *toga libera* or *virilis*. Cakes of *far*, honey, and oil (*liba*) were offered to the two gods at this festival. Liber is often invoked as *Liber Pater*, and we find even the expression *Jupiter Liber*, taking us back to the primitive stage of religion when no divine hierarchy of gods had been elaborated, and when Liber and Libera were in the sphere of their cultus the sole god and goddess. Originally Liber is probably only an epithet of Jupiter.

At an early period the Hellenic religion of Demeter, common to all the Greek colonies of Italy and Sicily, spread to Rome; then Liber and Libera were identified with Dionysus and Persephone, and associated with another Italian goddess Ceres, who was identified with Demeter. At the order of the Sibylline books, a temple was built to these three deities near the Circus Flaminius; the whole cultus was borrowed from the Greeks, down even to the terminology, and priestesses were brought from the Greek cities. The temple, *Ædes Cereris*, was founded by Aulus Postumius, 496 B.C., and dedicated by Spurius Cassius, 493 B.C. The chief festival of this cultus lasted eight days, from the 12th to the 19th of April; it was accompanied by games, called *Ludi Cereales* or *Liberales*. The plebeian ædiles, appointed about the time when the temple was founded, were closely attached to it, and from that time plebeian liberty continued in intimate relation to the *Ædes Cereris* and the gods there worshipped.

LIBERIA, a Negro republic on the Grain Coast of West Africa. Founded in 1822 by American philanthropists for the settlement of freedmen who wished to return to their native land, or to enjoy political and social privileges then denied them in the United States, it remained for twenty-five years under the tutelage of the mother country, but on the 26th July 1847 it was declared independent. In 1848 it was recognized as a sovereign state by Great Britain, which aided it in various ways, and by other Continental powers, and finally in 1861 by the United States. Its nominal boundaries are from the river Jong, a tributary of the Sherbar, in 7° 35′ N. lat., 12° 20′ W. long., and the river San Pedro, in 4° 45′ N. lat., 6° 40′ W. long., a distance of 380 miles, the limits of the state in the interior being usually stated at from 80 to 100 miles eastward, though this is unsettled, and the entire area of the country at 24,000 square miles, or 1000 miles less than Holland and Belgium combined. Like that of northern Guinea generally, the Liberian shore is low, but the country rises towards the interior, and is well-wooded and watered by numerous streams. The climate is, however, hot and unhealthy for Europeans, though of late years it has been improved by drainage, and is considered superior to that of any part of the neighbouring coast. The soil is fertile and well-suited for the growth of tropical crops, such as cotton, rice, sugar, indigo, yams, ground-nuts, bananas, ginger, cassava, pine-apples, cocoa-nuts, limes, oranges, tamarinds, and the Liberian variety of coffee[1] held in such high esteem. These products, in addition to palm oil, form the main support of the inhabitants, who in return import arms, ammunition, tobacco, salt provisions, implements of husbandry, cutlery, British cottons, and other manufactured goods. Coffee, palm oil, palm-kernels, rubber, ivory, dye woods, hides, ivory, arrowroot, sugar, cocoa, ginger, and rice form the principal articles of its commerce, which is carried on chiefly with Great Britain, Holland, Hamburg, and America. Copper, gold, iron, and deposits of gum-copal exist, but they are not worked; and all the large wild animals have long since been killed or driven out of the woods. Stock can be kept in the higher lands. The government is modelled on that of the United States, and consists of a president, and a congress composed of a senate of eight members elected for four years, and of a house of representatives of thirteen members elected for three years, in addition to a supreme court, and a cabinet of the American type. One additional representative is given for each additional 10,000 inhabitants by which the population may increase. Military service in the militia is obligatory on every male citizen between the ages of sixteen and fifty, but there is no standing army. There is no established church, and all faiths are equally tolerated. The state is divided into four counties (Mezurada, Grand Bassa, Sinoe, and Maryland[2]), and these again into townships, each 64 square miles in area. There are a number of little villages, but the only place of any consequence is Monrovia, the capital, containing 13,000 inhabitants, and in appearance very like a town in the southern United States, but in no way remarkable except for the large number of churches within its bounds. Besides Monrovia the chief ports are Robertsport, Marshall, Edina or Buchanan, Greenville, Sesters River, Sasstown, and Harper, and in 1881 foreigners were further permitted to trade at any point to the north of Robertsport. The present population of the republic (1882) comprises 18,000 civilized negroes, chiefly of American origin, and 1,050,000 half-wild natives, some of whom are adopting a settled life, and conforming to the habits of their tamed countrymen. Among the more interesting tribes are the Veis, the Bassas, the Krus, and the Mandingoes. The American Methodist Episcopal mission dates from 1833, the American Episcopal from 1834, and that of the American Baptists from 1835. The revenue of the state was returned at September 30, 1875, as 111,457 dollars, chiefly derived from customs, the national debt being 500,000 dollars, contracted in England in 1871. Of this neither principal nor interest has been paid. Socially and politically the state cannot be pronounced a marked success. The negroes in America display little desire to throw in their fortunes with it, now that they are free to go whither they list, nor do the barbarous tribes on the border of the republic seem to admire the black parody on a white man's government, which for sixty years has been presented to them. There is now and again a small immigration from the United States, but the Liberian civilization, cut off from the benefit of intercourse with a higher and broader culture, is apt to deteriorate, while neither the climate nor the laws and social surroundings are ever likely to attract many white men to its shores. It is, however, only fair to add that, though internal disorder is too often the rule, the state shows an appreciation of education and religion, and a keen desire to stand well in the good opinion of the powers with which it has relations by accredited representatives. It has formed treaties with most of the European countries, and with Hayti and the United States; and, though it has not paid its debts, successive Governments are in the habit of registering vows to meet this first obligation of a nation towards its neighbours. British coin and an irredeemable

[1] Liberian coffee (see COFFEE, vol. vi. p. 110) has been introduced into Brazil, Ceylon, the Dutch Indies, &c. The quantity actually exported from Liberia is comparatively small.

[2] Maryland was originally a separate colony, founded in 1831; it became an independent republic in 1854, and about 1860 was incorporated with its older neighbour.

paper currency are the money chiefly in circulation, but all accounts are kept in United States dollars and cents. The weights employed are also British, except that gold from the interior is bought and sold by the usano = 16 akis = 16,000 cowries = 314·76 grains troy. The gondar-ardeb (7·74 imperial pints), the massuah-ardeb (2·32 imp. gals.), and the kuba (1·788 imp. pints) are also in common use.

See Gurley's *Life of Jehudi Ashmun*, 1835; Stockwell, *The Republic of Liberia*, 1868: Wilson, *West Africa*, 1856; Hutchinson, *Impressions of West Africa*, 1858: Ritter, in *Zeitschrift für allgemeine Erdkunde*, vol. i., 1853; Brown, *Countries of the World*, vol. vi. pp. 123–127, 1881; Bowen, *Central Africa*, 1857; Thomas, *West Coast of Africa*, 1860; "Die Negerrepublik Liberia," in *Unsere Zeit*, vol. iii., 1858; U.S. Consular Reports, 1881.

LIBERIUS, pope from 352 to 366, the successor of Julius I., was consecrated according to the *Catalogus Liberianus* on May 22. His first recorded act was, after a synod had been held at Rome, to write to Constantius, then in quarters at Arles (353–54), asking that a council might be called at Aquileia with reference to the affairs of Athanasius; but his messenger Vincentius of Capua, so far from being successful in his mission, was himself compelled by the emperor at a conciliabulum held in Arles to subscribe against his will a condemnation of the orthodox patriarch of Alexandria. In 355 Liberius was one of the few who, along with Eusebius of Vercelli, Dionysius of Milan, and Lucifer of Cagliari, refused to sign the condemnation of Athanasius, which had anew been imposed at Milan by imperial command upon all the Western bishops; the consequence was his relegation to Berœa in Thrace, Felix II. (antipope) at the same time being consecrated his successor by three "catascopi haud episcopi," as Athanasius called them. At the end of an exile of more than two years he yielded so far as to subscribe the third Sirmian formula giving up the "homoousion,"—an act which procured his immediate and triumphant return to Rome, but has ever since caused considerable embarrassment to maintainers of the indefectibility of Roman orthodoxy. The remainder of his pontificate was uneventful. He died on September 24, 366, and was succeeded by Damasus I. With the rest of the first sixty popes he shares the title of "Saint." His biographers used to be perplexed by a letter purporting to be from Liberius, in the works of Hilary, in which he seems to write, in 352, that he had excommunicated Athanasius at the instance of the Oriental bishops; but the document is now held to be spurious. See Hefele, *Conciliengesch.*, i. p. 648 *sq.*

LIBOURNE, the chief town of an arrondissement, and in point of population the second town of the department of Gironde, France, is situated at the confluence of the Isle with the Dordogne, 337 miles by rail south-west from Paris, and 22 miles east from Bordeaux. The sea is 56 miles off, but the tide affects the river so as to admit of vessels of 300 tons burden reaching the town. The Dordogne is here crossed by a stone bridge 492 feet long, and a suspension bridge across the Isle connects Libourne with the adjoining Fronsac, the citadel of which, 235 feet above the sea, was at one time occupied by a palace of Charlemagne, and subsequently became an important fortress. Libourne is regularly built, but has no monuments of much architectural or historical interest; the (restored) Gothic church has a stone spire 232 feet high. On the quay there is a machicolated clock-tower which is a remnant of the ramparts of the 14th century; and the town-house, containing a small museum, is a quaint relic of the 16th century. There is a statue of the Duc Decazes, who was born in the neighbourhood. The principal articles of commerce are the wines and brandies of the district, the growths of chief repute being those of St Émilion, a short distance above Libourne, on the right bank of the Dordogne, and of Canon, a little below Fronsac. There is also some trade in yarn, grain, and wood for cooperage. Woollen stuffs and some articles of army outfit are manufactured; and nailmaking, tanning, shoemaking, and shipbuilding are also carried on. The harbour is used exclusively by small vessels for the export of wines; the shipping owned in the place does not exceed 2500 tons. The population of Libourne in 1876 was 15,231.

Like other sites at the confluence of important rivers, that of Libourne was appropriated at an early period. Under the Romans *Condate* stood rather more than a mile to the south of the present Libourne, where the old Gothic chapelle de Condat now is; it was destroyed during the troubles of the 5th century. Resuscitated by Charlemagne, it was rebuilt, under its present name, and on the site and plan it still retains, by Edward, prince of Wales, in 1270. It suffered considerably in the struggles of the French and English for the possession of Guienne in the 14th century, and again during the religious wars, and finally in the war of the Fronde in the minority of Louis XIV. Nevertheless it ultimately outgrew both its powerful neighbours Fronsac and Saint Émilion, the latter of which is archæologically one of the most curious spots in France.

LIBRARIES

HISTORY AND DESCRIPTION.

Ancient Period.

LIBRARIES, in our modern sense of collections of printed or written literature, imply an advanced and elaborate civilization. If the term be extended to any considerable collection of written documents, they must be nearly as old as civilization itself. The earliest use to which the invention of inscribed or written signs was put was probably to record important religious and political transactions. These records would naturally be preserved in sacred places, and accordingly the earliest libraries of the world were probably temples, and the earliest librarians priests. And indeed before the extension of the arts of writing and reading the priests were the only persons who could perform such work as, *e.g.*, the compilation of the *Annales Maximi*, which was the duty of the pontifices in ancient Rome. The beginnings of literature proper in the shape of ballads and songs may have continued to be conveyed orally only from one generation to another, long after the record of important religious or civil events was regularly committed to writing. The earliest collections of which we know anything therefore were collections of archives. Of this character appear to have been such famous collections as that of the Medians at Ecbatana or the Persians at Susa. It is not until the development of arts and sciences, and the growth of a considerable written literature, and even of a distinct literary class, that we find collections of books which can be called libraries in our modern sense. It is of libraries in the modern sense, and not, except incidentally, of archives that we are to speak.

The researches which have followed the discoveries of Botta and Layard have thrown unexpected light not only upon the history but upon the arts, the sciences, and the literatures of the ancient civilizations of Babylonia and Assyria. In all these wondrous revelations no facts are more interesting than those which show the existence of extensive libraries so many ages ago, and none are more eloquent of the elaborateness of these forgotten civilizations.

In the course of his excavations at Nineveh in 1850, Layard came upon some chambers in the south-west palace, the floor of which, as well as of the adjoining rooms, was covered to the depth of a foot with tablets of clay, covered with cuneiform characters, in many cases so small as to require a magnifying glass. These varied in size from an inch to a foot square. A great number of them were broken, as Layard supposed by the falling in of the roof, but as the late Mr George Smith thought by having fallen from the upper story, upon which he believed the collection to have been placed. These tablets formed the library of the great monarch Assur-bani-pal—the Sardanapalus of the Greeks—the greatest patron of literature amongst the Assyrians. It is estimated that this library consisted of some ten thousand distinct works and documents, some of the works extending over several tablets. The tablets appear to have been methodically arranged and catalogued, and the library seems to have been thrown open for the general use of the king's subjects.[1] A great portion of this library has already been brought to England and deposited in the British Museum, but it is calculated that there still remain some 20,000 fragments to be gathered up. For further details as to Assyrian libraries, and the still earlier Babylonian libraries from which the Assyrians drew their science and literature, see BABYLONIA, vol. iii. p. 191.

Of the libraries of ancient Egypt our knowledge is much less full and precise. It seems to be ascertained that the oldest hieroglyphic writings now extant run some centuries farther back than 2000 B.C. We possess a papyrus manuscript which is assigned to the age of Amenophis I. of the 18th dynasty, perhaps about 1600 B.C., and the fabric is so perfect as to point to a much earlier invention.[2] With the invention of papyrus came the age of books. The temples were the centres of literary activity, and to each of them were attached professional scribes who occupied a very respectable position. Their function was regarded as a religious one, for the distinction between religion and science had not yet been made. The sacred books of Thoth—forty-two in number—constituted as it were a complete encyclopædia of religion and science. But they did not forbid speculation, or a wider development of the principles contained in them. So there arose a great mass of literature in the shape of exposition and commentary. To such an extent did this increase that at the time of the Greek conquest of Egypt the Thoth literature is said to have amounted to 36,525 books.[3] Books were collected not only in the temples but also at the tombs of kings. The most famous of these libraries dates from the 14th century B.C., and was the so-called library of King Osymandyas, described by Diodorus Siculus, who relates that it bore an inscription which he renders by the Greek words ΨΥΧΗΣ ΙΑΤΡΕΙΟΝ, "the dispensary of the soul." Osymandyas has been identified with the great king Ramses I., and the seat of the library is supposed by Wilkinson to have been the Ramesseum, the magnificent palace temple near Thebes.[4] Lepsius thinks he has found the tombs of two of the librarians of Osymandyas.[5] According to Eustathius there was also a great collection in a temple at Memphis. A heavy blow was dealt to the old Egyptian literature by the Persian invasion, and many of their books were carried away by the conquerors. They were only delivered from the yoke of Persia to succumb to that of Greece, and henceforward their civilization was dominated by foreign influences. Of the libraries of Greece under the Ptolemies we shall therefore speak a little further on.

Of the libraries of ancient Greece we have very little knowledge, and such knowledge as we possess comes to us for the most part from late compilers. Amongst those who are known to have collected books are Pisistratus, Polycrates of Samos, Euclid the Athenian, Nicocrates of Cyprus, Euripides and Aristotle (Athenæus, i. 4). At Cnidus there is said to have been a special collection of works upon medicine. Pisistratus is said to have been the first of the Greeks who collected books on a large scale. Aulus Gellius, indeed, tells us in language perhaps "not well suited to the 6th century B.C.,"[6] that he was the first to establish a public library. The authority of Aulus Gellius is hardly sufficient to secure credit for the story that this library was carried away into Persia by Xerxes and subsequently restored to the Athenians by Seleucus Nicator. Plato is known to have been a collector; and Xenophon tells us of the library of Euthydemus. The library of Aristotle was bequeathed by him to his disciple Theophrastus, and by Theophrastus to Neleus, who carried it to Scepsis, where it is said to have been concealed underground to avoid the literary cupidity of the kings of Pergamus. Its subsequent fate has given rise to much controversy, but, according to Strabo (xiii. pp. 608, 609), it was sold to Apellicon of Teos, who carried it to Athens, where after Apellicon's death it fell a prey to the conqueror Sulla, and was transported by him to Rome. The story told by Athenæus (i. 4) is that the library of Neleus was purchased by Ptolemy Philadelphus. The names of a few other libraries in Greece are barely known to us from inscriptions; of their character and contents we know nothing. If indeed we are to trust Strabo entirely, we must believe that Aristotle was the first person who collected a library, and that he communicated the taste for collecting to the sovereigns of Egypt. It is at all events certain that the libraries of Alexandria were the most important as they were the most celebrated of the ancient world. Under the enlightened rule of the Ptolemies a society of scholars and men of science was attracted to their capital. It seems pretty certain that Ptolemy Soter had already begun to collect books, but it was in the reign of Ptolemy Philadelphus that the libraries were properly organized and established in separate buildings. Ptolemy Philadelphus sent into every part of Greece and Asia to secure the most valuable works, and no exertions or expense were spared in enriching the collections. Ptolemy Euergetes, his successor, is said to have caused all books brought into Egypt by foreigners to be seized for the benefit of the library, while the owners had to be content with receiving copies of them in exchange. Nor did the Alexandrian scholars exhibit the usual Hellenic exclusiveness, and many of the treasures of Egyptian and even of Hebrew literature were by their means translated into Greek. There were two libraries at Alexandria; the larger, in the Bruchium quarter, was in connexion with the Museum, a sort of academy, while the smaller was placed in the Serapeum. The number of volumes in these libraries was very large, although it is difficult to attain any certainty as to the real numbers amongst the widely varying accounts. According to a scholium of Tzetzes, who appears to draw his information from the authority of Callimachus and Eratosthenes, who had been librarians at Alexandria, there were 42,800 volumes or rolls in the Serapeum and 490,000 in the Bruchium.[7] This enumeration seems to refer to the librarianship of Callimachus himself under Ptolemy Euergetes. In any case the figures agree tolerably well with those given by Aulus Gellius[8] (700,000) and Seneca[9] (400,000). It should be observed that, as the ancient roll or volume usually contained a much smaller quantity of matter than a modern book—so that, *e.g.*, the history of Herodotus might form nine "books" or volumes, and the *Iliad* of Homer twenty-four—these numbers must be dis-

counted for the purposes of comparison with modern collections.[1] The series of the first five librarians at Alexandria appears to be pretty well established as follows:—Zenodotus, Callimachus, Eratosthenes, Apollonius, and Aristophanes; and their activity covers a period of about a century.[2] The first experiments in bibliography appear to have been made in producing catalogues of the Alexandrian libraries. Amongst other lists, two catalogues were prepared by order of Ptolemy Philadelphus, one of the tragedies, the other of the comedies contained in the collections. The Πίνακες of Callimachus formed a catalogue of all the principal books arranged in 120 classes. When Cæsar set fire to the fleet in the harbour of Alexandria, the flames accidentally extended to the larger library of the Bruchium, and it was destroyed.[3] Antony endeavoured to repair the loss by presenting to Cleopatra the library from Pergamus. This was very probably placed in the Bruchium, as this continued to be the literary quarter of Alexandria until the time of Aurelian. Thenceforward the Serapeum became the principal library. The usual statement that from the date of the restoration of the Bruchium under Cleopatra the libraries continued in a flourishing condition until they were destroyed after the conquest of Alexandria by the Saracens in 640 A.D. can hardly be supported. It is very possible that one of the libraries perished when the Bruchium quarter was destroyed by Aurelian, 273 A.D. In 389 or 391 an edict of Theodosius ordered the destruction of the Serapeum, and its books were pillaged by the Christians. When we take into account the disordered condition of the times, and the neglect into which literature and science had fallen, there can be little difficulty in believing that there were but few books left to be destroyed by the soldiers of 'Amr. The familiar anecdote of the caliph's message to his general (vol. i. p. 494) rests mainly upon the evidence of Abulfaragius, so that we may be tempted to agree with Gibbon that the report of a stranger who wrote at the end of six hundred years is overbalanced by the silence of earlier and native annalists. It is, however, so far from easy to settle the question that a cloud of names could easily be cited upon either side, while some of the most careful inquirers confess the difficulty of a decision.[4]

The magnificence and renown of the libraries of the Ptolemies excited the rivalry of the kings of Pergamus, who vied with the Egyptian rulers in their encouragement of literature. Despite the obstacles presented by the embargo placed by the Ptolemies upon the export of papyrus, the library of the Attali attained considerable importance, and, as we have seen, when it was transported to Egypt numbered 200,000 volumes. We learn from a notice in Suidas that in 221 B.C. Antiochus the Great summoned the poet and grammarian Euphorion of Chalcis to be his librarian.

The early Romans were far too warlike and practical a people to devote much attention to literature, and it is not until the last century of the republic that we hear of libraries in Rome. The collections of Carthage, which fell into their hands when Scipio sacked that city (146 B.C.), had no attractions for them; and with the exception of the writings of Mago upon agriculture, which the senate reserved for translation into Latin, they bestowed all the books upon the kinglets of Africa.[5] It is in accordance with the military character of the Romans that the first considerable collections of which we hear in Rome were brought there as the spoils of war. The first of these was that brought by Æmilius Paulus from Macedonia after the conquest of Perseus (167 B.C.). The library of the conquered monarch was all that he reserved from the prizes of victory for himself and his sons, who were fond of letters. Next came the library of Apellicon the Teian, brought from Athens by Sulla (86 B.C.). This passed at his death into the hands of his son, but of its later history nothing is known. The rich stores of literature brought home by Lucullus from his eastern conquests (about 67 B.C.) were freely thrown open to his friends and to men of letters. Accordingly his library and the neighbouring walks were much resorted to, especially by Greeks. It was now becoming fashionable for rich men to furnish their libraries well, and the fashion prevailed until it became the subject of Seneca's scorn and Lucian's wit. The zeal of Cicero and Atticus in adding to their collections is well known to every reader of the classics. Tyrannion is said to have had 30,000 volumes of his own; and that M. Terentius Varro had large collections we may infer from Cicero's writing to him: "Si hortum in bibliotheca habes, nihil deerit." Not to prolong the list of private collectors, Serenus Sammonicus is said to have left to his pupil the younger Gordian no less than 62,000 volumes. Amongst the numerous projects entertained by Cæsar was that of presenting Rome with public libraries, though it is doubtful whether any steps were actually taken towards its execution. The task of collecting and arranging the books was entrusted to Varro. This commission, as well as his own fondness for books, may have led Varro to write the book upon libraries of which a few words only have come down to us, preserved by a grammarian. Varro also appears to have been the first to ornament a library with the statues and busts of learned men, though the idea is sometimes attributed to Asinius Pollio. The greater honour of being the first actually to dedicate a library to the public is said by Pliny and Ovid to have fallen to Pollio, who erected a library in the Atrium Libertatis on Mount Aventine, defraying the cost from the spoils of his Illyrian campaign. The library of Pollio was followed by the public libraries established by Augustus. That emperor, who did so much for the embellishment of the city, erected two libraries, the Octavian and the Palatine. The former was founded (33 B.C.) in honour of his sister, and was placed in the Porticus Octaviæ, the lower part of which served as a promenade, while the upper part contained the library. The charge of the books was committed to C. Melissus. The other library formed by Augustus was attached to the temple of Apollo on the Palatine hill, and appears from inscriptions to have consisted of two departments, a Greek and a Latin one, which seem to have been separately administered. The charge of the Palatine collections was given to Pompeius Macer, who was succeeded by Julius Hyginus, the grammarian and friend of Ovid. The Octavian library perished in the fire which raged at Rome for three days in the reign of Titus. The Palatine was, at all events in great part, destroyed by fire in the reign of Commodus. The story that its collections were destroyed by order of Pope Gregory the Great in the 6th century is now generally rejected. The successors of Augustus, though they did not equal him in their patronage of learning, maintained the tradition of forming libraries. Tiberius, his immediate successor, established one in his splendid house on the Palatine, to which Gellius refers as the "Tiberian library," and

[1] This view as to the smallness of the ancient book before Callimachus has been pushed perhaps a little too far. See Theodor Birt's ingenious suggestions in *Das antike Buchwesen*, Berlin, 1882, p. 489 *sq.*, &c. Birt, indeed, agrees that these large numbers must be discounted, but only on the ground of the very considerable number of duplicates in the Alexandrian libraries.

[5] Pliny, *H. N.*, xviii. 5.

Suetonius relates that he caused the writings and images of his favourite Greek poets to be placed in the public libraries. Vespasian established a library in the Temple of Peace erected after the burning of the city under Nero. Domitian restored the libraries which had been destroyed in the same conflagration, procuring books from every quarter, and even sending to Alexandria to have copies made. He is also said to have founded the Capitoline library, though others give the credit to Hadrian. The most famous and important of the imperial libraries, however, was that created by Ulpius Trajanus, known as the Ulpian library, which was first established in the Forum of Trajan, but was afterwards removed to the baths of Diocletian. In this library were deposited by Trajan the "libri lintei" and "libri elephantini," upon which the senatus consulta and other transactions relating to the emperors were written. The library of Domitian, which had been destroyed by fire in the reign of Commodus, was restored by Gordian, who added to it the books bequeathed to him by Serenus Sammonicus. Altogether in the 4th century there are said to have been twenty-eight public libraries in Rome.

Nor were public libraries confined to Rome. Besides a library at Tibur, which is twice mentioned by Gellius, and was probably founded by Hadrian, the younger Pliny mentions that he had himself dedicated a library to his fellow-townsmen at Comum; and an inscription discovered at Milan proves that he also contributed a large sum to the support of a library there. Hadrian established a library at Athens; and Strabo mentions the library of Smyrna. Gellius also mentions a library at Patræ. From one of his references (xix. 5) to the Tiburtine library we may infer that it was not unusual for books to be lent out from these libraries. Considerable care was bestowed by the Romans upon the placing of their libraries. The room or building generally had an eastern aspect. The books or rolls were arranged upon the shelves of presses running round the walls, with additional presses placed in the middle of the room. Thus the library discovered at Herculaneum contained 1756 MSS. placed on shelves running round the room to a height of some 6 feet, with a detached central press. These presses in large libraries were numbered. They were often made of precious woods and richly ornamented, while the room was adorned with portraits and statues.

As the number of libraries in Rome increased, the librarian, who was generally a slave or freedman, became a recognized public functionary. The names of several librarians are preserved to us in inscriptions, including that of C. Hymenæus, who appears to have fulfilled the double function of physician and librarian to Augustus. The general superintendence of the public libraries was committed to a special official Thus from Nero to Trajan Dionysius, an Alexandrian rhetorician, discharged this function. Under Hadrian it was entrusted to his former tutor C. Julius Vestinus, who afterwards became administrator of the Museum at Alexandria.

When the seat of empire was removed by Constantine to his new capital upon the Bosporus, the emperor established a collection there, in which Christian literature was probably admitted for the first time into an imperial library. Diligent search was made after the Christian books which had been doomed to destruction by Diocletian. Even at the death of Constantine, however, the number of books which had been brought together amounted only to 6900. The smallness of the number, it has been suggested, seems to show that Constantine's library was mainly intended as a repository of Christian literature. However this may be, the collection was greatly enlarged by some of Constantine's successors, especially by Julian and Theodosius, at whose death it is said to have increased to 100,000 volumes. Julian, himself a close student and voluminous writer, though he did his best to discourage learning among the Christians, and to destroy their libraries, not only augmented the library at Constantinople, but founded others, including one at Nisibis, which was soon afterwards destroyed by fire. From the Theodosian code we learn that in the time of that emperor a staff of seven copyists was attached to the library at Constantinople under the direction of the librarian. The library was burnt under the emperor Zeno in 477, but was again restored.

Meanwhile, as Christianity made its way and a distinctively Christian literature grew up, the institution of libraries became part of the organization of the church. When the church of Jerusalem was founded in the 3d century a library was added to it, and it became the rule to attach to every church a collection of the books necessary for the inculcation of Christian doctrine. The largest of these libraries, that founded by Pamphilus at Cæsarea, and said to have been increased by Eusebius, the historian of the church, to 30,000 volumes, is frequently mentioned by St Jerome. St Augustine bequeathed his collection to the library of the church at Hippo, which was fortunate enough to escape destruction at the hands of the Vandals.

The removal of the capital to Byzantium was in its result a serious blow to literature. Henceforward the science and learning of the East and West were divorced. The libraries of Rome ceased to collect the writings of the Greeks, while the Greek libraries had never cared much to collect Latin literature. The influence of the church became increasingly hostile to the study of pagan letters. The repeated irruptions of the barbarians soon swept the old learning and libraries alike from the soil of Italy. With the close of the Western empire in 476 the ancient history of libraries may be said to cease.

Mediæval Period.

During the first few centuries after the fall of the Western empire, literary activity at Constantinople had fallen to its lowest ebb. In the West, amidst the general neglect of learning and literature, the collecting of books, though not wholly forgotten, was cared for by few. Sidonius Apollinaris tells us of the libraries of several private collectors in Gaul. Publius Consentius possessed a library at his villa near Narbonne which was due to the labour of three generations. The most notable of these appears to have been the prefect Tonantius Ferreolus, who had formed in his villa of Prusiana, near Nîmes, a collection which his friend playfully compares to that of Alexandria. The Goths, who had been introduced to the Scriptures in their own language by Ulfilas in the 4th century, began to pay some attention to Latin literature. Cassiodorus, the favourite minister of Theodoric, was a collector as well as an author, and on giving up the cares of government retired to a monastery which he founded in Calabria, where he employed his monks in the transcription of books.

Henceforward the charge of books as well as of education fell more and more exclusively into the hands of the church. While the old schools of the rhetoricians died out new monasteries arose everywhere. Knowledge was no longer pursued for its own sake, but became subsidiary to religious and theological teaching. The proscription of the old classical literature, which is symbolized in the fable of the destruction of the Palatine library by Gregory the Great, was only too effectual. The Gregorian tradition of opposition to pagan learning long continued to dominate the literary pursuits of the monastic orders and the labours of the scriptorium.

During the 6th and 7th centuries the learning which had been driven from the Continent took refuge in the British Islands, where it was removed from the political disturbances of the mainland. In the Irish monasteries during this period there appear to have been many books, and the Venerable Bede was superior to any scholar of his age. Theodore of Tarsus brought a considerable number of books to Canterbury from Rome in the 7th century, including several Greek authors. The library of York, which was founded by Archbishop Egbert, was almost more famous than that of Canterbury. The verses are well known in which Alcuin describes the extensive library under his charge, and the long list of authors whom he enumerates is superior to that of any other library possessed by either England or France in the 12th century, when it was unhappily burnt. The inroads of the Northmen in the 9th and 10th centuries had been fatal to the monastic libraries on both sides of the channel. It was from York that Alcuin came to Charlemagne to superintend the school attached to his palace; and it was doubtless inspired by Alcuin that Charles issued the memorable document which enjoined that in the bishoprics and monasteries within his realm care should be taken that there shall be not only a regular manner of life, but also the study of letters. When Alcuin finally retired from the court to the abbacy of Tours, there to carry out his own theory of monastic discipline and instruction, he wrote to Charles for leave to send to York for copies of the books of which they had so much need at Tours. While Alcuin thus increased

Charlemagne.

the library at Tours, Charlemagne enlarged that at Fulda, which had been founded in 774, and which all through the Middle Ages stood in great respect. Lupus Servatus, a pupil of Hrabanus Maurus at Fulda, and afterwards abbot of Ferrières, was a devoted student of the classics and a great collector of books. His correspondence illustrates the difficulties which then attended the study of literature through the paucity and dearness of books, the declining care for learning, and the increasing troubles of the time. Nor were private collections of books altogether wanting during the period in which Charlemagne and his successors laboured to restore the lost traditions of liberal education and literature. Pepin le Bref had indeed met with scanty response to the request for books which he addressed to the pontiff Paul I. Charlemagne, however, collected a considerable number of choice books for his private use in two places. Although these collections were dispersed at his death, his son Louis formed a library which continued to exist under Charles the Bald. About the same time Everard, count of Friuli, formed a considerable collection which he bequeathed to a monastery. But the greatest private collector of the Middle Ages was doubtless Gerbert, Pope Sylvester II., who showed the utmost zeal and spent large sums in collecting books, not only in Rome and Italy, but from Germany, Belgium, and even from Spain.

The hopes of a revival of secular literature fell with the decline of the schools established by Charles and his successors. The knowledge of letters remained the prerogative of the church, and for the next four or five centuries the collecting and multiplication of books were almost entirely confined to the monasteries. Several of the greater orders made these an express duty; this was especially the case with the Benedictines. It was the first

St Benedict.

care of St Benedict, we are told, that in each newly founded monastery there should be a library, "et velut curia quædam illustrium auctorum." Monte Cassino became the starting point of a long line of institutions which were destined to be the centres of religion and of literature. It must indeed be remembered that literature in the sense of St Benedict meant Biblical and theological works, the lives of the saints and martyrs, and the lives and writings of the fathers. Of the reformed Benedictine orders the Carthusians and the Cistercians were those most devoted to literary pursuits. The abbeys of Fleury, of Melk, and of St Gall were remarkable for the splendour of their libraries. In a later age the labours of the congregation of St Maur form one of the most striking chapters in the history of learning. The Augustinians and the Dominicans rank next to the Benedictines in their care for literature. The libraries of St Geneviève and St Victor, belonging to the former, were amongst the largest of the monastic collections. Although their poverty might seem to put them at a disadvantage as collectors, the mendicant orders cultivated literature with much assiduity, and were closely connected with the intellectual movement to which the universities owed their rise. In England Richard of Bury praises them for their extraordinary diligence in collecting books. Sir Richard Whittington built a large library for the Grey Friars in London, and they possessed considerable libraries at Oxford.

Monastic libraries.

It would be impossible to attempt here an account of all the libraries established by the monastic orders. We must be content to enumerate a few of the most eminent.

In Italy Monte Cassino is a striking example of the dangers and vicissitudes to which monastic collections were exposed. Ruined by the Lombards in the 6th century, the monastery was rebuilt and a library established to fall a prey to Saracens and to fire in the 9th. The collection then reformed survived many other chances and changes, and still exists. It affords a conspicuous example of monastic industry in the transcription not only of theological but also of classical works. The library of Bobbio was famous for its palimpsests. The collection, of which a catalogue of the 10th century is given by Muratori,[1] was finally transferred to the Ambrosian library at Milan. Of the library of Pomposia, near Ravenna, Montfaucon has printed a catalogue dating from the 11th century.[2]

Of the monastic libraries of France the principal were those of Fleury, of Cluny, of St Riquier, and of Corbie. At Fleury Abbot Macharius in 1146 imposed a contribution for library purposes upon the officers of the community and its dependencies, an example which was followed elsewhere. After many vicissitudes, its MSS., numbering 238, were deposited in 1793 in the town library of Orleans. The library of St Riquier in the time of Louis the Pious contained 256 MSS., with over 500 works.[3] Of the collection at Corbie in Picardy we have also catalogues dating from the 12th and from the 17th centuries. Corbie was famous for the industry of its transcribers, and appears to have stood in active literary intercourse with other monasteries. In 1638, 400 of its choicest manuscripts were removed to St Germain-des-Prés. The remainder were removed after 1794, partly to the national library at Paris, partly to the town library of Amiens.

The chief monastic libraries of Germany were at Fulda, Corvey, Reichenau, and Sponheim. The library at Fulda owed much to Charlemagne and to its abbot Hrabanus Maurus. Under Abbot Sturmius four hundred monks were hired as copyists. In 1561 the collection numbered 774 volumes. The library of Corvey on the Weser, after being despoiled of some of its treasures in the Reformation age, was presented to the university of Marburg in 1811. It then contained 109 volumes, with 400 or 500 titles. The library of Reichenau, of which several catalogues are extant, fell a prey to fire and neglect, and its ruin was consummated by the Thirty Years' War. The library

[1] *Antiq. Ital. Med. Æv.*, iii. 817–24.
[2] *Diarium Italicum*, chap. xxii.
[3] Catalogue printed in Edwards, *Memoirs of Libraries*, i. 297–301.

of Sponheim owes its great renown to John Tritheim, who was abbot at the close of the 15th century. He found it reduced to 10 volumes, and left it with upwards of 2000 at his retirement. The library at St Gall, formed as early as 816 by Gozbert, its second abbot, still exists.

In England the principal collections were those of Canterbury, York, Wearmouth, Whitby, Glastonbury, Croyland, Peterborough, and Durham. Of the library of the monastery of Christ Church, Canterbury, originally founded by Augustine and Theodore, and restored by Lanfranc and Anselm, a catalogue has been preserved dating from the 13th or 14th century, and containing 698 volumes, with about 3000 works. Bennet Biscop, the first abbot of Wearmouth, made five journeys to Rome, and on each occasion returned with a store of books for the library. It was destroyed by the Danes about 867. Of the library at Whitby there is a catalogue dating from the 12th century. The catalogue of Glastonbury has also been printed.[1] When the library of Croyland perished by fire in 1091 it contained about 700 volumes. The library at Peterborough was also rich; from a catalogue of about the end of the 14th century it had 344 volumes, with nearly 1700 titles. The catalogues of the library at the monastery of Durham have been printed by the Surtees Society, and form an interesting series.

These catalogues with many others[2] afford abundant evidence of the limited character of the monkish collections, whether we look at the number of their volumes or at the nature of their contents. We must remember that the beliefs and discipline imposed upon the monk hardly allowed of his caring for literature for its own sake; we must also remember that the transcription of manuscripts so industriously pursued in the monasteries was a mechanical employment. The scriptoria were manufactories of books and not centres of learning. Indeed the very pains bestowed upon carefulness and neatness of transcription, and especially upon the illustrating and ornamenting of the more beautiful manuscripts, were little calculated to divert the attention of the monks from the vehicle to the thought which it expressed. The pride taken by so many communities in the richness and splendour of their libraries was often doubtless the pride of the collector and not of the scholar. That in spite of the labours of so many transcribers the costliness and scarcity of books remained so great may have been partly, but cannot have been wholly, due to the scarcity of writing materials. It may be suspected that indolence and carelessness were the rule in most monasteries, and that but few of the monks keenly realized the whole force of the sentiment expressed by one of their number in the 12th century—"Claustrum sine armario quasi castrum sine armamentario." Nevertheless it must be admitted that to the labours of the monkish transcribers we are indebted for the preservation of Latin literature.

The first conquests of the Arabians, as we have already seen, threatened hostility to literature. But, as soon as their conquests were secured, the caliphs became the patrons of learning and science. Greek manuscripts were eagerly sought for and translated into Arabic, and colleges and libraries everywhere arose. Baghdad in the East and Cordova in the West became the seats of a rich development of letters and science during the age when the civilization of Europe was most obscured. Cairo and Tripoli were also distinguished for their libraries. The royal library of the Fatimites in Africa is said to have numbered 100,000 manuscripts, while that collected by the Omayyads of Spain is reported to have contained six times as many. It is said that there were no less than seventy libraries opened in the cities of Andalusia. Whether these figures be exaggerated or not—and they are much below those given by some Arabian writers, which are undoubtedly so—it is certain that the libraries of the Arabians and the Moors of Spain offer a very remarkable contrast to those of the Christian nations during the same period.[3]

The literary and scientific activity of the Arabians appears to have been the cause of a revival of letters amongst the Greeks of the Byzantine empire in the 9th century. Under Leo the Philosopher and Constantine Porphyrogenitus the libraries of Constantinople awoke into renewed life. The compilations of such writers as Stobæus, Photius, and Suidas, as well as the labours of innumerable critics and commentators, bear witness to the activity, if not to the lofty character of the pursuits, of the Byzantine scholars. The labours of transcription were industriously pursued in the libraries and in the monasteries of Mount Athos and the Ægean, and it was from these quarters that the restorers of learning brought into Italy so many Greek manuscripts. In this way many of the treasures of ancient literature had been already conveyed to the West before the fate which overtook the libraries of Constantinople on the fall of the city in 1453.

Meanwhile in the West, with the reviving interest in literature which already marks the 14th century, we find arising outside the monasteries a taste for collecting books. St Louis of France and his successors had formed small collections, none of which survived its possessor. It was reserved for Charles V. to form a considerable library which he intended to be permanent. In 1373 he had amassed 910 volumes, and had a catalogue of them prepared, from which we see that it included a good deal of the new literature. In our own country Guy, earl of Warwick, formed a curious collection of French romances, which he bequeathed to Bordesley Abbey on his death in 1315. Richard d'Aungervyle of Bury, the author of the *Philobiblon*, amassed a noble collection of books, and had special opportunities of doing so as Edward III.'s chancellor and ambassador. He founded Durham College at Oxford, and equipped it with a library a hundred years before Humphrey, duke of Gloucester, made his benefaction of books to the university. The taste for secular literature, and the enthusiasm for the ancient classics, gave a fresh direction to the researches of collectors. A disposition to encourage literature began to show itself amongst the great. This was most notable amongst the Italian princes. Cosimo de' Medici formed a library at Venice while living there in exile in 1433, and on his return to Florence laid the foundation of the great Medicean library. The honour of establishing the first modern public library in Italy had been already secured by Niccolo Niccoli, who left his library of over 800 volumes for the use of the public on his death in 1436. Frederick, duke of Urbino, collected all the writings in Greek and Latin which he could procure, and we have an interesting account of his collection written by his first librarian, Vespasiano. The ardour for classical studies led to those active researches for the Latin writers who were buried in the monastic libraries which are especially identified with the name of Poggio. For some time before the fall of that capital, the perilous state

[1] By Hearne in his edition of John of Glastonbury.

[2] Many such catalogues may be found in the collections of D'Achery, Martene and Durand, and Pez, and in the bibliographical periodicals of Naumann and Petzholdt. The Rev. Joseph Hunter has collected some particulars as to the contents of the English monastic libraries, and Mr Edwards has printed a list of the catalogues known to exist (*Libraries and Founders of Libraries*, 1865, pp. 448-54). There are said to be over six hundred such catalogues in the Royal Library at Munich.

[3] Among the Arabs, however, as among the Christians, theological bigotry did not always approve of non-theological literature, and the great library of Cordova was sacrificed by Almanzor to his reputation for orthodoxy, 978 A.D.

of the Eastern empire had driven many Greek scholars from Constantinople into western Europe, where they had directed the studies and formed the taste of the zealous students of the Greek language and literature. The enthusiasm of the Italian princes extended itself beyond the Alps. Matthias Corvinus, king of Hungary, amassed a collection of splendidly executed and magnificently bound manuscripts, which at his death are said to have reached the almost incredible number of 50,000 volumes. The library was not destined long to survive its founder. There is reason to believe that it had been very seriously despoiled even before it perished at the hands of the Turks on the fall of Buda in 1527. A few of its treasures are still preserved in some of the libraries of Europe. While these munificent patrons of learning were thus taking pains to recover and multiply the treasures of ancient literature by the patient labour of transcribers and calligraphers, an art was being elaborated which was destined to revolutionize the whole condition of literature and libraries. With the invention of printing, so happily coinciding with the revival of true learning and sound science, the modern history of libraries may be said to begin.

Modern Libraries.

These are most conveniently described in geographical order, and a general survey on this method will be found in the tables at the end of this article. The following sketch supplies additional details.

The United Kingdom.

The British Museum ranks in importance before all the great libraries of the world, with the single exception of the Bibliothèque Nationale at Paris, and far excels the latter institution in the systematic arrangement and accessibility of its contents. Recent changes have somewhat limited its former universality of character, but it still remains the grand national repository of literature and archæology. The library consists of over 1,550,000 printed volumes and 50,000 manuscripts. This extraordinary opulence is principally due to the enlightened energy of the late Sir Antonio Panizzi. The number of volumes in the printed book department, when he took the keepership in 1837, was only 240,000; and during the nineteen years he held that office about 400,000 were added, mostly by purchase, under his advice and direction. It was Panizzi likewise who first seriously set to work to see that the national library reaped all the benefits bestowed upon it by the Copyright Act.

The foundation of the British Museum dates from 1753, when effect was given to the bequest (in exchange for £20,000 to be paid to his executors) by Sir Hans Sloane, of his books, manuscripts, curiosities, &c., to be held by trustees for the use of the nation. A bill was passed through parliament for the purchase of the Sloane collections and of the Harleian MSS., costing £10,000. To these, with the Cottonian MSS., acquired by the country in 1700, was added by George II., in 1757, the royal library of the former kings of England, coupled with the privilege, which that library had for many years enjoyed, of obtaining a copy of every publication entered at Stationers' Hall. This addition was of the highest importance, as it enriched the museum with the old collections of Archbishop Cranmer, Henry prince of Wales, and other patrons of literature, while the transfer of the privilege with regard to the acquisition of new books, a right which has been maintained by successive Copyright Acts, secured a large and continuous augmentation, the yearly average of which has now reached 8000 or 9000 volumes. A lottery having been authorized to defray the expenses of purchases, as well as for providing suitable accommodation, the museum and library were established in Montague House, and opened to the public 15th January 1759. In 1763 George III. presented the well-known Thomason collection (in 2220 volumes) of books and pamphlets issued in England between 1640 and 1662, embracing all the controversial literature which appeared during that period. The Rev. C. M. Cracherode, one of the trustees, bequeathed his collection of choice books in 1799; and in 1820 Sir Joseph Banks left to the nation his important library of 16,000 volumes. Many other libraries have since then been incorporated in the museum, the most valuable being George III.'s royal collection (15,000 volumes of tracts, and 65,259 volumes of printed books, including many of the utmost rarity, which had cost the king about £130,000), which was presented (for a pecuniary consideration, it has been said) by George IV. in 1823, and that of the Right Honourable Thomas Grenville (20,240 volumes of rare books, all in fine condition and binding), which was acquired under bequest in 1846. The Cracherode, Banksian, King's, and Grenville libraries are still preserved as separate collections. Other libraries of minor note have also been absorbed in a similar way, while, at least since the time of Panizzi, no opportunity has been neglected of making useful purchases at all the British and Continental book auctions.

The collection of English books is far from approaching completeness, but, apart from the enormous number of volumes, the library contains an extraordinary quantity of rarities. Few libraries in the United States equal either in number or value the American books in the museum. The collection of Slavonic literature, due to the initiative of the late Mr Watts, is a remarkable feature; after that of the St Petersburg Imperial Library it is believed to be the largest in existence. Indeed, in cosmopolitan interest the museum is without a rival in the world, possessing as it does the best Hungarian collection out of that country, the best Dutch library out of Holland, and in short the best library in any European language out of the territory in which the language is vernacular. The Hebrew books number over 12,000, the Chinese nearly 27,000, and the printed books in other Oriental languages about 13,000 volumes. Periodical literature has not been forgotten, and the series of newspapers is of great extent and interest. Great pains are taken by the authorities to obtain the copies of the newspapers published in the United Kingdom to which they are entitled by the provisions of the Copyright Act, and upwards of 1900 are annually collected, filed, and bound. Under the English Copyright Act there were received, in 1881, not counting single pieces, such as broadsides, songs, &c., 8857 volumes and pamphlets, and 21,792 parts of volumes, and through the international copyright treaties 941 volumes and 433 parts.

The department of MSS. is at least equal in importance to that of the printed books. The collection of MSS. in European languages ranges from the 2d century before Christ down to our own times, and includes the Alexandrian MS. (*q.v.*). The old historical chronicles of England, the charters of the Anglo-Saxon kings, and the celebrated series of Arthurian romances are well represented; and care has been taken to acquire on every available opportunity the unprinted works of English writers. The famous collections of MSS. made by Sir Robert Cotton, and Harley earl of Oxford, have already been mentioned, and from these and other sources the museum has become rich in early Anglo-Saxon and Latin codices, some of them exhibiting marvels of skill in calligraphy and ornamentation, such as the charters of King Edgar and Henry I. to Hyde Abbey, which are written in gold letter thers interesting for different reasons, such as the book of urham, in Latin and Anglo-

Saxon, reputed to have been Bede's own copy. The Burney collection of classical MSS. furnished important additions, so that from this source and from the collection of Arundel MSS. (transferred from the Royal Society in 1831), the museum can boast of an early copy of the *Iliad*, and one of the earliest known codices of the *Odyssey*. There is likewise an extensive series of ancient Irish texts, with many modern transcripts, the Bridgewater MSS. on French history, and Lord Guilford's similar collection to illustrate the history of Italy. Special reference may be made to the celebrated Bedford Missal, illuminated for the duke of Bedford, regent of France, and to Henry VI.'s copy of Hardyng's chronicle. The Oriental collection is also extremely rich and ample, including the library formed by Mr Rich (consul at Baghdad in the early part of this century), and a vast quantity of Arabic, Persian, and Turkish MSS.; the Chambers collection of Sanskrit MSS.; several other collections of Indian MSS.; and a copious library of Hebrew MSS. (including that of the great scholar Michaelis, and codices of great age, recently brought from Yemen). The collection of Syriac MSS., embracing the relics of the famous library of the convent of St Mary Deipara in the Nitrian desert, formed by the abbot Moses of Nisibis, in the 10th century, is the most important in existence; of the large store of Abyssinian volumes many were amassed after the campaign against King Theodore. The number of genealogical rolls and documents relating to the local and family history of Great Britain is very large. Altogether there are now over 50,000 MSS. (of which 8500 are Oriental), besides 45,000 charters and rolls.

The musical works comprise upwards of 11,000 volumes of vocal and nearly 6000 volumes of instrumental music, the number of separate pieces amounting to more than 70,000. The catalogue is in manuscript. The collection of maps, charts, plans, and topographical drawings is also a remarkable one. The maps are nearly 116,000 in number. Letter A of a printed catalogue of the maps is already in type.

The name of Panizzi is inseparably connected with his circular reading-room, opened in 1857. This is encompassed by the new library, with shelf-space for a million and a half volumes. The presses inside the reading-room, arranged in three tiers, contain upwards of 80,000 volumes, those on the ground floor (20,000) being books of reference to which readers have unlimited access. The comfortable accommodation for readers is briefly described below. Perhaps not the least convenient arrangement here is the presence of the superintendent, whose duty it is to help readers in their difficulties; the varied qualifications of the present holder of the office are well known. The electric light has been successfully used until 8 o'clock P.M. through the darker months from the earlier part of October. In order to enjoy the privilege of reading at the British Museum, the applicant (who must be over twenty-one years of age) must obtain a renewable ticket of admission through a recommendation from a householder addressed to the principal librarian. Formerly no person was admitted until the ticket had been presented at the entrance, but latterly this rule has been considerably relaxed. During 1881 the number of readers was 133,842. In spite of the hostile criticism to which it has sometimes been subjected, it cannot be denied that the general catalogue of the printed books (which now runs to upwards of 2000 volumes in manuscript) is a marvellous work executed in a praiseworthy manner. Some slight notion of the extent of the catalogue may be derived from the fact that it contains the works of over 2400 authors of the name of Smith. But the rapidly increasing size of the catalogue has impelled the trustees to resort to print in order to diminish the bulk. Since 1880 the titles of all accessions have been printed, and as it becomes necessary to break the manuscript volumes, the titles contained in them are also printed; in course of time, therefore, the whole of the titles will have been put into type. The sheets are published at regular intervals, and can be purchased. It is proposed to issue separately headings of special interest, whether of subjects or of authors, *e.g.*, Shakespeare, Bible, Liturgies, &c. Considerable progress has been made in the preparation for the press of a catalogue of English books printed before the year 1640.

The printed catalogues of books commence with one published in 2 vols. folio, 1787, followed by that of 1813–19 in 7 vols. 8vo; the next is that of the library of George III., 1820–29, 5 vols. folio, with 2 vols. 8vo, 1834, describing the geographical and topographical collections; and then the *Bibliotheca Grenvilliana*, 1842–72, 4 vols. 8vo. The first vol. (letter A) of a general catalogue appeared in 1841 in a folio volume which has never been added to. The octavo catalogue of the Hebrew books came out in 1867; that of the Sanskrit and Pali literature is in 4to, 1876; and the Chinese catalogue is also in 4to, 1877. There are also printed lists of the books of reference (1871) and bibliographies (1881) in the reading-room. Private enterprise has done a great deal towards cataloguing the American books (by Mr H. Stevens, 4 vols. 8vo), and the British topographical literature has recently been the subject of a similar publication by Mr J. P. Anderson, 8vo, 1881.

The printed catalogues of the MSS. are—that of the old Royal Library, 1734, 4to; the Sloane and others hitherto undescribed, 1782, 2 vols. 4to; the Cottonian, 1802, folio; the Harleian, 1808, 4 vols. folio; the Hargrave, 1818, 4to; the Lansdowne, 1819, folio; the Arundel, 1840, folio; the Burney, 1840, folio; the Oriental (Arabic and Ethiopic), 5 pts., folio, 1838–71; the Syriac, 1870–73, 3 pts., 4to; the Ethiopic, 1877, 4to; the Persian, 1879–80, 2 vols. 4to; and the Spanish, 1875–80, 3 vols. 8vo. There are also catalogues of the Greek and Egyptian papyri, 1839–46, 5 pts., folio. The additional MSS. from 1831–75 are described in 10 vols. 8vo, 1835–77, with indexes (1783–1835) in folio and (1854–75) in 8vo. A catalogue of the MS. music was produced in 1842, 8vo; and one of the MS. maps in 1844, 2 vols. 8vo.

The binding is done upon the premises, and the sum expended each year is £9000. The average sum annually spent upon the purchase of books is about £10,000, and upon MSS. £2500. Since the catalogues ceased to be transcribed £3000 is annually spent on printing.

Other London libraries.

London is very badly off as regards public libraries, and the largest general collection which is available without any tedious preliminary forms is that of the corporation of the city of London at the Guildhall. A library was established here by Sir Richard Whittington between 1421–26, and several notices in the civic records show how well in those times the citizens cared for their books. But it did not remain without accident; in 1522 the Lord Protector Somerset carried off three cart-loads of books, and during the great fire of 1666 the remainder was destroyed together with the library buildings. Nothing was done to repair the loss until 1824, when a committee was appointed, and rooms set apart for library purposes. In 1840 a catalogue of 10,000 volumes was printed, and in 1859 a second was prepared of 40,000 volumes. In consequence of the large and increasing number of the readers, the present fine building was commenced about ten years later, and, after having cost £90,000, was opened in 1873 as a free public library. There are now upwards of 80,000 printed volumes and 300 MSS. The contents are of a general character, and include a special collection of books about London, the Solomons Hebrew and rabbinical library, and the libraries of the Clockmakers' Company and the old Dutch church in Austin Friars. The only rate-supported library in the metropolis is that of the united parishes of St Margaret and St John at Westminster (13,527 volumes), founded in 1857, principally by the influence of the late Lord Hatherley, with a small branch at Knightsbridge. The Notting Hill Free Public Library (5000 volumes) is supported by Mr James Heywood, and the Bethnal Green Free Library and South London Free Library by voluntary subscriptions.

Of libraries of a more special character, those principally devoted to theology have perhaps the first claim to notice. The archiepiscopal library at Lambeth was founded in 1610 by Archbishop Bancroft, and has been enriched by the gifts of Laud, Tenison, Manners Sutton, and others of his successors; it is now lodged in the noble hall built by Juxon. The treasures consist of the illuminated MSS., and a rich store of early printed books; of the latter two catalogues have been issued by S. R. Maitland. The MSS. are described in H. J. Todd's catalogue, 1812. Sion College is a guild of the parochial clergy of the city and suburbs of London, and the library was founded in 1629 for their use; laymen may also read (but not borrow) the books when recommended by some beneficed metropolitan clergyman. The library is especially rich in liturgies, Port-Royal authors, pamphlets, &c. The copyright privilege was commuted in 1835 for an annual sum of £363, 15s. 2d. The present building was erected immediately after the great fire. The chamber in the old cloisters, in which the library of the dean and chapter of Westminster is preserved, is well known from the charming description by Washington Irving in his *Sketch Book*. There are about 11,000 volumes, mostly of old theology and history, including many rare Bibles and other valuable books. The library of the dean and chapter of St Paul's was founded in very early times, and now numbers some 8700 volumes, mainly theological, besides over 10,300 pamphlets, with a good collection of early Bibles and Testaments, Paul's Cross Sermons, and works connected with the cathedral. Dr Williams's library was founded by the will of an eminent Presbyterian divine of that name; it was opened in 1729. The books (30,000 printed volumes and 1000 MSS.) are housed in a new building, completed in 1873. Theology of all schools of opinion is represented, and there are special collections of theosophical books and MSS., the works of Boehme, Law, and other mystical writers. The MSS. include the original minutes of the Westminster Assembly, letters and treatises of Richard Baxter, &c. The British and Foreign Bible Society has a remarkable collection of Bibles and Biblical literature, of which a printed catalogue was published in 1855. Perhaps the best library of Catholic theology in London is that of the Oratory at South Kensington, established in 1849.

Of the law libraries, that at Lincoln's Inn is the oldest and the largest. It dates from 1497, when John Nethersale, a member of the society, made a bequest of forty marks, part of which was to be devoted to the building of a library for the benefit of the students of the laws of England. A catalogue of the printed books was published in 1859, and the MSS. were catalogued by the Rev. Joseph Hunter in 1837. The library of the Inner Temple is known to have existed in 1540. In the middle of the 17th century it received a considerable benefaction from William Petyt, the well-known keeper of the Tower records. There are now about 36,000 volumes, including the pamphlets collected by John Adolphus for his *History of England*, books on crime and prisons brought together by Mr Crawford, and a selection of works on jurisprudence made by John Austin. A library in connexion with the Middle Temple was in existence during the reign of Henry VIII., but the date usually assigned to its foundation is 1641, when Robert Ashley left his books to the inn of which he had been a member. Gray's Inn Library was perhaps established before 1555. In 1669 was made the first catalogue of the books, and the next, still extant, in 1689. The Incorporated Law Society (1831) has a good law and general library (30,000 volumes), including the best collection of private Acts of Parliament in England, and a large number of pamphlets relating to Anglo-Catholic controversies brought together by the late Rev. Joseph Mendham. The catalogue was printed in 1869.

The collegiate library at Dulwich dates from 1619, and a list of its earliest accessions, in the handwriting of the founder, may still be seen. There are now about 7000 volumes of miscellaneous works of the 17th and 18th centuries, with a few rare books. A catalogue of them was printed in 1880; and one describing the MSS. (567) and the muniments (606) was issued during the succeeding year. The last two classes are very important, and include the well-known "Alleyn Papers" and the theatrical diary of Philip Henslow. Soon after the foundation of the University of London in 1837, an endeavour was made to provide a library, but it has had to look to gifts rather than to purchases for its accessions. In 1871 the university obtained, in this manner, the library of the historian Grote, and in the same year Lord Overstone purchased and presented the mathematical collection of De Morgan. A catalogue was printed in 1875. The books at University College (1828) are much more numerous, and here also a considerable proportion are donations, including the Morrison Chinese library of 10,000 volumes, the Daulby-Roscoe Icelandic books, the Graves mathematical and physical library, and the Barlow Dante bequest. A printed catalogue of the greater portion was brought out in 1879. The library at King's College includes a collection of works on Eastern subjects bequeathed by Dr Marsden, as well as the scientific books formerly belonging to Sir Charles Wheatstone. The medical library is distinct. The educational library at the South Kensington Museum numbers about 42,200 volumes, and may be consulted by teachers and students of the departmental schools, and by other persons on the same terms as the art library mentioned below. The ninth edition of the catalogue appeared in 1876.

The library of the Patent Office is the largest scientific and technical collection, indeed the only one which is readily open to the public. There are at present 80,000 volumes, including a very extensive series of the transactions and journals of learned bodies. A catalogue is now in the press. Transactions and proceedings of societies, with scientific periodicals, compose almost the whole library of the Royal Society, which extends to about 40,000 volumes. The diarist Evelyn induced the seventh duke of Norfolk to present to the Society the Arundel library, part of which had formerly belonged to Matthias Corvinus. The MSS., however, were sold to the British Museum in 1831 for £3559, and a quantity of rare printed books have also been disposed of. Scientific inquirers are freely admitted to the Museum of Practical Geology in Jermyn Street, where there are over 30,000 volumes on geology, mineralogy, mining, and metallurgy, including the former collections of De la Beche and Murchison. A printed catalogue was issued in 1878. For the libraries of other scientific institutions see the tables.

Medical and surgical libraries are attached to all the chief hospitals and medical societies (see the tables).

For the fine arts there is the National Art Library (1852) at the South Kensington Museum, which is now an excellent collection of 56,000 volumes, 56,000 photographs, 25,000 drawings, and 80,000 prints. Art students are admitted free, as are ordinary visitors on Museum pay days; otherwise a charge of 6d. per week is made to the latter. The library of the Royal Academy of Arts, after its journey from Somerset House to Trafalgar Square, has been lodged in the old ball-room of Burlington House since 1875. At the National Gallery is preserved for official use the library (3500 volumes) formerly belonging to Sir C. L. Eastlake, P.R.A., which is particularly rich in catalogues and descriptions of picture galleries. The Royal Institution of British Architects (1834) possesses over 6500 volumes on architectural and allied subjects, including an almost complete collection of editions of Vitruvius. The library of the Royal Academy of Music (1822) is almost exclusively musical, and, although numbering less than 1000 volumes, contains many rare and interesting works. The library of the Sacred Harmonic Society is said to be one of the best arranged and most valuable musical collections in England. A third edition of the printed catalogue appeared in 1872, when the library contained 4851 volumes.[1]

[1] For a very complete account of the chief public and private musical collections both at home and abroad, see the article "Musical Libraries," in Dr Grove's *Dictionary of Music*, ii. 417.

The best library of archæology and kindred subjects is that of the Society of Antiquaries, consisting of nearly 20,000 printed volumes and 500 MSS. It is rich in early printed books, topography, heraldry, and numismatics, and includes a curious collection of books on pageants presented by Mr Fairholt, and the remarkable assemblage of lexicographical works formerly belonging to the late Albert Way, given by his widow. There is a good muster of heraldic works at the Herald's College, and the library of Sir John Soane (15,000 volumes) is still preserved in the museum at his house in Lincoln's Inn Fields. The printed catalogue (1878) shows that it is a fairly good collection of books on architecture and antiquities.

Among subscription libraries, the London Library stands first in order of importance. It was founded in 1841 as a lending library for the use of scholars, and Dean Milman, Sir G. C. Lewis, Mr Gladstone, Thomas Carlyle, Henry Hallam, and other eminent men took part in its formation. By means of a moderate subscription, funds were raised for the purchase of books on general subjects, which now amount to about 90,000 volumes. The latest catalogue was printed in 1875, with a supplement in 1881. The London Institution (1805) is a proprietary library to which proprietor's nominees and yearly subscribers also have admission. For reference purposes reader's tickets are very liberally granted to other persons. The books now number about 70,000 volumes in general literature; the departments of history and topography are especially rich, and the number is rapidly growing. A complete catalogue was published in 1837–43; almost the whole collection, including reference and circulating libraries very minutely classified, is contained in one room. Porson filled the position of librarian here at the close of his life, but he proved no better a librarian than did Casaubon before him at Paris. The library of the Royal Institution of Great Britain was founded in 1803 by the subscriptions of the members, amounting, in 1806, to £6000. There are now 40,000 volumes in scientific and general literature; they are not lent out. There is an interesting series of 56 volumes of MS. correspondence relating to the American war.

The libraries of the two branches of the legislature may be named with those of the great public offices. The Foreign Office library contains about 70,000 volumes, including the old library of the Board of Trade (20,000 volumes); history, geography, and law are well represented, and the department of treaties and diplomacy is of course very complete. The India Office library was formed by a vote of the court of directors of the East India Company in 1801. The services in India were also invited to aid in the creation of an institution which should become a permanent repository of Oriental lore, and many munificent donations were received in consequence of the appeal. The printed books now number nearly 40,000, chiefly on Indian and Oriental subjects, with about 10,000 Sanskrit, Arabic, Persian, Pali, and other Oriental manuscripts. Loth's excellent catalogue of the Arabic codices was published in 1877, and other catalogues are now ready for the press. At the Colonial Office there is a collection of about 12,000 works relating to colonial history and administration, and the Home Office possesses about 5000 volumes of parliamentary, historical, and legal works. The Admiralty library extends to about 25,000 volumes, chiefly voyages and travels; a printed catalogue was issued in 1875. At the War Office there are also 25,000 volumes, mainly topographical and military. The MS. records are estimated to extend to 100,000 volumes, but only those of the last twenty years are kept in Pall Mall, the remainder being at the Record Office. These records extend from the time of Queen Elizabeth, and there are some of earlier date. The older volumes belonged to the late Board of Ordnance, and the series also includes the despatches from generals commanding armies on foreign service. All these libraries are for official use only, but at the India Office strangers are admitted upon proper introduction.

Many of the principal clubs possess libraries; that of the Athenæum is by far the most important. It now numbers about 48,000 volumes of books in all departments of literature, and is especially rich in well-bound and fine copies of works on the fine arts, archæology, topography, and history. The pamphlets, of which there is a complete printed catalogue, as well as of the books, form a remarkable series, including those collected by Gibbon and Mackintosh. Next comes the Reform Club, with about 50,000 volumes, chiefly in belles-lettres, with a fair proportion of parliamentary and historical works. The Oxford and Cambridge Club has 20,000 volumes in general and classical literature. At the Garrick there is a small dramatic collection; and the United Service Club, besides a number of books on professional subjects, possesses the fine library which formerly belonged to Dugald Stewart.

A few libraries which could not be brought into any of the foregoing classes may now be spoken of. First comes the library of the Royal Geographical Society (1832), a valuable collection of 20,000 volumes of voyages and travels, and works on the sciences connected with geography, with many costly Government publications and geographical serials. The catalogue has been printed with supplements down to 1880. The maps and charts number 35,000, with 500 atlases and 240 large diagrams. Since 1854, in consideration of an annual grant of £500 from the treasury, the map room has been open for public reference. At the Royal United Service Institution there are also about 20,000 volumes, chiefly naval and military, with a printed catalogue, 1865. Besides the members, officers of both services are admitted. The Royal Asiatic Society has a library of nearly 8000 printed books, with 750 MSS. in Sanskrit, Persian, Turkish, &c., 5000 Chinese books, and 220 Japanese. Besides the art and educational libraries at South Kensington, there are also deposited at the museum, and open under the same regulations, the library of the Rev. Alexander Dyce, bequeathed in 1869, and the books of John Forster, left in 1876. The Dyce collection (15,000 volumes) is strong in the English drama and poetry, Italian literature, and classical authors. The Forster library (19,000 volumes) abounds in history, biography, travels, plays, and fiction, tracts, Americana, proclamations, ballads, &c.; the manuscripts include three note-books of Leonardo da Vinci, and the Garrick correspondence in 39 volumes.

Notices of a considerable number of other metropolitan libraries, not mentioned in the preceding pages, may be found in the tables at the end of this article.

Cathe- librar-

With one or two exceptions, libraries are attached to the cathedrals of England and Wales. Though they are of course intended for the use of the cathedral or diocesan clergy, they are in most cases open to any respectable person who may be properly introduced. They seldom contain very much modern literature, chiefly consisting of older theology, with more or less addition of classical and historical literature. They vary in extent from a few volumes, as at Llandaff or St David's, to 15,000 volumes, as at Durham. Together they possess nearly 150,000 printed and manuscript volumes. As a rule, very little is spent upon them, and they are very little used.

The library of Christ Church, Oxford, belongs alike to the college and the cathedral, but will be more properly described as a college library. The cathedral library of Durham dates from monastic times, and possesses many of the books which belonged to the monastery. These were added to by Dean Sudbury, the second founder of the library, and Bishop Cosin. The collection has been considerably increased in more modern times, and now contains

15,000 volumes. It is especially rich in MSS., some of which are of great beauty and value; a catalogue of them was printed in 1825. The library has good topographical and entomological collections. The chapter spend £370 per annum in salaries and in books. The library at York numbers about 11,000 volumes, and has been very liberally thrown open to the public. It is kept in the former chapel of the archbishop's palace, and has many valuable MSS. and early printed books. The foundation of the library at Canterbury dates probably from the Roman mission to England, 596 A.D., although the library does not retain any of the books then brought over, or even of the books said to have been sent by Pope Gregory to the first archbishop in 601. It is recorded that among Lanfranc's buildings was a new library, and Becket is said to have collected books abroad to present to the library. The collection now numbers about 9900 printed books, with about 110 MS. volumes, and between 6000 and 7000 documents. A catalogue was printed in 1802. The present building was erected in 1867 on part of the site of the monastic dormitory. The library at Lincoln contains 7400 volumes, of which a catalogue was printed in 1859. It possesses a fine collection of political tracts of the age of Elizabeth, James, and Charles I. The present collection at Chichester dates from the Restoration only; that at Ely is rich in books and tracts relating to the non-jurors. The library at Exeter possesses many Saxon MSS. of extreme interest, one of them being the gift of Leofric, the first bishop. The treasures of Lichfield were destroyed by the Puritans during the civil war, and the existing library is of later formation. Frances, duchess of Somerset, bequeathed to it nearly 1000 volumes, including the famous Evangeliary of St Chad. The collection at Norwich is chiefly modern, and was presented by Dr Sayers. The earlier library at Peterborough having almost wholly perished in the civil war, Bishop White Kennett became the virtual founder of the present collection. Salisbury is rich in incunabula, and a catalogue has recently been printed. Winchester Cathedral Library is mainly the bequest of Bishop Morley in the 17th century. The library at Bristol, then numbering 6000 or 7000 volumes, was burnt and pillaged by the mob in the riots of 1831. Only about 1000 volumes were saved, many of which were recovered, but few additions have been made to them. At Chester in 1691 Dean Arderne bequeathed his books and part of his estate "as the beginning of a public library for the clergy and city." The library of Hereford is a good specimen of an old monastic library; the books are placed in the Lady Chapel, and about 230 choice MSS. are chained to oaken desks. The books are ranged with the edges outwards upon open shelves, to which they are attached by chains and bars. The four Welsh cathedrals were supplied with libraries by a deed of settlement in 1709. The largest of them, that of St Asaph, has about 1750 volumes.

The Bodleian Library, though it had been preceded by various efforts towards a university library, owed its origin to Sir Thomas Bodley. After a long and honourable career as a diplomatist he determined, as he says, to take his farewell of state employments, and concluded to set up his staff at the library door in Oxon. Contributing largely himself, and procuring contributions from others, he opened the library with upwards of 2000 volumes in 1602. In 1610 he obtained a grant from the Stationers' Company of a copy of every work printed in the country. The additions made to the library soon surpassed the capacity of the room, and the founder proceeded to enlarge it. By his will he left considerable property to the university for the maintenance and increase of the library. The example set by Bodley found many noble imitators. Amongst the chief benefactors have been Sir Henry Savile, Archbishop Laud, John Selden, Sir Kenelm Digby, Lord Fairfax, Richard Gough, Francis Douce, Richard Rawlinson, Rev. Robert Mason, and F. W. Hope. The library now contains almost 400,000 printed volumes, and about 30,000 manuscripts. The number of separate works exceeds a million. But the number of volumes conveys a very inadequate idea of the valuable character of the collection. In the department of Oriental manuscripts it is perhaps superior to any other European library; and it is exceedingly rich in other manuscript treasures. It possesses a splendid series of Greek and Latin *editiones principes*, and of the earliest productions of English presses. Its historical manuscripts contain most valuable materials for the general and literary history of the country.

The last general catalogue of the printed books was printed in 4 vols. folio, 1843–51. In 1859 it was decided to prepare a new manuscript catalogue on the plan of the great catalogue at the British Museum, and this has recently been completed in duplicate. It extends to over 700 folio volumes, in which the books are entered on manifolded slips. It is an alphabetical author-catalogue; and the Bodleian, like the British Museum, has no accessible subject index. A catalogue on subjects is now, however, in course of preparation. There are also printed catalogues of the books belonging to several of the separate collections. The MSS. are in general catalogued according to the collections to which they belong, and they are all indexed, although they are not all catalogued as yet. Five volumes have been published under the late Mr Coxe's editorship of the "Catalogi Codicum MSS. Bibliothecæ Bodleianæ," 1853–63, in quarto, and there is a folio catalogue of Oriental MSS.

In 1860 the beautiful building known as the "Radcliffe Library," now called the "Camera Bodleiana," was offered to the curators of the Bodleian by the Radcliffe trustees. It is used as a storehouse for the more modern books, including the new periodicals, which lie upon its tables; and it also serves as a reading-room. It is the only room open after the hour when the older building is closed owing to the rule as to the exclusion of artificial light. The separation of the books is a source of some inconvenience in practice, and it has been proposed of late years to remove the entire collections to a new building which should be erected for the purpose of accommodating them.

The library is open by right to all graduate members of the university, and to others (over eighteen years of age) upon producing a satisfactory recommendation. No books are allowed to be sent out of the library except by special leave of the curators, in which respect there is a marked contrast with the practice at the University Library at Cambridge, and still more so with the conspicuous liberality in this respect of the university libraries of Germany. The hours are from 9 to 4 and 9 to 3, according to the time of year, the Camera being open from 10 to 10 all the year round. The library is only closed altogether some twenty-nine working days in the year. The general control of the library is committed to a board of thirteen curators. The permanent endowment is comparatively small; the ordinary expenditure, chiefly defrayed from the university chest, is about £4500.

The other important collections not connected with particular colleges are the Radcliffe Library and the library of the Taylor Institution. The former was founded by the famous physician Dr John Radcliffe, who died in 1714, and bequeathed, besides a permanent endowment of £350 a year, the sum of £40,000 for a building. The library was opened in 1749. Many years ago the trustees resolved to confine their purchases of books to works on medicine and natural science. When the university museum and laboratories were built in 1860, the trustees allowed the books to be transferred to the museum. The completeness and convenience of the arrangements make the Radcliffe the model of a working scientific library. The Taylor Institution is due to the benefaction of Sir Robert Taylor, an architect, who died in 1788, leaving his property to found an establishment for the teaching of modern languages. The library was established in 1848, and is devoted to the literature of the modern European languages. It contains a fair collection of works on European philology, with a special Dante collection, about 1000 Mazarinades and 400 Luther pamphlets. It contains altogether 30,000 volumes, with a few MSS. The Finch collection, left to the university in 1830, is also kept with the Taylor Library. Books are lent out to members of the university and to others on a proper introduction. The endowment affords an income of £800 to £1000 for library purposes, and about 2000 volumes are added yearly.

The libraries of the several colleges vary considerably in extent and character. That of All Souls was established in 1443 by Archbishop Chichele, and enlarged in 1710 by the munificent bequest of Christopher Codrington. It devotes special attention to jurisprudence, of which it has a large collection. It possesses 40,000 printed volumes and 300 MSS., and fills a splendid hall 200 feet long. The library of Brasenose College has a special endowment fund, so that it has, for a college library, the unusually large income of £200. The library of Christ Church is rich in divinity and topography. It embraces the valuable library bequeathed by Charles Boyle, third earl of Orrery, amounting to 10,000 volumes, the books and MSS. of Archbishop Wake, and the Morris collection of Oriental books. The building was finished in 1761, and closely resembles the basilica of Antoninus at Rome, now the Dogana. Corpus possesses a fine collection of Aldines, many of them presented by its founder Bishop Fox, and a collection of 17th century tracts catalogued by Mr Edwards, with about 400 MSS. Exeter College Library has 25,000 volumes, with special collections of classical dissertations and English theological and political tracts. The library of Jesus College has few books of later date than the early part of the last century. Many of them are from the bequest of Sir Leoline Jenkins, who built the existing library. There are also some valuable Welsh MSS. The library of Keble College consists largely of theology, including the MSS. of many of Keble's works. The library of Magdalen College has about 22,500 volumes (including many volumes of pamphlets) and 250 MSS. It has scientific and topographical collections. The library of Merton College has of late devoted itself to foreign modern history. New College Library has about 17,000 printed volumes and about 350 MSS., several of which were presented by its founder, William of Wykeham. Oriel College Library, besides its other possessions, has a special collection of books on comparative philology and mythology, with a printed catalogue. The fine library of Queen's College is strong in theology, in English and modern European history, and in English county histories. St John's College Library is largely composed of the literature of theology and jurisprudence before 1750, and possesses a collection of medical books of the 16th and 17th centuries. The newer half of the library building was erected by Inigo Jones at the expense of Laud, who also gave many printed and manuscript books. The room used as a library at Trinity College formed part of Durham College, the library of which was established by Richard of Bury. Wadham College Library includes a collection of botanical books bequeathed by Richard Warner in 1775 and a collection of books, relating chiefly to the Spanish Reformers, presented by the executors of Benjamin Wiffen. Worcester College Library has of late specially devoted itself to classical archæology. It is also rich in old plays.

It must be admitted that the college libraries as a rule have not been used to any great extent. Of late, however, there have been signs of awakening interest. About 1871 there was a meeting of college librarians; and it was agreed that the colleges, instead of making merely sporadic purchases from the whole field of literature, should rather husband their limited resources and restrict themselves each to some special department. But the idea has not been carried out very thoroughly, and a good deal must be done before the college libraries can be said to be as useful and efficient as they might be.

Cambridge. The history of the University Library at Cambridge dates from the earlier part of the 15th century. Two early lists of its contents are preserved, the first embracing 52 volumes dating from about 1425, the second a shelf-list, apparently of 330 volumes, drawn up by the outgoing proctors in 1473. Its first great benefactor was Thomas Scott of Rotherham, archbishop of York, who erected in 1475 the building in which the library continued until 1755. He also gave more than 200 books and manuscripts to the library, some of which still remain. The library received other benefactions, but nevertheless appeared "but mean" to John Evelyn when he visited Cambridge in 1654. In 1666 Tobias Rustat presented a sum of money to be invested to buy the choicest and most useful books. In 1715 George I. presented the library of Bishop Moore, which was very rich in early English printed books, forming over 30,000 volumes of printed books and manuscripts. The funds bequeathed by William Worts and John Manistre, together with that of Rustat, produce at present about £1500 a year. The share of university dues appropriated to library purposes amounts to £3000 a year. In addition the library is entitled to new books under the Copyright Acts. The number of printed volumes in the library cannot be exactly stated, as no recent calculation on the subject exists. It has been variously estimated at a quarter or half a million. The calendar states it as 200,000. It includes a fine series of *editiones principes* of the classics and of the early productions of the English press. The MSS. number 5723, in which are included a considerable number of adversaria or printed books with MS. notes, which form a leading feature in the collection. The most famous of the MSS. is the celebrated copy of the four gospels and the Acts of the Apostles, which is known as *Codex Bezæ*, and which was presented to the university by that Reformer. A catalogue of the MSS. has been published in 4 vols., 1856–61. There is no printed catalogue of the books, although the catalogue is in print, the accessions being printed and cut up and arranged in volumes. The regulations of the library with regard to the lending of books are very liberal, as many as ten volumes being allowed out to one borrower at the same time.

There is a library attached to the Fitzwilliam Museum bequeathed to the university in 1816. It consists of the entire library of Lord Fitzwilliam, with the addition of an archæological library bought from the executors of Colonel Leake, and a small number of works, chiefly on the history of art, since added by purchase or bequest. It contains a collection of engravings of old masters, a collection of music, printed and MS., and a collection of illuminated MSS., chiefly French and Flemish, of the 14th to 16th centuries. The books are not allowed to be taken out.

The library of Trinity College, which is contained in a magnificent hall built by Sir Christopher Wren, has about 90,000 printed and 1918 MS. volumes, and is especially strong in theology, classics, and bibliography. It owes to numerous gifts and bequests the possession of a great number of rare books and manuscripts. Amongst these special collections are the Capell collection of early dramatic and especially Shakespearian literature, the collection of German theology and philosophy bequeathed by Archdeacon Hare, and the Grylls bequest in 1863 of 9600 volumes, including many early printed books. There are printed catalogues of the Sanskrit and other Oriental MSS. by Dr Aufrecht and Professor Palmer, and of the incunabula by the present librarian, Mr Sinker. The library is open to all members of the college, and the privilege of using it is liberally extended to properly accredited students.

None of the other college libraries rivals Trinity in the number of books. The library of Christ's College received its first books from the foundress. Clare College Library includes a number of Italian and Spanish plays of the end of the 16th century left by George Ruggle. The library of Corpus Christi College first became notable through the bequest of books and MSS. made by Archbishop Parker in 1575. The printed books are less than 5000 in number, and the additions now made are chiefly in such branches as throw light on the extremely valuable collection of ancient MSS., which attracts scholars from all parts of Europe. There is a printed catalogue of these MSS. Gonville and Caius College Library is of early foundation. A catalogue of the MSS. was printed in 1849, with pictorial illustrations, and a list of the incunabula in 1850. The printed books of King's College includes the fine collection bequeathed by Jacob Bryant in 1804. The MSS. are almost wholly Oriental, chiefly Persian and Arabic, and a catalogue of them has been printed. Magdalene College possesses the curious library formed by Pepys and bequeathed by him to the college, together with his collections of prints and drawings and of rare British portraits. It is remarkable for its treasures of popular literature and English ballads, as well as for the Scottish manuscript poetry collected by Sir Richard Maitland. The books are kept in Pepys's own cases, and remain just as he arranged them himself. The library of Peterhouse is the oldest library in Cambridge, and possesses a catalogue of some 600 or 700 books dating from 1418, in which year it was completed. It is chiefly theological, though it possesses a valuable collection of modern works on geology and natural science, and a unique collection of MS. music. Queen's College Library contains about 30,000 volumes, mainly in theology, classics, and Semitic literature, and has a printed class-catalogue. The library of St John's College is rich in early printed books, and possesses a large collection of English historical tracts. Of the MSS. and rare books there is a printed catalogue. For the other college libraries see the tables.

Free Public Libraries.—In the year 1850 Mr Ewart introduced the first Public Libraries Act into the House of Commons, and it has since been supplemented and amended by the Acts of 1855, 1866, 1871, and 1877. Mr Ewart had previously carried through parliament the Museums Act of 1845; and small libraries had been established in connexion with museums under that Act at Salford and Warrington. The number of towns which have established rate-supported libraries, or in which the Acts have been adopted, now amounts to at least ninety-six, ten of these towns being in Scotland, and one only in Ireland. It is noticeable that the Acts have not been adopted in any of the great capital towns of the three kingdoms, except in one single parish of Westminster. Many of our largest towns are also in default. Glasgow may be considered to be sufficiently provided for by the munificent Mitchell bequest. Of the libraries which have actually been opened sixteen are in places of over 100,000 inhabitants, twenty in towns of between 50,000 and 100,000 inhabitants, sixteen in towns of between 30,000 and 50,000, eleven in towns of between 20,000 and 30,000 inhabitants, seventeen in towns of between 10,000 and 20,000 inhabitants, and finally six in towns of less than 10,000 inhabitants. Free public libraries.

Taking the latest returns we have been able to obtain which are with a few exceptions those of the year 1880-81, the number of volumes in stock and of the total issues is as follows. In eighty-one libraries returning their number of volumes, there is a total of 1,448,192 volumes in stock; while the total issues for the year in seventy-six libraries amounted to the enormous number of 9,023,742 volumes. Even these figures afford a very inadequate idea of the service rendered by these institutions in supplying popular reading. They take no account of the visits made to the newsrooms which are almost invariably connected with the libraries, or of the use made of the magazines and periodicals which lie upon the tables. The free public libraries generally consist of a lending department, with a reference library wherever the institution can provide one. A very large proportion of the issues from the lending departments consists of fiction, the percentage varying in different libraries from about 50 to as much as 75 per cent. of the whole. It is only in the case of the wealthier institutions, such as those in the great towns of Liverpool, Manchester, and Birmingham, that the reference departments are so important as to claim consideration here in respect of the intrinsic character of their collections. Even some of the smaller libraries, however, present features of interest in their collections of local books, or of books illustrating the trade or industry of the district, or the life and writings of some great man connected with or born in the locality.

The Salford Free Public Library was one of the libraries which were established under the Museums Act of 1845, and was opened in 1850 in connexion with the museum and picture gallery at Peel Park. The buildings are pleasantly situated in grounds of 46 acres in extent. The reference library now contains 33,500 volumes, and besides the central lending departments there are three branches in different parts of the borough. The income from the penny rate is about £3300; but this is found to be inadequate.

The Manchester Free Library was the first to be established under the Act of 1850. A public subscription of nearly £13,000 was raised to defray the expenses of its establishment, and the library was opened in September 1852. The working of this library was a success from the outset. The issues in the first year were in the reference departments 61,080 volumes, and in the lending departments 77,232. The progress made since then may be measured by the number of volumes issued last year (1881), which amounted to 966,468, and by the fact that six branch libraries have been established. The rate produces an income of £11,000. The reference library now possesses a valuable collection of 65,000 volumes, chiefly of standard works. It contains several special collections, chiefly connected with the industries and history of the district. The library of the English Dialect Society, of which a catalogue has been printed, is deposited here. In addition, the library possesses a very extensive series of periodicals, and a larger collection of political and commercial tracts than can be found anywhere in the country except at the British Museum. A good catalogue was printed in 1864, and a new and extensive index has just appeared.

The library at Liverpool, which was established under a special Act passed in 1852, is the most successful of all the free public libraries, and is connected with a splendid museum and art gallery, the former formed around the nucleus of the ornithological specimens bequeathed to the town by the thirteenth earl of Derby. The rapid extension of museum and library soon rendered larger premises a necessity. The late Sir William Brown took upon himself the entire cost of the present extensive buildings, which were opened in 1860. In 1880 was opened the Picton Reading-Room. It is a circular room 100 feet in diameter, surmounted by a dome, the entire height being 56 feet. It contains 50,000 volumes, and will accommodate over 300 readers. Since April 1881 the electric light has been employed. Under the reading-room is a large circular lecture-room accommodating 1500 persons, in which lectures are regularly delivered. There is a numerous collection of local books and pamphlets. The Binns collection, consisting of maps, plans, drawings, portraits, &c., all having reference to the county of Lancaster, is very interesting and valuable. The issues from the reference library in 1880 were 870,716, and with the issues from the two lending departments make the enormous aggregate of 1,307,131. The rate produces an income of £13,000 per annum, of which more than £5000 is expended upon the libraries. An elaborate catalogue of the reference library was published in 1872, and a supplement is now being printed. In 1853 Bolton established a library which now has a circulation of over 240,000 volumes. In 1855 libraries were established at Birkenhead and Sheffield. At Birkenhead the rate produces £1500, and 130,000 volumes were lent out last year. At Sheffield, where the rate produces £4750, there are three branches, and the total issues last year were 384,266. The reference library has only 9000 volumes.

The Acts, after having been rejected at Birmingham in 1852, were adopted in 1860. By 1868 four branches had been opened in addition to the central reference and lending libraries. The issues from the lending departments last year were 400,000 volumes. The reference library consisted of over 50,000 volumes. The Shakespeare Memorial Library consisted of about 7000 volumes. There were also the Staunton Warwickshire collections of books and MSS. and the Cervantes books. All these collections were unfortunately destroyed by a fire on January 11, 1879. The inhabitants of Birmingham have shown much public spirit in repairing the losses then sustained so far as is possible, and the new central reference and lending libraries are expected to be open early in 1882, when it is anticipated that there will be as many volumes ready to be placed in the reference library as there were when the former library was destroyed. No town in England is so surrounded with free libraries as Birmingham. The rate at Birmingham produces over £6000.

The free library at Nottingham (1867) has recently had new quarters found for it in the new university buildings. It has two branches, and its issues are about 160,000. The rate produces £2200. The local collections include a Byron library. The library at Leeds (1868) has no less than twenty-one branches, and together they count over 109,000 volumes. The issues last year, in addition to the use made of the central reference library, were 639,613. The rate produces nearly £5000. At Leicester there is only a halfpenny rate, which produces about £800. The issues last year were 192,317. At Bradford (Acts adopted 1871) the rate produces £3200, and there are five branches with a circulation of 291,276 volumes, besides the use made of the reference library. At Plymouth (Acts adopted 1871, library opened 1876) the circulation was 171,851 last year; at Rochdale (Acts adopted 1872) 168,514. At each place there is a good collection of local literature, and at Rochdale a collection of works on the woollen manufacture. The library at Newcastle, opened in 1880, has issued from its lending departments, in its first year, no less than 301,925 volumes to about 14,000 readers. A splendid building is in course of erection to accommodate the reference library. This department is intended to contain a complete collection of all standard works, and also a collection of books and manuscripts relating to Newcastle and the northern counties generally. The rate produces £2800. At Bristol a town library had been established in 1614 by Robert Redwood and Archbishop Matthew, and this has formed the nucleus of the collections formed under the Acts when they were adopted in 1875. The total number of volumes is about 46,000. The issues were 432,646 at the central library and its three branches. At Southport (1875) Mr Atkinson gave the building called after him for a library and art gallery. The issues last year were 110,778. The rate produced £775, and an additional voluntary rate produced a little over £100 besides.

It will be seen from this summary statement that the libraries established under the Acts have in the cases mentioned been abundantly used. The merit of these results is very largely due to the enlightened energy of those who are entrusted with their administration.

Amongst the English libraries that have not yet been described there are few that call for special mention. Some of these have been founded by individuals, and still bear their names. The most notable of these is the fine old library established by Humphrey Chetham at Manchester in 1653, which is still housed in the old collegiate buildings where Raleigh was once entertained by Dr Dee. The collection consists largely of older literature, and numbers 40,000 volumes, with 300 MSS. It is freely open to the public, and may be said to have been the first free library in England. Dr Shepherd's library at Preston was bequeathed by the founder, a physician of the town, to the corporation of Preston in trust for the inhabitants in the year 1759. It is a library of reference, accessible on a recommendation from an alderman. The William Salt Library, a special Staffordshire library with numerous MSS. and other collections, formed to bring together materials for a history of Staffordshire, was opened to the public in 1874.

Some mention should be made also of the more important subscription or proprietary libraries, which were formed for the most part in the latter half of the 18th century. It is difficult for us to realize how few collections of books were accessible to the public of the last century even in London. The earliest circulating library in the metropolis was established about the middle of the century. The first in Birmingham was opened by Hutton in 1757. The idea of a proprietary library appears to have been first carried out at Liverpool in 1758. The library then formed still flourishes at the Lyceum, and possesses a collection of 72,000 volumes and an income of £1200 a year. In 1760 a library was formed at Warrington which has been merged in the Warrington Museum. The Leeds library was established in 1768, and now has 85,000 volumes, and an income of £1430. In 1772 the Bristol museum and library was formed, and numbered Coleridge, Southey, and Landor among its earlier members. It now reckons 50,000 volumes, and an income of £1400 a year. The Birmingham (old) library was formed in 1779, and its rules were drawn up by Dr Priestley, who had already taken an active share in the management of the libraries at Warrington and Leeds. The library has now 40,000 to 50,000 volumes, and an income of £1600. Many similar institutions are noticed in the tables, while others have given place to the trade circulating libraries and to the libraries established under the Free Libraries Acts.

A few modern collegiate libraries, finally, claim a summary notice. The library of the university of Durham dates only from 1833, and was begun by a gift of books from Bishop Van Mildert, to which many other donations have since succeeded. The Routh collection includes a large collection of early tracts. The Winterbottom collection is chiefly classical, and the Maltby collection classical and theological. The library of the Owens College, Manchester, was formed on the establishment of the college in 1851 by a gift of books from Mr James Heywood, F.R.S. It has since been largely increased by donations and bequests, including the libraries of Bishop Lee, Mr Crace Calvert, and others. It has an endowment fund of £2500. The library at Stonyhurst College has gradually grown since the establishment of the college in 1794. There is a printed catalogue of books printed before 1551. The Walshian Library at St Mary's College, Oscott, was established by Bishop Walsh in 1839, having been purchased by him from the Marchese Marini. It has 70 MSS. and many early printed books.

The principal library in Scotland is that of the Faculty of Advocates, who in 1680 appointed a committee of their number, which reported that "it was fitt that, seeing if the recusants could be made pay their entire money, there wold be betwixt three thonsand and four thousand pounds in cash; that the same be imployed on the best and fynest lawers and other law bookes, conforme to a catalogue to be condescended upon by the Facultie, that the samen may be a fonde for ane Bibliothecque whereto many lawers and others may leave their books." In 1682 the active carrying out of the scheme was committed to the Dean of Faculty, Sir George Mackenzie of Rosehaugh, who may be regarded as the founder of the library. In 1684 the first librarian was appointed, and the library appears to have made rapid progress, since it appears from the treasurer's accounts that in 1686 the books and furniture were valued at upwards of £11,000 Scots, exclusive of donations. In the year 1700, the rooms in the Exchange Stairs, Parliament Close, in which the library was kept, being nearly destroyed by fire, the collection was removed to the ground floor of the Parliament House, where it has ever since remained. The library retains the copyright privilege conferred upon it in 1709. The number of volumes in the library is computed to amount to 265,000; of the special collections the most important are the Astorga collection of old Spanish books, purchased by the faculty in 1824 for £4000; the Thorkelin collection, consisting of about 1200 volumes relating chiefly to the history and antiquities of the northern nations, and including some rare books on old Scottish poetry; the Dietrich collection of over 100,000 German pamphlets and dissertations, including many of the writings of Luther and Melanchthon, purchased for the small sum of £80; and the Combe collection.

The faculty appear early to have turned their attention to the collection of MSS., and this department of the library now numbers about 3000 volumes. Many of them are of great interest and value, especially for the civil and ecclesiastical history of Scotland before and after the Reformation. There are thirteen monastic chartularies which escaped the destruction of the religious houses to which they belonged. The MSS. relating to Scottish church history include the collections of Spottiswoode, Woodrow, and Calderwood. The Woodrow collection consists of 154 volumes, and includes his correspondence, extending from 1694 to 1726. Sir James Balfour's collection and the Balcarres papers consist largely of original state papers, and include many interesting royal letters of the times of James V., Queen Mary, and James VI. The Sibbald papers, numbering over 30 volumes, are largely topographical. The Riddel notebooks, numbering 156 volumes, contain collections to illustrate the genealogy of Scottish families. There are about one hundred volumes of Icelandic MSS., purchased in 1825 from Professor Finn Magnusson, and some Persian and Sanskrit, with a few classical, manuscripts. The department has some interesting treasures of old poetry, extending to 73 volumes. The most important are the Bannatyne MS., in 2 vols. folio, written by George Bannatyne in 1568, and the Auchinleck MS., a collection of ancient English poetry, named after Alexander Boswell of Auchinleck, who presented it in 1774.

The first catalogue of the printed books was compiled in 1692, and contains a preface by Sir George Mackenzie. Another was prepared under the care of Ruddiman in 1742. In 1853 the late Mr Halkett commenced a catalogue, which has been printed in 6 vols. 4to, with a supplement, and includes all the printed books in the library at the end of 1871, containing about 260,000 entries. It is an illustration of the public spirit with which they conduct their library, that the whole cost of printing this extensive catalogue, over £5000, has been borne by the members of the faculty. The library, managed by a keeper and staff, under a board of six curators, is easily accessible to all persons engaged in literary work, and is for all practical purposes the public consulting library of Scotland.

The origin of the University Library of Edinburgh is to be found in a bequest of his books of theology and law made to the town in 1580 by Clement Little, advocate. This was two years before the foundation of the university, and in 1584 the town council caused the collection to be removed to the college, of which they were the patrons. As it was the only library in the town, it continued to grow and received many benefactions, so that in 1615 it became necessary to erect a library building. Stimulated perhaps by the example of Bodley at Oxford, Drummond of Hawthornden made a large donation of books, of which he printed a catalogue in 1627, and circulated an appeal for assistance from others. In 1678 the library received a bequest of 2000 volumes from the Rev. James Nairne. In 1709 the library became entitled to the copy privilege, which has since been commuted for a payment of £575 per annum. In 1831 the books were removed to the present library buildings, for which a parliamentary grant had been obtained. The main library hall (190 feet in length) is one of the most splendid apartments in Scotland. One of the rooms is set apart as a memorial to General Reid, by whose benefaction the library has greatly benefited. Amongst the more recent accessions have been the Halliwell-Phillips Shakespeare collection, the Laing collection of Scottish MSS., the Baillie collection of Oriental MSS. (some of which are of great value), and the Hodgson collection of works on political economy. The library now consists of about 140,000 volumes of printed books with 2000 MSS.

The library of the Writers to Her Majesty's Signet was established by the society in 1755. At first it consisted of law books exclusively, but in 1788 they began to collect the best editions of works in other departments of literature. During the librarianship of Macvey Napier (1805–37) the number of volumes was more than sextupled, and in 1812 the library was removed to the new hall adjoining the Parliament House. In 1834 the upper hall was devoted to the collection. This is a magnificent apartment

142 feet long, with a beautiful cupola painted by Stothard. The library now contains nearly 70,000 volumes, exclusive of pamphlets, and includes some fine specimens of early printing, as well as many other rare and costly works. It is especially rich in county histories and British topography and antiquities. A catalogue of the law books was printed in 1856. The late David Laing, who became librarian in 1837, published the first volume of a new catalogue in 1871. The second volume is nearly completed. The books are lent out to the Writers and even to strangers recommended by them. This library, like that of the Advocates, is most liberally opened to literary inquirers, and has thus acquired a quasi-public or national character.

There are various other important libraries in Edinburgh, but no considerable lending library open freely to the poorest of the people, and two attempts which have been made to introduce the Libraries' Acts have been unsuccessful.

The first mention of a library at St Andrews is as early as 1456. The three colleges were provided with libraries of their own about the time of their foundation—St Salvator's 1455, St Leonard's 1512, St Mary's 1537. The University Library was established about 1612 by King James VI., and in the course of the 18th century the college libraries were merged in it. The copyright privilege was commuted in 1837. The collection numbers 90,000 volumes exclusive of pamphlets, with about 200 MSS., chiefly of local interest. About 1200 volumes are added yearly. A library is supposed to have existed at Aberdeen since the foundation of King's College by Bishop Elphinstone in 1494. The present collection combines the libraries of King's College and Marischal College, now incorporated in the university. The latter had its origin in a collection of books formed by the town authorities at the time of the Reformation, and for some time kept in one of the churches. The library has benefited by the Melvin bequest, chiefly of classical books, and those of Henderson and Wilson, and contains some very valuable books. The general library is located in Old Aberdeen, while the medical and law books are in the New Town. The library has a grant, in lieu of the copy privilege, of £320. The library of the university of Glasgow dates from the 15th century, and numbers George Buchanan and many other distinguished men amongst its early benefactors. A classified subject-catalogue is in progress. The annual accessions are about 1500, and the commutation-grant £707. Connected with the university, which is trustee for the public, is the library of the Hunterian Museum, formed by the eminent anatomist Dr William Hunter. It is a collection of great bibliographical interest, as it is rich in MSS. and in fine specimens of the early printing, especially in Greek and Latin classics. The printed books number about 13,000 volumes, and the MSS. some 600 volumes. All the Scottish university libraries lend books to students, on deposit of £1, to graduates, for an annual subscription of half a guinea, and to persons engaged in literary research, by permission of the senatus.

The Mitchell Library at Glasgow bids fair to be the most important public library outside Edinburgh. It was founded by a munificent bequest of £70,000 from the late Mr Stephen Mitchell. The library was opened in 1877, in temporary premises, and already contains over 36,000 volumes. It includes a special collection of Scottish poetry called "The Poets' Corner," and a collection of Glasgow literature, including early specimens of Glasgow printing. The library is open to all persons over fourteen years of age, and the number of readers during the first three years in which the library has been opened is believed to be without precedent. The number of volumes issued in 1880 was 390,732.

The English Libraries Act of 1850 was extended to Scotland in 1854, and the first town to put it into operation was Airdrie, in 1856. The largest of the libraries which have been opened under the Acts is at Dundee, which possesses 35,500 volumes, with a circulation of 252,314. The rate produces £2390. Although the resources of the other towns in which the Acts have so far been adopted do not enable them to rival the larger English towns, the results are proportionately quite as satisfactory. The turnover of their stock of books is generally large, and the reading done appears to be more solid and serious than in England. The percentage of fiction issued is at least 10 or 15 per cent. below the average rate in the English free libraries.

The establishment of the library of Trinity College, Dublin, is contemporaneous with that of the Bodleian at Oxford, and it is an interesting circumstance that, when Challoner and Ussher (afterwards the archbishop) were in London purchasing books to form the library, they met Bodley there, and entered into friendly intercourse and co-operation with him to procure the choicest and best books. The commission was given to Ussher and Challoner as trustees of the singular donation which laid the foundation of the library. In the year 1601 the English army determined to commemorate their victory over the Spanish troops at Kinsale by some permanent monument. Accordingly they subscribed the sum of £1800 to establish a library in the university of Dublin. For Ussher's own collection, consisting of 10,000 volumes and many valuable MSS., the college was also indebted to military generosity. On his death in 1655 the officers and soldiers of the English army then in Ireland purchased the whole collection for £22,000 with the design of presenting it to the college. Cromwell, however, interfered alleging that he proposed to found a new college, where the books might more conveniently be preserved. They were deposited therefore in Dublin Castle, and the college only obtained them after the Restoration. In 1674 Sir Jerome Alexander left his law books with some valuable MSS. to the college. In 1726 Dr Palliser, archbishop of Cashel, bequeathed over 4000 volumes to the library; and ten years later Dr Gilbert gave the library nearly 13,000 volumes which he had himself collected and arranged. In 1741 the library received a valuable collection of MSS. as a bequest from Dr Stearne. In 1802 the collection formed by the pensionary Fagel, which had been removed to England on the French invasion of Holland, was acquired for £10,000. It consisted of over 20,000 volumes. In 1805 Mr Quin bequeathed a choice collection of classical and Italian books. There have been many other smaller donations, in addition to which the library is continually increased by the books received under the Copyright Act. The library now contains 192,000 volumes and 1880 MSS., and about 3000 volumes are added every year. There is no permanent endowment, and purchases are made by grants from the board. The whole collections are contained in one building, erected in 1732, consisting of eight rooms. The great library hall is a magnificent apartment over 200 feet long. A new reading-room was opened in 1848. A catalogue of the books acquired before 1872 is now in course of printing. There is no printed catalogue of the MSS. Graduates of Dublin, Oxford, and Cambridge are admitted to read permanently, and temporary admission is granted by the board to any fit person who makes application. Books and MSS. are lent out only under special regulations. A lending library has been established to make provision for the needs of the students.

The public library, St Patrick's, Dublin, sometimes called Marsh's Library after its founder, was established about 1694 by Archbishop Marsh, was incorporated by Act of Parliament in 1707, and endowed by its founder at his death in 1713. The building was erected by the founder, and the original oak fittings still remain. There is no room for additions, and a large collection of modern books was refused a few years ago on that account. The endowment is too small to allow of purchases from the funds of the library, so that it still retains the character of a 17th century library. The books are chiefly theological, and in the learned languages; they include the libraries of Bishop Stillingfleet and of Elias Bouhereau, a French refugee, who was the first librarian.

The library of the Royal Dublin Society was commenced shortly after the formation of the society in 1731. With the exception of about 10,000 volumes of the publications of learned societies and scientific periodicals, with a few early editions, its books were transferred to the state, in 1877, to assist in forming the national library of Ireland. The manuscript collections of Walter Harris on Irish history were purchased and placed in the library for public use by the Irish parliament. The library of the Royal Irish Academy was established on the formation of the Academy in 1785, for the purpose of promoting the study of science, literature, and antiquities in Ireland. The library possesses about 40,000 printed volumes and about 1400 MSS. There is a large collection of MSS. and books relating to the history, ancient language, and antiquities of Ireland. They include the Betham collection, acquired partly by public subscription in 1851. The library is partly supported by a Government grant of £200 per annum, and is freely open on a proper introduction. Under the direction of the present honorary librarian, the publication of Irish MSS. in the library was begun in 1870, and has since continued. The library of King's Inns was founded, pursuant to a bequest of books and legal MSS. under the will of Mr Justice Robinson in 1787, to form the nucleus of a library for law students. It is partly supported from the funds of the benchers, but partly also by a treasury grant of £433, 6s. 8d. in lieu of the copy privilege. No books are lent out, and the use of the library is confined to students and barristers; so that the public has no advantage in return for the annual contribution of public money.

There is no library in Dublin corresponding in extent and public accessibility to the British Museum in London, or the Advocates' Library in Edinburgh. About 1850 it was proposed to supply the deficiency by combining the libraries of the Dublin Society and the Irish Academy, both of which had long received grants of public money, together with the collection of Archbishop Marsh. Accordingly in 1854 an Act of Parliament was passed "for the establishment of a national gallery and for the care of a public library in Dublin." The scheme thus authorized has never been carried out. In 1877, however, the National Library of Ireland was established in the apartments of Leinster House. The library is under the Science and Art Department of South Kensington, and is superintended by a body of twelve trustees in Dublin. For the last two years it has received an annual vote of £1000 from parliament for the purchase of books. As already mentioned, the books of the Royal Dublin Society have been transferred to it. It is freely open to the public on a respectable introduction, and is much used.

The public library of Armagh was founded by Lord Primate Robinson in 1770, who gave a considerable number of books and an endowment. The books are freely available, either on the spot, or by loan on deposit of double the value of the work applied for. At Belfast the Queen's College Library has about 36,000 volumes, with a special collection of books on the languages and literatures of the East. The library of the Queen's College, Cork, contains about 25,000 volumes, 1600 of the most valuable of which have been presented by Mr Crawford. The library is easily accessible to literary inquirers, and is much used by strangers. The library of Maynooth College is chiefly theological, and contains the collections bequeathed by the late president, Monsignor Russell. There are about 40,000 volumes and a few MSS.

Dundalk is at present the only town that has a library under the Public Libraries Acts, which were adopted there in 1856. The rate produces only about £80.

France.

French libraries (other than those in private hands) belong either to the state, to the departments, to the communes, or to learned societies, educational establishments, and other public institutions; the libraries of judicial or administrative bodies are not considered to be owned by them, but to be state property. Besides the unrivalled library accommodation of the capital, France possesses a remarkable assemblage of provincial libraries. The communal and school libraries also form striking features of the French free library system.

Five and twenty years ago (see *Tableau statistique des bibliothèques publiques*, 1857) there were in the departments,—exclusive of those not literally free, and of all Parisian libraries,—340 public libraries containing 3,734,260 volumes and 44,436 MSS. In 1857 there were only 32 provincial libraries which owned more than 30,000 volumes each; there are now 54 which are of that extent and upwards.[1] In Paris there are now 16 containing over 30,000 volumes each.

Libraries of Paris.—The Bibliothèque Nationale (still the most extensive library in the world) has had an advantage over all others in the length of time during which its contents have been accumulating, and in the great zeal shown for it by several kings and other eminent men. Enthusiastic writers find the original of this library in the MS. collections of Charlemagne and Charles the Bald, but these were dispersed in course of time, and the few precious relics of them which the national library now possesses have been acquired at a much later date. Of the library which St Louis formed in the 13th century (in imitation of what he had seen in the East) nothing has fallen into the possession of the Bibliothèque Nationale, but much has remained of the royal collections made by kings of the later dynasties. The real foundation of the institution (formerly known as the Bibliothèque du Roi) may be said to date from the reign of King John, the Black Prince's captive, who had a considerable taste for books, and bequeathed his "royal library" of MSS. to his successor Charles V. Charles V. organized his library in a very effective manner, removing it from the Palais de la Cité to the Louvre, where it was arranged on desks in a large hall of three stories, and placed under the management of the first librarian and cataloguer, Claude Mallet, the king's valet-de-chambre. His catalogue was a mere shelf-list, entitled *Inventaire des Livres du Roy nostre Seigneur estans au chastel du Louvre*; it is still extant, as well as the further inventories made by Jean Blanchet in 1380, and by Jean le Bègue in 1411 and 1424. Charles V. was very liberal in his patronage of literature, and many of the early monuments of the French language are due to his having employed Nicholas Oresme, Raoul de Presle, and other scholars to make translations from ancient texts. Charles VI. added some hundreds of MSS. to the royal library, which, however, was sold to the regent, duke of Bedford, after a valuation had been established by the inventory of 1424. The regent transferred it to England, and it was finally dispersed at his death in 1435. Charles VII. and Louis XI. did little to repair the loss of the precious Louvre library, but the news of the invention of printing served as a stimulus to the creation of another one, of which the first librarian was Laurent Paulmier. The famous miniaturist Jean Foucquet of Tours was named the king's *enlumineur*, and although Louis XI. neglected to avail himself of many precious opportunities that occurred in his reign, still the new library developed gradually with the help of confiscation. Charles VIII. enriched it with many fine MSS. executed by his order, and also with most of the books that had formed the library of the kings of Aragon, seized by him at Naples. Louis XII., on coming to the throne, incorporated the Bibliothèque du Roi with the fine Orleans library at Blois, which he had inherited. The Blois library, thus augmented, and further enriched by plunder from the palaces of Pavia, and by the purchase of the famous Gruthuyse collection, was described at the time as one of the four marvels of France. Francis I. removed it to Fontainebleau in 1534, enlarged by the addition of his private library. He was the first to set the fashion of fine artistic bindings, which was still more cultivated by Henry II., and which has never died out in France. During the librarianship of Amyot (the translator of Plutarch) the library was transferred from Fontainebleau to Paris, not without the loss of several books coveted by powerful thieves. Henry IV. removed it to the Collége de Clermont, but in 1604 another change was made, and in 1622 it was installed in the Rue de la Harpe. Under the librarianship of J. A. de Thou it acquired the library of Catherine de' Medici, and the glorious Bible of Charles the Bald. In 1617 a decree was passed that two copies of every new publication should be deposited in the library, but this was not rigidly enforced till Louis XIV.'s time. The first catalogue worthy of the name was finished in 1622, and contains a description of some 6000 volumes, chiefly MSS. Many additions were made during Louis XIII.'s reign, notably that of the Dupuy collection, but a new era dawned for the Bibliothèque du Roi under the patronage of Louis XIV. The enlightened activity of Colbert, one of the greatest of collectors, so enriched the library that it became necessary for want of space to make another removal. It was therefore in 1666 installed in the Rue Vivien (now Vivienne) not far from its present habitat.

[1] In 1877 a *questionnaire* was issued in order to obtain materials for a more complete report, but the results have not yet been made public.

The departments of engravings and medals were now created, and before long rose to nearly equal importance with that of books. Marolles's prints, Foucquet's books, and many from the Mazarin library were added to the collection, and, in short, the Bibliothèque du Roi had its future pre-eminence undoubtedly secured. Nic. Clément made a catalogue in 1684 according to an arrangement which has been followed ever since (that is, in twenty-three classes, each one designated by a letter of the alphabet), with an alphabetical index to it. After Colbert's death Louvois emulated his predecessor's labours, and employed Mabillon, Thevenot, and others to procure fresh accessions from all parts of the world. A new catalogue was compiled in 1688 in eight volumes by several distinguished scholars. The Abbé Louvois, the minister's son, became head of the library in 1691, and opened it to all students —a privilege which although soon withdrawn was afterwards restored. Towards the end of Louis XIV.'s reign it contained over 70,000 volumes. Under the management of the Abbé Bignon numerous additions were made in all departments, and the library was removed to its present home in the Rue Richelieu. Among the more important acquisitions were 6000 MSS. from the private library of the Colbert family, Bishop Huet's forfeited collection, and a large number of Oriental books imported by missionaries from the further East, and by special agents from the Levant. Between 1739 and 1753 a catalogue in eleven volumes was printed, which enabled the administration to discover and to sell its duplicates. In Louis XVI.'s reign the sale of the La Vallière library furnished a valuable increase both in MSS. and printed books. A few years before the Revolution broke out the latter department contained over 300,000 volumes and opuscules. The Revolution was serviceable to the library, now called the Bibliothèque Nationale, by increasing it with the forfeited collections of the *émigrés*, as well as of the suppressed religious communities. In the midst of the difficulties of placing and cataloguing these numerous acquisitions, the name of Van Praet appears as an administrator of the first order. Napoleon increased the amount of the Government grant; and by the strict enforcement of the law concerning new publications, as well as by the acquisition of several special collections, the Bibliothèque made considerable progress during his reign towards realizing his idea that it should be universal in character. At the beginning of this century the recorded numbers were 250,000 printed volumes, 83,000 MSS., and 1,500,000 engravings. After Napoleon's downfall the MSS. which he had transferred from Berlin, Hanover, Florence, Venice, Rome, the Hague, and other places had to be returned to their proper owners. The MacCarthy sale in 1817 brought a rich store of MSS. and incunabula. From that time onwards to the present, under the enlightened administration of MM. Taschereau and Delisle, the accessions have been very extensive.

The official estimate of the number of volumes in the *Département des Imprimés* now reaches the extraordinary total of about 2,290,000, but the contents have not been actually counted since 1791, and as the above enumerates pieces of which many are included in one volume, perhaps something like 1,827,000 is nearer the proper number. The annual additions are about 45,000. The *réserve* (consisting of articles of the highest importance) extends to more than 50,000 volumes. The collection of books on French history is in itself an enormous library, amounting to 440,000 volumes. The maps and charts, said to number 300,000, are included in this department. The *Département des MSS.* comprehended, in 1876, 91,700 volumes. The *Département des Médailles* possessed, in 1873, 143,030 coins, medals, engraved stones, &c., and since that date has acquired many important accessions. More than 2,200,000 engravings are in the *Département des Estampes*, where 20,000 pieces are annually received under the copyright law. The annual vote for purchases and binding is 200,000 francs.

Admittance to the *Salle de Travail* is obtained by a *bulletin personnel*, which is procurable without difficulty. This, the reading-room for students, was built in 1868, and affords accommodation for 344 readers. There are but few books of reference, and readers are only allowed five books a day. The *Salle publique* contains 40,000 books, which are freely available to the public. Plans are now under consideration for an enlargement of the Bibliothèque, and a sum of 3,700,000 francs is to be devoted to that purpose.

The Bibliothèque Nationale does not possess a general catalogue at the disposal of readers; the MS. catalogues of the various classes of the printed books are for official use only. Besides the old catalogue of 1739-53, there is the very elaborate *Catalogue de l'Histoire de France* (1855–79, 11 vols. 4to), with a lithographed supplement; the indexes will appear shortly. The third volume of the *Catalogue des Sciences Médicales* is now in the press, and that devoted to English history is nearly finished in manuscript. The vellum books have been described by Van Praet (1822–23, 6 vols. 8vo, and supplement, 1877). The MSS. are much better provided for. The printed catalogues of these commence with that of Anicet Melot, 1739–44, 4 vols. folio, continued in a way by the *Notices et Extraits des MSS. du Bibl. du Roi*, 1787–1875. The work of M. Paulin Paris, *Les MSS. François; leur histoire et celle des textes allemands, anglois, italiens, et espagnols* (1836–48, 7 vols. 8vo), is well known. Catalogues of the Italian, Spanish, Belgian, Pali, Sanskrit, Ethiopian, and Chinese MSS. have also appeared between 1807 and 1844. The first and second volumes in 4to of a new *Catalogue des MSS. Français* have been printed, and two volumes of the *Inventaire* of M. Delisle, besides five parts of his *Inventaire des MSS. Latins* (1863–71). The authorities have also brought out a *Catalogue des Manuscrits Hebreux et Samaritains* (1866, 4to), besides those of *MSS. Syriaques et Sabéens* (1874, 4to), *MSS. Ethiopiens* (1877), and *MSS. Espagnols* (1879).

Paris is much better provided than London or any other city in the world with great public libraries. Besides the Bibliothèque Nationale there are four libraries, each over 120,000 volumes (with others less extensive), to which the public have free access, the Bibliothèque de l'Arsenal being the largest of them. The collection of the Marquis de Paulmy d'Argenson was the basis of this library, which also acquired a portion of the books of the Duc de la Vallière in 1781. It is peculiarly rich in romances, the drama, and French poetry, and possesses 80,000 volumes on French history alone. It is freely open, but there are not many readers.—The Bibliothèque Mazarine was founded by the great cardinal, who in 1643 placed about 12,000 volumes at the disposal of the public. The books were chiefly brought together through the exertions of Gabriel Naudé, who tells us that in 1648 they amounted to 40,000 volumes. After the death of Mazarin, his magnificent library was bequeathed to the college bearing his name; it remained under the direction of the Sorbonne from 1688 to 1791, since which time it has been subject to the control of the state. It is rich in incunabula and theology, including the works of Protestant divines, and is annually visited by over 12,000 readers.—The Bibliothèque Sainte Geneviève was founded in 1624, at the abbey of that name, by Cardinal François de la Rochefoucauld. Other persons also gave books, and in 1687 the library is said to have contained 20,000 printed volumes and 400 MSS. In 1710 C. M. Le Tellier bequeathed his collection, and in the *Almanach Royal* of the same year an announcement appeared that the library would be open to students during certain hours every day. Louis, Duc d'Orléans, the son of the Regent, took up his abode here, and in 1730 the library was considerably enlarged by him. It was opened to the public in 1790, and at the time of the Revolution there were 80,000 printed volumes and 2000 MSS.; there are now 120,000 volumes and 2392 MSS. The reading-room is open in the evening, and is much frequented, especially by students. The library contains a good collection of incunabula, many of which have been described by Dibdin, a number of rare Italian and Spanish chronicles, and a very complete series of periodicals from the 17th century to the empire.—The Bibliothèque de l'Université (or the Sorbonne) was formerly restricted to the use of the members of the five faculties of Paris, but the public has been freely admitted during the last thirty years.—The Bibliothèque de l'Institut having been plundered during the Revolution, the old town library was transferred to it. Persons not members are admitted upon the recommendation (which lasts twelve months) of any academician.—The Bibliothèque de la Ville, founded in the 18th century, and reorganized at the time of the Revolution, was destroyed in 1871. It has since been entirely re-established in the Hôtel Carnavalet, which contains the historical museum of the city, and comprehends 60,000 volumes of books and 40,000 engravings, entirely relating to the history and description of Paris. The other public libraries are under the authority of the minister of public instruction, but the Bibliothèque de la Ville is under the control of the prefect of the Seine. The municipal libraries in Paris are 20 in number, with 70,000 volumes; there are besides 440 school libraries, with 44,120 books.

Of other libraries in Paris, not included in our tables, we may name the Bibliothèque de la Préfecture de Police (10,000 volumes, with curious MSS. relating to the Revolution), Bibliothèque du

Tribunal de première instance (28,000 volumes), Bibliothèque de l'École Polytechnique (30,000 volumes), Bibliothèque de l'École Normale (26,000 volumes, which acquired the library of Georges Cuvier in 1833), Bibliothèque des Invalides (28,000 volumes, a good collection on history and military affairs), Bibliothèque de l'École Nationale des Beaux Arts (15,000 volumes, 12,000 drawings, 100,000 prints and photographs), Bibliothèque du Conservatoire de Musique (30,000 volumes, one of the finest collections of musical literature in the world), Bibliothèque des Archives Nationales (founded by Danon in 1808, containing 25,000 volumes on palæography, history, and jurisprudence,—as this is the record office of France, the archives are very extensive), Bibliothèque du Luxembourg (25,000 volumes), Bibliothèque du Lycée Louis le Grand (30,000 volumes), Bibliothèque du Ministère de l'Intérieur (17,000 volumes, including Parisian and provincial history and documents).

Besides the various collections belonging to learned and scientific societies, educational institutions, and other bodies, outside Paris, over 215 French provincial towns possess public libraries, which range in number of volumes from 2000 or 3000 to 190,000, as at Bordeaux. Most of them were founded at the end of the last or the beginning of the present century, but some are earlier. The library at Lyons was established by Francis I. in 1530, that at Nantes dates from 1588, La Rochelle from 1604, Abbeville, Besançon, and Troyes from the latter part of the same century, and Orléans from the beginning of the 17th century. The large majority were formed by confiscation at the time of the Revolution. In February 1790 the Assemblée Nationale abolished the different religious communities, and in September of the same year the provincial tribunals and parliaments met with the same fate. The books (said to number 10 or 12 millions) of these corporations were declared national property, a committee was appointed to consider what should be done with them, and a general catalogue of all the sequestered effects ordered to be drawn up. In consequence of the recommendations of the committee, the Convention Nationale (January 27, 1794) decreed the establishment and augmentation of public libraries. The orders of the Convention were not carefully executed, and pitiable stories are told of valuable works sold by the yard as they lay upon the ground, of precious manuscripts and printed rarities left to rot in the open air or burnt for fuel. As the government became more settled, the libraries (when not destroyed) of condemned persons were restored to their representatives. A very large number of books still remained, however, and it is to them that the town libraries of France chiefly owe their riches. Theology, law, history, and the severer literature of the 17th and 18th centuries consequently predominate, although for many years more modern requirements have been mainly considered in the acquisition of books. Many collections of local and provincial literature have been formed, as at Angers, Auxerre, Chaumont, Grenoble, La Rochelle, Lille, Marseilles, Orléans, Toulouse, Tours, and Versailles. Some of the libraries are very extensive. Douai and Troyes have 100,000 volumes each; Lyons and Rouen over 120,000; Besançon, 130,000; Aix and Nantes, 150,000; Grenoble, 170,000; and Bordeaux, 190,000 volumes. All have catalogues, mostly alphabetical; a few of them are in print. The *Catalogue général des MSS. des bibliothèques publiques des départements* is a noble undertaking on the part of the French Government. The first volume came out in 1849, and the latest, the sixth, in 1879; the treasures of eighteen libraries have now been catalogued (about 9650 MSS.), and there remain over 45,000 MSS. to be described. Besides this, Angers, Amiens, Auxerre, Caen, Carpentras, Chartres, Orléans, and Tours possess separate printed catalogues of their MSS. The chambers annually vote large sums for books, which are distributed to the town libraries by the minister of public instruction. The sums granted by the different municipalities for their libraries vary in amount; for instance, Grenoble (170,000 volumes and eight persons employed) gives 26,314 francs, Bordeaux (190,000 volumes and eight persons) 21,350 francs, and Nantes (150,000 volumes and four persons) 13,600 francs.

Popular libraries of every description, including military and workmen's libraries, owe much to the "Société Franklin pour la propagation des bibliothèques populaires," which, founded in 1862, has since been of immense service in originating and helping those institutions. Between 1868 and 1878 the Société had spent 550,000 francs on these purposes. It issues a *Catalogue Populaire* of a good selection of recommended books, and publishes a journal of its proceedings.

School libraries had an organized existence in France as far back as 1831, and by 1848 the books which had been distributed by the state amounted in value to 2 millions of francs; two years later, however, no trace of books or libraries could be found.[1] In 1860 the question was again taken up, and in 1862 the minister of public instruction ordered that in every primary school a library should be established under the care of the schoolmaster. For some years the Government annually granted 120,000 francs, a sum which was raised to 200,000 francs in 1878; for their share of the expenses the departments contributed in 1875 as much as 170,000 francs. As an instance of the rapidity with which the school libraries have increased, it may be stated that Haute-Marne, which only possessed 44 of them in 1866, ten years later had 548; in 1877 there were about 17,764 *bibliothèques scolaires* possessing 1,716,904 works, and there are now over 20,000 of them in France. The libraries, which are intended not only for the use of school children but also for their parents and other adults, are regulated by a commission sitting at the ministry of public instruction.

Germany (with Austria and Switzerland).

Germany is emphatically the home of large libraries; her want of political unity and consequent multiplicity of capitals have had the effect of giving her a considerable number of large state libraries, and the number of her universities has tended to multiply considerable collections.

Berlin is well supplied with libraries, seventy-two being registered by Petzholdt in 1875, with about 1,293,030 printed volumes. The largest of them is the Royal Library, which was founded by the "Great Elector" Frederick William, and opened as a public library in a wing of the electoral palace in 1661. From 1699 the library became entitled to a copy of every book published within the royal territories, and it has received many valuable accessions by purchase and otherwise. It is now estimated to contain upwards of 700,000 printed volumes and over 15,000 MSS. The amount yearly expended upon binding and the acquisition of books, &c., is £4800. The catalogues are in manuscript, and include a general alphabetical author-catalogue, and a systematic subject-catalogue in a handy form. The building, erected about 1780 by Frederick the Great, has long been too small, and a new one is in contemplation. The conditions as to the use of the collections are, as in most German libraries, very liberal. Any adult person is allowed to have books in the reading-room. Books are lent out to all higher officials, including those holding educational offices in the university, &c., and by guarantee to almost any one recommended by persons of standing; admission to the journal-room is more strictly limited. By special leave of the librarian, books and MSS. may be sent to a scholar at a distance, or, if especially valuable, may be deposited in some public library where he can conveniently use them. There appears to be no limit to the number of books which may be borrowed, although it is prescribed that not more than "three works" must be asked for on one day. Professor Lepsius reports the issues for last year as 71,400 works, to above 5000 readers. The University Library (1831) numbers 200,000 volumes with 353 MSS. The number of volumes lent out in 1880 was 40,101. The library possesses the right to receive a copy of every work published in the province of Brandenburg. Some of the governmental libraries are important, especially those of the Military Academy and the General Staff, which was increased in 1872 by acquiring the library of the "École d'Application" at Metz. In 1850 some popular libraries were established by a society for giving scientific lectures. There are now thirteen such libraries with over 54,000 volumes, but the yearly number of readers is only about 12,000.

The libraries of Munich, though not so numerous as those of Berlin, include two of great importance. The Royal Library, the largest collection of books in Germany, was founded by Duke Albrecht V. of Bavaria (1550–79), who made numerous purchases from Italy, and incorporated the libraries of the Nuremberg physician and historian Schedel, of Widmannstadt, and of J. J. Fugger. The number of printed volumes is estimated at about one million, although it is long since any exact enumeration has been made. The library is especially rich in incunabula, many of them being derived from the libraries of the monasteries closed in 1803. The Oriental MSS. are

[1] See De Watteville, *Rapport sur les Bibliothèques scolaires*, 1879

numerous and valuable, and include the library of Martin Haug. The amount annually spent upon the library is £5400, of which £2050 is expended upon books and binding. The catalogues of the printed books are in manuscript, and include (1) a general alphabetical catalogue, (2) an alphabetical repertorium of each of the 195 subdivisions of the library, (3) biographical and other subject catalogues. A printed catalogue of the MSS. in 8 volumes is nearly complete; the first was published in 1858. The library is open only twenty-nine hours during the week, while the Royal Library at Berlin is, except in the three winter months, open for thirty-nine. The library of the British Museum is now open for sixty-six hours per week, but it lends no books out. The regulations for the use of the library are very similar to those of the Royal Library at Berlin. The building erected for this collection under King Louis I. in 1832–43 is regarded as a model library structure. The archives are bestowed on the ground floor, and the two upper floors are devoted to the library, which occupies seventy-seven apartments.—The University Library was originally founded at Ingolstadt in 1472, and removed with the university to Munich in 1826. It participated in 1803 in the division of the literary treasures of the disestablished monasteries. At present the number of volumes in the general library amounts to 290,000, besides which several special collections are also deposited in the library to the number of 32,800 volumes. The MSS. number 1744. The various libraries of Munich have upwards of 1,400,000 volumes.

Dr Petzholdt has registered no less than 49 libraries in Dresden, where indeed his inquiries were likely to be particularly exhaustive. The Royal Public Library in the Japanese Palace was founded in the 16th century. Among its numerous acquisitions have been the library of Count Bünau in 1764, and the manuscripts of Ebert. Special attention is devoted to history and literature. The library does not claim to possess more than 350,000 volumes, although Petzholdt in 1875 reckoned them as at least 500,000 printed books, as well as 400,000 dissertations. The MSS. number 6500 volumes. Admission to the reading-room is granted to any respectable adult on giving his name, and books are lent out to persons qualified by their position or by a suitable guarantee. Here, as at other large libraries in Germany, works of belles-lettres are only supplied for a literary purpose. The number of persons using the reading-room in a year is about 3900, and about 10,000 works (not volumes) are lent to about 500 readers.—The "Prinzliche Secundo-Genitur" Library, now in the possession of Prince George of Saxony, and of which Dr Petzholdt, the Nestor of bibliographers, is librarian, is a private library to which access is permitted.

The Royal Public Library of Stuttgart, although only established in 1765, has grown so rapidly that it now possesses about 425,000 "numbers" of printed works and 3800 MSS. There is a famous collection of Bibles, containing 7200 volumes. The annual expenditure is about £2640, of which £1250 is devoted to books and binding. The library also enjoys the copy-privilege in Würtemberg. "The borrowing of books for home use is open to all members of the German empire resident in Stuttgart, whose personal and economic circumstances offer the necessary guarantees for the safety of the national property. The library may, moreover, be used from any part of Würtemberg on payment of the cost of carriage." The annual number of borrowers is over 1800, who use nearly 17,000 volumes. The number issued in the reading-room is at least twice as great. The number of parcels despatched from Stuttgart is nearly 900.—Admission is also gladly granted to the Royal Private Library, founded in 1810, which contains about 50,000 volumes and 600 MSS. The other libraries of Stuttgart, of which Petzholdt reckons 11, are not of importance.—The Grand-ducal Library of Darmstadt was established by the grand-duke Louis I. in 1817, on the basis of the still older library formed in the 17th century. The number of volumes used in the course of the year is about 30,000, of which 9000 are lent out to about 5000 readers.—The Ducal Library of Gotha was established by Duke Ernest the Pious in the 17th century, and contains many valuable books and MSS. from monastic collections. It numbers about 240,000 works, with upwards of 6000 MSS. The catalogue, now in course of publication, of the Oriental MSS., chiefly collected by Seetzen, and forming one-half of the collection, is one of the best in existence. Other great Ducal Libraries are noticed in the tables.

Libraries of varying extent and importance are attached to all the twenty-one universities of Germany, most of them being coeval with the universities themselves. Thus the oldest library is that of Heidelberg, which in its earlier form dates from 1386. In 1608 it had become so important that Joseph Scaliger wrote of it "Locupletior est et meliorum librorum quam Vaticana." In 1623 the library was carried to Rome as a present to the pope, but some of the treasures were ultimately restored. The later collection was first formed in 1703. The collection of MSS. is extremely valuable.—The library of Leipsic university dates from 1409, although it was not until the middle of the 16th century that it was properly organized.—The library of Göttingen owes much to the labours of the illustrious Heyne. It ranks as one of the most complete and best arranged of the German libraries. New buildings for its accommodation are in course of erection.—The library at Strasburg, although founded only in 1871 to replace that which had been destroyed in the siege, already ranks amongst the largest libraries of the empire. Its books and MSS. together amount to 513,000. The remaining university libraries are noticed in the tables.

Some of the town libraries of Germany mentioned in the tables were amongst the earliest established after the revival of learning. The oldest of them is perhaps that of Ratisbon, which was founded at least as early as 1430. Since Ratisbon has ceased to be an imperial city it has had to part with many of its treasures to the library at Munich.

The whole number of libraries in the German empire enumerated by Dr Petzholdt is 1547, distributed amongst 584 towns.

A report issued in 1873–74 by the Austrian Statistical Commission, furnishes an account of the condition of the libraries in those portions of Austria which are represented in the Reichsrath, as they were at the end of the year 1870. The number of libraries registered was 577, of which 23, however, were private libraries. Of the rest 159 belonged to religious corporations and seminaries, 105 were military libraries, 56 belonged to literary and scientific societies, 189 were of an educational and scholastic, and the remaining 45 of a public character.

The largest library in Austria, and one of the most important collections in Europe, is the Imperial Public Library at Vienna, apparently founded by the emperor Frederick III. in 1440, although its illustrious librarian Lambecius, in the well-known inscription over the entrance to the library which summarizes its history, attributes this honour to Frederick's son Maximilian. However this may be, the munificence of succeeding emperors greatly added to the wealth of the collection, including a not inconsiderable portion of the dispersed library of Corvinus. Since 1808 the library has also been entitled to the copy privilege in respect of all books published in the empire. The sum devoted to the purchase of books is 26,250 florins annually. The main library apartment is one of the most splendid halls in Europe. Admission to the reading-room is free to everybody, and books are also lent out under stricter limitations.—The University Library of Vienna was established by Maria Theresa. The reading-room is open to all comers, and the library is open much longer than is the rule with university libraries generally. In winter, for instance, it is open from 5 to 8 in the evening, and it is even open from 9 to 12 on Sundays. In 1879, 159,768 volumes were used in the library, 16,300 volumes lent out in Vienna, and 4418 volumes sent carriage free to borrowers outside Vienna. The total number of libraries in Vienna enumerated by Dr Petzholdt is 101, and many of them are of considerable extent.

The number of monastic libraries in Austria is very considerable. Particulars are furnished, in the report already quoted, of 107 of them, varying from a few hundreds of volumes to as many as 80,000. Many other such libraries are known to exist in the 463 monasteries. The oldest of them, and the oldest library in Austria, is that of the monastery of St Peter at Salzburg, which was established by St Rupert in the 6th century. It possesses 60,000 volumes, with nearly 20,000 incunabula. The four next in point of antiquity are Kremsmünster (50,000), Lambach (22,000), Admont (80,000), and Melk (60,000), all of them dating from the 11th century. Of the 107 libraries enumerated in the report, 56 possessed 5000 volumes or upwards at the end of 1870. For further particulars as to the larger Austrian libraries the reader is referred to the tables.

The libraries in the Hungarian kingdom are not included in the report, and, as will be seen from the tables, are not very numerous. The most important of them are at Buda-Pest.

The public libraries of Switzerland have been very carefully registered by Dr Ernest Heitz, as they existed in 1868. Altogether no less than 2096 libraries are recorded, four-fifths of these belong to the class of "bibliothèques populaires et celles pour la jeunesse," and few are of literary importance. Only eighteen have as many as 30,000 volumes. The largest collection of books in Switzerland is the University Library of Basel, founded with the university in 1460. The monastic libraries of St Gall and Einsiedeln date respectively from the years 830 and 946, and are of great historical and literary interest.

Italy.

As the former centre of civilization, Italy is of course the country in which the oldest existing libraries must be looked for, and in which the rarest and most valuable MSS. are preserved. The Vatican at Rome and the Laurentian Library at Florence are sufficient in themselves to entitle Italy to rank before most other states in that respect, and the venerable relics at Vercelli, Milan, and La Cava bear witness to the enlightenment of the peninsula in times when other nations were slowly taking their places in the circle of Christian polity. The local rights and interests which so long helped to impede the unification of Italy were useful in creating and preserving at numerous minor centres many libraries which otherwise would probably have been lost during the progress of absorption that results from such centralization as exists in England. In spite of long centuries of suffering and of the aggression of foreign swords and foreign gold, Italy is still rich in books and MSS.; there are probably more books in united Italy than in any other country except France. When the Italian Government published its valuable report on "Biblioteche" in the *Statistica del Regno d'Italia* in 1865, a table of relative statistics was given, which professed to show that, while the number of books in Austria (2,408,000) was greater than the total contents of the public libraries in any one of the countries of Great Britain, Prussia, Bavaria, or Russia, it was surpassed in France (4,389,000) and in Italy (4,149,281), the latter country thus exhibiting a greater proportion of books to inhabitants than any other state in Europe, except only Bavaria. The opulent libraries of Rome and Venice had not yet become Italian, and were not included in the report.[1]

Public libraries. The public libraries (*biblioteche governative*) are under the authority of the minister of public instruction, and are subject to certain regulations finally agreed upon during the ministry of Signor Ruggiero Bonghi in 1876.[2] They are classed under the headings of (1) national libraries of Florence, Naples, Turin, Palermo, Vittorio Emanuele of Rome, the Brera of Milan, and the Marciana of Venice; (2) the libraries of the universities of the first class—Bologna, Naples, Padua, Pavia, Pisa, and Rome; (3) those of the universities of the second class—Cagliari, Catania, Genoa, Messina, Modena, Parma, and Sassari; (4) those of academies and institutions of fine arts; the last, although under Government control, are ruled by special regulations of their own. Small collections are sometimes handed over to the local authorities, should this be considered desirable, and the state will take into its own hands the administration of provincial or communal libraries if necessary. The librarians and subordinates are divided into (1) prefects, librarians, and sublibrarians; (2) assistant librarians; (3) attendants, or book distributors; (4) ushers, &c. Those of class 1 constitute the "board of direction," which is presided over by the prefect or librarian, and meets from time to time to consider important measures connected with the administration of the library. The candidates for posts in classes 1 and 2 must possess certain scholastic qualifications and serve for a specified time as *alunni* on probation. An important feature of the regulations consists of the scheme (unfortunately not yet in working order) which is eventually to supply Italy with a body of young librarians properly trained in all the theoretical and technical branches of their profession. Each library is to possess, alike for books and MSS., a general inventory or accessions-catalogue, an alphabetical author-catalogue, and a subject-catalogue. When they are ready, catalogues of the special collections are to be compiled, and these the Government intends to print, together with the subject-catalogues of the MSS. Various other small registers are provided for. The sums granted by the state for library purposes must be applied to (1) salaries and maintenance; (2) binding and repairs; (3) purchase of books, MSS., &c. Books are chosen by a committee nominated by the minister, which, in the national libraries, includes the members of the council of direction. In other libraries two members only of the council form part of the committee. In the university libraries two-fifths of the expenditure is decided by the committee, and the remainder by a council formed by the professors of the different faculties. The rules for lending books and MSS. allow them to be sent to other countries under very special circumstances.

The *biblioteche governative* are now 32 in number, and annually spend about 150,000 lire in books. From the three sources of gifts, copyright, and purchases, their accessions in 1879 were 35,541, being 5187 more than the previous year. The number of readers is now gradually increasing. In 1879 there were 895,749, who made use of 1,154,853 volumes, showing an increase of 10,393 readers and 130,051 books as contrasted with the statistics of the previous year.[3]

The minister of public instruction has kept a watchful eye upon the literary treasures of the suppressed monastic bodies. In 1875 there were 1700 of these confiscated libraries, containing two millions and a half of volumes. About 650 of the collections were added to the contents of the public libraries already in existence; the remaining 1050 were handed over to the different local authorities, and served to form 371 new communal libraries, and in 1876 the number of new libraries so composed was 415.

The Biblioteca Vaticana stands in the very first rank among European libraries as regards antiquity, since from the middle of the 5th century we have evidence of the existence of a pontifical library at Rome; and Pope Zachary (d. 752), himself a Greek, is known to have added considerably to the store of Greek codices. The Lateran Library shared in the removal of the papal court to Avignon, and it was on the return of the popes to Rome that the collection was permanently fixed at the Vatican. Nicholas V. (d. 1455) may, however, be considered the true founder of the library, and is said to have added 5000 MSS. to the original store. Calixtus III. also enriched the library with many volumes saved from the hands of the Turks after the siege of Constantinople. So large a proportion of the printed books of the 15th century having been produced by the Italian presses, it is natural to expect that a great number of specimens may be found in the papal library, and, but for the wholesale destruction of books and MSS. during the sack of Rome by the duke of Bourbon in 1527, the

[1] The *Statistica* describes 210 libraries, of which 164 were open to the public and 46 not accessible; 171 were general and 39 special libraries, the latter including 25 devoted to ascetic theology, 11 to science and literature, and 3 to the fine arts. Tuscany, Sicily, and Emilia were the richest in books, the latter province alone containing one quarter of the whole number.

[2] See the "Regulations of Italian Public Libraries," by Count Ugo Balzani, *Library Journal*, iv. pp. 183–87.

[3] Lists of foreign accessions to the *biblioteche governative* are published by the minister of public instruction from time to time. In 1877 E. Narducci made proposals for a general catalogue of their contents, and issued a specimen of *Boccaccio*.

Vatican Library would have been as rich in early printed literature as it is now rich in manuscripts. Sixtus V. erected the present building in 1588, and considerably augmented the collection. Gregory XV. received as a gift from Maximilian, duke of Bavaria, the library of the elector Palatine seized by Tilly at the capture of Heidelberg in 1622. The greater part of the library at Urbino, founded by Duke Federigo, was acquired in 1655 by Alexander VII. for the sum of 10,000 scudi, and some of the famous palimpsests from the Benedictine monastery of Bobbio were also added to the treasures of the Vatican. After the death of Christina, queen of Sweden, her collection of books and manuscripts, formed from the plunder seized at Prague, Würtzburg, and Bremen by her father Gustavus Adolphus, became by succession the property of the Ottoboni family, the head of which, Alexander VIII., in 1689 placed 1900 of the MSS. in one of the galleries. Clement VII. and Pius II. also enriched the Vatican with valuable manuscripts, including many Oriental. In 1740 Benedict XIV. united with it the Ottoboniana, and in the same pontificate the Marchese Aless. Capponi bequeathed his precious collections. Clement XIII. in 1758, Clement XIV. in 1769, and Pius VI. in 1775 were also important benefactors. For over two hundred years the history of the Vatican was one of unbroken prosperity, but it suffered a serious blow at the close of the 18th century, when MSS. dating before the 9th century, and the most choice artistic specimens, altogether to the number of 500, were carried off by the French to Paris in 1798. The greater part were, however, restored in 1815, and most of the Palatine MSS., which formed part of the plunder, ultimately found their way to the university of Heidelberg in 1816. Pius VII. acquired for the Vatican the library of Cardinal Zelada in 1800; Leo XII. was able to add the noble collection of fine art literature of Count Cicognara in 1823; and Gregory XVI. also largely augmented the library. Pius IX. in 1856 added 40,000 volumes belonging to Cardinal Mai.

Few libraries are so magnificently housed as the Biblioteca Vaticana. The famous *Codici Vaticani* are placed in the *salone* or great double hall, which is decorated with frescos depicting ancient libraries and councils of the church. At the end of the great hall an immense gallery, also richly decorated, and extending to 1200 feet, opens out from right to left. Here are preserved in different rooms the codici Palatini, Regin., Ottoboniani, Capponiani, &c. Most of the printed books are contained in a series of six chambers known as the *Appartamento Borgia.* The printed books only are on open shelves, the MSS. being preserved in closed cases.

The present official estimate of the number of printed volumes is about 220,000, including 2500 15th century editions, of which many are vellum copies, 500 Aldines, and a great number of bibliographical rarities.[1] There are 25,600 MSS., of which 19,641 are Latin, 3613 Greek, 609 Hebrew, 900 Arabic, 460 Syriac, 78 Coptic, &c. Among the Greek and Latin MSS. are some of the most valuable in the world, alike for antiquity and intrinsic importance. It is sufficient to mention the famous Biblical *Codex Vaticanus* of the 4th century, the *Virgil* of the 4th or 5th century, the *Terence* equally ancient, the palimpsest *De Republica* of Cicero, conjectured to be of the 3d century, discovered by Cardinal Mai, and an immense number of richly ornamented codices of extraordinary beauty and costliness. The archives are apart from the library, and are quite inaccessible to the public; no catalogue is known to exist. Leo XII. has appointed a committee to consider what documents of general interest may expediently be published, and a greater liberality in the use of them is said to be contemplated.

The Biblioteca Vaticana is now open from 8 to 12 every morning between November and June, with the exception of Sundays, Thursdays, and the principal feast days. Permission to study is obtained from the cardinal secretary of state. The want of proper catalogues for the use of readers is a great drawback. There are imperfect written lists (for the use of the librarians alone) of the printed books, and various catalogues of special classes of the MSS. have been published. New catalogues, however, are in course of preparation. The Oriental MSS. have been described by J. S. Assemanni, *Bibliotheca orientalis Clementino-Vaticana*, Rome, 1719–28, 4 vols. folio, and *Bibl. Vat. codd. MSS. catalogus ab S. E. et J.S. Assemanno redactus*, ib., 1756–59, 3 vols. folio, and by Cardinal Mai in *Script. Vet. nova collectio.* The Coptic MSS. have been specially treated by G. Zoega, Rome, 1810, folio; and by F. G. Bonjour, Rome, 1699, 4to. There are printed catalogues of the Capponi (1747) and the Cicognara (1820) libraries.

Next in importance to the Vatican library is the Casanatense, so called from the name of its founder, Cardinal Casanata (1700). It contains about 130,000 volumes of printed books, including a large number of 15th century impressions and early editions with woodcuts, as well as about 2500 MSS., amongst which are one of the 7th century and several of the 8th, 9th, and 10th centuries. They are carefully arranged in eleven rooms, the large central hall being one of the finest in Rome. Books are not allowed to be taken out of the reading-rooms, but admission is freely granted, and the annual number of readers is about 18,000. The subvention is a small one, but additions continue to be made, and the library is well administered. All the officials, in accordance with the founder's will, belong to the Dominican order. The incomplete catalogue of the printed books, prepared by A. Audiffredi (Rome, 1761–88, 4 vols. folio), still remains a model of cataloguing.—The Biblioteca Vittorio Emanuele forms part of the Collegio Romano, and was made up from the old Jesuit library, enriched by accessions from a number of other suppressed institutions. It now consists of 360,000 volumes, with 5000 MSS., and is united to the Casanatense by a bridge. The entire edifice is spacious enough to contain a million of volumes, besides the Kircherian and other museums which are already located in it.[2]—The Biblioteca Angelica possesses all the authentic acts of the Congregatio de Auxiliis, and the precious collections of Cardinal Passionei and Lucas Holstenius.—The Biblioteca Alessandrina della R. Università di Roma, founded by Alexander VII., is considerably used by students: there were in 1879 57,000 readers. The greater part of the printed books formerly in the collection of the dukes of Urbino is now in this library.[3]—The Biblioteca del Senato is very rich in collections of municipal history and statutes of Italian cities. The printed catalogue (1878) describes no less than 1067 statutes or volumes containing them, relating to 443 localities.—The Biblioteca Vallicelliana was founded by S. Filippo Neri, and contains some valuable manuscripts, including a Latin Bible of the 8th century attributed to Alcuin, and some inedited writings of Baronius.—In 1877 Professor A. Sarti presented to the city of Rome his collection of fine-art books, 10,000 volumes, which was placed in charge of the Accademia di San Luca, which already possessed a good artistic library.—Of private libraries accessible by permission, we note the Biblioteca Barberina, including many rare editions with valuable autographs, but especially remarkable for its MSS.; these were chiefly collected by Cardinal Fr. Barberini, the nephew of Urban VIII., and comprehend the letters and papers of Galileo, Bembo, and Bellarmine, the reports on the state of Catholicism in England in the time of Charles I., and a quantity of inedited materials for the history of the Stuarts. A catalogue was published at Rome in 1681, 3 vols. folio.—The Corsiniana, founded by Clement XII. (Lorenzo Corsini), is also a private library; it is rich in incunabula, and includes one of the most remarkable collections of prints in Italy, the series of Marc-Antonios being especially complete.—The library of the Collegium de Propaganda Fide was established by Urban VIII. in 1626, and in 1687 the rector Andrea Bonvicini obtained permission to preserve in it prohibited books. It was

Other Roman libraries.

[1] The books have never been actually counted, and this estimate has been reduced by some persons to half the number.

[2] See *Collegio Romano, Discorso di Ruggiero Bonghi*, Rome, 1876.

[3] Signor E. Narducci produced a catalogue of the MSS. other than Oriental in 1877. The Casanatense, Vitt. Emanuele, Angelica, and Alessandrina are Governmental, and in 1878 the minister of public instruction published a catalogue of the Oriental MSS. in the three last. The Oriental MSS. of the other *biblioteche governative* will be treated in subsequent volumes.

destroyed by the French army in 1798, and owes its present richness almost entirely to testamentary gifts, among which may be mentioned those of Cardinals Borgia, Caleppi, and Pietro. It is a private collection for the use of the congregation and of those who belong to it, but permission may be obtained from the superiors. There are at least thirty libraries in Rome which are more or less accessible to the public. One is now in course of formation which will include everything relating to the emancipation of Italy.

At Subiaco, a few miles from Rome, the library of the Benedictine monastery of Santa Scolastica is not a very large one, comprising only 6000 printed volumes and 400 MSS., but the place is remarkable as having been the first seat of typography in Italy. It was in this monastery that Schweynheim and Pannartz, fresh from the dispersion of Fust and Schoeffer's workmen in 1462, established their press and produced a series of very rare and important works which are highly prized throughout Europe. The Subiaco Library, although open daily to readers, is only visited by students who are curious to behold the cradle of the press in Italy, and to inspect the series of original editions preserved in their first home

The great national libraries are as follows :—

The Biblioteca Nazionale of Florence, formed from the union of Magliabechi's library with the Palatina, is the largest in Italy. The Magliabechi collection became public property at his death in 1714, and, with the accessions made from time to time, held an independent place until 1862, when the Biblioteca Palatina (formed in 1815 from the old Pitti Library and the collections of Poggiali and Rzewuzky) was incorporated with it. An old statute by which a copy of every work printed in Tuscany was to be presented to the Magliabechi Library was formerly much neglected, but has been maintained rigorously in force since 1860. There are many valuable autograph originals of famous works in this library, and the MSS. include the most important extant *codici* of Dante and later poets, as well as of the historians from Villani to Machiavelli and Guicciardini. Amongst the printed books is a very large assemblage of rare early impressions, a great number of the *Rappresentazioni* of the 16th century, at least 200 books printed on vellum, and a copious collection of municipal histories and statutes, of *testi di lingua*, and of geographical and topographical maps. The MS. portolani, 25 in number, are for the most part of great importance ; the oldest is dated 1417, and several seem to be the original charts executed for Sir Robert Dudley (duke of Northumberland) in the preparation of his *Arcano del Mare*. The annual increment of books in this library is about 12,000. It is open freely to the public, and about 50,000 readers annually make use of it. About 60,000 printed volumes and 2500 MSS. are consulted annually, not including some 1500 books and 50 MSS., which are lent out yearly to certain students.—The Biblioteca Nazionale at Naples, though only opened to the public in 1804, is the largest library of that city. The nucleus from which it developed was the collection of Cardinal Seripando, which comprised many MSS. and printed books of great value. Acquisitions came in from other sources, especially when in the year 1848 many private and conventual libraries were thrown on the Neapolitan market.[1] The Biblical section is rich in rarities, commencing with the Mainz Bible of 1462, printed on vellum. Other special features are the collection of *testi di lingua*, that of books on volcanoes and that of works printed at famous presses, particularly those executed by the typographers of Naples. The MSS. include a palimpsest containing writings of the 3d, 5th, and 6th centuries under a grammatical treatise of the 8th, 2 Latin papyri of the 6th century, over 50 Latin Bibles, and a great number of illuminated books with miniatures. There are more than 40 books printed on vellum in the 15th and 16th centuries, including a fine first Homer. There are several MS. maps and portolani, one of them dating from the end of the 14th century. About 10,000 readers use this library, consulting some 140,000 books yearly.—The Bibliotheca Nazionale of Milan, better known as the Brera, founded in 1770 by a decree of the empress Maria Theresa, consists of 163,123 printed volumes and 3646 MSS., with a yearly increment of about 6000 volumes, and the annual number of readers is said to amount to 45,000. It comprises nearly 2300 books printed in the 15th century (including the rare *Monte Santo di Dio* of Bettini, 1477), 913 Aldine impressions, and a xylographic *Biblia Pauperum*. Amongst the MSS. are an early Dante and autograph letters of Galileo, some poems in Tasso's autograph, and a fine series of illustrated service-books, with miniatures representing the advance of Italian art from the 12th to the 16th century. These were formerly in the Certosa at Pavia.—The Bibliotheca Nazionale of Palermo, founded from the Collegio Massimo of the Jesuits, with additions from other libraries of that suppressed order, is rich in 15th century books, which have been elaborately described in a catalogue printed in 1875, and in Aldines and bibliographical curiosities of the 16th and following centuries.—The Biblioteca Nazionale of Turin is extensively used by readers, whose annual number amounts to 120,000. The majority of the books are works for scientific study, but amongst them are several rarities, comprising a Sedulius MS. of the 5th century, the celebrated MS. of the *De Imitatione* (on which the assignment of its authorship to Gersen is founded,—see KEMPIS), and several productions of the earliest German and Italian printers.—The Biblioteca Marciana, or library of St Mark at Venice, was founded in 1362 by a donation of MSS. from the famous Petrarch (most of them now lost), and instituted as a library by Cardinal Bessarion in the 15th century. It is open daily, and is used by about 40,000 readers annually. The precious contents include Greek MSS. of great value, of which more than 1000 were given by Cardinal Bessarion, important MS. collections of works on Venetian history, rare incunabula, and a great number of volumes, unique or exceedingly rare, on the subject of early geographical research. Amongst the MSS. is a Latin Homer in the autograph of Boccaccio, an invaluable codex of the laws of the Lombards, and the autograph MS. of Sarpi's *History of the Council of Trent*. Since the fall of the republic and the suppression of the monasteries afterwards, a great many private and conventual libraries have been incorporated with the Marciana.

Naples.

Unive- sity librar

Of the university libraries under Government control it is sufficient to notice the Biblioteca della Università at Bologna, founded in 1712 by Count Luigi F. Marsigli or Marsili. The MSS. comprise a rich Oriental collection of 547 MSS. in Arabic, 173 in Turkish, and several in Persian, Armenian, and Hebrew. Amongst the Latin codices is a Lactantius of the 6th or 7th century. The other noteworthy articles include a copy of the Armenian gospels (12th century), the Avicenna, with miniatures dated 1194, described in Montfaucon's *Diarium Italicum*, and some unpublished Greek texts. Amongst the Italian MSS. is a rich assemblage of municipal histories. Mezzofanti was for a long time the custodian here, and his own collection of books has been incorporated in the library, which is remarkable likewise for the number of early editions and Aldines which it contains. It possesses the Mainz Latin Bible dated 1462 ; the Lactantius and Augustine *De Civitate Dei* printed by Schweynheim and Pannartz, the Foligno Dante of 1472, and a copy of Henry VIII.'s *Assertio Sacramentorum* with the royal author's autograph. A collection of drawings by Agostino Caracci is another special feature of worth. The Manfredi palace, in which the library is arranged, is a fine building begun in 1714 and finished in 1744. The grand hall with its fine furniture in walnut wood merits particular attention. The library is open to the public ; the yearly number of readers is about 25,000, and of books consulted 40,000.[2]

La Ca

Of the remaining Government libraries the following may be named.—The Biblioteca del Monastero della S. Trinità, at La Cava dei Tirreni in the province of Salerno, is after the Biblioteca dell' Archivio Capitolare at Vercelli the most ancient library in the Italian kingdom, its foundation being said to be contemporaneous with that of the Benedictine abbey itself (beginning of the 11th century). It only contains some 10,000 volumes, but these include a number of MSS. of very great rarity and value, ranging from the 8th to the 14th century. Amongst these is the celebrated Codex Legum Longobardorum, dated 1004, besides a well-known geographical chart of the 12th century, over 100 Greek MSS., and about 1000 charters beginning with the year 840, more than 200 of which belong to the Lombard and Norman periods.—At Florence the Marucelli Library, founded in 1752, is remarkable for its artistic wealth of early woodcuts and metal engravings. The number of these and of original drawings by the old masters amounts to 80,000 pieces.—At Modena is the famous Biblioteca Palatina, sometimes called the Biblioteca Estense from having been founded by the Este family at Ferrara in 1393 ; it was transferred to Modena by Cesare D'Este in 1598. Muratori, Zaccaria, and Tiraboschi were librarians here, and made good use of the treasures of the library. It is particularly rich in early printed literature and valuable codices.—The oldest library at Naples is the Biblioteca Brancacciana, with many valuable MSS. relating to the history of Naples. Two planispheres by Coronelli are preserved here. It was founded in 1673 by Cardinal F. M. Brancaccio.—The Regia Biblioteca di Parma, founded definitively in 1779, owes its origin to the grand-duke Philip, who employed the famous scholar Paciaudi to organize it. It is now a public library containing 213,995 volumes, including 4000 MSS., with an annual increment of nearly 1000 volumes. Amongst its treasures is De Rossi's magnificent collection of Biblical and rabbinical MSS.

Moder

Medic Laure zia-ia.

Chief among the great libraries not under Government control comes the world-famed Biblioteca Mediceo-Laurenziana at Florence, formed from the collections of Cosimo the Elder, Pietro de' Medici, and Lorenzo the Magnificent (which, however, passed away from the family after the expulsion of the Medici from Florence, and were repurchased by Cardinal Giovanni, afterwards Leo X.). It was first constituted as a public library in Florence by

[1] A pamphlet by the present chief librarian, Vito Fornari, Naples, 1874, gives many useful details, although he there overstates the number of MSS. as 10,000 (there may be some confusion between volumes and works).

[2] Notices of other libraries of this class will be found in the tables.

Clement VII., who charged Michelangelo to construct a suitable edifice for its reception. It was opened to the public by Cosimo I. in 1571, and has ever since gone on increasing in value, the accessions in the 18th century alone being enough to double its former importance. The printed books it contains are probably no more than 3000 in number, but are almost all of the highest rarity and interest. It is, however, the precious collection of MSS., amounting to about 7000 articles, which gives its chief importance to this library. They comprise some of the most valuable codices in the world,—the famous Virgil of the 4th or 5th century, Justinian's *Pandects* of the 7th, a Homer of the 10th, and several other very early Greek and Latin classical and Biblical texts, as well as copies in the handwriting of Petrarch, about 100 codices of Dante, a *Decameron* copied by a contemporary from Boccaccio's own MS., and Cellini's MS. of his autobiography. Bandini's catalogue of the MSS. occupies 13 vols. folio, printed in 1764–78.—At Genoa the Biblioteca Franzoniana, founded about 1770 for the instruction of the poorer classes, is noteworthy as being the first European library lighted up at night for the use of readers.—

o. The famous Biblioteca Ambrosiana at Milan was founded in 1609 by Cardinal Fed. Borromeo. It contains 164,000 printed volumes and 8100 MSS. Amongst the MSS. are a Greek Pentateuch of the 5th century, the famous Peshito and Syro-Hexaplar from the Nitrian convent of St Maria Deipara, a Josephus written on papyrus, supposed to be of the 5th century, several palimpsest texts, including an early Plautus, and St Jerome's commentary on the Psalms in a volume of 7th century execution, full of contemporary glosses in Irish, Gothic fragments of Ulfilas, and a Virgil with notes in Petrarch's handwriting.[1] Noteworthy amongst the printed books is Valdarfer's Boccaccio of 1471, as well as the Virgil of 1470 (Venice), and the editio princeps of Isocrates, both printed on vellum. Cardinal Mai was formerly custodian here. In 1879 Professor C. Mensinger presented his "Biblioteca Europea," consisting of 2500 volumes, 300 maps, and 5000 pieces, all relating to the literature and linguistics of European countries.[2]—The Melzi and Trivulzio libraries should not pass without mention here, although they are private and inaccessible without special permission. The former is remarkable for its collection of early editions with engravings, including the Dante of 1481, with twenty designs by Baccio Bandinelli. The latter is rich in MSS. with miniatures of the finest and rarest kind, and in printed books of which many are unique or nearly so. It consists of 70,000 printed volumes.—

te ino. The foundation of the monastery of Monte Cassino is due to St Benedict, who arrived there in the year 529, and established the prototype of all similar institutions in western Europe. He brought with him a few manuscripts, four or five of which are still to be seen. The library of printed books now extends to about 20,000 volumes, chiefly relating to the theological sciences, but including some rare editions. A collection of the books belonging to the monks is in course of formation; it contains about the same number of volumes. But the chief glory of Monte Cassino consists of the *archivio*, which is quite apart; and this includes 30,000 or 40,000 bulls, diplomas, charters, and other documents, besides 1000 MSS. dating from the 6th century downwards. The latter comprehend some very early Bibles and important codices of patristic and other mediæval writings. There are good written catalogues, and a calendar is now being published, *Bibliotheca Casinensis*, of which 4 volumes have appeared. These libraries enjoy no special revenues, and owe their accessions entirely to donations.—At Ravenna the Biblioteca Classense has a 10th century codex of Aristophanes and two 14th century codices of Dante. Here are also the autograph correspondence of Muratori, and many unpublished letters of modern writers.—

rcelli. At Vercelli the Biblioteca dell' Archivio Capitolare, the foundation of which can be assigned to no certain date, but must be referred to the early days when the barbarous conquerors of Italy had become Christianized, comprises nothing but MSS., all of great antiquity and value. Amongst them is an Evangeliarium S. Eusebii in Latin, supposed to be of the 4th century; also the famous codex containing the Anglo-Saxon homilies which have been published by the Ælfric Society.—The "Frari" at Venice contains an enormous collection of archives, the invaluable state paper records of the Venetian republic.

Not a few of the communal and municipal libraries, as will be seen from the tables, are of great extent and interest.

Belgium and Holland.

The national library of Belgium is the Bibliothèque Royale at Brussels, of which the basis may be said to consist of the famous Bibliothèque des Ducs de Bourgogne, the library of the Austrian sovereigns of the Low Countries, which had gradually accumulated during three centuries.[3] After suffering many losses from thieves and fire, in 1772 the Bibliothèque de Bourgogne received considerable augmentations from the libraries of the suppressed order of Jesuits, and was thrown open to the public. On the occupation of Brussels by the French in 1794 a number of books and MSS. were confiscated and transferred to Paris (whence the majority were returned in 1815); in 1795 the remainder were formed into a public library under the care of La Serna Santander, who was also town librarian, and who was followed by Van Hulthem. At the end of the administration of Van Hulthem a large part of the precious collections of the Bollandists was acquired. In 1830 the Bibliothèque de Bourgogne was added to the state archives, and the whole made available for students. Van Hulthem died in 1832, leaving one of the most important private libraries in Europe, described by Voisin in *Bibliotheca Hulthemiana*, Brus., 1836, 5 vols., and extending to 60,000 printed volumes and 1016 MSS., mostly relating to Belgian history. The collection was purchased by the Government in 1837, and, having been added to the Bibliothèque de Bourgogne (open since 1772) and the Bibliothèque de la Ville (open since 1794), formed what has since been known as the Bibliothèque Royale de Belgique. The printed volumes now number 350,000, with 30,000 MSS., 100,000 prints, and 50,000 coins and medals. The yearly additions to the books amount to between 1500 and 3000; the other departments receive few accessions. The special collections, each with a printed catalogue, consist of the Fonds van Hulthem, for national history; the Fonds Fétis, for music; the Fonds Goethals, for genealogy; and the Fonds Müller, for physiology. The catalogue of the MSS. has been partly printed, but in an imperfect manner.

The University Library of Ghent, known successively as the Bibliothèque de l'École Centrale and Bibliothèque Publique de la Ville, was founded upon the old libraries of the Conseil de Flandres, of the College des Échevins, and of many suppressed religious communities. It was declared public in 1797, and formally opened in 1798. On the foundation of the university in 1817 the town placed the collection at its disposal, and the library has since remained under state control. The printed volumes now amount to 250,000, with 1600 MSS; the annual increment is about 2500 volumes. There are important special collections on archæology, Netherlands literature, national history, books printed in Flanders, and 23,000 historical pamphlets of the 16th and 17th centuries. There are printed catalogues of the works on jurisprudence (1839), and of the MSS. (1852).—The Bibliothèque de l'Université Catholique of Louvain is based upon the collection of Beyerlinck, who bequeathed it to his alma mater in 1627; this example was followed by Jacques Romain, professor of medicine, but the proper organization of the library commenced in 1636. There are now said to be 250,000 volumes.—The Bibliothèque de l'Université of Liége dates from 1817, when on the foundation of the university the old Bibliothèque de la Ville was added to it. There are now 105,746 printed volumes, 87,254 pamphlets, 1544 MSS., and 142 incunabula. The Liége collection (of which a printed catalogue appeared in 3 vols. 8vo, 1872), bequeathed by M. Ulysse Capitaine, extends to 12,061 volumes and pamphlets. A printed catalogue of the medical books was published in 1844, and one of the MSS. in 1875.

The national library of Holland is the Koninklijke Bibliotheek at the Hague, which was established in 1798, when it was decided to join the library of the princes of Orange with those of the defunct Government bodies in order to form a library for the States General, to be called the National Bibliotheek. In 1805 the present name was adopted; and since 1815 it has become the national library. In 1848 the Baron W. Y. H. van Westreenen van Tiellandt bequeathed his valuable books, MSS., coins, and antiquities to the country, and directed that they should be preserved in his former residence as a branch of the royal library. There are now upwards of 200,000 volumes of printed books, with an annual increment of 4000 volumes. The MSS. number 4000, chiefly historical, but including many fine books of hours with miniatures. Books are lent all over the country. Some twenty-five years ago it was decided for economical reasons to restrict the purchases to political, historical, and legal works, but recently, in consequence of an increase in the yearly subsidy, literature has been added to these three classes. The library boasts of the richest collection in the world of books on chess, Dutch incunabula, Elzevirs, and Spinozana. There is one general written catalogue arranged in classes, with alphabetical indexes. In 1800 a printed catalogue was issued, with four supplements down to 1811; and since 1866 a yearly list of additions has been published. Special mention should be made of the excellent catalogue of the incunabula published in 1856.

The next library in numerical importance is the famous Bibliotheca Academiæ Lugduno-Batavæ, which dates from the foundation of the university of Leyden by William I., prince of Orange, on February 8, 1575. It has acquired many valuable additions from the books and MSS. of the distinguished scholars, Golius, Joseph

---

[1] Ceriani has published many of the unique treasures of this collection in his *Monumenta Sacra et Profana*.

[2] This, as well as the Brera library, is exhaustively described in *Gli Istituti scientifici, letterari, ed artistici di Milano*, published by the Società Storica Lombarda in 1880; a special treatise on the Brera was published in 1873 by the librarian G. Sacchi. See also Boscha, *De origine et statu Bibliothecæ Ambrosianæ*, 1672.

[3] A most interesting account of the history of this library may be read in the introduction to *Catalogue des MSS. de la bibliothèque royale des ducs de Bourgogne* by M. Marchal, Brussels, 1842, 3 vols. 4to.

Scaliger. Isaac Voss, Ruhnken, and Hemsterhuis. The MSS. comprehend many of great intrinsic importance; the Oriental codices number 2400. The library of the Society of Netherland Literature has been placed here since 1877; this is rich in the national history and literature. The Arabic and Oriental MSS. known as the Legatum Warnerianum are of great value and interest; and the collection of maps bequeathed in 1870 by J. J. Bodel Nyenhuis is also noteworthy. The library is contained in a building which was formerly a church of the Béguines, adapted in 1860 somewhat after the style of the British Museum. The catalogues (one alphabetical and one classified) are on slips, the titles being printed. A catalogue of books and MSS. was printed in 1716, one of books added between 1814 and 1847 in 1848, and a supplementary part of MSS. only in 1850. A catalogue of the Oriental MSS. was published in 6 vols., 1851–77.

The University Library at Utrecht dates from 1582, when certain conventual collections were brought together in order to form a public library, which was shortly afterwards enriched by the books bequeathed by Hub. Buchelius and Ev. Pollio. Upon the foundation of the university in 1636, the town library passed into its charge. Among the MSS. are some interesting cloister MSS. and the famous "Utrecht Psalter," which contains the oldest text of the Athanasian creed. The last edition of the catalogue was in 2 vols. folio, 1834, with supplement in 1845, index from 1845–55 in 8vo, and additions 1856–70, 2 vols. 8vo. The titles of accessions are now printed in sheets and pasted down for insertion.

Amsterdam. The basis of the University Library at Amsterdam consists of a collection of books brought together in the 15th century and preserved in the Nieuwe Kerk. At the time of the Reformation in 1578 they became the property of the city, but remained in the Nieuwe Kerk for the use of the public till 1632, when they were transferred to the Athenæum. Since 1877 the collection has been known as the University Library, and in 1881 it was removed to a building designed upon the plan of the new library and reading-room of the British Museum. The library includes the best collection of medical works in Holland, and the Bibliotheca Rosenthaliana of Hebrew and Talmudic literature is of great fame and value; a catalogue of the last was printed in 1875. The libraries of the Dutch Geographical and other societies are preserved here. A general printed catalogue was issued in 6 vols. 8vo, Amsterdam, 1856–77; one describing the bequests of J. de Bosch Kemper, E. J. Potgieter, and F. W. Rive, in 3 vols. 8vo, 1878–79; a catalogue of the MSS. of Professor Moll was published in 1880, and one of those of P. Camper in 1881.

Denmark, Norway, and Sweden.

Copenhagen. The commencement of the admirably managed national library of Denmark, the great Royal Library at Copenhagen, may be said to have taken place during the reign of Christian III. (1533–59), who took pride in importing foreign books and choice MSS.; but the true founder was Frederick III. (1648–70); to him is mainly due the famous collection of Icelandic literature and the acquisition of Tycho Brahe's MSS. The present building (in the Christiansborg Castle) was commenced in 1667. Among notable accessions may be mentioned the collections of C. Reitzer, the count of Danneskjöld (8000 volumes and 500 MSS.), and Count de Thott; the last bequeathed 6039 volumes printed before 1531, and the remainder of his books, over 100,000 volumes, were eventually purchased. In 1793 the library was opened to the public, and it has since remained under state control. Two copies of every book published within the kingdom must be deposited here. The incunabula and block books form an important series. There is a general classified catalogue in writing in 295 folio volumes for the use of readers; and an alphabetical one on slips arranged in boxes for the officials. A good catalogue of the De Thott collection was printed in 12 vols. 8vo, 1789–95; a catalogue of the French MSS. appeared in 1844; of Oriental MSS., 1846; of the Danish collection, 1875, 8vo. Annual reports and accounts of notable MSS. have been published since 1864. There were 7000 additions in 1880.

The University Library, founded in 1482, was destroyed by fire in 1728, and re-established shortly afterwards. A copy of every Danish publication must be deposited here. The MSS. include the famous Arne-Magnean collection (see vol. xii. p. 626).

The chief library in Norway is the University Library at Christiania, established at the same time as the university, September 2, 1811, by Frederick II., with a donation from the king of many thousands of duplicates from the Royal Library at Copenhagen, and since augmented by important bequests.

The Royal Library at Stockholm was first established in 1585. The original collection was given to the university of Upsala by Gustavus II., that formed by Christina is at the Vatican, and the library brought together by Charles X. was destroyed by fire in 1697. The present library was organized shortly afterwards. The Benzelstjerna-Engeström Library (14,500 printed volumes and 1200 MSS., rich in materials for Swedish history) is now annexed to it. Natural history, medicine, and mathematics are left to other libraries. Among the MSS. the *Codex Aureus* of the 6th or 7th century, with its interesting Anglo-Saxon inscription, is particularly noteworthy. The catalogues are in writing, and are both alphabetical and classified; printed catalogues have been issued of portions of the MSS. The present building was opened in 1882.

Upsala. The University Library at Upsala was founded by Gustavus Adolphus in 1620, from the remains of several convent libraries; he also provided an endowment. The MSS. chiefly relate to the history of the country, but include the *Codex Argenteus*, containing the Gothic gospels of Ulfilas. The general catalogue is in writing. A catalogue was printed in 1814; special lists of the foreign accessions have been published each year from 1850; the Arabic, Persian, and Turkish MSS. are described by C. J. Tornberg, 1846. The library at Lund dates from the foundation of the university in 1668, and was based upon the old cathedral library. The MSS. include the De la Gardie archives, acquired in 1848.

Spain and Portugal.

The chief library in Spain is the Biblioteca Nacional (formerly the Biblioteca Real) at Madrid. The printed volumes number 400,000 volumes, with 200,000 pamphlets; the accessions in 1880 amounted to 25,840 articles. Spanish literature is of course well represented, and, in consequence of the numerous accessions from the libraries of the suppressed convents, the classes of theology, canon law, history, &c., are particularly complete. The number of bibliographical rarities was largely increased by the incorporation of the valuable collection formed by the well-known bibliographer Don Luis de Usoz. There are 30,000 MSS., contained in 10,000 volumes and bundles; they include some finely illuminated codices, historical documents, and many valuable autographs. The collection of prints extends to 120,000 pieces, and was principally formed from the important series bought from Don Valentin Carderera in 1865. In 1880 54,875 books were issued to 51,966 readers. The annual revenue is only £1600. The printed books have one catalogue arranged under authors' names, and one under titles; the departments of music, maps and charts, and prints have subject-catalogues as well. There is a general index of the MSS., with special catalogues of the Greek and Latin codices and genealogical documents. The first (and only) volume of a printed catalogue of the Greek MSS. appeared in 1769. The cabinet of medals is most valuable and well arranged. Of the other Madrid libraries (see the tables) it is enough to mention the Biblioteca de la Academia de la Historia (20,000 volumes and 1500 MSS.), which contains some printed and MS. Spanish books of great value, including the well-known Salazar collection.—The history of the library of the ESCORIAL has been given at vol. viii. p. 541. In 1808, before the invasion, the Escorial is estimated to have contained 30,000 printed volumes and 3400 MSS.; Joseph removed the collection to Madrid, but when it was returned by Ferdinand 10,000 volumes were missing. There are now 32,142 printed volumes, with 583 Greek, 1905 Arabic, 73 Hebrew, and 2050 Latin MSS. The Arabic MSS. have been described by M. Casiri, 1760–70; and a catalogue of the Greek codices by Müller was issued at the expense of the French Government in 1848. There is an imperfect written catalogue of the printed books, and the present librarian is now engaged upon a catalogue of the Latin MSS. Permission to study at the Escorial, which is one of the royal private libraries, must be obtained by special application.[1]

Among the libraries of Portugal the Bibliotheca Nacional at Lisbon naturally takes the first place. In 1841 it was largely increased from the monastic collections, which, however, seem to have been little cared for according to a report prepared by the principal librarian three years later. There are now said to be 200,000 volumes of printed books, among which theology, canon law, history, and Portuguese and Spanish literature largely predominate. The MSS. number 9415, including many of great value. There is also a cabinet of 40,000 coins and medals.—The Bibliotheca da Academia, founded in 1780, is preserved in the suppressed convent of the Ordem Terceira da Penitencia. In 1836 the Academy acquired the library of that convent, numbering 30,000 volumes, which have since been kept apart. The Archivo Nacional, in the same building, contains the archives of the kingdom, brought here after the destruction of the Torre do Castello during the great earthquake.

The Bibliotheca Publica Municipal at Oporto is the second largest in Portugal, although only dating from July 9, 1833, the anniversary of the debarkation of D. Pedro, and when the memorable siege was still in progress; from that date to 1874 it was styled the Real Bibliotheca do Porto. The regent (ex-emperor of Brazil) gave to the town the libraries of the suppressed convents in the northern provinces, the municipality undertaking to defray the expense of keeping up the collection, but only £180 is yearly spent on books and bindings, and £380 on salaries. Recent accessions consist

[1] Gachard, *Les bibliothèques de Madrid et de l'Escorial; notices et extraits des MSS. qui concernent l'histoire de Belgique*, Brussels, 1875, 4to; Ch. Graux, *Essai sur les origines du fonds grec de l'Escurial.*

mainly of Portuguese and French books. The important Camoens collection is described in a printed catalogue, Oporto, 1880. A notice of the MSS. may be found in *Catalogo dos MSS. da B. Publica Eborense*, by H. da Cunha Rivara, Lisbon, 1850–70, 3 vols. folio, and the first part of an *Indice preparatorio do Catalogo dos Manuscriptos* was produced in 1880.

Russia.

The Imperial Public Library at St Petersburg is the third largest library in the world, and now claims to possess 1,000,000 printed volumes. The commencement of this magnificent collection may be said to have been the books seized by the Czar Peter during his invasion of Courland in 1714; the library did not receive any notable augmentation, however, till the year 1795, when, by the acquisition of the famous Zaluski collection, the Imperial Library suddenly attained a place in the first rank among great European libraries. The Zaluski Library was formed by the Polish count Joseph Zaluski, who collected at his own expense during forty-three years no less than 200,000 volumes, which were added to by his brother Andrew, bishop of Cracow, by whom in 1747 the library was thrown open to the public. At his death it was left under the control of the Jesuit College at Warsaw; on the suppression of the order it was taken care of by the Commission of Education; and finally in 1795 it was transferred by Suwaroff to St Petersburg as a trophy of war. It then extended to 260,000 printed volumes and 10,000 MSS., but in consequence of the withdrawal of many medical and illustrated works to enrich other institutions, hardly 238,000 volumes remained in 1810. Literature, history, and theology formed the main features of the Zaluski Library; the last class alone amounted to one-fourth of the whole number. Since the commencement of this century, through the liberality of the sovereigns, the gifts of individuals, careful purchases, and the application of the law of 1810, whereby two copies of every Russian publication must be deposited here, the Imperial Library has attained its present extensive dimensions. Nearly one hundred different collections, some of them very valuable and extensive, have been added from time to time. They include, for example, the Tolstoi Sclavonic collection (1830), Tischendorf's MSS. (1858), the Dolgorousky Oriental MSS. (1859), and the Firkowitsch Hebrew (Karaite) collection (1862–63), the libraries of Adelung (1858) and Tobler (1877), that of the Slavonic scholar Jungmann (1856), and the national MSS. of Karamzin (1867). This system of acquiring books, while it has made some departments exceedingly rich, has left others comparatively meagre. The library was not regularly opened to the public until 1814; it is under the control of the minister of public instruction. In the printed book department the yearly average of readers is now 107,000, and of books consulted 285,300. The annual grant from the treasury is 79,174 silver roubles; an income of 3438 roubles is derived from other sources. The official estimate of the number of printed books is 1,000,000 volumes, with 19,059 maps and 75,000 prints and photographs. The yearly accessions amount to about 28,000. The Russian books number 100,000 and the Russica 30,000 volumes; the Aldines and Elzevirs form a nearly perfect collection; and the incunabula are numerous and very instructively arranged.

The manuscripts include 26,000 codices, 41,340 autographs, 4689 charters, and 576 maps. The glory of this department is the celebrated *Codex Sinaiticus* of the Greek Bible, brought from the convent of St Catherine on Mount Sinai by Tischendorf in 1859. Other important Biblical and patristic codices are to be found among the Greek and Latin MSS.; the Hebrew MSS. include some of the most ancient that exist, and the Samaritan collection is one of the largest in Europe; the Oriental MSS. comprehend many valuable texts, and among the French are some of great historical value.

The general catalogues are in writing, but the following special catalogues of the printed books have been published:—the Tolstoi collection of early printed Russian books, 1829; the Aldines, 1854; the Elzevirs, 1862, and another in 1864, by C. F. Walther; editions printed during the reign of Peter the Great, by Bytschkoff, 1867; the foreign books relating to Peter the Great by P. Minzloff, 1872; and the Russica, 2 vols., 1873. Lists of the foreign books have been issued since 1863, and the *Comptes Rendus* published since 1850 contain notices of the most important acquisitions.

The following catalogues of the MSS. are in print:—the Tolstoi Slavonic collection, 1825; Dorn's catalogue of the Oriental MSS., 1852; old German, 1853; the Greek, by Muralt, 1864; the Khanikoff Oriental codices, by Dorn, 1865; Russian MSS. on the history of Peter the Great, by Bytschkoff, 1872; the French, 1874; Samaritan, 1875; Hebrew Biblical, 1875; Slavonic and Russian miscellaneous, parts 1 and 2, 1878–80.

The nucleus of the library at the Hermitage Palace was formed by the empress Catherine II., who purchased the books and MSS. of Voltaire and Diderot. In the year 1861 the collection amounted to 150,000 volumes, of which nearly all not relating to the history of art were then transferred to the Imperial Library.

The second largest library in Russia is contained in the public museum at Moscow. The class of history is particularly rich, and Russian early printed books are well represented. The MSS. number 5000, including many ancient Sclavonic codices and historical documents of value. One room is devoted to a collection of Masonic MSS., which comprehend the archives of the lodges in Russia between 1816 and 1821. There is a general alphabetical catalogue in writing; the catalogue of the MSS. has been printed, as well as those of some of the special collections.

For other Russian libraries see the tables.

India, China, and Japan.

Of Indian libraries it is sufficient to notice those that have importance for Oriental letters. At Calcutta the Sanskrit college has 1652 printed Sanskrit volumes and 2769 Sanskrit MSS., some as old as the 14th century; there is also a large collection of Jain MSS. A catalogue is now being prepared for publication.—The Arabic library attached to the Arabic department of the Madrasa was founded about 1781, and now includes 731 printed volumes, 143 original MSS. and 151 copies; the English library of the Anglo-Persian department dates from 1854, and extends to 3251 volumes.—The library of the Asiatic Society of Bengal was founded in 1784, and now contains 15,000 printed volumes, chiefly on Eastern and philological subjects, with a valuable collection of 9500 Arabic and Persian MSS. A catalogue is now passing through the press.

At Bombay the library of the Bombay branch of the Royal Asiatic Society, established in 1804 as the Literary Society of Bengal, is now an excellent general and Oriental collection of 40,000 printed volumes and 200 MSS., described in a printed catalogue of 1875. The Moolla Feroze Library was bequeathed for public use by Moolla Feroze, head priest of the Parsis of the Kudmí sect in 1831, and consisted chiefly of MSS. in Arabic and Persian on history, philosophy, and astronomy; some additions of English and Gujaratí works have been made, as well as of European books on Zoroastrianism. A catalogue has been printed.

The library of Tippoo Sahib, consisting of 2000 MSS., fell into the hands of the British, and a descriptive catalogue of them by Charles Stewart was published at Cambridge in 1809, 4to. A few were presented to public libraries in England, but the majority were placed in the college of Fort William, then recently established. The first volume, containing Persian and Hindustaní poetry, of the *Catalogue of the Libraries of the King of Oudh*, by A. Sprenger, was published at Calcutta in 1854. The compiler shortly afterwards left the Indian service, and no measures were taken to complete the work. On the annexation of the kingdom in 1856 the ex-king is believed to have taken some of the most valuable MSS. to Calcutta, but the largest portion were left behind at Lucknow. During the siege the books were used to block up windows, &c., and those which were not destroyed were abandoned, and plundered by the soldiers. Many were burnt for fuel; a few, however, were rescued and sold by auction, and of these some were purchased for the Asiatic Society of Bengal.

Perhaps the most remarkable library in India is that of the rájá of Tanjore, which dates from the end of the 16th or beginning of the 17th century, when Tanjore was under the rule of the Telugu Náiks, who collected Sanskrit MSS. written in the Telugu character. In the 18th century the Marhattas conquered the country, and since that date the library increased but slowly. By far the greater portion of the store was acquired by Sharabhojí Rájá during a visit to Benares in 1820–30; his successor Sivají added a few, but of inferior value. There are now about 18,000 MSS. written in Devanágarí, Nandinágarí, Telugu, Kannada, Granthí, Malayálam, Bengali, Panjábí or Kashmirí, and Uriya; 8000 are on palm leaves. Dr Burnell's printed catalogue describes 12,375 articles.

Thanks to the enlightened policy of the Government of India, we are beginning to know much more respecting native libraries than was possible a few years ago, and since 1868 a yearly sum of 24,000 rupees has been granted to carry on the work of searching for Sanskrit MSS. The first part of a list of those in private hands in southern India has been published by Dr G. Oppert; it contains a description of 8376 MSS., and another volume is in course of preparation. Dr Bühler, in his investigation of Santinath's library at Cambay, found 300 MSS. of great antiquity, six dating from the beginning of the 12th century. A pandit has examined the Samghavina Pada Library in Pathan, and a catalogue has been prepared for printing. A copy of the oldest Sanskrit dictionary, the *Sasvata Kosha*, of which only one other copy (at the Bodleian) is known, was found here. Dr Bühler also purchased 429 volumes for the Government. Inquiries made in Behar have not met with much result. Notices of Sanskrit MSS. in the presidency of Bengal have been prepared under the direction of Dr Rajendralala Mitra; seven fasciculi (1000 pp.) have been printed, describing 842 articles. The same scholar has also printed a catalogue (755 pp.) of the library of the maharaja of Bikanir, describing 2000 Sanskrit MSS.; and his analysis of the Sanskrit Buddhist literature of Nepal will shortly be published. The total number of Sanskrit MSS. acquired in this presidency is now 1612, some of which are new to Europeans. Two catalogues of 180 Sanskrit MSS. discovered in the North-Western Provinces and Oudh during 1878–80 have been prepared.

and the following libraries (containing many important texts) of the Punjab have been examined :—that of Pandit Rikhikesha, of 500 books; Pandit Jwala Datta Prasada, 2500 MSS., the largest collection in the province; and Pandit Dilaram, 430 MSS. The efforts of Dr Forchhammer will probably bring to light many valuable Sanskrit MSS., both in Upper and Lower Burmah.

The Raffles Library at Singapore was established as a proprietary institution in 1844, taken over by the Government in 1874, and given legal status by an ordinance passed in 1878. It now contains 11,000 volumes in general literature, but books relating to the Malayan peninsula and archipelago have been made a special feature, and since the acquisition of the collection of J. R. Logan in 1879 the library has become remarkably rich in this department.

The library of the Genootschap van Kunsten en Wetenschappen at Batavia contains books printed in Netherlandish India, works relating to the Indian Archipelago and adjacent countries, and the history of the Dutch in the East. There are now 20,000 printed volumes and 1630 MSS., of which 243 are Arabic, 445 Malay, 303 Javanese, 60 Batak, and 517 on lontar leaves in the ancient Kawi, Javanese, and Bali languages, &c. The last edition of the catalogue appeared in 1877; printed catalogues of the Arabic, Malay, Javanese, and Kawi MSS. have also been issued.

China.—The Great Imperial Library was founded by K'in Lung, 18th century, and from a catalogue which has been issued appears to have contained about 12,000 works, extending to 168,000 volumes. There are many provincial libraries in China, and the chief Buddhist monasteries also possess collections of books.

Japan.—The library of the Tokio Fu (municipality of Tokio) at Leido, in the old Chinese university, contains 63,000 Chinese and Japanese volumes, and 5000 European, principally English and Dutch. The reading-room is supplied with native daily papers, and the chief foreign periodicals. The library is open for purposes of reference, and books may be borrowed by special permission. The Asakusa Library, now occupying the former fireproof rice storehouses of the shogun, is one of the oldest in the country, and is reported to contain 143,000 volumes, including many ancient books and MSS.; an entrance fee of about ½d. is charged here. The Imperial University has a good collection of European and Japanese science and general literature. The libraries of the large temples often contain rare books of value to the philologist, and many of the leading towns throughout the country are provided with free libraries. Lending libraries of native and Chinese literature have existed in Japan from very early times.

British Colonies.

Of such libraries as may be found in the British colonies there are very few that call for particular mention here.

The largest collection of books in Canada is the library of parliament at Ottawa. Though founded in 1815, it contained very few books until 1841, when the two libraries of Upper and Lower Canada were joined. After being destroyed by fire, the library was re-established in 1855, chiefly for parliamentary use. It now contains 100,000 volumes, and is open to the public except when parliament is sitting. Books are lent out. The main library is a handsome octagonal apartment with beautiful carved work in Canadian white wood.

In the South African Public Library at Capetown, which was established in 1818, there are 39,000 volumes, including the collection bequeathed by Sir George Grey, comprising, besides MSS. and early printed books, an unrivalled collection of works in the native languages of Africa, Australia, &c. The library is open to any respectable person.

The largest library in the Australian colonies is the Public Library of Victoria at Melbourne, which was established in 1853. In 1881 it numbered 89,387 volumes with 22,257 pamphlets; it possesses a collection of works on Australasia. The library has a printed catalogue (1880). It is supported by an annual parliamentary vote, which amounted last year to £5495. Readers are admitted without any formality, and have free access to the shelves. Although books are not lent out of the library individually, there is a system by which parcels of from 100 to 400 books are lent to libraries, mechanics' institutes, &c., in the inland towns of Victoria. There are several other not inconsiderable libraries in Melbourne. Next in importance to the Melbourne Library is the Sydney Free Public Library, which is said to contain the largest collection of works on Australasia anywhere to be found. It has a lending as well as a reference department, and is much used.

Particulars of other colonial libraries will be found in the tables.

United States.

The libraries of the United States, as we should expect to find in a country where intelligence and education are so widely diffused, are exceedingly numerous. A great mass of information with regard to them has been published by the Bureau of Education, particularly in the comprehensive *Special Report on Public Libraries* issued in 1876. From this report, and the annual reports of the commissioners of education which have since appeared, we learn that the number of public libraries already registered is 3842, with upwards of 12,569,450 volumes. It is of course true that the great majority of these libraries are not numerically important. On the other hand, many of them are very rapidly growing, and their very youth implies that their shelves are not burdened with much obsolete literature. The recent development of American libraries is indeed very striking. Of the libraries reported in 1875, about 64 appear to have been established before 1800, and 30 of these between 1775 and 1800. Between 1800 and 1825 there were established 179 libraries, between 1825 and 1850 as many as 551, and finally between 1850 and 1875 no less than 2240, which in the latter year contained as many as 5,481,068 volumes. It will be convenient to deal with these libraries in groups according to the historical order of their development. The earliest libraries formed were in connexion with educational institutions, and the oldest is that of Harvard (1638). It was destroyed by fire in 1764, but active steps were at once taken for its restoration. From that time to the present, private donations have been the great resource of the library. In 1840 the collection was removed to Gore Hall, which was erected for the purpose with a noble bequest from Christopher Gore, formerly governor of Massachusetts. There are also nine special libraries connected with the different departments of the university. The total number of volumes in all these collections is 259,000, exclusive of over 200,000 pamphlets. The annual increase is about 7000 volumes, and the library has an endowment fund of over $200,000. There is a MS. card-catalogue in two parts, by authors and subjects, which is accessible to the readers. The only condition of admission to use the books in Gore Hall is respectability; but only members of the university and privileged persons may borrow books. The library of Yale College, New Haven, was founded in 1700, but grew so slowly that, even with the 1000 volumes received from Bishop Berkeley in 1733, it had only increased to 4000 volumes in 1766, and some of these were lost in the revolutionary war. During the present century the collection has grown more speedily, and now the main library numbers 102,000 volumes, while the special libraries in the control of the college bring up the total to 143,000 volumes. The yearly increase is about 4500 volumes, and the library has a book fund of $100,000. Amongst the other important university libraries are those of the college of New Jersey, (Princeton), Dartmouth College (Hanover), Amherst College, Cornell University, and Brown University (Providence, R. I.). In 1875 the number of college libraries (not reckoning academy and school libraries) was 312, besides 299 libraries belonging to college students' societies.

The establishment of proprietary or subscription libraries runs back into the first half of the 18th century, and is connected with the name of Benjamin Franklin. It was at Philadelphia, in the year 1731, that he set on foot what he calls "his first project of a public nature, that for a subscription library. . . . . The institution soon manifested its ability, was imitated by other towns and in other provinces." The Library Company of Philadelphia was soon regularly incorporated, and gradually drew to itself other collections of books, including the Loganian Library, which was vested in the company by the State legislature in 1792 in trust for public use. Hence the collection combines the character of a public and of a proprietary library, being freely open for reference purposes, while the books circulate only among the subscribing members. It numbers at present 123,000 volumes, of which 11,000 belong to the

Loganian Library, and may be freely lent The printed classed catalogue of the library has been praised by Brunet and Allibone. In 1869 Dr James Rush left a bequest of over one million dollars for the purpose of erecting a building to be called the Ridgeway branch of the library. The building is very handsome, and has been very highly spoken of as a library structure. Philadelphia has another large proprietary library—that of the Mercantile Library Company, which was established in 1821. It possesses 143,135 volumes, and its members have always enjoyed direct access to the shelves. The library of the Boston Athenæum was established in 1807, and numbers 122,000 volumes. It has recently published an admirable dictionary-catalogue. The collection is especially rich in art and in history, and possesses a part of the library of Washington. The Mercantile Library Association of New York, which was founded in 1810, has the largest of all the subscription libraries counting over 193,000 volumes. New York possesses two other large proprietary libraries, one of which claims to have been formed as early as 1700 as the "public" library of New York. It was organized as the New York Society Library in 1754, and has been especially the library of the old Knickerbocker families and their descendants, its contents bearing witness to its history. It contains about 80,000 volumes. The Apprentices' Library has about 63,000 volumes, and makes a special feature of works on trades and useful arts. It is maintained by the General Society of Mechanics and Tradesmen. Finally, the Brooklyn Library deserves mention, if only for its very useful and admirable catalogue, the printing of which was completed in December 1880, and which embraces 60,000 volumes.

Although the State libraries of Pennsylvania and New Hampshire are known to have been established as early as 1777, it was not until some time after the revolution that any general tendency was shown to form official libraries in connexion with the State system. It is especially within the last thirty years that the number of these libraries has so increased that now every State and Territory possesses a collection of books and documents for official and public purposes. These collections depend for their increase upon annual appropriations by the several States, and upon a systematic exchange of the official publications of the general Government and of the several States and Territories. The largest is that of the State of New York at Albany, which contains 116,000 volumes, and is composed of a general and a law library, of which a printed catalogue has been published with full subject-indexes. The State libraries are libraries of reference, and only members of the official classes are allowed to borrow books, although any well-behaved person is admitted to read in the libraries.

In addition to the libraries maintained by the several States, there are the collections belonging to the general Government, most of which are at Washington. The most important of them is of course the Library of Congress, but there are also considerable libraries attached to the house of representatives, the senate, the department of state, the patent office, and the office of the surgeon-general.

The Library of Congress was first established in 1800 at Washington, and was burned together with the Capitol by the British army in 1814. President Jefferson's books were purchased to form the foundation of a new library, which continued to increase slowly until 1851, when all but 20,000 volumes were destroyed by fire. From this time the collection has grown rapidly, and now consists of 396,000 volumes with 130,000 pamphlets. In 1866 the library of the Smithsonian Institution, consisting of 40,000 volumes, chiefly in natural science, was transferred to the library of congress. The library is specially well provided in history, jurisprudence, the political sciences, and Americana. Since 1832 the law collections have been constituted into a special department. This is the national library. In 1870 the registry of copyrights was transferred to it under the charge of the librarian of congress. As two copies of every publication which claims copyright are required to be deposited in the library, the receipts under this head are nearly 25,000 articles per annum. The sum annually appropriated by congress for the management and increase of the library is $52,840. The present accommodation is inadequate, and a separate building is to be erected of size to contain two million volumes. There is an alphabetical card-catalogue kept constantly up to date, and a printed catalogue of subject-matters. The library is open every day in the year, except on four legal holidays, from 9 A.M. to 4 P.M., and admission is granted to all persons over sixteen years of age without formality or introduction, but books are only lent to members of the official classes.

Since the organization of the Government in 1789, no less than one hundred and sixty historical societies have been formed in the United States, most of which still continue to exist. Many of them have formed considerable libraries, and possess extensive and valuable manuscript collections. The oldest of them is the Massachusetts Historical Society, which dates from 1791.

The earliest of the scientific societies owes its origin to Franklin, and dates from 1743. The most extensive collection is that of the Academy of Natural Sciences of Philadelphia, which consists of 35,000 volumes and 40,000 pamphlets. For information as to the numerous professional libraries of the United States—theological, legal, and medical—the reader may be referred to the report already mentioned.

Of all the libraries of the United States none have achieved a greater fame, and none are more zealously and admirably conducted, than those which are supported from the public funds of some of the great cities. Legislation on the subject of free public libraries was almost synchronous in England and America. Of the free town libraries of America, much the largest and most successful is the Boston Public Library, which was established in 1852. Besides the liberal appropriations made by the city for its support, it has been the object of a long series of splendid gifts in money and books. Among the more conspicuous of its benefactors have been Joshua Bates, Theodore Parker, and George Ticknor. Since the library has been opened to the public there has thus been gathered "the largest collection of books, under one administration, upon this continent" The number of volumes in the library on July 1, 1881, was 395,478, and the annual accessions are over 17,000 volumes. In addition to the income available from trust funds, the annual appropriation by the city is $115,000. Besides the central library, with the Bates Hall and Lower Hall, there are eight branches, and the total circulation is considerably over 1,000,000 volumes per annum. Any inhabitant of Boston over fourteen years of age is admitted to read in the library and to borrow books. The principal catalogue of the library is upon cards, in addition to which there are printed catalogues of special collections, and a perfect multitude of useful class catalogues and bibliographical helps of various kinds. The number of persons engaged in the service of the library is one hundred and forty-three. The library is open to readers from 9 A.M. to 6 P.M. from October to March, and until 7 P.M. during the rest of the year. Books are delivered for home use until 9 in the evening. The periodical room is open from 9 A.M. to 9 P.M. on week days, and on Sundays from 2 to 9. A new building is in contemplation.

Of the remaining free town libraries, the most important are those of Cincinnati and Chicago. The public library of Cincinnati, which was established on its present footing in 1867, has 122,930 volumes besides pamphlets. Its expenditure last year was $51,465, and its total issues, including those from the two branches, were 768,565. The reading-rooms are open every day in the year from 8 A.M. to 10 P.M. The library buildings were completed in 1873 at a cost of about $400,000, and are "among the handsomest in the world." The Chicago Public Library was established in 1872, and owed its origin to the sympathy felt for Chicago in England after the great fire of 1871. The number of volumes now in the library is 76,120. There is a very full and minute card-catalogue, in one alphabet, of authors and subjects; the contents of collections, volumes of essays, &c., are analysed under their subjects. The reading-room is open three hundred and sixty-five days in the year from 9 A.M. to 9 P.M., and is not even closed for the purpose of taking stock or cleaning. The library has not yet an appropriate building. Of smaller free town libraries there is a considerable number, especially in Massachusetts. Of the entire number ten only possess over 30,000 volumes each. It is the opinion of the energetic and enlightened managers of these libraries that a free public library is the proper corollary of a free system of public education, and it is their aim as far as possible to direct the taste and to methodize the reading of those who use the collections under their charge.

We cannot conclude this brief sketch without mentioning some notable illustrations of that public-spirited munificence which is nowhere perhaps so frequently found as in the United States. The Astor Library in New York was founded by a bequest of John Jacob Astor, whose example was followed successively by his son and grandson. The library was opened to the public in 1854, and at the end of 1880 the collection due to their joint benefaction contained 192,547 volumes. It consists of a careful selection of the most valuable books upon all subjects. It is a library of reference, for which purpose it is freely open, and books are not lent out. It is "a working library for studious persons," and such persons on a proper introduction are allowed to pursue their studies in the alcoves. In 1880 the number of general readers was 45,670, and the number of visits to the alcoves was 7961. The total endowment is over $1,100,000. There is a printed catalogue for about half the library, with a printed index of subjects, and a similar catalogue for the rest is in preparation. The Lenox Library was established by Mr James Lenox in 1870, when a body of trustees was incorporated by an Act of the legislature. In addition to the funds intended for the library building and endowment, amounting to $1,247,000, the private collection of books which Mr Lenox has long been accumulating is extremely valuable. Though it does not rank high in point of mere numbers, it is exceedingly rich in early books on America, in Bibles, in Shakesperiana, and in Elizabethan poetry. The Peabody Institute at Baltimore was established by Mr George Peabody in 1857, and contains a reference library open to all comers, numbering about 72,000 volumes. The institute has an endowment of $1,000,000, which, however, has to support, besides the library, a conservatoire of music, an art gallery, and courses of popular lectures. The largest legacy yet made for a public library has recently fallen to the citizens of Chicago in the Newberry bequest of over $2,000,000 for the founding of a free public library in the north division of Chicago.

South America and Mexico.

Argentine Republic. The importance of public libraries has been fully recognized by the Argentines, and at present more than two hundred of them are in the country. They are due to benefactions, but the Government in every case adds an equal sum to any endowment. A central commission exists for the purpose of facilitating the acquisition of books and to promote a uniform excellence of administration. The most considerable is the Biblioteca Nacional at Buenos-Ayres, which contains at present 40,000 volumes, and has been almost doubled since 1872. It is passably rich in MSS., some of great interest, concerning the early history of the Spanish colonies.

The chief library of Brazil is the Bibliotheca Publica Nacional at Rio de Janeiro, founded in 1807, and now comprising 120,000 printed volumes with 1000 MSS. National literature and works connected with South America are special features of this collection. The Royal Library of Ajuda (including 4000 MSS.) was taken to Brazil by King João VI., but was sent to Portugal on the declaration of independence. Since 1873 the annual Government grant has been largely increased. Among other libraries of the capital may be mentioned those of the Faculty of Medicine (18,000 volumes), Marine Library (19,500 volumes), National Museum (9000 volumes), Portuguese Literary Club (53,000 volumes), Bibliotheca Fluminense (43,000 volumes), Benedictine Monastery (9000 volumes), and the Bibliotheca Municipal (15,500 volumes). In the official report on Brazil, submitted at the Philadelphia Exhibition in 1876, it was stated that the aggregate number of volumes in all the libraries of the empire accessible to the public was then 460,272 volumes. In 1875 the libraries were visited by 85,044 persons.

The Biblioteca Nacional at Santiago is the chief library in Chili. The catalogue is printed, and is kept up by annual supplements.

Only sixteen out of the twenty-nine states and territories of the Mexican republic have public libraries, and only a small proportion of the contents consists of modern literature. Many, however, possess rare and valuable books, of interest to the bibliographer and historian, which have come from the libraries of the suppressed religious bodies. It is calculated that books in all the public libraries amount to about 250,000 volumes. There are about seventy-three scientific and literary associations in the republic, each possessing books. The Society of Geography and Statistics, founded in 1851, is the most important of them, and owns a fine museum and excellent library. After the triumph of the Liberal party the cathedral, university, and conventual libraries of the city of Mexico came into the possession of the Government, and steps were taken to form them into one national collection. No definite system was organized, however, until 1867, when the church of San Augustin was taken and fitted up for the purpose. Two copies of every book printed in Mexico must be presented to this library. The only other public library in the city is the Biblioteca Cinco de Mayo, which is under the management of the Lancastrian Society.

The Biblioteca Nacional at Lima was founded by a decree of the liberator San Martin on August 28, 1821, and placed in the house of the old convent of San Pedro. The nucleus of the library consisted of those of the university of San Marcos and of several monasteries, and a large present of books was also made by San Martin. The library is chiefly interesting from containing so many MSS. and rare books relating to the history of Peru in vice-regal times. The volumes marked "Papeles varios" contain reports on the superstitions of the Indians, abstracts of the ecclesiastical councils of Lima, and memoirs on provincial administration and petitions. It is reported (1881) that the whole library has been seized by the Chilians and transferred to Santiago.

LIBRARY MANAGEMENT.

Library Buildings.[1]—The conditions of no two libraries being precisely alike, it is impossible to lay down rules to suit all, but certain principles of general application may be stated. In the first place the internal arrangements ought to be devised by a person thoroughly acquainted with the practical working of such a library as the building is intended to accommodate. The reading-rooms, book-rooms, work-rooms, and offices should be made to fall into the most convenient relations one to the other. And as libraries grow with wonderful rapidity the plan ought to admit of easy development. The site should be dry and airy, and permit isolation of the fabric, which should be constructed of fire-proof materials, iron being preferable to stone, and brick to either. Every floor should be laid upon rolled iron beams, supported by lattice girders, the space between the beams being fitted in with porous terra cotta, and the beams covered with concrete. To protect them against fire, girders and pillars must be covered with terra cotta. Iron doors (or, better still, stout wooden doors plated with thin iron) should separate the different rooms.[2] The safety and convenient disposal of the books must never be sacrificed to outside show. The old form of library, the museum-like room with alcoves and a large block of vacant space in the centre, or the series of apartments with books on the walls only, is no longer in favour. The reading-room, commodious, well lighted, and supplied with works of reference, should be away from the main collection, and the lending department should be kept apart from the reference library. It is convenient to have separate rooms for ladies and for readers to whom special facilities may be granted; and let ample provision be made for work-rooms, librarians' offices, cataloguing rooms, and a bindery if necessary. The chief portion of the books (at any rate those in most demand) should be on the ground floor, and more than two stories are to be avoided. Plenty of light and good ventilation are two conditions of great importance. The basement should be vaulted. As the store-room, or that in which the main collection is deposited, is one to which readers have seldom the right of access, the greatest economy as to shelvage and passage way may be effected. Bookcases may be placed against the walls, but not too close to them, and double presses, about 3 feet apart, arranged across the floor. To prevent the objectionable use of high ladders, no shelf should stand more than 8 feet above the ground. If the room be sufficiently lofty it may contain one or more perforated iron floors, sustained by the upright portion of the presses, also of iron. Spiral staircases are to be avoided. Lifts may be introduced with advantage. In many college libraries in America (*e.g.* at Princeton) the circular form, with cases radiating from the centre, has been adopted successfully. The spacious rotundas of the British Museum and that of the Liverpool Free Public Library are good examples of the circular reading-room.

Mr Justin Winsor has devised an excellent plan for a library of one million volumes capacity (see "Library Buildings," in *Report on Public Libraries of U.S.*, p. 465), and the same system might be applied to one much less extensive. Another distinguished American librarian, Mr W. F. Poole of Chicago, has made some novel suggestions on library architecture which have met with considerable approval. He objects to the waste of space in the central portion of most large library rooms, to the difficulty of ventilating and heating them, to shelving books in galleries on the walls, to the destruction of bindings from gas and heat ("books cannot live where man cannot live"), to the excessive labour of procuring books from long distances, the insecurity from fire, the inconvenience of keeping many volumes (other than those of reference) in the public reading-room, and the unnecessary cost of the present system. To remedy these defects a plot of land is required 200 feet square, and surrounded with open spaces. At the middle of the principal side may be placed the main building, 60 feet front and 75 feet deep, devoted to administrative and working purposes. The books will be stored, not in one central repository, but in a series of rooms thrown out in wings from the central edifice, and

[1] Plans of most of the chief libraries of Europe may be seen in the *Memoirs of Libraries* of Mr Edwards (2 vols., 1859), and in the *Katechismus der Bibliothekenlehre* of Dr Petzholdt (1871); the volumes of the *Library Journal* contain representations of many new American libraries.

[2] A recipe to make wood incombustible, and other suggestions, are given by C. Walford in *Manchester Trans. Libr. Assoc.*, 1880, p. 65.

extending round the four sides of the quadrangle with a vacant space in the middle. Each room is 50 feet wide, 15 feet high, and as long as convenient. Ten of these rooms will occupy the ground floor, so that, carrying the same construction four stories high, there will be forty different rooms in the whole structure. Each will be devoted to one large, or two or more small, classes of books. Alcoves and galleries are not to be permitted, but the books will be shelved on the walls or on double presses within reach. Every room will receive light on two sides, will be furnished with tables and chairs for readers, and provided with an attendant; no general reading-room will therefore be wanted. As a protection against fire, each room will be cut off by means of brick fire-walls extending to the roof, and access from one room to the other will be by a light iron corridor on the inside of the quadrangle. At the rear of the central building will be a lift for readers, and there will be staircases as well. In this way, on one story there will be about 25,250 square feet in the different wings, which, after deducting sufficient space for readers' tables, &c., will give about 20,200 square feet for books. As each square foot will shelve 25 volumes, each story will hold 505,000 volumes, or on the four stories 2,020,000 volumes. One of the front rooms (to hold 67,500 volumes) might serve as a circulating library. Mr Poole estimates the cost of such a building in America at $530,000, or complete with shelving and furniture $640,000. (See *Library Journal*, vi. 69 *sq.*) In the same volume, p. 77 *sq.*, is a description of the proposed plan for a new national library building at Washington. In this scheme the architect has in view the centralization towards a circular reading-room, good light, the possible expansion of the library for one hundred years, accessibility to all parts, economical administration, and division into different fire-proof compartments.

Of the various systems for heating libraries open fire-places have the best appearance, are very safe, and best convey heat; close stoves are the cheapest at first hand. Perhaps steam heating is the safest and most economical for large buildings. Unprotected gas jets are very injurious to the books. If gas be used at all, the sun-light system or the Benham light is the best means of conveying away the fumes and heated air. The electric light is used with great success at Liverpool and in the British Museum.

elves. *Bookcases and Shelves, Furniture and Appliances.*[1]—For presses and shelves, should wood be preferred, English oak or the cheaper deal (well seasoned) is the best material; or the presses may be made of iron and the shelves of slate or galvanized iron. At the British Museum the presses are all on one scale and all of the same model,—the standards being of galvanized iron, with holes for brass pins, which are so shaped that the space is altered by merely turning them half-way round. The shelves are also of galvanized iron, covered with leather, on wooden frames; movable pads covered with leather protect the books at either end from being rubbed, and there are leather falls to keep the dust out. In the Radcliffe iron bookcase, invented by Dr Acland, the framework is of iron, and the shelves of wood, faced with leather. It is 7 feet high, and stands on any floor-space 48 inches by 18 inches; books are placed on both sides to the number of 500 octavos. Danner's revolving bookcase is useful for reference books; it is square, stands about 5 feet high, occupies no more space than a chair, and holds about 250 volumes. Economy of space is also a feature in Mr Virgo's bookcase, in the front of which is a door, itself shelved, which, on being swung round, discloses another row of shelves behind. The Eastlake portable bookcase can be taken to pieces, and is made to stand against a wall. In providing for shelf room it is usual to allow about 110 square feet of shelving to 1000 volumes; and in giving directions for presses and shelves it is well to have them planned upon a uniform scale. Perhaps the best supports for the shelves are Tonks's movable shelf-fittings, consisting of two rows of metal strips, with oblong perforations at intervals of ¾ inch, in which are inserted small metal plates. The tops of reading tables, trays and barrows for carrying books, and such shelves as may be intended for heavy or choice books, should be padded. Very large volumes had better be kept flat in sliding trays. There is much diversity of opinion as to whether the fronts of the presses should be glazed or not, or whether they should be protected by wooden doors, curtains, or wire screens; many librarians object to glass doors as harbouring dry rot, and to any opaque screen as concealing the books.

The arrangement of the reading-room of the British Museum furnishes a good example of perfect supervision combined with every consideration for the comfort of readers. The tables are here arranged as the spokes of a wheel, with smaller square tables between them for large volumes. Each reader at the radiating tables has a separate place 4 feet 3 inches long, and is screened from his opposite neighbour by a division running along from one end to the other; in front is a hinged desk, with racks, inkstand, and a folding shelf for books. The framework of each table is of iron, forming channels by which air is conveyed through screens at the top of the longitudinal divisions. A tubular foot-rail affords facility for warming the feet in cold weather. The catalogue-stands (with presses of special bibliographies near them) are placed in two concentric circles around the enclosure of the superintendent, who can thus observe every reader in the room.

A speedy supply of books is ensured by the use of the automatic book-delivery contrived for the Harvard bookstore (of six stories) by Mr Justin Winsor. At the delivery-desk a keyboard shows the digits which combine the various shelf-marks; and the number of the book wanted, being struck upon it, is repeated at the floor on which the work is located, where it is sought for by an attendant and placed in a box attached to an endless belt, which carefully deposits it on a cushioned receptacle close by the delivery-desk.

Many English lending libraries find that a great saving of time and trouble both to officials and readers is made by the use of the indicator for public reference. There are many varieties of this invention, but the main principle is a frame containing a series of small pigeon-holes, each numbered and referring by that number to a book; when a volume is lent out, the borrower's card, &c., are placed in the pigeon-hole and signify that it is absent. This roughly describes the Birmingham indicator (Mr Morgan's); in that of Mr Elliot, the title of the book is pasted against each pigeon-hole; Mr W. H. K. Wright uses at Plymouth a system which serves as a catalogue and register of books lent as well; and Mr A. Cotgreave has improved the original idea by his indicator-book, a sort of ledger of the persons to whom each volume is lent, which is placed in the small pigeon-hole previously spoken of. The card-ledger of Mr G. Parr, used at the London Institution, is for the use of the librarians alone and not for the readers; it is applied to a borrowing system which permits several volumes to be taken away by the same person, and also acts as a register of borrowers.[2]

For the purpose of stamping the name of the library on the books, &c., some persons prefer the embossing stamp, and some the ink stamp now very conveniently made in india-rubber. Props, either to screw upon the shelves, or made of thick blocks of wood, or of tin folded at right angles, are useful for preventing books falling about in a slovenly manner. Reading cases are necessary for periodicals and choice bindings; periodical cases are made conveniently of wood with strong leather backs. In order to keep the consecutive numbers of current periodicals and newspapers clean and in perfect order, some kind of temporary binder is required. The contents of the different shelves or recesses may be printed on labels made of leather or cloth. The "Van Everen" printed numbers and letters for the marks on the shelves and the backs of the books are to be purchased at a small cost.

Classification and Shelf-Arrangement.—The defect of most classificatory systems, especially of those which profess to be particularly philosophical and logical, is that they are better adapted for a systematic review of human knowledge than for the arrangement of a miscellaneous collection of books. A small library will not require so extensive a scheme as a larger one, and a popular library needs less minute classification than one for reference or for the use of more learned readers. Again, the classes which are best represented in the library, and its special or local collections, deserve more elaborate treatment than the classes in which it possesses but few volumes. The same system cannot invariably be used in all respects both for the shelves and for the catalogue, as a book can have but one position in the presses, but the title may appear under any number of headings in different parts of the catalogue. For these reasons, the natural order should be followed as far as possible. That is to say, the books should suggest their own classification, which should be made to harmonize with the requirements of the library, and the various classes should not be strained to fit some arbitrary method, however logical in theory. As the title of a book is often an unsafe guide to its contents, no one should attempt classification by the help of the title alone. In vol. ii. of Edwards's *Memoirs of Libraries*, he gives a number of schemes both on philosophical and on natural or practical principles; and Petzholdt, in his *Bibliotheca Bibliographica* (Leipsic, 1866), has drawn up an account of no less than one hundred and seventeen different methods of classification, a number which could now be largely increased, as the practical ingenuity of American librarians alone has added many to the roll. Some of these schemes have been elaborated with great care, but, however interesting on account of the useful hints they may now and then supply, most of them are useless either for the catalogue or the shelves. All these are systems to classify the whole range of literature, but there are many classified bibliographies and other guides useful for the scientific arrangement of special departments.[3]

Books are usually arranged upon the shelves either in order of (1) their sizes, (2) authors' names, (3) subjects, or sometimes (4) of accession, or by a modification of two or more of these systems. The arrangement by subjects is that which displays

[1] Details in the works of Edwards and Petzholdt the *Library Journal*, the publications of the Library Association, and of the Library Bureau (Boston, U.S.).

[2] See *Oxford Trans. Lib. Assoc.*, 1879, p. 76; *Manchester Trans.*, 1880, pp. 71 *sq.*

[3] For instance, in the class of fine arts may be consulted the *Bibliographie des Beaux-Arts* (Paris, 1874–8), which the late M. Ernest Vinet left incomplete; and botany may be classified with the help of Mr B. D. Jackson's *Guide to the Literature of Botany* (London, 1881). In the *Memoirs of Libraries* (ii. 922) may be found a useful classification for MSS., and further on an account of perhaps the best systems for prints and maps, being those of the Bibliothèque Nationale

most conveniently the richness or poverty of the collection. Although a library may possess the most complete of subject catalogues, it cannot be considered in perfect order without classification on the shelves. In carrying out shelf-arrangement ample space should be left for additions, and in fixing upon the places of the bookcases those containing the works in most demand should be nearest the point of delivery. In some libraries the books are located without any classification, and the shelf marks are all in all. At Munich and many other Continental libraries there are thirty or forty classes, designated by single or double letters, and the books are arranged in sets of octavo, quarto, and folio in the different classes under the names of their authors, so that Macaulay's *History of England* would be found in the octavo alphabet under M of the class "history." Mr Richard Garnett supplies an interesting description of the system of classifying books on the shelves followed at the British Museum in the *Trans. of Conf. of Libs.* (London, 1878, pp. 108, 188). There are ten classes:—(1) theology, (2) jurisprudence, (3) natural history and medicine, (4) archæology and arts, (5) philosophy, (6) history, (7) geography, (8) biography, (9) belles lettres, (10) philology; and the classes have five hundred and fifteen divisions. Periodicals, academical publications, state papers, the Oriental departments, the Grenville Library, and the reference library are all distinct, but the principle of classification is practically identical. By allowing intervals in the numbering of the presses space is allowed for new ones to contain additions, and as the different presses are alike in size, they may be shifted at will and no alteration of press-marks is wanted. Mr Edwards (*Mem. of Libs.*, ii. 814) proposes a system for a public free library of upwards of thirty thousand volumes to be arranged under (1) theology, (2) philosophy, (3) history, (4) politics and commerce, (5) sciences and arts, (6) literature and polygraphy. A novel scheme, marked with many practical advantages, is the Amherst or Dewey system,[1] according to which the library is divided into ten classes, the first being a zero or general class, including bibliography, polygraphy, general periodicals, &c., while the others are philosophy, which is numbered 100; theology, 200; sociology, 300; philology, 400; natural science, 500; useful arts, 600; fine arts, 700; literature, 800; and history, 900. These classes are then separated again into nine special divisions of the main subject, preceded by a zero or general division. Each of these divisions again has nine sections (preceded by a zero). Thus 513 is the third section (geometry) of the first division (mathematics) of the fifth class (natural science). This is the classification or class number, and is affixed to every book and pamphlet belonging to the library. The zero in a class number has its normal power, and signifies a general treatise, so that 500 is a book on natural science in general. The system was devised in the first instance for classifying and indexing, but it can also be used for numbering and arranging books and pamphlets on the shelves. For this purpose the absolute location by shelf and book-marks is wholly abandoned, and the relative location by class and book-number used instead. Accompanying the *class*-number is the *book*-number, which prevents confusion of different books on the same subject. Thus the first geometry catalogued is marked 513·1, the second 513·2, and so on. The books of each section are all together, arranged by book-numbers, and these sections are also arranged in simple numerical order throughout the library. The number 513·11 will therefore mean the eleventh book in subject 513, or the eleventh geometry belonging to the library.—A representative specimen of the philosophical method is that devised by Dr W. J. Harris for the catalogue of the Public School Library of St Louis, which is classed in a modified form of the Baconian plan. The main classes are (1) science, including philosophy, theology, social and political sciences, and natural science and the useful arts, (2) art, (3) history, (4) appendix, including polygraphy, cyclopædias, and periodicals. These main classes are again divided into one hundred subclasses, many of which are divided still further. Thus, under natural history, class 50 is zoology; 50*a*, vertebrates; 50*a* i., mammals, &c.—The divisions *Médecine* and *Histoire de France* in the great printed catalogue of the Bibliothèque Nationale are excellent examples of classification.[2]

Every volume upon the shelves should have a mark to indicate its position. One system is to designate each press by a number, each shelf by a letter, and if necessary, each volume on the shelf by another consecutive number, so that 13 D 16 is the sixteenth volume on the fourth shelf of the thirteenth press. The principles underlying numbering systems as well as shelf-arrangement are discussed by Mr Melvil Dewey (see *Library Journal*, iv. 7, 75, 117, 191), and the combined system of numbering and arranging of Mr J. Schwartz, as well as his mnemonic system of classification (*ib.*, iii. 6; iv. 3), are also well worth attention. The new scheme of classification devised for the use of the Boston Athenæum by Mr Cutter is also described in the *Library Journal*, iv. 234. A catalogue for the Winchester Library (1879) was prepared by Mr Cutter on the principles there detailed.

Many authorities strongly recommend that, instead of a fixed mark for the shelves, the location of books should be indicated by a running number or combination of letters and numbers; so that, although the books should not always remain in the same place, their relative position would be unaltered, and, while they could be found just as readily by means of the number, any quantity of additions could be introduced without affecting the whole scheme.

In a circulating library it may be found convenient to designate each press by letter, and to omit to number the shelves from top to bottom, but number each volume consecutively. The shelf-notation may be placed inside each volume or on a label upon the back.

Binding.[3]—The best binding is the cheapest in the end, since it lasts longer under all circumstances, and is always better treated by readers. Morocco resists wear and tear and the action of gas and heated air better than any other leather. Vellum is the most durable material, but it is not suitable for all purposes. Then follow in order of merit calf, russia, basil, roan, buckram, and cloth. Morocco should be used as much and russia as little as possible. Buckram, linoleum, cretonne, leatherette, &c., have met with favour from time to time, but are not recommended. Olive, light brown, and red are said to be the most lasting colours; then come dark blue and green, light blue and green. Black is a lasting colour. Some persons assign a particular colour to each class of literature, but, as there are more classes than colours to suit them, such an arrangement consistently carried out can only lead to confusion; besides, a want of variety on the shelves destroys at once the individual appearance which it is always desirable to give to each set of books in order to make them easily distinguishable. The council of the Library Association have suggested as a pattern for ordinary library binding that the volumes should be sewn all along, with the first and last sheets overcast, on strong cords, the slips to be drawn in all along, and the backs made close (flexible); half-bound, with corners of same material; smooth cloth sides; edges cut, sprinkled, and burnished, or, if so directed, top edge only cut, &c., the others trimmed and left with proof; end-papers of stout Cobb's paper, with cloth joints in quartos and folios; lettered with author's name, short title, and date; gilt fillets, but no other tooling; two-page plates to be guarded so as to open out flat; all materials of the best quality, and the work to be done carefully.[4] In making contracts some such specification as that suggested by the Library Association should be decided upon. Full instructions should always accompany work sent out, and a copy must be kept in a binding-register. Rare and valuable books demand special treatment and a special binder. The British Museum authorities have adopted a style of binding in half-morocco, with the leather coming only just over the back to act as a hinge, the sides whole cloth, the corners tipped with vellum.

Pamphlets.

How to deal with pamphlets is a troublesome question. At the British Museum each was formerly done up separately in slight binding. This is certainly the best system, but out of the reach of most libraries from its cost. Failing this, the pamphlets can be arranged in solander cases as they come in, and afterwards bound up in volumes according to size and subject, with the contents marked on the fly leaf of each. The rebinding of a MS. is to be avoided; it is better to preserve the old cover and place the book in a case. Drawings and prints are best preserved in sunk mounts, and maps, charts, &c., should be backed with thin linen.

Hints.

Practical Hints.—Collate every volume when it comes in, so as to prevent binder's imperfections; remove plate-paper when the book is quite dry; strings and silk registers are to be avoided, as they tear the leaves; preserve old bindings as far as possible, and do not permit book-plates, the names of former owners, and MS. notes of any kind to be destroyed; be careful with metal clasps and corners; let gilding be used sparingly; do not hurry the binder overmuch, as he may retaliate by returning his work insufficiently dried and pressed; be careful with letterings; index dictionaries and works of reference on the fore edges; bind up paper wrappers; never let a binder exercise his fatal proclivity to cut away full margins.

For the removal of grease and ink-spots, and the restoration of old bindings, prints, &c., consult *L'art de restaurer les estampes et les livres* (Paris, 1858) and *La réparation des vieilles reliures* (*ib.*, 1858), both by A. Bonnardot, and Rouveyre, *Connaissances nécessaires à un Bibliophile* (Paris, 1880). To restore calf-bindings which have become impoverished, it has been recommended[5] that they should be lightly washed with a soft sponge dipped in a preparation consisting of ½ oz. of the best glue, dissolved in a pint of warm water, to which add a teaspoonful of glycerin and a little flour paste. Should the state of the leather be very bad, a second

[5] By Mr C. P. Russell, *Oxford Meeting of Library Association*, p. 100.

dressing may be found necessary. The volumes must be rubbed with chamois leather when dry. Neat's-foot or olive oil has been suggested for the same purpose, but it ought to be used with a sparing hand. Much has been written about the effect of gas and heat upon binding.[1] The question is still undecided, but it seems likely that the deterioration of the leather is caused more directly by the over-heated air, so that thorough ventilation, especially as regards the upper shelves, is most important for the well-being of a library. Morocco, vellum, and buckram resist this action best, and calf, russia, and roan worst. Professor H. A. Hagen has studied the various kinds of bookworms and other insect pests of librarians.[2] Most libraries of the first class bind on the premises, and M. Hipp. Gariel of the Bibliothèque de Grenoble is persuaded, after a very careful inquiry, that any library which binds as many as nine hundred volumes a year will save largely by keeping up a binding establishment of its own.[3]

Catalogues and Cataloguing.—A library is useless without a proper equipment of good catalogues, which to be thoroughly efficient should be compiled upon a well-considered plan, carefully kept up to date, and made accessible to every reader. The variety of different catalogues is very great, and no one form can be adopted alike by libraries for study and those for popular reading, nor yet by those which combine the two functions in whatever proportions. As regards the amount of information necessary to be given, the titles of the books may be either short, or not more than a single line to each, as in the *London Library Catalogue* (1875); medium, or several lines to each, as in the *Royal Academy Library Catalogue* (1877); or full, as in the *Catalogue of the Huth Library*, 5 vols. large 8vo (1880), where the title is copied in extenso and a quantity of bibliographical details are added.

The chief questions to be answered by a catalogue are:—1. Has the library a certain work by a certain author? 2. What has it by any given author? 3. Has it a certain book of which the title only is known to the inquirer? 4. Has it a certain book of which the subject only is known to the inquirer? 5. What has it on a given subject? 6. What works in certain classes or languages has it? To supply this information, catalogues are arranged sometimes under the names of the authors in alphabetical order (1 and 2); or under the first words of the titles (3); or classified under subjects, whether in alphabetical or systematic order (4 and 5); or by a combination of two or more of these methods. A dictionary-catalogue answers all six questions under the names of authors, the titles of books, the subjects and forms of literature (*i.e.*, essays, or French, German, &c.), which are arranged in one alphabet and connected one with the other by a complete system of cross-references. A modified form of short-title dictionary-catalogue, with the names of authors, titles of books, and subjects in one alphabet, is a useful type for a popular library to adopt. No author-catalogue can be considered complete without an index of subjects,[4] and every classified catalogue requires an index of authors, if alphabetical, and of both authors and classes if systematic. An ideal catalogue would furnish references under each name and subject to every work, part of work, or even magazine article contained in the library which illustrated it. This can rarely be attempted, but a near approach to perfection is shown by the new catalogues of the Boston Athenæum and the Brooklyn Mercantile Library; the last is a model of thoroughness. It is becoming a laudable practice to give the contents of collected works and periodicals in catalogues; and good examples of the value of annotations are the catalogues of the classes of history, biography, travel, and historical fiction in the Boston Public Library.

In making choice of a form of catalogue the way is sufficiently plain should the alphabetical system under authors be adopted, neither can there be much cause for discussion in fixing upon an alphabetical subject-catalogue; but, should it be decided to compile a systematic subject-catalogue, the question becomes a much more serious one. A subject-index of some sort is an indispensable supplement to any catalogue merely arranged under authors. The references had better be strictly alphabetical in form; for instance, a work on ants should be indexed under that word and not under the general heading of insects or entomology; but there is no reason why there should not be cross references under the larger to the smaller headings. In an appendix to Mr Cutter's article on "Library Catalogues"[5] there is a descriptive list of more than a thousand printed catalogues of American libraries, among which many useful types might be selected. All the printed catalogues of European libraries which were published before 1840 are mentioned in Vogel's *Literatur europ. öff. u. Corporations-Bibliotheken* (Leipsic, 1840).

Librarians should take a share in the compilation of their catalogues at any sacrifice of time and trouble, for by no other means can they obtain so exact an acquaintance with their collections. No cataloguer should be allowed to prepare a title except from the very copy of the book which he is cataloguing.

In order to secure precision and uniformity in the descriptions of the books and in the headings under which they are placed, some well-considered code of rules is absolutely necessary as a guide to the cataloguer. All such rules are founded more or less upon those of the British Museum, printed in 1841,[6] which have been followed with modifications by Professor Jewett (in the *Smithsonian Report on the Construction of Catalogues*, 1852), by Mr E. Edwards (*Memoirs of Libs.*, 1859, vol. ii.), by Mr F. B. Perkins (in the *American Publisher*, 1869), with many additions by Mr C. A. Cutter (in his *Rules for a printed Dictionary-Catalogue*, 1876),[7] by the condensed rules of the American Library Association (*Library Journal*, iii. 12), and by the Library Association of the United Kingdom (as finally agreed upon and printed in their *Monthly Notes*, ii. 81). The authorities of the Cambridge University Library have also printed their rules. In drawing up a set of rules the special wants of the library and the readers should be first considered, and then the most suitable rules chosen from one or other of the schemes mentioned above. But when rules are decided upon, no alteration should be permitted during the compilation of the catalogue, as bad rules uniformly followed are better than good rules without uniformity.

Among disputed questions, that of how best to describe the sizes of books is perhaps the most difficult. What is wanted is a system that can be understood by every one, and which is capable of being applied to old as well as to new books.[8] For books printed before the introduction of machine-made paper about the beginning of the century, the correct bibliographical size may be derived from the fold of the sheet, that is, roughly speaking, a quarto is a sheet folded four times, an octavo eight times, &c. The great variety of modern papers (a different scale of sizes being used in each country) renders this method no longer available, and it seems generally admitted that some system of fixed measurements of heights to denote certain sizes is wanted for library purposes. A report on the subject, giving details of three rival schemes, including that of the American Library Association, an ingenious adaptation of the "demy" scale paper, and one following the ordinary binder's scale, may be found in *Trans., &c., of Manchester Meeting*, 1880 (p. 11), of the Library Association. A committee of the same body subsequently devised a plan which endeavoured to embrace the different merits of all three schemes, but it has not yet been generally adopted.[9]

Printed catalogues.

Printed catalogues are doubtless costly, and they soon become out of date, but they are much easier to consult than manuscript volumes, and possess the great advantage that they admit of being used away from the library. On the whole the balance of convenience is strongly in their favour, and few libraries of any importance fail to print as soon as they can. For free public libraries printed catalogues are absolutely necessary, and they are extremely useful in those of a more learned or special character.

As regards the form of catalogue most suitable for library reference, card-catalogues are used comparatively little in England, but are found to act satisfactorily in many American libraries. They possess many peculiar advantages, among others being the facility with which titles may be added, withdrawn, or rearranged. Readers do not object to turning over the cards, as the labour is shortened by indexes standing above the rows; and there are many contrivances to prevent the unauthorized removal of the titles.[10]

It is obvious that, if a universal catalogue of printed literature existed, it would be only necessary for each library to mark in a copy the particular works it chanced to possess. Such a plan on a small scale has been adopted in many cathedral and college libraries, where a copy of the Bodleian printed catalogue is used for the purpose. A satisfactory step in the direction of co-operative cataloguing has been made by Mr Henry Stevens in his proposals for a bibliographical clearing-house,[11] which shall supply exact copies of the title pages of rare (and eventually of more common) books by means of photography. Mr Stevens has now many thousands of these "photograms" of titles, which are all reduced to a uniform scale, with the full titles and collations added in ordinary type. They are very convenient for card-catalogues.

Thus far the wants of readers have been principally considered; but librarians ought to possess two other kinds of very important catalogues, which they must keep up in their own interests. The first is the accessions-catalogue, or record of every book, part of book, pamphlet, or periodical as it comes in; and the second the shelf-catalogue, or stock-book of the library, a register of the con-

[1] See *Conf. of Lib.*, 1878, p. 232; also *Library Journal*, i. 124; iii. 64, 229; iv. 255, 435; v. 50, 213.

[4] Of such an index a very complete specimen may be seen in the *Catalogue of the Royal Medical and Chirurgical Society's Library*, 1879, 3 vols. 8vo.

[5] See *U S. Report*, p. 577

[6] Prefixed to the printed catalogue of letter A. The rules, which were compiled by Sir A. Panizzi, Th. Watts, J. Winter Jones, J. H. Parry, and E. Edwards, have been conveniently arranged by Mr Nichols in *Handbook for Readers at the British Museum*, 1866, and have been reprinted with additional rules by Mr Hy. Stevens in his *Catalogue of the American Books in the British Museum*.

[9] See *Monthly Notes*. i. 61, 62.

[10] The Bonnange and other systems of card-catalogues are described in *Report on Public Libraries of U.S.*, pp. 555, &c.

[11] *Transactions of Conference of Librarians*, London, 1878, p. 70.

ents of every press and every shelf. These tell the source and date of every addition, and enable all the books to be checked at any time. A novel form of accessions-catalogue is that of the Liverpool Free Public Library, which is a sort of large photographic album to show printed titles of accessions in alphabetical order; loose sheets are laced into the body of the catalogue to provide for any number of additions as quickly as possible. In the same library the titles of new books are also pasted upon blocks arranged in a frame for the information of readers.

Administration.—In any library which manages its own financial matters, however small, all accounts should be as carefully kept as those of a trading establishment. In the same way a periodical stock-taking should be made by means of the shelf-catalogue. It is a great convenience to display recent accessions for a short time in some place put apart for the purpose. A recommendation and complaint-book are both useful. The rapid and efficient supply of books is greatly promoted by requiring that all demands should be made in writing and not verbally. The books should be carefully dusted from time to time by experienced persons; and the leaves of all new books, &c., should be cut by the library staff.

In issuing and taking note of books lent, either the ledger or the slip-system may be used, or a combination of the two, something like a shelf-catalogue. Accounts are kept either against the borrower, against the book, or against time; the first, with the ledger system, may be well for small libraries, but in larger institutions the slip-system must be resorted to, and it is better to keep the accounts against the books, with perhaps a ledger-index of borrowers. Where more than one volume is lent at a time a small card is sometimes placed in a pocket in each book; the card, whether marked with borrower's name, &c., or not, being retained as a voucher, as in the "card-ledger" spoken of on p. 537, which is on the slip-system with the account against the borrower. The special feature of the "card-ledger" is that no writing whatever is required. It is necessary to introduce some device for overdrawn or reserved books.

Besides furnishing the materials for reading, it is now recognized that a popular library has also the function of indicating the method of reading and study. A collection of well-chosen books suitable for girls and boys is now a good feature in many English free libraries. At the Providence Public Library, Rhode Island, Mr W. E. Foster issues daily notes on current topics and events, with detailed references by which the subject may be illustrated by the resources of the library; more complete special lists, *e.g.*, on Herbert Spencer, Irish landlord and tenant, &c., are also issued from time to time. Library lectures are now given at several free libraries in Engand, but, to make these efforts distinctly useful in adding to the good work of the institution, they should be restricted to lectures on books and courses of reading, so that, by illustrating certain works or departments of the library, these lectures may gradually lead readers to a more careful consideration of literature. Aimless and purposeless reading is the bane of a free public library, and it should be the desire of its authorities to do what can be done to induce people to use with due circumspection books of a higher class and of a more useful and informing character. The admirable catalogue of history, biography, and travel of the Boston Public Library, with its suggestive notes and illustrations, had the effect of lowering the reading of fiction from 74 per cent. to 69 per cent. In the same library even the reading of novels has been elevated by the catalogue of English prose fiction arranged on the same plan.

Experience shows that in all that relates to such questions as preliminary forms, age of readers, days and hours of admission, Sunday-opening, access to catalogues, shelves, and librarians, fines, loans of books, guarantees, number of volumes allowed, time of reading, &c., a liberal tendency is always beneficial both to the library and the public.

In view of an outbreak of fire, some well considered plan should be fixed upon. Extincteurs and hand-pumps should be kept ready for use in central positions. The means for extinguishing fire should be familiar to the members of the staff, who should all be practised in fire-drill, in order that each may know his proper place and duty in case of emergency. Full directions should be suspended in conspicuous places. In the case of fire breaking out after library hours, it should be thoroughly understood where the keys are to be found, what officials should be sent for, and what apparatus is ready for use within the building.

Librarians.—Without insisting upon quite so wide a range of subjects as did F. A. Ebert in his *Bildung des Bibliothekars* (Leipsic, 1820), one may expect the librarian of a great library to be a man of liberal education, and specially endowed with sympathy with books and reading; a practical acquaintance with bibliography, including palæography, and bibliology, is also necessary, as well as with the theory and practice of library management. To be thoroughly qualified, a librarian should have had the practical experience of library-work which it is impossible to obtain from any amount of book reading. Besides this, he ought to be a man of business habits and a good administrator.

These acquirements imply qualifications of a somewhat higher character than may perhaps be necessary in all public libraries; but some knowledge of languages and literatures, bibliography, bibliology, and general library management should be possessed by any person holding the chief position in the administration of any library, however small. As regards the qualifications of the librarian of a popular institution or of library-assistants, it may be useful to give the outline of a plan recently proposed by a committee of the Library Association for their examination (see *Monthly Notes*, vol. ii.). There should be a preliminary examination, chiefly in the subjects of a sound English education, special attention being paid to English literature; proficiency in the elements of one or more classical or modern languages would be specially indorsed upon the certificate, one language to be necessary. The suggested subjects for the preliminary examination are—arithmetic, English grammar and composition, English history, geography, and English literature. After having been engaged in library work for not less than one year, a second-class certificate might be awarded to any librarian or assistant who should pass a satisfactory examination in English literature, especially of the last hundred years, some one other European literature, principles of the classification of the sciences, elements of bibliography, including cataloguing and library management,—a cataloguing knowledge of at least two languages besides English to be necessary. A first-class certificate would be given, after a satisfactory examination, to a librarian or assistant of at least two years' experience, for an advanced knowledge of the subjects last mentioned, with the addition of general literary history. A cataloguing knowledge of at least three languages would be necessary for the higher certificate,—an acquaintance with any others, as well as proficiency in any subjects (not more than two in number) offered by the candidate, being specially indorsed.

Women are gradually making their way in libraries. At Manchester and elsewhere they are successfully employed as assistants; and in several other places in England the chief charge of the library is maintained in a very efficient manner by a lady. In the United States the majority of the librarians are ladies (at the Boston Public Library no less than two-thirds of the staff), and many of the most accomplished cataloguers are of the same sex.

The first general meeting of librarians took place at New York, September 15 to 17, 1853, upon an invitation signed by Professor C. C. Jewett, Mr W. F. Poole, and others "for the purpose of conferring together upon the means of advancing the prosperity and usefulness of public libraries, and for the suggestion and discussion of topics of importance to book collectors and readers." About eighty persons attended, many questions were debated, and the suggestion to form a permanent association met with considerable favour. Nothing came of it, however, and twenty-three years had elapsed when, having in view the Centennial Exhibition of 1876, a second meeting was convened on October 4 to 6, at Philadelphia, which was attended by one hundred and two Americans and one English representative. At the Philadelphia conference of 1876, the American Library Association, which has since done so much good work in practical librarianship, was founded. In October 1877 a conference of librarians was held in London, under the presidency of the late Mr J. Winter Jones, and attended by two hundred and sixteen librarians and others, including representatives of the French, German, and Greek Governments, all the chief libraries of the United Kingdom, as well as certain of those of the United States, Belgium, Denmark, France, Italy, and Australia. Altogether one hundred and forty different libraries sent representatives, and nearly the whole field of library-science was reviewed at the different sittings. *The Transactions and Proceedings of the Conference of Librarians* (London, 1878) is the title of the official report of the meeting. The chief result of the conference was perhaps the foundation of the Library Association of the United Kingdom, of which the "main object shall be to unite all persons engaged or interested in library work, for the purpose of promoting the best possible administration of libraries; it shall also aim at the encouragement of bibliographical research." Monthly meetings of the association take place at the London Institution, and the members hold an annual conference in some one or other locality, where the different libraries are inspected, various questions of library economy are discussed, and new library appliances are exhibited. Full reports of these meetings have been published; *Monthly Notes* are also issued. Every important British library is now represented in the association, which numbers over 360 members.

Guides to Selection of Books.—As it is not only necessary to find out the best treatises on given subjects, but also to decide upon the respective merits of different editions and even of different states or copies of the same edition, an acquaintance with bibliography, or the science dealing with the technical features of books and MSS., and with bibliology, or that which deals more especially with their literary aspect, is to be expected in those forming a library.[1]

[1] The article BIBLIOGRAPHY (vol. iii. p. 651 *sq.*) will afford a general idea of the immense extent of this literature; in addition to the special works there mentioned, reference may be made to Sabin's *Bibliography of Bibliography*, New York, 1877.

So necessary is bibliography in library selection that Dr Cogswell, as a preliminary step to collecting books for the Astor Library, formed a bibliographical apparatus of five thousand volumes to help him in his arduous task. To assist librarians and collectors in their choice, among earlier works may be mentioned that of G. Peignot, *Manuel du Bibliophile, ou traité du choix des livres*, Dijon, 1823, still interesting on account of the descriptions of the favourite reading of eminent men. *Catalogue of my English Library* (London, 1853) is the title of a little volume prepared by Mr Henry Stevens to assist in getting together the best editions of the standard English authors. The idea was followed on a larger scale by M. Hector Bossange in *Ma Bibliothèque Française* (Paris, 1855). The best guide for ordinary purposes, but far from perfect, is *The best Reading: hints on the selection of books, on the formation of libraries, public and private*, by F. B. Perkins (4th ed., New York, 1877). The list is restricted to books now in the market; prices are appended. The titles are very brief, and are arranged in an alphabet of subjects; and a selection is appended of the chief French, German, Italian, and Spanish authors. A new edition of Porter's *Books and Reading* appeared in 1881. Current German literature is well looked after in G. Schwab and K. Klüpfel's *Wegweiser durch die Literatur der Deutschen* (4th ed., Leipsic, 1870), with several supplements. The leading literary reviews, as well as the publishers' trade journals, will guide in the acquisition of the books of the day. The careful cataloguing and excellent descriptive notes in the New York *Publishers' Weekly* are good examples of what book committees are glad to have before them. An examination of the authorities quoted by authors of repute will frequently help in deciding upon the merits of rival treatises, and the printed catalogues of well-chosen libraries are also useful. To his practical little treatise, *Free Libraries and Newsrooms*, Mr J. D. Mullins appends a list of books he considers desirable for free public libraries, and to form the basis of a collection of high-class fiction, Mr F. B. Perkins has drawn up a list of the best hundred novels procurable in English (*Library Journal*, i. 166). The *Coming Catalogue*, about which we hear now and then from America, will contain selected lists of books, with short notes.

Acquisition.

Acquisition of Books.—Public libraries must look to purchases as their chief means of getting the books they want. The best system is to draw up lists of the desired works and editions, and circulate the lists among the leading booksellers, who will notify the prices and conditions of the copies they may be able to supply; announcements of books wanted can also be inserted in the booksellers' trade organs. Second-hand booksellers will willingly furnish their catalogues, which, if they are not required to purchase from, are always useful for reference. It is usually more convenient to give commissions for books at sales than for the librarian to attend in person; but an occasional visit to the auction rooms will give much information as to current prices of books, a matter which, coupled with frequent visits to the shops of second-hand booksellers and the diligent study of their catalogues, will be carefully attended to by the capable librarian. The works of Brunet, Lowndes, and Graesse may also be consulted for the prices of old books. It is perhaps needless to add that the state of condition and binding makes a great difference in the market value of copies of the same book. Libraries will frequently dispose of their duplicates or surplus copies to other institutions at a low price. For new books, periodicals, newspapers, &c., special terms may always be arranged with local tradesmen.

From time to time the Governments of Great Britain, France, and the United States have had under consideration various schemes for the international exchange of books upon a systematic basis, but the proposals were never carried into effect, and it was left to the public spirit of a French gentleman, M. Alexandre Vattemare, to devise and carry out for some years a large scheme for the interchange of books among the chief public institutions of Europe and America. In 1853 M. Vattemare was able to state that one hundred and thirty such establishments had participated in the benefits of the system, but unfortunately it gradually fell off. Earlier than 1851, however, a similar agency was in full working order at the Smithsonian Institution, and it has been kept up with efficiency to the present time. The institution acts as a medium for the exchange of their publications among the chief learned bodies and other public institutions of Europe and America, and undertakes the cost of receiving and sorting the parcels, and the renumeration of the agents in the chief centres of the Old World to whom they are sent, and by whom they are distributed free of charge. The corresponding societies are only required to deliver their parcels without expense at Washington.

On several occasions the United States Congress has passed special Acts directing the exchange of Government publications with those of other countries, and in 1848 the joint committee on the library was authorized to appoint agents for the exchange of books and public documents. As the scheme did not appear to work satisfactorily, the Act was repealed four years later. But since 1867 it has been ordered that fifty copies of all documents printed by either House of Congress or by any Government department be placed with the joint committee on the library, to be exchanged for foreign works. It is most unfortunate that this enlightened policy is not followed by the English authorities.

Many learned bodies which issue their proceedings willingly present them to libraries, and authors find this a useful means of spreading a knowledge of their works, when they are not of sufficient public interest to ensure a large or rapid sale. Library committees may often secure valuable additions by a discreet application; indeed, privately printed works and local publications (unless given spontaneously) are almost only to be had in this manner.

Many valuable works are issued at the expense of Governments. It might be naturally expected that these should be sent, free of charge, to all public libraries of any importance. In England, however, this is not done. In countries where the public libraries are subject to the minister of public instruction, as in France and Italy, more is done in this direction, especially as regards expensive volumes. In 1853 a select committee of the House of Commons recommended that parliamentary papers should be sent free of charge to free public libraries, but the recommendation has never been carried out.

In America official publications can be obtained without charge by public institutions from the secretary of the interior upon the order of a senator or representative, but the system is said not to be in a satisfactory condition.

Many valuable English Government publications, notably the state papers and chronicles, and the fine art handbooks of the South Kensington Museum, are easily to be had at less than the cost of production, and parliamentary papers are neither inaccessible nor highly priced. Although there is no fixed rule as to distribution, some of the departments may now and then be induced to present copies of their publications on being applied to in a proper manner.

Copyright Acts.

The privilege of demanding copies of all books, periodicals, newspapers, musical publications, maps, and prints, when published, under the provisions of the various Copyright Acts, is enjoyed by only a very few, generally only by one, of the chief national libraries in each country. This system has grown up under the different enactments of the censorship of the press. The first Act of Parliament passed in England to enjoin printers to present their publications was that of 14 Charles II. c. 33, which directed that *three* copies should be sent, one to his Majesty's library, and one to each of the universities of Oxford and Cambridge. By 8 Queen Anne c. 20 the number was increased to *nine*, and by the 41 George III. c. 107 to *eleven*, viz., to (1) the Royal Library; (2) University Library of Cambridge; (3) Bodleian Library; (4) Edinburgh University Library; (5) Glasgow University Library; (6) King's College Library, Aberdeen; (7) University Library, St Andrews; (8) Sion College Library, London; (9) Advocates' Library, Edinburgh; (10) Trinity College Library, Dublin; (11) King's Inns Library, Dublin. This was in force till 1835, when by the 6 & 7 William IV. c. 110 the privilege was abolished as regards six of the eleven libraries mentioned, and a yearly grant, estimated at £3028, allowed in compensation. The Act under which five libraries, viz., the British Museum, the Bodleian, the Cambridge University, the Advocates', Edinburgh, and Trinity College, Dublin, now receive the copyright books is 5 & 6 Vict. c. 45. (See COPYRIGHT, vol. vi. p. 358.)[1]

As instances of the variety in practice in different countries, it may be mentioned that in France the Bibliothèque Nationale is entitled to a copy of every book, &c., printed within the dominion of the republic; in Belgium and the Netherlands one copy must be sent to the respective national libraries in order to secure the advantages of copyright; in Spain the Biblioteca Nacional of Madrid enjoys the privilege of one copy; in Portugal two copies are claimed, one by the Bibliotheca Nacional at Lisbon, and one by the Bibliotheca Publica of Oporto; in the United States a copy of every work must be sent to the library of Congress; the Imperial Library at St Petersburg receives two copies of every book printed in Russia; by the Brazilian law the Biblioteca Nacional of Rio de Janeiro is entitled to a copy of everything published within the municipality; and in Mexico two copies have to be delivered to the National Library.

Authorities.—There have been many books written about library-management; a complete list of those published down to about 1865, with critical notes, is given in Petzholdt's *Bibliotheca Bibliographica* (Leipsic, 1866). Among recent treatises the valuable works of Mr Edward Edwards—*Memoirs of Libraries* (1859, 2 vols. 8vo), *Free Town Libraries* (1869), *Libraries and Founders of Libraries* (1865), *Lives of the Founders of the British Museum* (1870, 2 vols. 8vo)—should be in the hands of all librarians. Petzholdt's *Katechismus der Bibliothekenlehre* (Leipsic, 1871) is a practical little volume. The report of the Bureau of Education on *Public Libraries of the U.S.* (Washington, 1876, 2 parts 8vo), besides giving an exhaustive account of all the American libraries, also includes a great variety of valuable information on library economy. The six volumes of the *Library Journal* contain much that is useful for practical librarianship; it is a well edited periodical. Petzholdt's *Anzeiger* is of a more bibliographical character. The different publications of the Library Association include a great deal of interesting matter.

[1] In the recent *Report of the Royal Commission on Copyright*, 1878, a recommendation is made that the privilege should in future be granted to the British Museum alone.

TABLES OF THE PRINCIPAL LIBRARIES THROUGHOUT THE WORLD.

In compiling the following tables officials of each of the libraries have been personally applied to, and in most instances the information has been supplied by them. An attempt has been made to give particulars of all libraries of general or special interest in the United Kingdom. As regards those of other countries the list has been usually limited to those of 30,000 vols. and upwards, with a few exceptions. In India and the British Colonies there are few collections of that extent.

The abbreviation L. A. in the United Kingdom signifies that the library is under the Public Libraries' Act; o. b. l. means open by leave.

I. GREAT BRITAIN AND IRELAND.

(H. R. T.—E. C. T.)

LIBURNIANS were a people who at different times were prominent on the Adriatic coasts. They were originally, one cannot doubt, one of the homogeneous Illyrian tribes (see ILLYRIA). Living in a barren rocky country along the north-eastern coast of the Adriatic, they devoted themselves to the sea, and were the chief navigators of the Adriatic in the early period. They settled on the coast of Picenum, where the town of Truentum was always counted Liburnian; and the Greek colonists found them at Corcyra and other places. They were pressed on all sides by other races, but were still a powerful people in the time of Scylax (Scyl., p. 7). The islands that lay along the coast were peopled by them and called by their name. They were a race of pirates, who used swift boats with a large sail. These Liburnian ships became famous when the Romans adopted them in several of their naval wars. The heavy and lofty ships that had been developed by the later Greek states proved unequal to the light and swift Liburnian boats. The country was incorporated by the Romans in the province of Dalmatia.

LIBYA was a geogr phical name by which the Greeks usually designated Africa, with the exception of Egypt, although sometimes the continent was thought to be divided between Libya and Ethiopia. Libya enters into the sphere of ancient history only in so far as it came into contact with the civilized races of antiquity, and the present article will touch this point only; the natural features and the ethnology will be found under other headings (see AFRICA). The native tribes came several times into collision with the kings of ancient Egypt. In the reign of Rameses the Great and his successor they invaded the Delta, and various expeditions were made by the Pharaohs into the outlying country, on the south particularly (see EGYPT). Herodotus mentions one important expedition sent out by Pharaoh Necho (610–594 B.C.), which started from the Red Sea, circumnavigated the continent, and reached the mouth of the Nile after three years' absence. The truth of the tale has often been doubted, but one circumstance in which Herodotus himself expresses his disbelief, viz., that as they sailed west they had the sun on their right hand, has in modern times been generally accepted as proving that the voyage was actually made.

The Phœnician colonies on the north coast, Utica, Carthage, &c., beginning between 1000 and 800 B.C., established a powerful and civilized empire in a hitherto unknown part of Libya. Their trading expeditions gave them a wide acquaintance with the geography of the country, even with the Atlantic coast as far almost as the equator; but the contempt with which the Roman conquerors treated the literature of the Carthaginians allowed much valuable material to disappear. The historian Sallust, when prætor of Numidia, was still able to use the Punic records which he got interpreters to translate for him (Sall., *Jug.*, 17); and fortunately one record of an exploring voyage along the west coast, preserved in a temple in Carthage, was translated by some Greek traveller and is still available (see HANNO). For all that is known of the Carthaginian rule in Libya see CARTHAGE.

Greek mariners must have visited Libya at a very early period, for the edible lotus of the northern coast is mentioned in the *Odyssey*.

In the latter part of the 7th century B.C. the Greeks began to colonize the north coast. Between the Carthaginian territory and the borders of Egypt they planted a number of cities, and the Pentapolis of which Cyrene was the chief was among the richest and most flourishing of all the Greek states (see CYRENE). When the Persians invaded Egypt they made some attempt to extend their empire over Libya; but the expedition of Cambyses (about 525 B.C.) was too unfortunate to encourage them to further efforts. The camel was introduced into Egypt under the Persian rule, and from this time it became easier to make long journeys over the Libyan deserts. Herodotus shows much knowledge of the Sahara, and it is clear that his account must be founded on the reports of traders and caravan guides well acquainted with the desert route. Under the Macedonian kings knowledge of Libya was much extended; they sent exploring expeditions for scientific purposes into Abyssinia, while growing wealth and luxury caused a continually increasing demand for the ivory, spices, and other produce of Libya. In the period 500–200 B.C. it seems certain that commerce was maintained with the countries beyond the Sahara in at least two ways—by the Carthaginian ships trading along the Atlantic coast, and by the overland route across the desert to the Nile. The Roman conquest of Carthage closed the former route. Polybius indeed was commissioned by Scipio to explore the country, and sailed a long way down the west coast; but the Romans themselves had not the maritime enterprise required for such voyages. The record which Polybius wrote for his friend Scipio is quoted by Pliny and Stephanus. Sallust also collected information about the country, and under the emperor Nero an exploring expedition was sent into Abyssinia. The Romans added more to the knowledge of Libya in other ways,—by a better organization of the province and increased facilities of travel and trade, by the frontier wars against surrounding tribes, and finally by the expeditions sent directly into the heart of the country to procure wild animals for the amphitheatre. The passion of the Roman populace for seeing strange animals slaughtered in the public games was gratified by the emperors and magistrates. Enormous numbers of Libyan wild beasts were exhibited in the amphitheatre; even hippopotami and alligators are mentioned. One Roman officer, Maternus, penetrated at least as far as Lake Chad. The *Periplus* of Arrian preserves a record of the trade along the east coast of Libya in the 1st century. In these ways a fairly accurate knowledge of northern Libya was obtained, and Ptolemy could, in the 2d century, construct a good map of Africa as far south as 11° N., though his idea of the shape of the continent further to the south is less accurate than that of Herodotus.

See Ritter, *Erdkunde*, i.; Heeren, *Historical Researches*, or in the German *Ideen*, vol. ii.; and the geographical works of Forbiger, Kiepert, Bunbury, &c.

LICATA. See ALICATA, vol. i. p. 574.

LICHENS (*Lichenes*) may briefly be defined as cellular perennial plants, furnished with a vegetative system containing gonidia, and with a reproductive system consisting of female thecasporous fruits and male spermogonous organs. They constitute a distinct class of cellular cryptogams, intermediate between algæ and fungi, to both of which in some respects they present certain affinities. By the earlier authors they were regarded as being *Aerophycæ* or terrestrial algæ, while of recent years they have been viewed by some writers as being *Ascomycetous* fungi. From both of these, however, they are sufficiently distinguished and separated by the special structure of their thallus, by the presence of certain immediate principles proper to their tissues, and by their mode of life and nutrition. Their relations to these neighbouring classes, and their true systematic place, will be best elucidated on considering their structure and its bearings upon some recent speculations.

Structure of Lichens.

A complete lichen consists of a nutritive and vegetative system termed the thallus, and of reproductive bodies borne upon it in the form of *apothecia* and *spermogones*. Occasionally, however, there is no thallus present (*e.g.*, *Sphinctrina*, various *Lecideæ*, *Endococcus*), in which case the fructification is parasitical on the thalli of other lichens.

I. *Vegetative System.*—The thallus is very variable in external form and colour, as also in internal structure.

1. In external form it presents the following modifications. (*a*) The *foliaceous* thallus, which may be either peltate, *i.e.*, rounded and entire, as in *Umbilicaria*, &c., or variously lobed and laciniated, as in *Sticta*, *Parmelia*, &c. This is the highest type of its development, and is sometimes very considerably expanded. (*b*) The *fruticulose* thallus, which sometimes is filamentose, as in *Ephebe*, and may be either erect, becoming pendulous, as in *Usnea*, *Ramalina*, &c., or prostrate, as in *Alectoria jubata*, var. *chalybeiformis*. It is usually divided into branches and branchlets, bearing some resemblance to a miniature shrub amongst the *Phanerogamia*. An erect cylindrical thallus terminated by the fruit is termed a *podetium*, as in *Cladonia*. (*c*) The *crustaceous* thallus, which is the most common of all, forms a mere crust on the substratum, varying in thickness, and may be squamose (in *Squamaria*), radiate (in *Placodium*), areolate, granulose, or pulverulent (in various *Lecanoræ* and *Lecideæ*). In its pulverulent state it is either the rudimentary or the abortive condition of many species. (*d*) The *hypophlœodal* thallus is often concealed beneath the bark of trees (as in some *Verrucariæ* and *Arthoniæ*), or enters into the fibres of wood (as in *Xylographa* and *Agyrium*), being indicated externally only by a very thin film or macula. To this may also be referred the evanescent thallus which is denoted solely by gonidia sparingly scattered on the stone or wood (as in some *Caliciei* and *Lecideæ*). This is the simplest form under which lichenose vegetation occurs. These two latter forms of thalli may be either *determinate*, *i.e.*, of a definite shape with a distinct margin or boundary, or *effuse*, *i.e.*, spreading extensively over the substratum with no visible limits. The differences in these forms are no doubt connected with differences in the chemical composition of the thallus. In colour also the thallus externally is very variable. In the dry and more typical state it is most frequently white or whitish, and almost as often greyish or greyish glaucous. Less commonly it is of different shades of brown, red, yellow, and black. These various colours do not originate from any colouring matters contained in the cells themselves, but, according to investigations made by Nylander (see *Flora*, 1879, p. 558) they depend upon such as are deposited in the granulations and cellular walls, whence they appear on the epithallus. In the moist state of the thallus these colours are much less apparent, as the textures then become more or less translucent, and the epithallus usually presents the greenish colour of the gonidia (*e.g.*, *Parmelia Borreri*, *Peltidea aphthosa*, *Umbilicaria pustulata*, and pulverulent *Lecideæ*).

2. The internal structure of the thallus presents two principal modifications, viz., the *stratified* thallus, having its different elements (hyphæ and gonidia) arranged in layers, and the *unstratified* thallus, in which these different elements are confused in a homogeneous tissue.

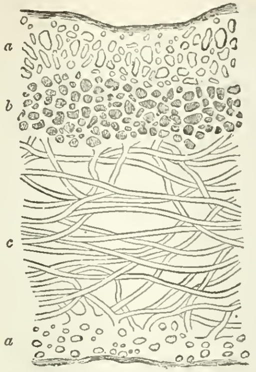

Fig. 1.—Section of Stratified Thallus of *Ricasolia herbacea*. *a*, cortical stratum; *b*, gonidial stratum; *c*, medullary stratum.

A. *The stratified thallus.*—On making a vertical section this is seen in a foliaceous lichen to consist of three layers constituting a *cortical*, a *gonidial*, and a *medullary* system, to which in the case of many crustaceous lichens is to be added a fourth, viz., a *hypothalline* stratum.

(*a*) The *cortical* stratum occupies the whole of the external surface of filamentose and fruticulose lichens, both the upper and under surfaces of some foliaceous and squamulose species, while it is found only on the upper surface of crustaceous lichens. It usually consists of a colourless cellular tissue, in which the cellules are closely compacted and form a pseudo-parenchyma. Its most superficial portion, termed by Nylander the *epithallus*, a sort of cuticle, is amorphous, often more indurated and coloured. In some lichens (*e.g.*, *Collema*) it is the only portion of the cortex present, while in pulverulent crustaceous thalli it is entirely wanting. (*b*) The *gonidial* stratum is situated immediately beneath the cortical stratum, and consists usually of greenish spherical cellules, or of granules destitute of a cellular membrane. It is not always continuous, but is often interrupted, the gonidia occurring in dissociated masses. Sometimes it is situated on the upper part of the medullary stratum, in which case the gonidia are arranged either between or amongst its exterior elements. In general its limits may readily be distinguished from the others by its peculiar colour. Various important matters relating to the gonidia will more appropriately be afterwards discussed at length. (*c*) The *medullary* stratum is more variable in its constituent elements, but, being always colourless, is easily recognized. It presents the three following principal modifications. (α) The *woolly* medulla consists of simple or branched filaments, which in foliaceous species are loosely intersected and entangled, and in fruticulose species are more or less conglutinated, assuming a longitudinal direction, and constituting, as in *Usnea*, a kind of solid axis for the support of the thallus. (β) The *cretaceous* medulla occurs only in crustaceous lichens, and is generally characterized by its tartareous appearance. It is more compact than the preceding, and consists for the most part of molecular granulations often intermixed with octahedral crystals of lime, and presenting but few traces of filamentose elements. (γ) The *cellulose* medulla consists of a tissue of angular, rounded, or oblong cellules containing gonidia in their interior or in their interstices (*e.g.*, *Pannaria*, *Endocarpon*). In some species (*e.g.*, *Verrucaria fuscula*) the cellules have a tendency to reunite into filaments and then to separate again into rows of cellules. (*d*) The *hypothalline* stratum is the inferior one of the thallus and that upon which the other strata are developed, though it is not always visible, and is sometimes entirely wanting. It usually presents itself under a twofold aspect, viz., the *hypothallus* and *rhizinæ*. (α) The *hypothallus* proper, which is immediately developed upon the prothallus (*i.e.*, the filaments of the germinating spore), is a horizontal stratum consisting of interlacing filaments or of elongated, short, or rounded cellules, and is sometimes of a white or whitish colour, but usually dark or blackish. In many crustaceous lichens it is represented only by a black or dark-coloured border limiting the thallus (*e.g. Lecidea geographica*, &c.). (β) The *rhizinæ* consist of vertical rhizoid fibrillæ, usually branching and tufted at their extremities, blackish or greyish in colour, rarely white, which occur on the lower surface of foliaceous lichens. They consist of several filamentose elements which are most frequently articulated and agglutinated (*e.g.*, *Parmelia*, *Physcia*), or sometimes simple and then always articulated (*e.g.*, *Sticta*). It is to be observed that the hypothallus and the rhizinæ serve merely as bases of attachment for the lichens to the substratum, and do not in any way aid in its nutrition.

B. *The unstratified thallus.*—This occurs amongst the *Lichenacei* (which, however, are most frequently stratified as above), and in various species belonging to the inferior genera, which have a pulverulent or hypophlœodal thallus. In these the constituent elements are more or less mixed together, though the gonidial stratum generally remains distinct, and is often visible when the others are absent. It is, however, the families of the *Byssacei* and *Collemacei* that are more especially characterized by an unstratified thallus. Here the cortical stratum is chiefly represented by a greenish (in *Collema*), rarely brown (in *Synalissa*, &c.), non-cellular epithallus, or in others (*Leptogium*) by a thin stratum of angulose cellules distinct from the other elements of the thallus. The gonidial granules are also disposed in a different manner to those of the *Lichenacei*. In the majority of the *Collemacei* they are strung together moniliformly, and distributed without order in a gelatinous pellucid substance; while sometimes they are agglomerated into small groups, and situated for the most part next to the epithallus. In *Ephebacei* they are not moniliformly arranged, but are tunicated or involved in a gelatinous cellulose stratum. The rest of the thallus consists of the medullary system (except in *Ephebacei*, in which there is no medulla), and is composed of tubular or hollow filaments, with roundish cavities containing the gonidial granules, and imbedded in the gelatinous substance, which very readily imbibes water. There are a few lichens in which there is no trace whatever of stratification, as the genus *Cænogonium*, in which the entire thallus is composed of filamentose membranous elements, and the peculiar family of the *Myriangiacei* (doubtfully, however, referable to lichens), in which it is equally cellulose throughout.

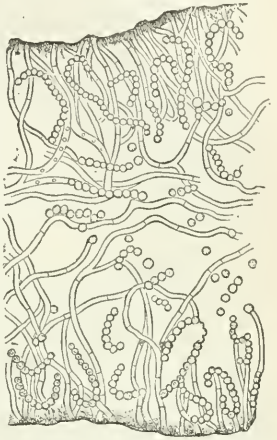

Fig. 2.—Section of Unstratified Thallus of *Collema conglomeratum*, with Moniliform Gonimia scattered amongst the Hyphal Filaments.

In addition to the hyphal and gonidial anatomical elements which thus enter into the structure of the thallus, there is another to be noticed, which, however, is to be regarded rather as an immediate principle. This is the *molecular granulations*, which are extremely small and (in form) irregular corpuscles, 0·001–0·002 millim. in diameter, and visible only when very highly magnified (300–400 diameters). They occur in all parts of the thallus, especially in the younger cellules, from the epithallus to the hypothallus, being especially abundant in the medulla of crustaceous species. In the epithallus they are variously coloured according to the colours which it presents, but in all other parts they are colourless. They occur also in the apothecia, in the epithecium, the thecæ, and the spores, and constitute the famous "microgonidia" of Dr Minks. By the application of sulphuric acid many of them are transformed into small acicular crystals, and in the spores they are frequently agitated by a Brownian movement.

We may here also, in connexion with the vegetative system of lichens, refer to certain peculiar *excrescences* which are sometimes presented by the upper or under surface of the thallus. Of these the principal are the following. (1) *Soredia* are pulverulent eruptions on the cortical stratum, varying in form, being rounded or diffuse, and either are scattered upon the upper surface of the thallus or border its margins. They are of a lighter colour than the thallus, and consist of a mass of gonidia and of molecular granulations intermingled with filamentose elements. They occur in many fruticulose, foliaceous, and crustaceous lichens, and their protrusion through the cortical stratum is owing most probably to an excessive development of the gonidial element. Occasionally also they appear on the disk of apothecia (in *Pertusaria*), which they render abortive, and in this case constitute the pseudo-genus *Variolaria* of elder authors. When detached from the thallus they are capable under certain favourable circumstances of giving rise to new plants, and thus act the part of bulbils in the *Phanerogamia*. It is no doubt by their means that many species which are never found in a fertile state (*e.g.*, *Thamnolia vermicularis*) are propagated. (2) *Cyphellæ* are small, urceolate, pale excavations which occur abundantly on the under surface of many species of *Sticta*. They are generally naked, but are often also pulverulent or sorediiferous in which latter case they are called *pseudo-cyphellæ*. Their physiological function is not definitely known, but they are most likely connected with the nutrition of the plants. (3) *Isidia* constitute an exuberant condition of some foliaceous and crustaceous thalli. They consist of elevated, coralloid, stipitate excrescences, which are sometimes branched, and which are always of the same colour and texture as the thallus itself. This isidioid condition in crustaceous thalli is the basis of the old pseudo-genus *Isidium*, which is merely an anomalous state of some species of *Pertusaria*. Isidia have the same functions as the soredia, and serve as propagula. (4) *Cephalodia* are orbicular and flattened or globular tubercles of a peculiar texture which occur on the thallus of many species belonging to different genera. They are usually epigenous, as in *Stereocaulon*, *Usnea*, *Lecanora gelida*, *Lecidea panæola*, &c. In a few species, however, they are hypogenous, as in *Peltidea venosa* and *Psoroma euphyllum*, while in various *Sticlei*, *Nephroma expallidum*, &c., they are endogenous, forming pyrenoid protuberances on the lower surface. Recently Nylander has detected both epigenous and hypogenous cephalodia on *Psoroma arenarium* and *Lecanora allorhiza*. They are of a paler colour than the rest of the thallus, from which they differ also in structure, being confusedly cellulose, and containing gonidial granules. According to Th. M. Fries (in *Flora*, 1866, p. 19) they are only morbid excrescences caused by algals intruding themselves under the cortex; but this is at once refuted by the fact of their forming constant characters of so many different species occurring in various situations. In these they evidently constitute normal organs, the use of which, however, is unknown.

II. *Reproductive System.*—This consists of *apothecia* or the female organs, of *spermogones* or the presumed male organs, and probably also of *pycnides* or a secondary kind of fructification.

1. The apothecia, like the thallus, are very variable in external form and colour, as also in their internal structure. In external form they present three principal modifications, viz., (1) *disciform* (or gymnocarpous), in which the shape is that of a disc (as in all the higher genera); (2) *nucleiform* (or angiocarpous), in which the shape is that of a rounded tubercle with an apical ostiole (as in *Endocarpon*, *Verrucaria*); and (3) *peridiiform*, similar in shape to the preceding, but closed, with no ostiole (as in *Thelocarpon*, *Endococcus*). The last two are but little variable in figure, and consequently do not in this respect admit of different designations. The disciform apothecia, however, present various shapes, of which the following are the principal:—(*a*) *peltate*, which are large, rounded, without any distinct thalline margin (*e.g.*, *Usnea*, *Peltigera*); (*b*) *lecanorine*, or scutelliform, which are orbicular and surrounded by a distinct, more or less prominent thalline margin (*e.g.*, *Parmelia*, *Lecanora*), having sometimes also in addition a proper one (*e.g.*, *Thelotrema*, *Urceolaria*); (*c*) *lecideine*, or patelliform, which are typically orbicular, with only a proper margin (*e.g.*, *Lecidea*), sometimes obsolete, and which are occasionally irregular in shape, angular or flexuose (*e.g.*, *Lecidea jurana*, *L. myrmecina*), or complicated and gyrose (*e.g.*, *Gyrophora*), and even stipitate (*e.g.*, *Bæomyces*); (*d*) *lirelliform*, which are of very irregular figure, elongated, branched or flexuose, with only a proper margin (*e.g.*, *Xylographa*, *Graphis*, &c.) or none (*e.g.*, some *Arthoniæ*), and are often very variable even in the same species. It may be here observed that young disciform apothecia are more or less nucleiform. In colour the apothecia are extremely variable, and it is but rarely that they are concolorous or subconcolorous with the thallus (*e.g.*, *Usnea*, *Ramalina*). Usually they are discolorous, and may be black, brown, yellowish, or also less frequently rose-coloured, rusty-red, orange-reddish, saffron, or of various intermediate shades. Occasionally in the same species their colour is very variable (*e.g.*, *Lecanora metaboloides*, *Lecidea decolorans*), while sometimes they are white or glaucous, rarely greenish, pruinose. Lecideine apothecia, which are not black, but otherwise variously coloured, are termed *biatorine*.

The two principal parts of which an apothecium consists are the *hypothecium* and the *thecium*.

(1) The hypothecium, which corresponds to the hypothallus, is the conceptacle of the apothecia. It is composed of cellular tissue, generally very dense, and often presenting an indistinct stratification. This tissue may in general be distinguished from that of the neighbouring parts of the thallus by its cellules being smaller, more compact, and differently coloured, though in some instances (as in certain *Pannariæ*) the limits are not determinable. In the apothecia of such genera as *Calicium*, *Bæomyces*, &c., the hypothecium is composed of hollow cemented filaments arranged longitudinally and constricted into a stipe for the support of the fruit. The hypothecium in disciform apothecia is usually termed the *excipulum* proper, while in nucleiform apothecia it is termed the *pyrenium*, and in peridiiform apothecia the *peridium*. When the pyrenium quite covers the nucleus it is said to be *entire*, *dimidiate* when it covers only the upper portion. The hypothecium is either colourless or dark, or reddish or yellowish, according as its cellules are tinged.

(2) The thecium, or as it is more frequently termed the *hymenium*, is that part of the apothecium which contains the organs of the fruit, viz., the *thalamium* and the *thecæ*, which are placed perpendicularly to the hypothecium. It is penetrated by an amyloid substance, colourless and very greedy of water, termed the *hymenial gelatine*, formed of the licheuine, which becomes bluish or wine-reddish when tinged with iodine. The thecium itself corresponds to the gonidial-medullary stratum, while its superficial portion, termed the *epithecium*, corresponds to the epithallus. (*a*) The thalamium generally consists of paraphyses which are erect colourless filaments arising from the hypothecium, and whose function is to aid in the expulsion of the spores by the pressure which they exercise upon the thecæ. They are of nearly equal height, closely placed together, usually very slender, though slightly variable in thickness, frequently articulated, and rarely branched or anastomosing. Internally they are hollow and filled with protoplasm, which sometimes is separated into little globules. Their apices are generally coloured, in most instances dilated, sometimes clavate, and are cemented together by gelatin. They are frequently confused together; occasionally they are but little evolute; while in many of the *Pyrenocarpei* they are entirely wanting, though in these the ostiolar filaments of the hypothecium have sometimes been mistaken for them. (*b*) The thecæ are large, oblong, cylindrical or ovoid cellules or vesicles containing the spores, and are usually more or less attenuated towards the base. In size and shape they vary considerably in the different genera and species according to the size, number, form, and arrangement of their spores. They differ also in the same species, within certain limits, according to age, the young theca being more slender than those which are older. In some genera which have very large spores (*e.g.*, *Variolaria*, *Pertusaria*) the thecæ are distended in proportion, and generally present a saccate or oblongo-ventricose form. The theca itself is a thin membranous cellule, the walls of which are at first of an equal thickness throughout, but in process of development they become gradually thinner, except at the summit, where they retain their original thickness. In some species the wall is remarkably thick at the apex (*e.g.*, *Arthonia*), and in others it is invested throughout with a kind of external cuticle (*e.g.*, *Pertusaria*). The thecæ are resorbed after the expulsion of the spores; though where their walls are extremely thin (as in *Calicium*) they are ruptured and disappear at a very early stage. The *spores* are the special reproductive organs of lichens, and are produced in the thecæ by free cell-formation, *i.e.*, by the separation and subsequent condensation of the protoplasm of the fully developed theca around certain points in its interior, corresponding in number to that of the spores to be formed. After the formation of the external spore-wall has taken place, the spores have a definite outline, and may consist of only one cellule or loculus (*simple* spores), or may be divided by one or more transverse partitional membranes (*septate* spores). Sometimes the loculi are restricted to the two ends or poles of the spore (one in each) and are said to be *polari-bilocular*, the two loculi being occasionally united by a longitudinal tube. At other times the transverse partitions are further divided by several longitudinal partitions, in which case the spore is said to be *murali-divided*, from the resemblance it then bears to the stones in a wall. The contents of the spores are

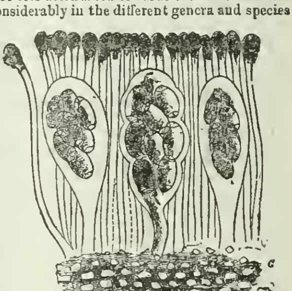

Fig. 3.—Vertical Section of Apothecium of *Physcia parietina*. *a*, paraphyses; *b*, thecæ with bilocular spores; *c*, hypothecium.

a homogeneous protoplasm, molecular granulations (often abundant), and a pale-yellow oily substance, which in the fully developed spore often becomes condensated into one or more globules, visible generally near its ends or in the middle. The number of the spores in each theca varies very much in different species, being in most lichens 8, occasionally 6, 4 or 2, or rarely only 1. In some species, however, they are 20–100, when the thecæ are said to be *polyspored*. In form they are also very variable, the principal shapes assumed by them in order of frequency being *ellipsoid*, *fusiform*, *oblongo-cylindrical*, *sphæroid*, and *acicular*, with several intermediate forms. They are still more variable as to size, being smallest in polyspored (*e.g.*, *Lecanora fuscata*, &c.), and largest in monospored species (*e.g.*, *Pertusaria communis*, &c.). The largest spores of all are found in *Varicellaria amicrosticta*, where they are 0·225–0·030 millimetre long, and 0·095–0·115 millim. thick. As to colour, they are either *colourless* (white, nearly hyaline or pale yellow under the microscope), or *coloured* (brownish, or brown, or blackish), while in *Sphærophoron* there is also a bluish-black superficial pigment. The spore-wall varies in thickness, and is typically composed of two strata, the outer of which is termed the *epispore* and is coloured, while the inner is termed the *endospore* and is colourless, gelatinous, and generally less distinct. Notwithstanding that in these respects the spores are so variable in different species, they are when mature remarkably constant in the same species, so that their characters afford valuable specific diagnoses. Apparently it is only those lichens which germinate from spores that occur in a fertile condition.

2. The spermogones, which are the presumed male organs of reproduction, at once differ in appearance from the apothecia in being very minute corpuscles. In many cases their outline is invisible to the naked eye, unless the thallus has been previously moistened, when they appear as minute points or papillæ. When magnified they externally bear a resemblance to the apothecia of the *Pyrenocarpei*, but internally, on microscopical examination, they are seen to differ essentially from these. In form they are nucleiform, round, or oblong, and are either sessile on the surface of the thallus, or more or less immersed in its substance, or sometimes enclosed in prominent thalline verrucæ. Usually they are simple, though occasionally two or several become confluent or aggregated into little groups. They almost always occur on the same thallus as the apothecia, or rarely on different thalli (*e.g.*, *Ephebe pubescens*), so that lichens are consequently monœcious and diœcious. In colour the spermogones are black or brown, or concolorous with the thallus itself. They are composed of two parts, viz., a shell or *conceptacle* and a *nucleus*.

(1) The conceptacle, which is analogous to the hypothecium of the apothecium, is composed of a tissue formed of very small cellules, which are cemented together and have thick walls. The *ostiole* at its summit is generally similar to that of nucleiform apothecia, and in the case of entirely immersed spermogones is the only portion visible.

(2) The nucleus consists of the *sterigmata* and *spermatia*, and of a mucilaginous substance (the spermatic gelatin) in the cavity between them, which very greedily imbibes water and aids in the expulsion of the spermatia. Sometimes also there are present in the nucleus a few elongated, articulated, and occasionally branching filaments intermixed with the sterigmata which are comparable with the paraphyses of the apothecia (*e.g.*, *Ramalina*). (*a*) The sterigmata are elongated cellules filled with a colourless fluid, and are attached to the interior face of the conceptacle growing from it convergently towards the centre, and often nearly filling its entire cavity. They present two important modifications, viz., *simple* sterigmata and *articulated* sterigmata or *arthrosterigmata*, both of which may become somewhat branched. When arrived at maturity they possess the faculty of producing from their apices or also from the articuli the spermatia, one at a time, though many in succession, as may be inferred from the immense number of them lying in the cavity of the nucleus. (*b*) The spermatia are very small, slender, colourless corpuscles, which at first appear as minute protrusions on the apices of the sterigmatic cells. They subsequently become gradually elongated, and, on reaching maturity, detach themselves from the sterigmata and lie free in the cavity of the nucleus, till in wet weather they are expelled through the ostiole of the spermogones. In form they present two principal modifications, viz., *acicular* and *ellipsoid*, of which the former, the more frequent, is rather variable. They may be slightly fusiformi-incrassate at one apex (*e.g.*, *Usnea*), or at both apices (*e.g.*, *Parmelia*), or they may be cylindrical and straight, the most common shape, or cylindrical and arcuate (*e.g.*, *Roccella*). The spermatia of arthrosterigmata are cylindrical and straight, but slightly thickened and obtuse at the apices. In size they also vary, though more in length than in thickness, the arcuate spermatia being sometimes very long (0·040 millimetre). These differences in form and size are often very useful in the discrimination of species, just as the two types of the sterigmata are sometimes of great service in the distinction of genera. The spermatia frequently exhibit a Brownian movement, but they possess no faculty of germination, their functions, as generally acknowledged, being the fertilization or fecundation of the spores. That the spermogones are rightly presumed to be the male organs of reproduction may legitimately be inferred alike from their relation to and their antagonism with the apothecia. In the former respect their position on the thallus relatively to the apothecia is similar to that of the sexual organs in other classes of plants; while in the latter respect spermogones are plentiful on thalli destitute of apothecia, and on those with apothecia are much more sparingly present. The manner, however, in which the spermatia impregnate the spores has not yet been definitely ascertained. Most probably, as suggested by Nylander (in *Syn.*, p. 40, note 1), the spermatia do not exercise any direct influence on the female organ in the hymenium, but their fecundating influence is rather exercised on the prothalline elements of the growing thallus. M. Stahl indeed has recorded and illustrated (*Beitr. zur Entwick. der Flechten*, 1877) the result of certain researches on *Collema microphyllum*, in which he supposed that he had detected sexual organs in the shape of an *ascogonium* and a *trichogyne*, regarded by him as a kind of *carpogonium*. These observations, however, have not been confirmed by subsequent researches on the same or any other species of *Collema*, while his attributing to the hyphæ a faculty of "contortion" or spirally coiling themselves, which from their nature they do not and cannot possess, is calculated to invalidate all that he otherwise observed and depicted.

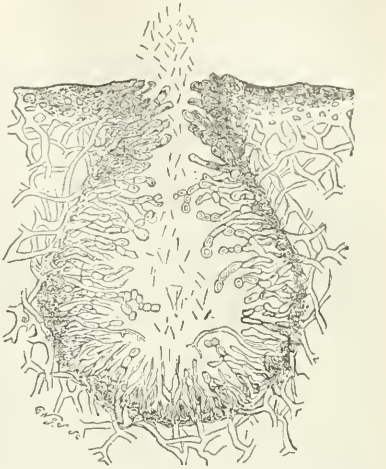

FIG. 4.—Vertical Section of a Spermogone of *Parmelia physodes* showing the Sterigmata and Spermatia

3. The pycnides are minute, dark-coloured pyrenodean conceptacles which occur on the thalli of various lichens, especially such as are crustaceous. In external appearance they resemble to some extent the spermogones, from which, however, they at once differ in their internal organization. They consist of simple filaments composed of narrow (often short) cellules, termed *basidia*, bearing on their apices bodies called *stylospores*, which are colourless, usually oblong, but variable in form and size, and filled with organic matter (in part at least oily) similar to the spores. Each basidium produces only a single stylospore, which, unlike the spermatia, has a germinative property. Their occurrence in lichens was first pointed out by Tulasne, who showed their affinity to certain analogous fruits (*Diplodia*, *Phoma*, *Septoria*, &c.) in various thecaspored fungi, and regarded them as supplementary or secondary sporiferous reproductive organs. Considering the number of parasitic *fungilli*

which frequently occur on lichens, it might be supposed that the pycnides in reality belonged to the same category. From their constant occurrence, however, on the same species, and the evident correlation between them and the accompanying fructifications, as also from the resemblance of their stylospores to the spores of the apothecia, there are good grounds for adopting the conclusion come to by Tulasne. They are very common on the margin of the thallus of isidiiferous states of *Peltigera canina* and *P. rufescens*, where they have often been mistaken for sperm gones, which in this genus have not yet been detected. Pycnides occur also in *Lecidea vermifera*, and abundantly in *L. tantilla*, in *Habrothallus*, in several species of *Strigula*, in *Spilonema revertens*, and will probably be yet observed in other lichens.

The Gonidia of Lichens.

In view of the important place occupied by the gonidia in the structure of lichens, and of the discussions that have recently taken place concerning them, they require to be considered somewhat in detail in order that their real nature and relation to the hyphæ, or the thalline filaments, may become apparent. The gonidia are spherical, ellipsoid, or variously rounded cellules, with thin, colourless walls composed of cellulose, containing chlorophyll (or a subsimilar colouring matter), homogeneous or granulose, with generally a solid nucleus in the centre. As to the origin of the chlorophyll, it may be observed in passing that this is the same in lichens as in other cryptogamic plants, *e.g.*, mosses and *Hepaticæ*, in which it occurs, the only visible difference being that gonidia often occur as discrete cellules. The gonidia increase by binary (very rarely by ternary or quarternary) division, the nucleus also dividing into two portions, each of which forms the centre of a secondary gonidial cellule. In the gonidial stratum, where they are arranged between the radicles of the hyphæ, their division necessarily proceeds only slowly, but in ecorticated thalli, leprose and others, in which they are free, they are readily multiplied by repeated division. In gonidia isolated from the thallus of some species belonging to *Cladonia*, *Evernia*, and *Physcia*, zoospores have been detected by M. Famintzin and M. Boranetzky (see *Ann. Sc. Nat.*, 1868, p. 137), and, although Nylander failed to perceive such in subsequent experiments (*Flora*, 1877, No. 23), he adds that it is possible they may be generated in free gonidia (*i.e.*, in unstratified thalli), which could not be the case in gonidia closely surrounded by thalline filaments. The subject will well repay further investigation. Other matters relating to the character and relations of the gonidia will be best elucidated by considering the forms which they present, and their origin in the thallus.

I. *The Forms of the Gonidia.*—These have been fully treated by Nylander in the *Flora*, *loc. cit.*, where also the first scientific exposition and classification of them have been given. According to the views there propounded, gonidia in their wider acceptation include three very distinct types :—(1) *Eugonidia* (or gonidia proper), which are involved in a distinct cellular membrane, and are usually bright green ; (2) *Gonimia* (or the gonidial granules already mentioned), which are naked, pale greenish, glaucous greenish or bluish ; and (3) *Gonidimia* (or *Leptogonidia*), which are intermediate between the two preceding, smaller, and of an oblong form. Of these the distinction between eugonidia and gonimia is fundamental, and of "so great weight that lichens seem to present a twofold parallel series" according to the presence of the one or the other in their texture. These two different anatomical elements, as observed by Nylander, have a certain biological analogy with the blood globules in animals, and similarly afford absolute characters. The principal forms presented by these three kinds of gonidia are the following. 1. Eugonidia consist of—(*a*) *Haplogonidia*, the most frequent, simple, of a protococcoid form, or sometimes glomerulose (as in granuloso-leprose thalli) ; (*b*) *Platygonidia*, being depressed and variously membranosely connated gonidia (*Syngonidia*), as in some foliicolous species (*e.g.*, *Platygramma phyllosema*) ; (*c*) *Chroolepogonidia* (or *Chrysogonidia*), containing chlorophyll and orange grains (endochrome) in the same cellule, more or less similar to *Chroolepa* (as in *Gyalecta chlorobæa*, *Arthonia pruinosa*, *Platygrapha periclea*, *Verrucaria insiliens*, and the genus *Thelopsis*) ; (*d*) *Confervogonidia*, somewhat resembling *Confervæ*, and forming the chief element of the thallus of *Cœnogonium*. 2. Gonidimia are smaller than gonidia proper, with the wall of the cellules less distinct. They occur in *Peltidea*, *Solorina*, and *Nephroma expallidum*. To these belong also *hymenial gonidia*, which are often very minute, and are present in the thalamium (destitute of paraphyses) of various *Pyrenocarpei* (*e.g.*, *Verrucaria pallida*, *V. umbrina*, and *V. hymenogonia*), rarely of *Arthoniæ* as in *A. chroolepida*. 3. Gonimia (including the gonimia of *Cephalodia*) consist of—(*a*) *Haplogonimia*, which are somewhat large (very large in *Phylliscum*), and either simple, or two or several aggregated ; (*b*) *Sirogonimia*, which are scytonemoid or sirosiphoid gonimia, distinguished by the gonimia being tunicated, and are characteristic of the family *Ephebacei* ; (*c*) *Hormogonimia*, the most common form, smaller, moniliformly arranged, and contained in syngonimia, especially characteristic of the family *Collemacei*, whence *Collema* (or *Nostoc*) itself, according to Nylander, is to be considered but as a single syngonimium ; (*d*) *Speirogonimia*, which are similar to the preceding, but are not moniliform, with the syngonimia subglobose, smaller and more scattered, as in *Omphalaria* and *Synalissa*. It will be perceived from the above that many of these forms are more or less similar to "gonidioid" algæ, though, as we shall presently see, they are not identical with these.

II. *The Origin of the Gonidia.*—By pre-microscopic authors this was a subject necessarily ignored, and indeed it is only within the last thirty years that it has been investigated by lichenists. The earliest theory as to their origin was that propounded by Bayrhoffer (*Einiges üb. d. Lichenen und deren Befruchtung*, 1851), confirmed by observations of Speerschneider (*Bot. Zeit.*, 1853, &c.), and supported by Schwendener (*Untersuch. üb. d. Flechtenthallus*, 1868). This was to the effect that the gonidia derived their origin from the hyphæ (*i.e.*, the thalline filaments), in the way succinctly detailed by M. Fries (in *Scand.*, 1871, p. 7, where it is fully endorsed). "The hyphæ," he says, "are not only elongated into filaments, but also put forth short branchlets, the terminal cell of which is gradually dilated, becomes subglobose, and is at length filled with chlorophyll (or a subsimilar matter) ; in a few that (terminal cell) is changed into a gonidium, and then by varied division germinates other gonidia." For several years this theory was accepted at second-hand by most authors who referred to the subject, though a different origin of the gonidia, presently to be noticed, was indicated by the celebrated Tulasne so early as 1852, in his "Mémoire sur les lichens" (*Ann. Sc. Nat.*). The erroneous nature of this theory was well pointed out by Schwendener, who (*Die Algentypen d. Flechtengonidien*, 1869) very correctly affirmed that the actual development of a gonidium from the terminal cell of a hypha had not been observed, though, strange to say, he had previously himself observed this phenomenon. Not being able otherwise to account for the origin of the gonidia, and following up one of two alternatives put forward by De Bary (*Morpholog. und Physiolog. der Pilze, Flechten*, &c., 1865, p. 291), he promulgated the hypothesis now familiarly known as Schwendenerism. The conclusion to which De Bary came on noticing the resemblance between the gonidia of *Collemaceæ* and certain algæ was as follows :—"Either the lichens in question," he says, "are the perfectly developed states of plants, whose imperfect forms have hitherto stood amongst the algæ, as *Nostocaceæ* and *Chroococcaceæ*, or these latter are typical algæ which assume the forms of *Collema*, *Ephebe*, &c., through certain parasitic *Ascomycetes* penetrating into them, spreading their mycelium into the continuously growing thallus, and frequently attached to their phycochrome-bearing cells." Taking this latter suggestion as his starting point, and assuming the identity of certain algal types with the gonidia of lichens, and the identity of the mycelium of fungi with their hyphæ, Schwendener extends the said alternative to various other groups of lichens than the *Collemaceæ*, and comes to the conclusion that a lichen is composed of a parasitic fungus (the hyphæ) and a number of low algæ (*Chlorophyllaceæ* and *Phycochromaceæ*), the former of which produces the reproductive bodies and is nourished by the latter. This theory was subsequently expanded and illustrated at length by Bornet (*Recherches sur les Gonidies des Lichens*, 1873), who affirms, as the result of numerous investigations, "that the connexion of the hyphæ with the gonidia is of such a nature as to exclude all possibility of the one organ being produced by the other," and that the theory of parasitism can alone explain it satisfactorily. To give any detailed account of the investigations of these authors, and the arguments by which they endeavour to support the hypothesis, would exceed the limits of the present article, even were all other matters relating to lichens to be excluded. Suffice it to state briefly that, according to Schwendenerism, a lichen is not an individual plant, but rather a community made up of two different kinds of individuals belonging to two distinct classes of cryptogams, viz., a master-fungus and colonies of algal slaves, which it has sought out, caught hold of, and retains in perpetual captivity in order to provide it with nourishment. To such a singular theory, which from its plausibility has met with considerable support in certain quarters, various *a priori* objections of great validity may be taken. Amongst others which have been adduced two may especially be noticed, having reference to the nature of this alleged parasitism, and the situations in which lichens are found. (1) The parasitism described is of a kind unknown in the vegetable kingdom, inasmuch as the host (the *Algæ*), instead of suffering any injury, only flourishes the more vigorously. Moreover, the algal slaves being entirely enclosed in the master-fungus, can evidently supply no nourishment to it whatever, while direct observation shows that it is through the surface of the thallus of the lichen that nourishment is conveyed to the gonidial stratum, where the active life chiefly has its seat. (2) As is well known, lichens shun such habitats as are most frequented by algæ and fungi, and occur in situations where neither of these are seen. Where then are the algal colonies which, according to the hypothesis, the fungus goes forth in quest of, and "presses into its service"? Either of these arguments is sufficient to throw more than doubt upon Schwendenerism. At the same time, as will be perceived, the origin of the gonidia in the thallus remains to be accounted for, in order that the hypothesis may be utterly subverted. It might at first sight be supposed that this was a matter of no very great difficulty, since by cultivating lichens from the spores it would readily become apparent. All attempts, however, in this direction (and many such have recently been made) have, owing to the peculiar character and conditions of lichen-growth, confessedly proved futile, and the experiments instituted have been productive of no definite results. This is not altogether to be regretted, since in nature itself, when lichens occur on certain substrata, we have in various instances the whole process of the evolution of their vegetative system placed before our eyes, from the first germinations of the spores to the formation of the perfect thallus. It is to Nylander, whose services here as elsewhere in lichenological science—structural, physiological, and systematic—are so valuable, that we owe the first clear enunciation as to the origin of the gonidia in the lichen-thallus. This, though previously indicated by him, as we shall presently see, was at greater length and still more definitely stated in several important papers in the *Flora*, viz., "De gonidiis et eorum formis animadversiones" (1877, No. 23), "Circa lichenes vitricolas notula" (1879, No. 19), and "De hypothallo notula" (1879, No. 36). In these he incontrovertibly demonstrates that the gonidia originate, not from the filaments themselves, but in the cellules of the first cortical glomerules which are produced upon the young hypothallus. This may very easily be studied in the earlier stages of development of crustaceous lichens growing on pure quartz rocks (*e.g.*, *Lecidea geographica*), on the smooth bark of young trees (*e.g.*, *Lecanora subfusca*), and more especially on the surface of old glass (*e.g.*, *Lecanora galactina* and *Lecidea alboatra*). In the case of the young thalli of *Lecanora cinerea* this was sufficiently well delineated by the celebrated Tulasne in 1852, the year subsequent to the promulgation of the Bayrhofferian theory, in his elaborate "Mémoire sur les Lichens," pl. iii. f. 3. Afterwards, as the evolution of the cortical stratum advances, its lower portion is resorbed, and the gonidia there become free, giving rise to the gonidial stratum, to the hyphæ in which they are not *adnate*, as has been represented, but only adherent by means of the gelatin which penetrates all the elements of the lichen. Often also growing gonidia, young and adult, may be observed in the pseudo-parenchymatous cortical cellules in lichens which in this respect are best adapted for examination, such as *Umbilicaria* (*vide* Nylander in *Flora*, 1875, p. 303), *Physcia pulverulenta*, *Psoroma hypnorum*, &c. Similarly, with respect to the origin of the gonimia, Nylander observes (*Flora*, 1868, p. 353) that the isidia in the *Collemacei* (more especially in *Collema*) "show very clearly under the microscope the entire history of the evolution of the thallus from its first origin from a cellule containing a single gonimium to a minute true nostoc, and ultimately to the perfect texture of a *Collema*." With these facts before us, to which various others might be added, such as the entire absence of any algals on pure substrata, where lichen growth presents itself in all its stages, we are compelled to come to the conclusion that the gonidia constitute a true organic system in lichens, and in nature are nowhere seen outside the thallus. Consequently those free algal forms, such as *Protococcus*, &c., regarded as the free gonidia of lichens, are true algæ, there being indeed a parallelism between them but no identity. On the other hand, as to the alleged identity of the lichen-hypha with a fungus-mycelium, it is to be observed that the two are totally different in their nature. The hyphæ of lichens (*myelohyphæ* of Nylander) are rigid, elastic, containing lichenine, not becoming putrid by maceration, with no faculty of penetrating or involving, while the hyphæ of fungi are caducous, soft, flexile, with thin walls, &c. Hence, as there is no algal in the lichen, so neither is there any fungus, though there is a parallelism between the fructification of lichens and the asciferous section of fungi (Crombie in *Pop. Sc. Rev.*, 1874).

Fig. 6.—Hypothalline condition of *Lecanora cinerea*, showing the origin of the first Cortical Gonidiogenous Cellules. (After Tulasne.)

Nutrition and Life of Lichens.

As already intimated, lichens derive their nourishment directly from the atmosphere, in the shape of rain (or dew) with the materials contained in it. Here, as elsewhere, water is the condition of life, and through its medium is conveyed to them the nutrient substances requisite for their existence and growth, from the clouds, from rivers, and, in the case of maritime species, even from the sea. Where, however, the atmosphere is impregnated with smoke, soot, or other deleterious ingredients, lichens will not grow nor flourish. Hence in our larger cities, or even in smaller manufacturing towns, scarcely any lichen vegetation, or none whatever, is seen. Even in their more immediate suburban districts they occur only in a gonidial or rudimentary state, constituting the pseudo-genus *Lepraria* of the older botanists, and increasing through long periods by bisection, but never developing into perfect plants. Indeed it is now a well-known fact that their fully developed condition is a sure indication of the purity of the air and the salubrity of the districts in which they occur. It has sometimes been stated that they draw some portion at least of their nutriment from the substratum to which they are affixed. For this, however, their structure is by no means well adapted, and such inorganic substances as iron and lime, which enter into their composition, are only as if mechanically derived in solution from the substratum. This in very many instances, *e.g.*, bare quartzose rocks, dead sapless wood, and pure naked glass, can evidently supply no nutriment whatever. Moreover, in the case of crustaceous species, such as *Lecanora tartarea*, &c., and also of terricole fruticulose species, such as *Cetraria islandica*, &c., the portion of the thallus next to the substratum is dead, so that no nutrient substances can be conveyed through it to the upper layers of the thallus. A very simple, but at the same time convincing, illustration of this is adduced by Nylander. "By immersing," he says, "any fruticulose thallus, such as *Usnea*, by the base in water, it remains entirely dry (with the exception of the part submersed), but if water be poured over the other portions, it quickly absorbs it, softens, and revives." The same thing may be seen in nature itself, in the case of such species as *Cladina rangiferina*, *Alectoria ochroleuca*, *Platysma nivale*, &c., growing on temporarily wet substrata, when the base of their thalli is soft and moist, and all the rest dry and rigid. It cannot therefore be doubted that the nutritive elements contained in the rain or other water are conveyed to the lichen through the surface of the thallus. It is in the superficial parts also, as Nylander has well observed (in *Flora*, 1874, No. 4), that "the active life has its seat, chiefly around the gonidia, manifesting itself in the putting forth of young parts (lobes, laciniæ, branches, isidia), and in the functions of the apothecia and the spermogones, so that the nourishing humours necessary for all the actions of life are especially and directly poured upon these." The vital activities, however, in lichens thus nourished are, as might be expected from the nature of the source whence their nutriment is derived, very intermittent, and in dry weather cease to operate, and become entirely dormant. Hence their life, unlike that of all other plants, is twofold, viz., one *active*, in which when moistened all the vegetative and reproductive functions are at work, and the other *passive*, in which when dry these functions are completely in abeyance. For such a peculiar duplex existence, at one time vegetating, at another lethargic, their organization in all its parts, gonidial and otherwise, is admirably adapted. More especially is this the case with respect to the lichenine found in their textures, which, being readily dried and as readily moistened, enables them to resist with impunity the greatest extremes of temperature, alternate periods of drought and wet, the scorching heat of the sun, the vehemence of stormy winds, and the nipping frosts of winter.

In this fitful and abnormal life of lichens we have the explanation in a great measure of their almost indefinite duration of existence. It is well known that they are perennial plants in the widest sense of the term, and that, though in the earlier stages of their existence their growth is comparatively rapid, yet this becomes extremely slow when they arrive at a certain age. The time required for the development of even the most rapidly growing species may be calculated by the appearance of such of these as are met with on gravestones, mortar of houses, stone walls, wooden palings, and such like, the date of whose erection is known. Amongst other instances which have come under the present writer's own observation may be adduced the case of *Physcia parietina*, growing in fair quantity on the stones of a granite wall built in 1836 in a maritime district where the plant is extremely abundant, and where atmospherical and other conditions are well suited for its growth. In a recent visit to the spot it was found that, although the thallus is now well developed, no fructification whatever is visible, though traces of spermogones are beginning to appear, so that in the space of forty-five years this plant has not yet attained full maturity. But slow as is the growth of lichens after a certain stage of their development, their tenacity of life is very remarkable, as might *a priori* be inferred from their capacity of enduring without injury the greatest extremes of temperature and of hygrometrical conditions. It is on record that, after the lapse of nearly half a century, the same specimen on the same spot of the same tree has been observed without any change in its condition. On this point also E. Fries (in *L. E.*, p. xlv.) notices that certain species such as *Physcia ciliaris*, kept in houses for upwards of a year, revive when again exposed to the influences of the atmosphere,—an observation which in the case of *Cladina rangiferina* similarly kept for a still longer period the present writer can fully corroborate. Endowed then with this singular intermittent vitality, we can easily understand how many individuals which occur on hard mountainous rocks or on the trunks of aged trees in ancient forests are in all probability many hundreds of years old. Nor does age seem in any way to weaken their fecundity, even when the thallus has apparently ceased to grow. This, as observed by Nylander (in *Syn.*, p. 5), is shown from the circumstance that were it otherwise "the already old fruits would be destitute of spores, which is never the case," unless in plants of some lower tribes, *e.g.*, *Graphidei* and *Verrucariæ*, in which the thallus is but sparingly gonidiose, and the life consequently is shorter. In other instances the central portion of the thallus sometimes normally perishes in old plants, as in *Pterygium centrifugum*, *Collema melænum*, *Parmelia centrifuga*, and *P. saxatilis*, leaving only peripherical circles, in which, however, the life of the individual still continues for ages. In fact, "the life of lichens bears in itself no cause of death, and is only to be ended by external injuries" (E. Fries, *L. E.*, *loc. cit.*), or by the alteration of climatic and atmospherical conditions. Hence the assumption is not unwarrantable that individuals of such confessedly long-lived species as *Lecidea geographica*, growing on rocks upon the summits of lofty mountains, date from more than "fabulous epochs," and probably outrival in longevity the ages assigned to the oldest trees on the surface of the globe.

Chemistry of Lichens, and Chemical Reactions.

Chemistry of Lichens.—This is still but little understood, notwithstanding that the subject has been more or less investigated by authors. Their examinations, however, have been too limited and desultory to enable us to give any detailed account of the different principles which enter into the composition of the lichen tissues. Moreover, with respect to those species which have been more particularly analysed, they have sometimes employed not only the same terms in different senses, but also different terms to denote the same substance. There can, however, be no doubt that the chemical composition of lichens not only produces great modifications in their form, but also considerable diversities in their properties.

The principal substance which occurs in lichens, especially in such as are foliaceous and fruticulose, is *lichenine*—a special kind of gelatin peculiar to them. It is intermediate in character between dextrin and starch, and very eagerly imbibes water, though if boiled in water it is dissolved and lost. *Starch* also very rarely occurs in large lenticular grains scattered in the tissues. In crustaceous lichens *oxalate of lime* predominates, and forms a large proportion of the thallus, *e.g.*, 65 per cent. in *Lecanora esculenta* according to Gœbel. *Chlorophyll* and its modification *phycochrome* are found in lichens only in relatively small quantities, as is also the case with most of the other principles they present. These are enumerated by Nylander (in *Syn.*, p. 51) according to the affinities they bear, as follows:—(1) phosphate of lime, sea-salt, manganese, iron; (2) picrolichenine, variolarine, orceine, cetrarine, inuline, erythrine, roccelline, picroerythrine; (3) gyrophoric acid, parellic acid, usneic acid, orceic acid, erythrinic acid; (4) sugar not crystallizable, oil, waxy matter, resinous matter. Several others, especially phosphates and acids, have been enumerated by authors, which in some instances have not been corroborated, and in others are doubtfully distinct. In illustration of the manner in which several of these principles enter into the composition of lichens, we may adduce the analyses given in one or two species which have been more fully subjected to experiment. In *Cetraria islandica* there have been detected *starch*, including lichenine and inuline, to the extent of 80 per cent.; *gummy* and *waxy* matters; a bitter principle, *cetraric acid*; a fatty principle, *lichestearic acid*; *fumaric acid*, which exists also in *Fumaria officinalis*; *gallic acid*, the astringent principle of galls; uncrystallizable *sugar*; various salts, such as *bitartrate of potash*, and *tartrate* and *phosphate of lime*. Again, in *Physcia parietina* there have been found several alimentary principles, as *gliadine*, *starch*, *sugar*, *gum*; several medicinal substances, as *resin*, *bitter matter*, *gallic acid*, and a peculiar ethereal *oil*; a yellow colouring matter called *chrysophanic acid*; also *wax*, *stearine*, and some salts, as *carbonate of lime*. The *ash* of lichens is said to constitute from 8 to 10 per cent. of their bulk, and consists of various earthy bases, such as potash, soda, lime, magnesia, alumina, silica, manganese, and peroxide of iron, in combination with various acids, such as carbonic, phosphoric, sulphuric, and hydrochloric. The whole subject, however, of the chemistry of lichens requires to be investigated in a more extensive and methodical manner than has hitherto been done either by chemists or lichenists.

Chemical Reactions in Lichens.—These have reference to the thallus and the apothecia, and in both respects afford valuable assistance in the systematic study of lichens. (*a*) *Thalline* reactions depend upon the presence in the thallus of certain colourable materials in the form of acids, and are manifested on the application of hydrate of potash and the hypochlorite of lime either on the cortical stratum or the medulla. Of these reagents, hydrate of potash (K), composed of equal weights of caustic potash and water, and hypochlorite of lime (CaCl), composed of chloride of lime and water of any strength, may give certain reactions or none, according to the presence or absence of particular acids in the thallus. If no reaction takes place, this is denoted by K –, CaCl –, and similarly if there is reaction by K +, CaCl +. A very convenient mode of symbolizing the positive and negative reactions of the cortical layer and the medulla of the same species is to place the reaction of the former above the latter, *e.g.*, K±, CaCl∓, denoting that with K the cortical stratum shows reaction and the medulla none, while with CaCl the cortical stratum gives none, but the medulla a distinct reaction. Again, there is often no reaction produced by K alone, but if CaCl be added to it while still moist, a decided reaction appears, for which K(CaCl)+ is the symbol; or, on the other hand, the reaction given by K may be neutralized by the immediate application of CaCl, in which case it is expressed by K+(CaCl) –. The positive reactions are due to the presence of particular acids in the thallus, such as *erythrinic* acid giving a crimson reaction with CaCl, *chrysophanic* acid giving a purple reaction with K, *glaucinic* acid giving a yellow reaction with CaCl, and *lecanoric* acid giving a citrine reaction with K. In most cases where the natural colour of the thallus (often also of the medulla) is yellow or orange, chrysophanic acid is present, and with K gives a purple reaction (*e.g.*, *Physcia lychnea*), but in others externally similar in colour and general appearance, where only *lecithophanic* acid is present (*e.g.*, *Lecanora laciniosa*), K gives no reaction whatever. Sometimes K produces at first a yellow colour which immediately changes into a red or purple, as in *Lecanora cinerea*, which at once enables us to distinguish it from the closely allied species *L. gibbosa* and *L. calcarea*. A solution of iodine (I) is also in certain cases useful as a test on the medulla, and in the discrimination of some species of *Collema*. The value of these chemical tests in lichens was first pointed out by Nylander in *Flora*, 1866, pp. 223, 224, was subsequently illustrated by him in *Flora*, 1869, *passim*, in the case of species belonging to various genera, and has since been generally acknowledged by lichenists and employed by them in all specific diagnoses. They are unquestionably most important, not only in the discrimination of many difficult and closely allied species, but also in enabling us to refer with certainty varieties to the species to which they properly belong. Nay, even a small fragment of the thallus, whether sterile or fertile, may by their aid be readily determined, while otherwise it would be either quite indeterminable or doubtful. Generally they may be obtained on any portion of the thallus, but they are frequently more vivid, as might be expected, in the growing or circumferential portions. It is, however, only immediate reactions which depend on the colouring matter contained in the cortical stratum and the medulla that are to be attended to, and not secondary or tardy reactions which may otherwise originate, *e.g.*, from the dissolution of the chlorophyll of the gonidia. At the same time it is to be observed, in order to prevent a misconception which has occasionally been entertained, that they do not *per se* constitute a special *specific* character, but only an additional and confirmatory specific character. As such their value is clearly apparent in cases where the external characters are similar or approximate, and doubt necessarily exists as to their specific value. (*b*) *Apothecial* reactions for the most part take place either externally on the epithecium or internally on the hymenial gelatin. The reactions of the epithecium are generally produced by K on species which have yellow or orange apothecia (*e.g.*, *Lecanora aurantiaca*, *Lecidea leucoxantha*), while others with concolorous apothecia (*e.g.*, *Lecanora epanora*, *Lecidea lucida*) give no reaction whatever, owing to the presence or absence of chrysophanic acid. In certain cases also the reaction with CaCl is very useful in enabling us to separate closely allied species with similar apothecia, *e.g.*, *Lecanora subcarnea* (epithecium CaCl –) from *L. glaucoma* (epithecium CaCl + yellow). Again, with respect to the reaction of the hymenial gelatin, this, as already observed, depends on the application of a solution of iodine. The formula by which the solution is to be prepared is—iodine, gr. j.; iodide of potash, gr. iij; distilled water, ½ ounce. In most lichens, where the spores are mature, this solution will tinge the hymenial gelatin in some cases only blue, in others at first blue and then wine-red, and in others wine-red or tawny wine-coloured only, without any preceding blue tinge. In such instances the reaction obtained is often very useful as a confirmatory specific character. Sometimes, however, the blue reaction takes place only on the thecæ (*e.g.*, *Pertusaria*, *Cladonia*, &c.), and at other times only on the epispore (*e.g.*, *Graphis*, *Thelotrema*, &c.). In the case of some species belonging to the inferior genera the reaction with I is especially valuable for the assistance it lends in distinguishing them from certain pyrenomycetous fungi, to which otherwise they might be supposed to belong. True, in some fungi (*e.g.*, *Peziza*) we obtain a reaction with I, and in some lichens we have no reaction visible; but otherwise in such exceptional instances their respective anatomical characters readily show to which class they belong.

Economic Uses of Lichens.

These are intimately connected with their chemical constituents, and are in some respects very important. In the arts, as food and as medicine, many of them have been highly esteemed, though others are not now employed for the same purposes as formerly.

1. *Lichens Used in the Arts.*—Of these the most important are such as yield, by maceration in ammonia, the valuable dyes known in commerce as archil, cudbear, and litmus. These, however, may with propriety be regarded as but different names for the same pigmentary substance, the variations in the character of which are attributable to the different modes in which the pigments are manufactured. Archil proper is derived from several species of *Roccella* (*e.g.*, *R. Montaguei*, *R. tinctoria*), which yield a rich purple dye and fetch a high price in the market. Of considerable value is the "perelle" prepared from *Lecanora parella*, and much used in the preparation of a red or crimson dye. Inferior to this is "cudbear," derived from *Lecanora tartarea*, which was formerly very extensively employed by the peasantry of north Europe for giving a scarlet or purple colour to woollen cloths. By adding certain alkalies to the other ingredients used in the preparation of these pigments, the colour becomes indigo-blue, in which case it is the litmus of the Dutch manufacturers. Amongst other lichens affording red, purple, or brown dyes may be mentioned *Ramalina scopulorum*, *Parmelia saxatilis* and *P. omphalodes*, *Umbilicaria pustulata* and several species of *Gyrophora*, *Urceolaria scruposa*, all of which are more or less employed as domestic dyes. Yellow dyes, again, are derived from *Chlorea vulpina*, *Platysma juniperinum*, *Parmelia caperata* and *P. conspersa*, *Physcia flavicans*, *Ph. parietina*, and *Ph. lychnea*, though like the preceding they do not form articles of commerce, being merely used locally by the natives of the regions in which they occur most plentifully. In addition to these, many exotic lichens, belonging especially to *Parmelia* and *Sticta* (*e.g.*, *Parmelia tinctorum*, *Sticta argyracea*), are rich in colorific matter, and, if obtained in sufficient quantity, would yield a dye in every way equal to archil. These pigments primarily depend upon special acids contained in the thalli of lichens, and their presence may readily be detected by means of the reagents already noticed. In the process of manufacture, however, they undergo various changes, of which the chemistry is still but little understood. At one time also some species were used in the arts for supplying a gum as a substitute for gum-arabic. These were chiefly *Ramalina fraxinea*, *Evernia prunastri*, and *Parmelia physodes*, all of which contain a considerable proportion of gummy matter (of a much inferior quality, however, to gum-arabic), and were employed in the process of calico-printing and in the making of parchment and cardboard. In the 17th century some filamentose and fruticulose lichens, viz., species of *Usnea* and *Ramalina*, also *Evernia furfuracea* and *Cladina rangiferina*, were used in the art of perfumery. From their supposed aptitude to imbibe and retain odours, their powder was the basis of various perfumes, such as the celebrated "Poudre de Cypre" of the hairdressers, but their employment in this respect has long since been abandoned.

2. *Nutritive Lichens.*—Of still greater importance is the capacity of many species for supplying food for man and beast. This results from their containing amylaceous substances, and in some cases a small quantity of saccharine

matter of the nature of mannite. One of the most useful nutritious species is *Cetraria islandica*, "Iceland moss," which, after being deprived of its bitterness by boiling in water, is reduced to a powder and made into cakes, or is boiled and eaten with milk by the poor Icelander, whose sole food it often constitutes. Similarly *Cladina rangiferina* and *Cl. sylvatica*, the familiar "reindeer moss," are frequently eaten by man in times of scarcity, after being powdered and mixed with flour. Their chief importance, however, is that in Lapland and other northern countries they supply the winter food of the reindeer and other animals, who scrape away the snow and eagerly feed upon them. Another nutritious lichen is the "Tripe de Roche" of the Arctic regions, consisting of several species of the *Gyrophorei*, which when boiled is often eaten by the Canadian hunters and Red Indians when pressed by hunger. But the most singular esculent lichen of all is the "manna lichen," which in times of drought and famine has served as food for large numbers of men and cattle in the arid steppes of various countries stretching from Algiers to Tartary. This is derived chiefly from *Lecanora esculenta*, which grows unattached on the ground in layers from 3 to 6 inches thick over large tracts of country in the form of small irregular lumps of a greyish or white colour. Speaking of the distribution of these nutritive lichens, whose qualities depend on the presence of amylaceous matter, Dr Lindsay (in *Pop. Hist. Brit. Lich.*, p. 82) very appropriately remarks that, "by a beautiful provision of nature, they occur precisely under the circumstances where they are most wanted—in northern or arctic countries, or on arid steppes, where grain stuffs are unknown, and food of a better kind is often scarce or deficient." In connexion with their use as food we may observe that of recent years in Scandinavia and Russia an alcoholic spirit has been distilled from *Cladina rangiferina* and extensively consumed, especially in seasons when potatoes were scarce and dear. Formerly also *Sticta pulmonaria* was much employed in brewing instead of hops, and it is said that a Siberian monastery was much celebrated for its beer which was flavoured with the bitter principle of this species.

3. *Medicinal Lichens.*—During the Middle Ages, and even in some quarters to a much later period, lichens were extensively used in medicine in various European countries. Many species had a great repute as demulcents, febrifuges, astringents, tonics, purgatives, and anthelmintics. The chief of those employed for one or other, and in some cases for several, of these purposes were *Cladonia pyxidata*, *Usnea barbata*, *Ramalina farinacea*, *Evernia prunastri*, *Cetraria islandica*, *Sticta pulmonaria*, *Parmelia saxatilis*, *Physcia parietina*, and *Pertusaria amara*. Others again were believed to be endowed with specific virtues, *e.g.*, *Peltigera canina*, which formed the basis of the celebrated "pulvis antilyssus" of Dr Mead, long regarded as a sovereign cure for hydrophobia; *Platysma juniperinum*, lauded as a specific in jaundice, no doubt on the *similia similibus* principle from a resemblance between its yellow colour and that of the jaundiced skin; *Peltidea aphthosa*, which on the same principle was regarded by the Swedes, when boiled in milk, as an effectual remedy for the *aphthæ* or rash on their children. Almost all of these virtues, general or specific, were imaginary; and at the present day, except perhaps in some remoter districts of northern Europe, only one of them is employed as a remedial agent. This is the "Iceland moss" of the druggists' shops, which is undoubtedly an excellent demulcent in various dyspeptic and chest complaints. Probably also *Pertusaria amara*, from the intensely bitter principle which it contains, might still with propriety be employed as a febrifuge. No lichen is known to be possessed of any poisonous properties, although *Chlorea vulpina* is believed by the Swedes to be destructive to wolves when powdered and "mixed with pounded glass." Nor are lichens, as has sometimes been alleged, injurious to the trees upon which they grow, except to a very limited extent. Not being parasites properly so called, the only injury they can inflict upon them is by slightly interfering with the functions of respiration, or, when growing very crowdedly upon the branches of orchard trees, by checking the development of buds

Classification of Lichens.

From the time of Acharius, the father of lichenological science, different authors have proposed different classifications of lichens, according to the degree of importance attached by them to one or other of their vegetative and reproductive organs. Most of these classifications, however, whether proposed by microscopical or pre-microscopical lichenists, have been too artificial and arbitrary, and indeed less natural in various ways than that originally propounded by Acharius. Of recent years they have been entirely superseded by other two systems, viz., that of the Massalongo-Koerberian and that of the Nylanderian school. With respect to the former of these, its characteristic feature is the prominence which it assigns to the form and structure of the spores not only in the differentiation of species but also in the foundation of genera. Though it has been adopted, with various modifications, by many Continental lichenists, yet essentially it also proceeds on an artificial principle, and necessitates the adoption of far too many genera, distinguished from each other merely by slight differences in the spores. The other system—that of Nylander, which was first proposed by him in his *Essai d'une Nouvelle Classification des Lichens* (1854–55),—has since then commended itself more and more to the acceptation of lichenists, so that even the disciples of the opposite school (the sporologists) have in many respects gradually approximated towards it in their most recent writings. Not only is it the only complete system of classification yet wrought out; it is also the most natural and philosophical of any hitherto propounded. In its main outline it proceeds upon the principle of showing the near relation of certain lichens to some genera of algæ on the one hand, and of certain other lichens to some genera of fungi on the other hand, and connects these three great classes of cryptogams together by a sort of twofold chain, commencing with those genera of lichens nearest allied to the algæ, working up to those genera best developed (*Stictei*), and thence retrograding and terminating with those nearest allied to the fungi. His genera also are principally founded, not upon a single special character, but upon the combined anatomical characters presented by the thallus, the apothecia, and the spermogones. It may here be further observed that we are indebted to the same accomplished lichenist for the succinct but comprehensive diagnoses, generic and specific, of the different parts of a lichen, which have tended so much to facilitate their systematic study. The following is a conspectus of the Nylanderian classification of lichens, with the leading characters of the different families and tribes, and an enumeration of all the principal genera of which these are composed.

Family I.—*Ephebacei*, Nyl.

Thallus but little turgid when moist, gonidial stratum consisting of gonimia which are tunicated; medullary filaments none.

Tribe 1. *Sirosiphei*, Nyl.—Thallus filamentoso-fruticulose, gonimia variously connate. Apothecia biatorine or lecideine. Spermogones with sterigmata or arthrosterigmata.

Genera: *Sirosiphon*, Ktz.; *Gonionema*, Nyl.; *Spilonema*, Born.

Tribe 2. *Pyrenopsei*, Nyl.—Thallus thinly granulose, rubricose within, gonimia simple or connate. Apothecia lecanorine or pyrenocarpous. Spermogones with simplish sterigmata.

Genera : *Euopsis*, Nyl. ; *Pyrenopsis*, Nyl.

Tribe 3. *Homopsidei*, Nyl.—Thallus either fruticolose with the gonimia seriated, or squamuliform or granulose with the gonimia subsolitary. Apothecia pyrenocarpous with or without paraphyses. Spermogones with simple sterigmata.

Genera : *Ephebe*, Fr. ; *Ephebeia*, Nyl. ; *Phylliscum*, Nyl. ; *Phylliscodium*, Nyl. ; *Collemopsidium*, Nyl.

Tribe 4. *Magmopsei*, Nyl.—Thallus pyrenopsidian, containing syngonimia, the gonimia arranged without order. Apothecia peridieine.

Genus : *Magmopsis*, Nyl.

Family II.—*Collemacei*, Nyl.

Thallus turgid when moist, gonidial stratum consisting of gonimia moniliformly arranged ; medulla not discrete.

Tribe 1. *Lichinei*, Nyl.—Thallus fruticulose or radiately laciniated, gonimia elongato-seriately moniliform, subconnate. Apothecia lecanorine or lecideine. Spermogones with sterigmata or arthrosterigmata.

Genera : *Lichina*, Ag. ; *Pterygium*, Nyl. ; *Leptogidium*, Nyl. ; *Lichinodium*, Nyl.

Tribe 2. *Collemei*, Nyl.—Thallus membranaceous, lobate, rarely fruticulose, granulose or subsquamulose, gonimia moniliformly arranged, cortical stratum none or distinct. Apothecia lecanorine or rarely pyrenocarpous. Spermogones with simplish sterigmata or arthrosterigmata.

Genera : *Leciophysma*, Fr. fil. ; *Synalissa*, DR. ; *Omphalaria*, DR. ; *Anema*, Nyl. ; *Paulia*, Fée ; *Schizoma*, Nyl. ; *Collema*, Ach. ; *Leptogium*, Ach. ; *Ramalodium*, Nyl. ; *Lichinella*, Nyl. ; *Amphidium*, Nyl. ; *Collemopsis*, Nyl. ; *Hydrothyria*, Russ.

Tribe 3. *Pyrenidiei*, Nyl.—Thallus fibrillose, gonimia moniliformly coherent, cortical stratum distinct. Apothecia pyrenoid.

Genus : *Pyrenidium*, Nyl.

Family III.—*Lichenacei*, Nyl.

Thallus not gelatinous, with a gonidial, rarely gonimic stratum ; medullary stratum more or less distinct.

Series I.—*Epiconiodei*, Nyl.

Apothecia with the spores usually naked and pulverulent on the surface of the fructification.

Tribe 1. *Caliciei*, Nyl.—Thallus horizontally expanded, sometimes none. Apothecia stipitate, capituliform or sessile. Spermogones with simple sterigmata.

Genera : *Sphinctrina*, Fr. ; *Calicium*, Pers ; *Stenocybe*, Nyl. ; *Coniocybe*, Ach. ; *Pyrgidium*, Nyl ; *Trachylia*, Fr. ; *Pyrgillus*, Nyl.

Tribe 2. *Tylophorei*, Nyl.—Thallus thinly crustaceous. Apothecia at first pyrenodean and then lecanorine with sporal mass. Spermogones with somewhat branched sterigmata.

Genus : *Tylophoron*, Nyl.

Tribe 3. *Sphærophorei*, Nyl.—Thallus fruticulose, branched. Apothecia at first nucleiform, becoming variously dehiscent, with sporal mass. Spermogones with simplish sterigmata or arthrosterigmata.

Genera : *Sphærophoron*, Pers. ; *Acroscyphus*, Lev. ; *Tholurna*, Norm.

Series II.—*Cladodei*, Nyl.

Apothecia terminal on podetia, rarely sessile, biatorine or rarely lecanorine.

Tribe 4. *Bæomycetei*, Nyl.—Thallus horizontally expanded. Apothecia substipitate. Spermogones with sterigmata or arthrosterigmata.

Genera : *Gomphillus*, Nyl. ; *Bæomyces*, Pers. ; *Glossodium*, Nyl. ; *Thysanothecium*, Berk. ; *Stereocauliscum*, Nyl.

Tribe 5. *Pilophorei*, Nyl.—Thallus granulose, cephalodiiferous, with rigid podetia. Apothecia cephalodine, on the podetia, with the paraphyses prolongated into the hypothecium. Spermogones with simplish sterigmata.

Genus : *Pilophoron*, Tuck.

Tribe 6. *Stereocaulei*, Nyl.—Thallus cæspitose, podetiiform, solid. Apothecia terminal or lateral, lecideine or rarely lecanorine. Spermogones with simple sterigmata.

Genera : *Stereocaulon*, Schreb. ; *Stereocladium*, Nyl. ; *Argopsis*, Fr. fil. ; *Oxocladium*, Mnt.

Tribe 7. *Cladoniei*, Nyl.—Thallus foliaceous or fruticulose, with fistulose podetia. Apothecia biatorine on the podetia, rarely sessile on the leaflets. Spermogones with simplish sterigmata.

Genera : *Heterodea*, Nyl. ; *Pycnothelia*, Ach. ; *Cladonia*, Hffm. ; *Cladina*, Nyl. ; *Cladia*, Nyl. ; *Ramalea*, Nyl.

Series III.—*Ramalodei*, Nyl.

Thallus efoliolose, fruticulose, or filamentose. Apothecia generally lecanorine.

Tribe 8. *Roccellei*, Nyl.—Thallus simplish or branched, internally with filamentose medulla. Apothecia irregular (normally lecanorine), adnate, terminal, or lateral. Spermogones with simplish sterigmata.

Genera : *Combea*, DN. ; *Roccella*, DC.

Tribe 9. *Siphulei*, Nyl.—Thallus podetiiform, simple or fruticulose, internally with filamentose or fistulose medulla. Apothecia unknown. Spermogones (where seen) with arthrosterigmata.

Genera : *Siphula*, Fr. ; *Endocena*, Cromb. ; *Thamnolia*, Ach.

Tribe 10. *Ramalinei*, Nyl.—Thallus fruticuloso-foliaceous rounded or compressed, with woolly medulla. Apothecia lecanorine-scutellate. Spermogones with arthrosterigmata.

Genus : *Ramalina*, Ach.

Tribe 11. *Usneei*, Nyl.—Thallus much branched, rounded, or compressed, with firm medullary axis. Apothecia parmelioid, peltate Spermogones with simplish sterigmata.

Genera : *Usnea*, Hffm. ; *Neuropogon*, N. and Fl. ; *Chlorea*, Nyl.

Tribe 12. *Alectoriei*, Nyl.—Thallus branched, rounded, or compressed, with woolly medulla. Apothecia parmelioid, scutelliform. Spermogones with simplish sterigmata or arthrosterigmata.

Genera : *Alectoria*, Ach. ; *Dactylina*, Nyl. ; *Dufourea*, Ach.

Tribe 13. *Cetrariei*, Nyl.—Thallus fruticulose or foliaceous, with woolly medulla. Apothecia parmelioid, marginal, obliquely affixed. Spermogones with simple sterigmata or arthrosterigmata.

Genera : *Cetraria*, Ach. ; *Platysma*, Hffm.

Series IV.—*Phyllodei*, Nyl.

Thallus foliaceous, usually depressed, lobate. Apothecia generally peltiform or lecanorine.

Tribe 14. *Parmeliei*, Nyl.—Thallus frondosely dilated, or lobate, or laciniated, with woolly, rarely solid, medulla. Apothecia parmelioid, scutelliform. Spermogones with simple sterigmata or arthrosterigmata.

Genera : *Evernia*, Ach. ; *Everniopsis*, Nyl. ; *Parmelia*, Ach. ; *Parmeliopsis*, Nyl.

Tribe 15. *Stictei*, Nyl.—Thallus large, lobate, cyphellate, or ecyphellate beneath ; gonidial stratum composed either of nodulose gonimia or of true gonidia. Apothecia lecanorine, rarely parmeleine. Spermogones with arthrosterigmata.

Genera : *Stictina*, Nyl. ; *Lobarina*, Nyl. ; *Sticta*, Ach. ; *Lobaria*, Nyl. ; *Ricasolia*, DN.

Tribe 16. *Peltigerei*, Nyl.—Thallus frondosely dilated, the cortical stratum often wanting beneath ; gonidial stratum consisting either of gonidia or (usually) of gonimia, rarely of gonidimia. Apothecia peltiform, adnate, or innate. Spermogones (where seen) with arthrosterigmata.

Genera : *Nephroma*, Ach. ; *Nephromium*, Nyl. ; *Peltidea*, Ach. ; *Peltigera*, Hffm. ; *Solorina*, Ach.

Tribe 17. *Physciei*, Nyl. Thallus stellato-orbicular, rarely fruticulose, internally with woolly medulla ; gonidial stratum consisting of true gonidia. Apothecia lecanorine. Spermogones with arthrosterigmata.

Genus : *Physcia*, Nyl.

Tribe 18. *Pyxinei*, Nyl.—Thallus stellato-laciniated, with woolly medulla and true gonidial stratum. Apothecia lecideine. Spermogones with arthrosterigmata.

Genus : *Pyxine*, Fr.

Tribe 19. *Gyrophorei*, Nyl.—Thallus umbilicately affixed, with woolly medulla and true gonidial stratum. Apothecia lecanoroid, or lecideine and gyrose. Spermogones with arthrosterigmata.

Genera : *Umbilicaria*, Hffm. ; *Gyrophora*, Ach.

Series V.—*Placodei*, Nyl.

Thallus variously crustaceous, sometimes evanescent, rarely hypophlœodal, without any filamentose medullary stratum. Apothecia lecanorine, or lecideine, or lirellæform.

Tribe 20. *Lecanorei*, Nyl.—Thallus crustaceous, rarely evanescent or obsolete ; gonidial stratum consisting of gonidia, rarely of gonimia. Apothecia lecanorine, rarely subbiatorine or typically biatorine. Spermogones with simple sterigmata or arthrosterigmata.

Genera : *Pannaria*, Del. ; *Gymnoderma*, Nyl. ; *Erioderma*, Fée ; *Heppia*, Næg. ; *Amphiloma*, Fr. ; *Psoroma*, Fr. ; *Lecanora*, Ach. ; *Glypholecia*, Nyl. ; *Peltula*, Nyl. ; *Dermatiscum*, Nyl. ; *Dirina*, Fr.

Tribe 21. *Pertusariei*, Nyl.—Thallus crustaceous, continuous ; gonidial system consisting of true gonidia. Apothecia endocarpoid or lecanoroid. Spermogones with simple sterigmata.

Genera : *Pertusaria*, DC. ; *Varicellaria*, Nyl.

Tribe 22. *Thelotremei*, Nyl.—Thallus crustaceous, or pulverulent, or areolate, with true gonidial stratum. Apothecia urceolato-impressed with double margin. Spermogones with simple or somewhat branched sterigmata.

Genera : *Phlyctis*, Wallr. ; *Tremotylium*, Nyl. ; *Thelotrema*, Ach. ; *Urceolaria*, Ach. ; *Belonia*, Krb. ; *Gyrostomum*, Nyl. ; *Ascidium*, Fée ; *Gymnotrema*, Nyl.

Tribe 23. *Lecideei*, Nyl.—Thallus variously crustaceous, pulverulent, evanescent or none proper, with the gonidial stratum consisting of gonidia (rarely chrysogonidia), rarely gonimia. Apothecia lecideine (or biatorine). Spermogones with simple or simplish sterigmata.

Genera : *Cœnogonium*, Ehrh. ; *Byssocaulon*, Mnt. ; *Pannularia*, Nyl. ; *Coccocarpi*, Pers. ; *Lecidea*, Ach. ; *Gyrothecium*, Nyl. ; *Epiphora*, Nyl.

Tribe 24. *Graphidei*, Nyl.—Thallus thinly crustaceous, or hypophlœodal, or rarely none proper; gonidial stratum consisting of gonidia (rarely chrysogonidia). Apothecia lirelline or rotundate. Spermogones with simple sterigmata.

Genera: *Xylographa*, Fr.; *Agyrium*, Fr.; *Lithographa*, Nyl.; *Graphis*, Ach.; *Thelographis*, Nyl.; *Helminthocarpon*, Fée; *Leucographa*, Nyl.; *Opegrapha*, Ach.; *Platygrapha*, Nyl.; *Stigmatidium*, Mey.; *Arthonia*, Ach.; *Melaspilea*, Nyl.; *Lecanactis*, Eschw.; *Schizographa*, Nyl.; *Glyphis*, Ach.; *Chiodecton*, Ach.

Series VI.—*Pyrenodei*, Nyl.

Thallus peltate, or crustaceous, or hypophlœodal, or evanescent. Apothecia nucleiform, with an apical ostiole.

Tribe 25. *Pyrenocarpei*, Nyl.—Thallus various, often macular or obsolete; gonidial system consisting of gonidia (rarely chrysogonidia), sometimes of gonimia. Apothecia pyrenodeine, often without paraphyses. Spermogones with simple sterigmata or arthrosterigmata.

Genera: *Cora*, Fr.; *Dichonema*, N. ab Es.; *Normandina*, Nyl.; *Endocarpon*, Hedw.; *Verrucarina*, Nyl.; *Verrucaria*, Pers.; *Thelenella*, Nyl.; *Thelopsis*, Nyl.; *Obryzum*, Wallr.; *Strigula*, Fr.; *Parathelium*, Nyl.; *Melanotheca*, Fée; *Trypethelium*, Ach.; *Astrothelium*, Eschw.

Series VII.—*Peridiodei*, Nyl.

Thallus thin, often wanting. Apothecia peridieine, without any ostiole.

Tribe 26. *Peridei*, Nyl.—Thallus thin, macular, or none proper. Apothecia consisting of a peridium. Spermogones (where seen) with simple sterigmata.

Genera: *Thelocarpon*, Nyl.; *Thelococcus*, Nyl.; *Endococcus*, Nyl.; *Mycoporum*, Flot.

Family IV.—*Myriangiacei*, Nyl.

Thallus unstratified, entirely and equally cellulose. Fructification not discrete.

Tribe 1. *Myriangiei*, Nyl.—Thallus noduloso-pulvinate. Apothecia sublecanorine. Spermogones unknown.

Genus: *Myriangium*, Mnt. and Berk.

In the Nylanderian arrangement, most of these tribes and genera are again divided into subtribes and subgenera, the latter being further subdivided into sections according to the affinities of the different species.

Habitats and Distribution of Lichens.

These two subjects are intimately related and present many interesting features which here we can only very generally notice without entering into details.

1. *Habitats of Lichens.*—These are extremely varied, and comprehend a great number of very different substrata. Chiefly, however, they are the bark of trees, rocks, the ground, mosses, and, rarely, perennial leaves. (*a*) With respect to *corticole* lichens, some prefer the rugged bark of old trees (*e.g.*, *Ramalina*, *Parmelia*, *Sticlei*) and others the smooth bark of young trees and shrubs (*e.g.*, *Graphidei* and some *Lecideæ*). Many are found principally in large forests (*e.g.*, *Usnea*, *Alectoria jubata*); while a few occur more especially on trees by roadsides (*e.g.*, *Physcia parietina* and *Ph. pulverulenta*). In connexion with corticole lichens may be mentioned those *lignicole* species which grow on decayed or decaying wood of trees and on old pales (*e.g.*, *Caliciei*, various *Lecideæ*, *Xylographa*). (*b*) As to *saxicole* lichens, which occur on rocks and stones, they may be divided into two sections, viz., *calcicole* and *calcifugous*. To the former belong such as are found on calcareous and cretaceous rocks, and the mortar of walls (*e.g.*, *Lecanora calcarea*, *Lecidea calcivora*, and several *Verrucariæ*), while all other saxicole lichens may be regarded as belonging to the latter, whatever may be the mineralogical character of the substratum. It is here worthy of notice that the apothecia of several calcicole lichens (*e.g.*, *Lecanora Prevostii*, *Lecidea calcivora*) have the power (through the carbonic acid received from the atmosphere) of forming minute faveoli in the rock, in which they are partially buried. (*c*) With respect to *terricole* species, some prefer peaty soil (*e.g.*, *Cladonia*, *Lecidea decolorans*), others calcareous soil (*e.g.*, *Lecanora crassa*, *Lecidea decipiens*), others argillaceous soil or hardened mud (*e.g.*, *Collema limosum*, *Peltidea venosa*); while many may be found growing on all kinds of soil, from the sands of the sea-shore to the granitic detritus of lofty mountains, with the exception of course of cultivated ground, there being no agrarian lichens. (*d*) *Muscicole* lichens again are such as are most frequently met with on decayed mosses and jungermannias, whether on the ground, trees, or rocks (*e.g.*, *Leptogium muscicola*, *Gomphillus calicioides*). (*e*) The *epiphyllous* species are very peculiar as occurring upon perennial leaves of certain trees and shrubs, whose vitality is not at all affected by their presence as it is by that of fungi. In so far, however, as is known, they are very limited in number (*e.g.*, *Lecidea Bouteillei*, *Strigula*). With the exceptions of these last, it is to be observed that all the rest may, under different conditions of locality and climate, be found growing for the most part indiscriminately on the substrata mentioned, a normally saxicole species becoming corticole, a terricole one becoming muscicole, and *vice versa*. Amongst other instances of this that might be adduced, the case of *Lecidea geographica*, a peculiarly saxicole species, growing on the stems of *Rhododendron* in the Tyrolese Alps, and that of *Lecidea rivulosa*, a like peculiarly saxicole species, growing on the bark of trees in Germany, are especially striking. Sometimes also various lichens occur abnormally in such unexpected habitats as dried dung of sheep, bleached bones of reindeer and whales, old leather, iron, and glass, in districts where the species are abundant. Consequently it is apparent that in many cases lichens are quite indifferent to the substrata on which they occur, whence we infer that the preference of several for certain substrata depends upon the temperature of the locality or that of the special habitat. Thus in the case of saxicole lichens the mineralogical character of the rock has of itself little or no influence upon lichen growth, which is influenced more especially and directly by their physical properties, such as their aptitude for imbibing and retaining heat and moisture. As a rule lichens have a propensity for open exposed habitats, though some are found only or chiefly in shady situations; while, as already observed, scarcely any occur where the atmosphere is impregnated with smoke. Many species also prefer growing in moist places by streams, lakes, and the sea, though very few are normally, and probably none entirely, *aquatic*, being always at certain seasons exposed for a longer or shorter period to the atmosphere (*e.g.*, *Lichina*, *Leptogium rivulare*, *Endocarpon fluviatile*, *Verrucaria maura*). Some species are entirely parasitical on other lichens (*e.g.*, various *Lecideæ* and *Pyrenocarpei*), and may be peculiar to one (*e.g.*, *Lecidea vitellinaria*) or common to several species (*e.g.*, *Habrothallus parmeliarum*). A few, generally known as *erratic* species, have been met with growing unattached to any substratum (*e.g.*, *Parmelia revoluta*, var. *concentrica*, *Lecanora esculenta*); but it seems somewhat doubtful if these are really free *ab initio* (*vide* Crombie in *Journ. Bot.*, 1872, p. 306). It is to the different characters of the stations they occupy with respect to exposure, moisture, &c., that the variability observed in many types of lichens is to be attributed. The fact also that in numerous instances they are so indifferent to the nature of their habitats clearly shows that they do not at all depend upon the substratum for their nourishment.

2. *Distribution of Lichens.*—From what has now been said it will readily be inferred that the distribution of lichens over the surface of the globe is regulated, not only by the presence of suitable substrata, but also and more especially by atmospherical and climatal conditions. At the same time it may safely be affirmed that their geographical range is more extended than that of any other class of plants, occurring as they do in the coldest and warmest regions—on the dreary shores of the palæocrystic sea and in the torrid valleys of tropical climes, as well as on

the greatest mountain elevations yet attained by man, on projecting rocks even far above the snow-line (*e.g., Lecidea geographica*), where, as in many other situations, fungus-mycelium and gonidioid algal are unknown. Our knowledge of the distribution of lichens in various countries, like that of other plants, is derived from general and local floras, from special works on lichenology, from the observations of scientific travellers and the collections made by them in distant parts of the world. Most of these, however, of an earlier date, are to be used with great caution, as the species recorded were, in the absence of microscopical examination, not sufficiently discriminated, and in many cases are *prima facie* entirely erroneous. Amongst botanical travellers whose contributions are most trustworthy may be mentioned pre-eminently Sir Joseph D. Hooker, whose remarks on this subject in his *Flora Antarctica* and in various papers in *Trans. Linn. Soc.*, vol. xiv., &c., are most valuable and suggestive. Again, in purely lichenological works, the general principles regulating lichen distribution (with statistical tables) are admirably expounded by Nylander in the introduction to his *Synopsis Methodica Lichenum*, while the only complete record of the distribution of species is that given by the same author in his *Enumération générale des Lichens.* Since the date of this latter work (1858) our knowledge of the range of lichens, both European and exotic, has been greatly extended, apart from the discovery of numerous species previously unknown. No special treatise, however, on the subject has been published, though there is now ample material, very much scattered no doubt, available for the purpose. It may, however, be observed that of the four thousand species (exclusive of numerous varieties and forms) which have been described, the geographical distribution is known almost as well as that of phanerogams and filices, as well, if not more so than that of mosses and hepatics, and far better than that of algæ and fungi. In arctic regions lichens form by far the largest portion of the vegetation, occurring everywhere on the ground and on rocks, and fruiting freely; while terricole species of *Cladonia* and *Stereocaulon* are seen in the greatest luxuriance and abundance spreading over extensive tracts almost to the entire exclusion of other vegetation. The lichen flora of temperate regions again is essentially distinguished from the preceding by the frequency of corticole species belonging to *Lecanora*, *Lecidea*, and *Graphidei*. In intertropical regions lichens attain their maximum development (and beauty) in the foliaceous *Stictei* and *Parmeliei*, while they are especially characterized by epiphyllous species, as *Strigula*, and by many peculiar corticole *Thelotremei*, *Graphidei*, and *Pyrenocarpei.* Some lichens, especially saxicole ones, seem to be cosmopolitan (*e.g., Lecanora subfusca, Cladonia pyxidata*); and others, not strictly cosmopolitan, have been observed in regions widely apart. A considerable number of species, European and exotic, seem to be *endemic*, but further research will no doubt show that most of them occur in other climatal regions similar to those in which they have hitherto alone been detected. To give any detailed account, however, of the distribution of the different genera (not to speak of that of individual species) of lichens would necessarily far exceed the limits at our disposal. Suffice it to say that both in horizontal and vertical range, they sufficiently correspond with the distribution of phanerogams in the several regions of vegetation into which the surface of the globe has been divided. The proportion of lichens to phanerogams in different regions increases in a regular ratio from the equator to the poles, and from the base to the summit of lofty mountains, till at length in more arctic and alt-alpine tracts lichens constitute almost and sometimes entirely the sole vegetation. (J. M. C.)

LICHFIELD, a city and municipal and parliamentary borough of Staffordshire, England, is situated in a pleasant and fertile valley, on a small tributary of the Trent, and on the South Staffordshire Railway, 16 miles north from Birmingham. The town is well built, and contains many handsome houses. Of the old Norman cathedral there are now no remains. The present building is supposed to belong to the end of the 12th or beginning of the 13th century. Its style is Early English approaching to Decorated, and it possesses an imposing central tower 285 feet in height, with two western spires 183 feet. The transepts, which contain some portions of Norman architecture, are richly ornamented, and adorned with windows of beautiful tracery. The total length of the building from east to west is 403 feet. The damage which it suffered during the civil wars was repaired by Bishop Hackett in 1671, and at present (1882) it is undergoing extensive restorations. A new building for the King Edward's grammar school was erected in 1850. In the market-place is a statue of Dr Johnson, facing the house where he was born. A guild-hall, a market-hall, a corn exchange, and a public library and museum are the principal buildings of a secular character. There are several charitable institutions. The industries of the town include brewing and coach-building; and in the neighbourhood there are large nurseries and market gardens. The municipal and parliamentary boroughs have the same area (3416 acres); the population in 1871 was 7347, and in 1881 8360.

Lichfield is spelt by Bede Licidfeld, the word being supposed to mean "Field of the Dead," from a massacre which took place near it of a large number of Christians. It was made an episcopal see in 669, St Chad being its first bishop. In the reign of Offa it was promoted to be an archbishopric, but in 803 the primacy was restored to Canterbury. In 1075 the see of Lichfield was transferred to Chester, and thence, a few years afterwards, to Coventry, but it was restored in 1148. The town has returned members to parliament since 1305, at which time it also received a charter of incorporation. Since 1867 it has returned only one member. It was made a city by Edward VI. in 1549.

See the histories of Lichfield by Jackson (1805) and Harwood (1806), and histories of the cathedral by Britton (1820) and Stone (1870).

LICHTENBERG, formerly a small German principality on the west bank of the Rhine, enclosed by the Nahe, the Blies, and the Glan, now forms the circle of St Wendel in the government district of Treves, Rhenish Prussia. The principality was constructed of parts of the old electorate of Treves, Pfalz-Zweibrücken, and Salm, and lay between Rhenish Bavaria and the old Prussian province of the Rhine. Originally called the lordship of Baumholder, it owed the name of Lichtenberg and its elevation to a principality to Ernest, duke of Saxe-Coburg, to whom it was presented by Prussia in 1815 in accordance with terms agreed upon at the congress of Vienna. The duke, however, restored it to Prussia in 1834, in return for an annual pension of £26,000 sterling. The area is 210 square miles, and the population 45,000.

LICHTENBERG, GEORG CHRISTOPH (1744–1799), physicist and satirical writer, was born at Oberramstadt, near Darmstadt, July 1, 1744. In 1763 he entered Göttingen university, where in 1770, after spending several years in England, he became extraordinary professor of physics, and five years later ordinary professor. This post he continued to hold till his death, February 24, 1799. As a physicist he is best known for his investigations in electricity, more especially as to the so-called Lichtenberg figures (see vol. viii. p. 66), which are fully described in two memoirs *De nova methodo naturam ac motum fluidi electrici investigandi* (Göttingen, 1778–79). He sent many excellent contributions to the Göttingen *Taschenkalender* from 1778 onwards, and to the *Göttingische Magazin der Literatur und Wissenschaft*, which he edited for three years (1780–82) along with J. G. A. Forster

His various scientific writings occupy the latter part of his *Vermischte Schriften*, edited by Kriess (9 vols., Göttingen, 1800–5; new edition, 6 vols., Gotha, 1844–46). The earlier volumes of these collected writings contain his satirical and humorous productions. His keen satire involved him in many a literary controversy with well-known contemporaries, such as Lavater, whose science of physiognomy he wittily ridiculed, and Voss, whose views on Greek pronunciation called forth a powerful satire *Ueber die Pronunciation der Schöpse des alten Griechenlandes* (1782). Notes of his lectures on natural philosophy, astronomy, and physical geography were published by Gamauf (Vienna, 1808–12, 1813, 1819); and more recently some of his brilliant sayings have been collected by Grisebach in one volume, *Lichtenberg's Gedanken und Maximen: Licht-Strahlen aus seinen Werken* (Leipsic, 1871).

LICINIUS. Publius Flavius Galerius Valerius Licinianus Licinius, Roman emperor, of Dacian peasant origin, was born probably about 250 A.D., and was elevated after the death of Severus to the rank of Augustus by Galerius, his former friend and companion in arms, on November 11, 307, receiving as his immediate command the provinces of Illyricum. On the death of Galerius in May 311, he shared the entire empire with Maximin, the Hellespont and the Thracian Bosphorus being their mutual boundary. In March 313 he entered into alliance with Constantine at Milan, and in the following month inflicted a decisive defeat on Maximin at Heraclea, with the result of establishing himself as master of the East, while Constantine (now his brother-in-law) was supreme in the West. In the following year his jealousy led him to encourage a treasonable enterprise on the part of Bassianus against Constantine. When his perfidy became known a civil war ensued, in which he was twice severely defeated—first near Cibalis in Pannonia (October 8, 314), and next in the plain of Mardia in Thrace; the outward reconciliation, which was effected in the following December, left Licinius in possession of Thrace, Asia Minor, Syria, and Egypt, but added numerous provinces to the Western empire. In 323 Constantine, tempted by the "advanced age and unpopular vices" of his colleague, anew declared war against him, and, having defeated his army at Adrianople (July 3, 323), succeeded in shutting him up within the walls of Byzantium. The defeat of the superior fleet of Licinius by Crispus, Constantine's eldest son, compelled his withdrawal to Bithynia, where a last stand was made; the battle of Chrysopolis (September 18) finally issued in his submission and death.

LIEBER, FRANCIS (1800–1872), a distinguished publicist and writer on political science, was by birth a German, by adoption a citizen of the United States. He was the son of Frederick William Lieber, and was born at Berlin, March 18, 1800. Upon the return of Napoleon Bonaparte from Elba, young Lieber, then only fifteen years of age, volunteered as a soldier, and served with his two brothers under Marshal Blücher in the campaign of 1815. He fought at Ligny, Waterloo, and Namur. In the last-named battle he was twice severely and dangerously wounded. At the close of the war he returned to his studies, and joined the Berlin gymnasium under Dr Jahn. Shortly afterwards he was arrested and thrown into prison for his political sentiments, the chief evidence against him being several songs of liberty which he had written. After several months' confinement he was discharged without a trial, but informed that he would not be permitted to pursue his studies at the Prussian universities. He accordingly went to Jena, where he took his degrees in 1820, subsequently continuing his studies at Halle and Dresden. When the Greek revolution broke out, young Lieber instantly resolved to take part in the struggle for Grecian independence. He made his way with great difficulty to Marseilles, travelling much of the way on foot, and thence embarked for Greece. His experiences there are recorded in his *Journal in Greece*, published at Leipsic in 1823, and at Amsterdam in the same year under the title of *The German Anacharsis*. Returning from Greece after the failure of the struggle, he landed at Ancona, and proceeded to Rome. There he made the acquaintance of Niebuhr, then Prussian ambassador to Rome, who took great interest in him and employed him as tutor to his son. He lived a year in the family of the historian, a period of his history which he afterwards embalmed in his *Reminiscences of Niebuhr*, first published in America, and afterwards in England. Returning from Rome to Berlin in 1823, he was soon again arrested by the Prussian authorities on the old charges of enmity to the Government and advocating republican opinions, and was imprisoned in the bastile of Koepnik, but was released after some months' confinement through the influence of Niebuhr. In 1825 he abandoned his country, and after spending a year in London went to the United States (1827), and as soon as possible was naturalized as a citizen of that country. Lieber took up his residence at Boston, and was occupied for five years in his laborious work *The Encyclopædia Americana* (13 vols.). In 1832 he removed to New York, where he published a translation of De Beaumont and De Tocqueville's work on the penitentiary system, with many notes. In 1833 he went to Philadelphia to prepare a plan of education for Girard College, then newly founded. While there he published *Letters to a Gentleman in Germany* and a supplement to his *Encyclopædia*. In 1835 he was appointed professor of history and political economy in South Carolina College at Columbia, S.C., where he remained more than twenty years, and during this period wrote and published the three great works upon which his fame as a writer chiefly rests—the *Manual of Political Ethics* (1838), *Legal and Political Hermeneutics* (1839), and *Civil Liberty and Self Government* (1853).[1]

In 1856 Lieber resigned the professorship in South Carolina College, and was immediately elected to a similar professorship in Columbia College, New York, and to the chair of political science in the law school of the same institution. He continued in the discharge of the duties of these positions until his death, which occurred October 2, 1872. During the great war for the preservation of the Union from 1861 to 1865, Lieber rendered services of great value to the Government of his adopted country, and was frequently consulted by the secretary of war. He was one of the first to point out by his pen the madness of secession, and was ever active in supporting the Government and upholding the Union. He prepared, upon the requisition of the president, the *Code of War for the Government of the Armies of the United States in the Field*, which was adopted and promulgated by the Government in General Orders No. 100 of the war department. This code has been characterized by many European publicists as a masterpiece, and it suggested to Bluntschli his codification of the law of nations, as may be seen in the preface to his *Droit International Codifié*. During this period also Lieber wrote his *Guerilla Parties with Reference to the Laws and Usages of War*, a valuable contribution to the law of war. At the time of his death he was by appointment of the Government of the United States the umpire of the commission for the adjudication of Mexican claims. The political writings of Francis Lieber are held in great estimation by all publicists. Sir Edward S.

[1] New editions of these works and of his miscellaneous writings have been published recently at Philadelphia.

Creasy, in his *First Platform of International Law*, alluding to his death, has justly said of him, "America and the civilized world in general have lately had to deplore in his death the loss of one whom the French jurist M. Laboulaye has truly styled 'une des figures les plus originales parmi les jurisconsultes de notre temps.'"

Besides the works already mentioned, Lieber published at various times many smaller works and pamphlets on different subjects, all of which attracted public attention, such as *The Origin and Development of the First Constituents of Civilization, Great Events Described by Great Historians, Essays on Property and Labour, The Laws of Property, Penal Laws and the Penitentiary System, Prison Discipline, The Relation between Education and Crime, The Pardoning Power, The Character of the Gentleman, International Copyright, Laura Bridgman's Vocal Sounds, On Anglican and Gallican Liberty, The Post Office and Postal Reforms, Independence of the Judiciary, Nationalism, Rise of the Constitution* (an unfinished work), and many minor tracts and publications. These works are all written with as much ease and purity of idiom as if English had been his native tongue, a fact not more remarkable than that he, a German, should have become the great American teacher of the philosophy of Anglican political science. (M. R. T.)

LIEBIG, Justus (1803–1837), was born at Darmstadt in 1803. His father carried on business as a drysalter and dealer in dye-stuffs, and made various experiments with a view to improved methods of preparing and purifying his wares. These led the son to take an interest in chemistry, and to seek for knowledge in the chemical books and periodicals in the grand-ducal library, which is rich in scientific works. At home he employed his time in repeating, as far as the means at his command admitted, the experiments he found described in books, and thus while still a boy attained a theoretical and practical knowledge of chemistry comparable with that of many full-grown professors of the science. He determined to be a chemist, to devote his life to the pursuit of science. The only kind of chemist available for teaching purposes was the chemist and druggist, and accordingly Liebig, at the age of fifteen, entered the shop of an apothecary at Heppenheim near Darmstadt to study chemistry. He soon found out how great is the difference between practical pharmacy and scientific chemistry, and returned to Darmstadt, after ten months, to look for another and more likely way of attaining his object. After some months spent in study at home he entered the university of Bonn, which he soon left for Erlangen. There he attended the lectures of Kastner on chemistry, and, besides the study of allied sciences, devoted some time to make up for the almost total neglect of school work caused by his early love of chemistry. He was much influenced by the metaphysical speculations of Schelling, and in after life referred to this influence as injurious to him as a scientific investigator. In those days there were no laboratories accessible to ordinary students, and Liebig had to content himself with what the university could give him in the lecture-room and in the library. Both at Bonn and at Erlangen he formed a students' chemical and physical society for the discussion of new discoveries and speculations as these appeared in scientific books or periodicals. In 1822 he left Erlangen with the degree of Ph.D. By means of the liberality of Louis I., grand-duke of Hesse-Darmstadt, Liebig was enabled to continue his chemical studies in Paris. There he made the acquaintance of Runge, Mitscherlich, and Gustav Rose. He attended the lectures of Gay-Lussac, Thenard, and Dulong, and, while carrying on the investigation into the composition and properties of the fulminates which he had already partly published, he attempted, as at Erlangen, to work up his neglected school studies. The results of his work on the fulminates were communicated to the Academy of Sciences, and attracted the favourable attention of Humboldt, who was at that time in Paris. Humboldt introduced Liebig to Gay-Lussac, who admitted him into his private laboratory as a pupil. Here he had opportunities of learning all the mysteries of the art from one of the most skilful and ingenious of experimenters. It was on the advice of Humboldt that Liebig determined to become a teacher of chemistry, but difficulties stood in his way. As a native of Hesse-Darmstadt, he ought, according to the academical rules of the time, to have studied and graduated at the university of Giessen, and Humboldt had to use his influence to induce the authorities to forgive his having attended the foreign university of Erlangen. After examination his Erlangen degree was recognized, and in 1824, in his twenty-first year, he was appointed extraordinary professor of chemistry in the university of Giessen. Two years later he was promoted to the post of ordinary professor, which he held for twenty-five years, notwithstanding the most tempting offers from other universities. It was here, in the small town and small university of Giessen, that by far the most of Liebig's work was done. He began by remedying the evil which as a student he had himself felt. He induced the Darmstadt Government to build a chemical laboratory in which any student of the university might obtain a thorough practical training. It is difficult for us, who live in a time when nearly every university and many schools possess well-arranged and often well-endowed laboratories, to understand how great a revolution was made in the practical teaching of physical science by the foundation of the Giessen laboratory. We can form some idea of it by reading Liebig's articles on the condition of chemistry in Austria and Prussia, in which he goes over in detail the means of teaching afforded in the various universities of those great countries. He tells us that in 1838 two young Prussians came to Giessen to study chemistry, unable to obtain entrance to a laboratory in their own country, but were ordered back again by the Prussian Government. Fortunately other Governments were less strict, or other students were less obedient, and crowds of young men anxious to study chemistry came to Giessen, and carried home the light there acquired. Partly by Liebig's urgent appeals to the interests and to the shame of the great German states, partly by the influence of his pupils, a great reform was effected, and German universities now vie with one another in offering opportunities of practical instruction in chemistry and the other physical sciences.

The amount and the importance of the laboratory work done by Liebig in Giessen were very great. Without considering here the work done by his students under his direction, of which no doubt a very large part was conceived by him, and in the execution of which he constantly contributed his assistance and advice, we shall look only at what appears under his own name. During the twenty-six years he spent at Giessen as ordinary professor, he contributed to scientific journals more than two hundred papers, about twenty of which were records of joint work, chiefly with Wöhler. During the same time he published his works on organic analysis, organic chemistry, chemistry applied to physiology and agriculture, his *Chemical Letters*, and many smaller treatises. From 1832 he was joint editor of the *Annalen der Pharmacie*, from 1837 of the *Handwörterbuch der reinen und angewandten Chemie*, and from 1847 to 1856 of the *Jahresbericht der Chemie*. These statements give some idea of the amount of his work; of its importance and of its effect on the history of science we shall speak later.

In 1845 he was raised to the hereditary rank of baron under the title of Freiherr von Liebig. In 1852 he accepted the invitation of the Bavarian Government to the ordinary professorship of chemistry in the university of Munich. This office he held till his death in 1873.

In private life Liebig was hospitable, courteous, and kindly. Honoured by all the great scientific societies of the world, and regarded by almost every one as the great authority in chemistry, he assumed no airs of superiority, and lived the simple and quiet life of a German professor. Liebig's influence on the history of chemistry may be considered under five heads:—(1) the effect of the opening of the Giessen laboratory, and of Liebig's constant efforts to induce other universities to follow this example; (2) the improvements introduced by him in methods of investigation and in apparatus; (3) the discovery of new facts; (4) the development of theory; and (5) the application of chemistry to physiology, agriculture, and the arts.

We have already spoken of the first. Under the second head by far the most important change introduced by Liebig was his method of organic analysis. Organic substances were analysed, and analysed with accuracy, before 1830, but such analyses could then be carried out only by highly skilled chemists, and involved great labour and the use of cumbrous apparatus. Liebig's method of organic analysis, which was published in all its details in 1831, and which (with important but secondary improvements) is that still used, made it easy for any advanced student to make a fairly accurate and very useful analysis of an organic substance. Analysis is to the chemist what astronomical methods for determining longitudes and latitudes are to the geographical explorer. Without it many interesting and useful discoveries may be made, but it is only when complete and accurate analyses are made of all the new substances produced in the course of a research that the research becomes fully available to other explorers. If Liebig had contributed nothing to organic chemistry but his method of analysis, he would still have been in a perfectly true sense the founder of modern organic chemistry. Many other improvements of apparatus are due to him; we need only mention the simple form of condenser called by his name, and constantly used by every chemist, and the easy and accurate method for determining the quantity of urea in a solution, which was the first step towards introducing precise chemical methods into practical medicine. This is also the proper place to refer to his analyses of the natural alkaloids, and his discovery of the method of determining their equivalents by the analysis of their chloroplatinates. In the third place we have to consider the new facts discovered by Liebig. The very great addition to our knowledge of organic chemistry made by Liebig naturally throws into the shade his contributions to inorganic chemistry, but we ought to remember his numerous analyses of mineral waters and his contributions to the difficult question of the accurate separation of cobalt and nickel. It is, however, in organic chemistry that Liebig's great discoveries were made. These discoveries are so intimately connected with his chemical theories that we may most conveniently consider them along with the fourth head, his contributions to the development of chemical theory.

The notion of compound radicals is to be found in chemistry as far back at least as the time of Lavoisier. Lavoisier says, "Some experiments of my own and some made by M. Hassenfratz have convinced me that in general nearly all the vegetable acids, such as tartaric, oxalic, citric, malic, acetic, pyrotartaric, pyromucic acids, have for their radical hydrogen and carbon, but united so as to form a single base, that all these acids differ from one another by the difference in proportion of these two substances and the degrees of oxidation." Berzelius adopted this view and expressed it thus,—"We find the difference between organic and inorganic bodies to be that, while in inorganic nature all the oxidized substances have a simple radical, all the organic substances have compound radicals. Just as ammonia is an alkali with a compound radical, but possessing nevertheless the greatest analogies with the mineral alkalies which have simple radicals, so we find the greatest analogy between the mineral and the organic acids, so that the relations of potash and soda to acetic, oxalic, citric acids are the same as their relations to sulphuric, nitric, phosphoric acids." These views were published by Berzelius in 1817. In 1815 Gay-Lussac had discovered cyanogen, and shown that this compound of carbon and nitrogen is the radical of prussic acid and its salts, in the same sense as chlorine is the radical of hydrochloric acid and the chlorides. Ampère had indicated a theory of the constitution of the ammonia salts, which Berzelius worked out in detail, according to which those salts contain a compound radical, ammonium, playing in them the part of potassium in the potash salts. Finally, Davy suggested in 1815 that the hydrated acids which correspond in function to hydrochloric acid should be regarded as the true acids, and proposed to represent them as compounds of hydrogen with a radical.

Such were the knowledge and the theoretical position of chemists on this question when Liebig became professor; the dates to which we have referred correspond to the time when as a schoolboy he was devouring the contents of chemical journals at Darmstadt, and no doubt he then became acquainted at first hand with the discoveries and speculations of Ampère, Davy, Gay-Lussac, and Berzelius.

We have seen that his first investigation referred to the fulminates. He continued his researches upon the compounds of cyanogen and the substances connected with them formed frequent subjects of his researches during his whole life. In this region of organic chemistry he made many important discoveries, of which the limits of this article do not allow a detailed account; we can only mention melone, mellam, ammeline, ammelide, and melanine, as substances discovered and investigated by him. In the course of these investigations he discovered the precise nature of the chemical changes which occur in the manufacture of bromide of potash. In 1831 he examined the action of chlorine upon alcohol, among other substances discovered chloral, and commenced the series of investigations into the derivatives of alcohol and ether to which we shall refer immediately. In 1832 Wöhler and Liebig published the results of their joint research on the oil of bitter almonds and its derivatives. This research may be said to stand at the head of modern organic chemistry. For elegance of method and for clearness of insight it is unrivalled, and will always remain a model of what such an investigation should be. They showed in the clearest manner that the compound C_7H_5O (here and elsewhere in this article we use the symbols now in common use, instead of those employed by the authors), to which they gave the name of benzoyl, is the constant part, or radical, of a great series of compounds. The importance of this investigation was generally recognized. Berzelius hailed it as the advent of real daylight on the subject of organic chemistry, and even suggested the names proin or orthrin (from πρωί and ὄρθρος) for the newly discovered radical.

We now come to the long controversy as to the constitution of alcohol and ether, which engaged so much of Liebig's time and energy. Gay-Lussac had shown in 1815 that alcohol and ether might, as far as their composition is concerned, be represented as compounds of olefiant gas and water, and further that, if we represent the quantities by volume of gas or vapour, ether contains one volume of olefiant gas and half a volume of water vapour, while alcohol contains equal volumes of the two. In 1828 Dumas and Boullay published an elaborate memoir on the preparations and properties of the ethers, in which they further developed the ideas suggested by Gay-Lussac. They regarded olefiant gas as the radical of all the etherial compounds, as ammonia is of the ammoniacal salts, and formulated them thus:—

	Base.	Acid.	Water.
Salammoniac	NH_3	HCl	...
Muriatic ether	C_2H_4	HCl	...
Nitrite of ammonia	$2NH_3$	N_2O_3	H_2O
Nitrous ether	$2C_2H_4$	N_2O_3	H_2O
Ether	$2C_2H_4$	...	H_2O
Alcohol	C_2H_4	...	H_2O
Ammonia solution	NH_3	...	$2H_2O$

We have given only a sample of their tables, leaving out among others some substances in reference to the composition of which they had fallen into error, error which Liebig detected and used as an argument, valid enough then no doubt, but of little interest now.

In 1833 Liebig proposed a quite different theory, one which stands to Dumas and Boullay's in the same relation which the ammonium theory holds to the ammonia theory of the constitution of the ammoniacal salts. Just as Ampère and Berzelius regarded salammoniac, not as NH_3,HCl, but as NH_4,Cl, so Liebig proposed for muriatic ether the formula C_2H_5,Cl instead of C_2H_4,HCl. The really cogent argument which he brought forward, the argument which we can now best appreciate, is that, while alcohol contains combined water, ether does not. According to Dumas and Boullay alcohol and ether are both hydrates, but in Liebig's view ether is $(C_2H_5)_2O$ and alcohol $(C_2H_5)_2O,H_2O$. If we wish to understand this argument we must recollect that to the chemists of that time oxidized hydrogen was water, and Liebig's arguments are as sound now as they were then, for the most recent views represent alcohol as $C_2H_5—O—H$, and this contains oxidized hydrogen, or, as we may say, half a molecule of water, and Liebig's tests do not distinguish preformed water, but hydrogen and oxygen combined as they are in water. Much debate and investigation followed, in the course of which the relations of all the substances derived from alcohol were thoroughly and practically studied in a fuller and more careful manner than would have been possible had there not been a theoretical point to defend and to attack. The enormous number of facts discovered by Liebig put him in a very favourable position as the advocate of his theory. Chemists could not do without a knowledge of these facts, and they could only get this knowledge through Liebig's papers, in which the facts were expressed in the language of his theory.

In 1835 Regnault began a series of most important researches into the compounds derived from olefiant gas. He showed that many of these substances might be classified and their relations explained by the assumption of a radical C_2H_3, to which he gave the name of aldehydene. Liebig saw that according to his view of the meaning of the word radical, as "the unchanging constituent in a series of compounds," the same radical may be assumed in alcohol and in acetic acid, and in 1839, in a note published in the *Annalen*, he puts the matter in a very clear light. He says, "Ether and ammonia have in their compounds a certain resemblance which was first indicated by Dumas and Boullay, and the view of the constitution of the ammonia salts which is generally held in France was the reason why ether was considered the first hydrate of olefiant gas, alcohol as the second hydrate, &c. ; in Germany and other countries the water necessary for the constitution of the salts of ammonia with oxygen acids was considered as an integral part of the base ; it was assumed that this water forms with the ammonia oxide of ammonium $(NH_4)_2O$, and this view in a certain sense smoothed the way for another, according to which the existence of organic oxides, capable of neutralizing acids, appeared very probable, as a necessary complement to the organic acids which chemists had long been inclined to regard as oxides of organic radicals. Ether was in these countries regarded as an organic oxide, and this difference of view excited a ten years' strife, as an immediate result of which we may regard the discovery of a great number of compounds which enriched science with innumerable important observations. No region of organic chemistry has been so thoroughly and so completely studied as the compounds connected with ether ; and now, when the existence of organic oxides is no longer denied, the support of the opposite opinion has come to an end, although it cannot be said that the question itself has been experimentally decided. If we compare in the light of our present knowledge the ammonia compounds with the ether compounds, we at once see that the opposing views were fundamentally the same in the two cases. The disputes took place because we were not at one as to the interpretation of the phenomena. The ether and ammonia compounds assume in fact the same form if amidogen is regarded as the unchangeable radical of the ammonia compounds, and acetyl [Regnault's aldehydene] as the starting point of the ether compounds. The two sets of compounds differ only in so far as we must ascribe to acetyl the power of forming acids, a power which amidogen does not possess."

He then gives a table containing in two columns the ammonia and the ether compounds, in which C_2H_3 corresponds to NH_2, C_2H_4 to NH_3, and C_2H_5 to NH_4, and adds, "These formulæ require no explanation ; they have been developed in order to show the extraordinary resemblance of the ammonia and the ether compounds, and to show why it was that many chemists regarded olefiant gas as the first member of the series of ether compounds. Both of the formerly antagonistic theories have, as may be easily seen, from this point of view the same foundation, and all further questions as to the truth of the one or other view is thus of course set at rest."

It was during the course of the controversy which then closed that Liebig had discovered aldehyde, chloral, and, simultaneously with Soubeiran, chloroform, besides numerous other substances of less general interest, and developed the theory now generally received of the formation of ether by the action of sulphuric acid on alcohol.

In the very short sketch given above of the discussion as to the constitution of ether, we mentioned that Liebig's ethyl theory was to some extent borrowed from Berzelius. Berzelius had suggested that ether was the oxide of a radical (Liebig's ethyl), but he was at first inclined to regard alcohol, not as the hydrate oxide of the same radical, but rather as the oxide of another one, which with our symbols would be written C_2H_6. But there was a deeper difference than this between the radical theories of Berzelius and Liebig. This essential difference first clearly showed itself in the notes which Liebig added to two letters from Berzelius to Wöhler, published in the *Annalen* in 1839. In these letters Berzelius gives his views of the constitution of oxychlorides, with which he classes such bodies as trichloracetic acid. All those bodies he represents as compounds of oxides and chlorides, in harmony with the dualistic system.

Thus, instead of SO_2Cl_2, $C_2HCl_3O_2$, &c., he writes SCl_6+2SO_3, $C_2Cl_6+C_2O_3$, &c. (taking the anhydrous acid). In his second letter on Malaguti's chlorinated ethers he naturally arrives at formulæ of extreme complexity. In his notes Liebig states that he does not agree with Berzelius, and that the analogy first pointed out by Berzelius between inorganic and organic compounds and his theory of organic radicals had been a guiding star in a labyrinth in which previously no one could find the way. "But, while there are points of resemblance, there are very many points of difference ; we should follow a theory as long as it gives us light and explains facts ; up to a certain point the principles of inorganic chemistry help us in organic chemistry, beyond it they leave us, and produce instead of removing complications; beyond this point we require new principles."

These new principles were supplied by Liebig's radical theory. As Liebig showed, abstract discussions as to the truth of a theory are out of place in an experimental science ; the question is not as to their essential truth but as to their practical fruitfulness. Do they help us to understand old and to discover new facts ? If they do, the morrow may take thought for its own theories. These are not Liebig's words, but they seem to express his ideas.

Liebig early expressed his approval of Davy's views as to the constitution of acids, but he rarely used the language or the notation corresponding to that view. This divergence between his theory and his habitual language is interesting as showing that he held that the same truth may be expressed in more than one way, and that where no immediate point is to be gained it is well to employ the language best understood by those whom we address. In this as in his preference for what was called the equivalent system of notation over that of Berzelius, he showed his sound practical judgment and common sense. We now see that the notation of Berzelius was nearer the truth, but its advantages could not be felt until chemistry had advanced further, and its retention would have led to complications of formulæ and obscuring of relations. The resemblance indeed of our present notation to that of Berzelius is to a great extent accidental, and the advance was hastened rather than hindered by what now looks like a retrograde step.

There is one other point which we have to mention under the present head. Liebig at once saw the importance of Graham's researches on the phosphates. He applied Graham's idea of polybasicity to organic acids, and satisfactorily proved, notwithstanding the opposition of Berzelius, that tartaric acid is dibasic and citric acid tribasic.

We have hitherto said nothing as to the relation of Liebig's theories to those at present held by chemists. On this subject a word may suffice. The great revolt against the radical theory led by Laurent and Gerhardt produced a long and acrimonious controversy. In that controversy Liebig took his part, and many hard and some unfair things were said by him. The controversy itself was of course the means of producing a vast amount of thorough research, and was thus, like all such contests, of direct use; it also led to the revision of all theoretical opinions from a totally new point of view. From this ordeal the radical theory has emerged, not very different in appearance. But it has undergone a profound change. Its foundations have been immensely strengthened, it has been to a great extent explained. Some chemists seem to think that this makes it an entirely new theory. We cannot share this view. Our reasons for believing in ethyl and benzoyl differ from the reasons adduced by Wöhler and Liebig only in this that we have arguments which they had not ; their arguments remain. We now know something of the reason why such radicals exist; we can, to a certain extent, deduce their properties from those of the elements which they contain, but explanation is something different from refutation ; the theory has grown, but still remains the same theory.

Liebig all his life showed a special predilection for the study of the immediate products of animal life. He investigated with untiring zeal the substances contained in urine and in the juice of flesh. In these researches he discovered many new substances, and cleared up doubts and difficulties as to their relations to one another and to other bodies. Late in life he expressed the most lively interest in Volhardt's synthesis of sarcosin and creatine, substances with the preparation of which he had long before been engaged. In this connexion it is right that we should mention his elaborate investigation on uric acid and its derivatives. This line of study led him to interest himself in the chemistry of food, and the importance of his work in this direction can scarcely be overestimated. We do not refer alone to his methods of preparing the extract of meat and the food for infants, which have perhaps spread his fame more widely than his strictly scientific work could have done ; we refer rather to the influence which his analyses and calculations have had on medical opinion and practice. And this leads us to our fifth head, Liebig's influence on the application of chemistry to physiology, agriculture, and the arts.

Before Liebig undertook his investigations into the chemistry of vegetation, the views (they can scarcely be called theories) held as to the manner in which plants are nourished were vague in the extreme. The only point satisfactorily made out was that under the influence of light the green parts of plants are capable of decomposing carbonic acid, giving off oxygen and retaining the carbon. Saussure, to whose careful experiments the establishment of this fact, first noticed by Priestley, is mainly due, believed that the nitrogen of the plant came from soluble organic substances absorbed by the roots, and expressly says that the main use of ammonia in manure is as a solvent of humus, which he supposed to be one source of the carbon in plants ; and, although the ashes of the various plants had been analysed, the importance of the mineral constituents of vegetables was not at all recognized. Liebig undertook the investigation of this question in 1840. He showed that the plant derives its nourishment partly from the air, partly from the soil ; the carbonic acid and water, the ammonia and nitric acid, which he showed to be the sources of the plant's nitrogen, come from the atmosphere ; while the potash, soda, lime, iron, magnesia, sulphuric acid, phosphoric acid, and silica come from the soil. No exhaustion can take place of the former, but the soil contains only a limited amount of the latter in a soluble state, and when this is used up the soil becomes barren. Not only so, but the absence of any one of the necessary substances makes the soil barren. He showed how manure acts by restoring these deficient ingredients, and how, when the land is left fallow, atmospheric influences decompose the insoluble minerals and supply the soil with what has been removed. He further showed that plants use and therefore remove from the soil the articles of plant food in various proportions and thus explained the advantage of a rotation of crops. The artificial manures which he introduced contained the essential mineral substances, and a small quantity of ammoniacal salts, because he held that while the air supplies ammonia it does not always supply it fast enough, particularly to the less leafy plants. He bought a field near Giessen for his experiments, and treated it with the artificial manure, but the result was disappointing. The manure was not inactive, but not nearly so active as it should have been. It was many years before he detected the cause. To prevent the rain washing away the alkalies in the manure, he had taken great pains to render them insoluble. Way's experiments on the absorption of manure by soils (1850) occurred to him as suggesting an explanation, and in 1857 he made a number of experiments on the retention of various substances by earth. In these he confirmed and extended Way's observations, and thus saw that his effort to make his manure better had made it worse. As he says, "I had sinned against the wisdom of the Creator, and received my righteous punishment. I wished to improve His work, and in my blindness believed that, in the marvellous chain of laws binding life on the earth's surface and keeping it always new, a link had been forgotten which I, weak powerless worm, must supply."

Now, just as he showed that plants require certain—often small—quantities of particular substances, else they will not grow at all, however great may be the quantities of other kinds of food supplied, so he showed that animals also require, not only a proper quantity of food, but also the right proportion of the different kinds of food, mineral as well as organic. In the classification of the kinds of organic food into heat-producing and blood-forming, it was necessary to examine whether the carbohydrates, starch, sugar, &c., should be placed alongside of fat. He was thus led to inquire into the power of the animal body to produce fat from starch or sugar, and came to the conclusion, contrary to the opinion of Dumas and Boussingault, that this transformation does take place.

Liebig's investigations into the relations of organic chemistry to physiology led him to the conviction that the only source of animal heat is the heat produced by the oxidation of the tissues, and, strange as it may appear, he had to defend this view against what he truly enough, though perhaps somewhat impolitely, called the absurd nonsense of his medical opponents. He also succeeded in demolishing, it is to be hoped finally, the ridiculous belief in the possibility of the spontaneous combustion of the human body.

Liebig's theory of FERMENTATION (*q.v.*) aimed at explaining the phenomena on purely chemical principles. He ridiculed the physiological theories, and looked upon the growth of fungi rather as incident of the fermentation, adducing the fermentative changes of amygdaline and similar substances as cases of fermentation without life.

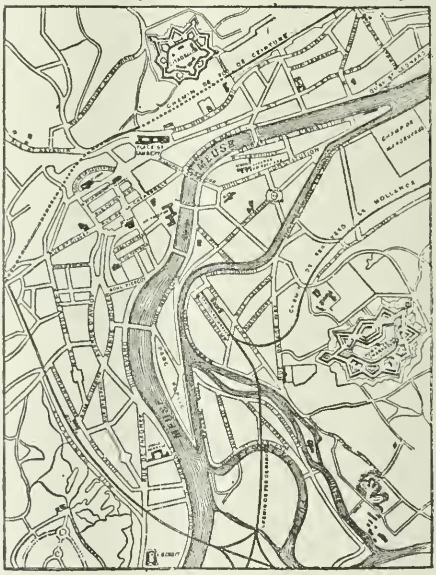
We have still to notice one of Liebig's chemical discoveries, of secondary interest chemically, but of great practical importance. This is his discovery of a method for depositing a uniform film of metallic silver on smooth clean surfaces. This method may render it possible to use reflectors for astronomical telescopes of a sizo unattainable with the old speculum metal.

The most important of Liebig's works separately published are as follows:—*Anleitung zur Analyse organischen Körper*, 1837, 2d ed., 1853; *Die Chemie in ihrer Anwendung auf Agricultur und Physiologie*, 1840, 9th ed., 1875-76; *Die Thier-Chemie oder die organische Chemie in ihrer Anwendung auf Physiologie und Pathologie*, 1842, 3d ed., 1847; *Handbuch der Chemie mit Rucksicht auf Pharmacie*, 1843; vol. i. of Geiger's *Handbuch der Pharmacie*, new ed.; *Chemische Briefe*, 1844, 6th ed., 1878; *Chemische Untersuchungen über das Fleisch und seine Zubereitung als Nahrungsmittel*, 1847; *Grundsätze der Agricultur-Chemie*, 1855; *Zur Theorie und Praxis in der Landwirthschaft*, 1856; *Naturwissenschaftliche Briefe über die moderne Landwirthschaft*, 1859; *Reden und Abhandlungen*, 1874, a posthumous collection of some of his addresses and shorter publications. Liebig's scientific papers were chiefly published in Poggendorff's *Annalen* till 1839, and in Liebig's *Annalen* from 1832 onwards. His criticism of Bacon appeared in the *Augsburger allgemeine Zeitung* in 1863 and 1864, and also as a separate publication. (A. C. B.)

LIECHTENSTEIN, a sovereign and independent principality, the smallest in Germany, is bounded on the N.E and E. by the Austrian Vorarlberg, on the S. by the Swiss canton of Grisons, and on the W. by the Rhine, while on the north it tapers almost to a point. The state, consisting of the lordships of Vaduz and Schellenberg, is only 15 miles in length, hardly over 5 miles in its average breadth, and comprises an area of 68 square miles. Excepting in the immediate neighbourhood of the Rhine, the surface of the country is mountainous, being traversed from south to north by spurs of the Rhætian Alps, which at some points attain an altitude of about 7000 feet. The climate is mild, and the soil generally fertile and well watered. The chief products are corn, wine, flax, fruit, and timber. Agriculture and the tending of cattle form the chief employment of the inhabitants. A branch of the Vorarlberg railway from Feldkirch to Buchs passes through the state. In 1876 the population amounted to 8664, of old German extraction, and Roman Catholics by confession. The capital is Vaduz or Liechtenstein, with 960 inhabitants.

Until 1866 Liechtenstein formed part of the German confederation, but from that date it has been constitutionally independent, although for the sake of convenience the postal system, customs, and currency are under the general Austrian administration, from which the principality receives annually some £1600 as its share in the customs dues. According to the charter of the 26th September 1862, Liechtenstein is a constitutional monarchy, the sovereign prince sharing the legislative power with a diet of fifteen members (elected sexennially), of whom three are nominated by the prince, and twelve elected by popular suffrage. The chief control of the principality is carried on at Vienna by a court chancellory, which also serves as the judicial court of appeal of first instance, the ultimate court of appeal being at Innsbruck. The immediate direction of the principality in administrative and judicial matters is at Vaduz. The inhabitants are free from military service and direct taxation. The annual revenue amounts to about £6000. Although the sovereignty of the prince is so small, his estates in Austria and elsewhere render him one of the wealthiest landed proprietors in Germany, his income from them amounting to nearly £140,000 sterling. The house of Liechtenstein, one of the oldest in Central Europe, was elevated to the princely dignity in the early part of the 17th century. Anthony Florian in 1713 obtained a vote and seat in the imperial diet, and after the union, in 1719, of the lordships of Vaduz and Schellenberg into one principality under the name of Liechtenstein, his privileges were, in 1723, confirmed to his successors. See Jacob von Falke, *Geschichte des fürstlichen Hauses Liechtenstein*, 2 vols. (Vienna, 1868-77).

LIÉGE (Germ., *Lüttich*; Dutch, *Luik*; Walloon, *Lîge*; usually Latinized as *Leodium*), a city of Belgium, the chief town of the province of Liége, is situated in 50° 39′ N. lat. and 5° 31′ E. long., 56 miles east of Brussels (62½ by



Plan of Liége

rail), and 16 miles south-south-west of Maestricht. It occupies a remarkably fine position on the banks of the Meuse, which at this point is joined by the Ourthe. On the left-hand side stands the older city with the citadel and the more important historical buildings; on the right hand lies the lower and more modern portion, commanded by the fort of the Chartreuse. The river, there 460 feet across, is spanned by several bridges, of which the Pont des

Arches, rebuilt in 1860-63, dates originally from the 8th century, and plays a prominent part in the local annals. Place St Lambert is the historical centre of Liége. Here still stands the noble building—erected (1508–40) by Cardinal de la Marck in a late Gothic style—which down to the revolution was the palace of the prince-bishops, and is now with its modern extensions occupied by the public courts and other administrative offices. And here, till it was ruined by the revolutionists in 1794, and completely removed in 1808, stood the old cathedral of St Lambert, originally founded in 712, and rebuilt after a great fire at the close of the 12th century. The rank of cathedral was in 1802 transferred to the abbey-church of St Paul, the foundation of which is assigned to 968, though the nave is no older than the 16th century, and the choir belongs to 1280. The stained glass and the wood carving of the pulpit by Geefs deserve particular mention. Other churches of note are St Jacques, a fine Gothic building founded in 1016, with a Romanesque west tower and a polygonal choir; St Barthélemy, a completely modernized basilica of the 12th century; St Martin, founded in 962 and rebuilt in the middle of the 16th century; and the Holy Cross, founded by Notker in 979, with a west choir dating from the 12th century, and the east choir and nave from the 14th. The university of Liége, established in 1817, is a flourishing institution with about 40 professors and 800 students, a library of 100,000 volumes, a botanic garden (1819, formerly the Jesuits' garden), a school of mines (1825), a school of arts and manufactures, a normal grammar school, and several other auxiliary foundations. There is no theological faculty,—the theological seminary, with a large library of its own, being an independent institution. The city further possesses a blind asylum, a deaf and dumb institute, schools of design, painting, and music, a zoological garden, a municipal museum, &c. The Place d'Avroi is adorned by an equestrian statue of Charlemagne by Jehotte; and in front of the theatre stands a bronze statue of Gretry, the composer, who was born at Liége.

Liége is the centre of a great mining district rich in coal, lead, zinc, and iron; the coal-mines extend under the city and the river. In 1879 358,100 tons of coal were raised in the province, 22,156 persons being employed in the pits. The iron, lead, and zinc foundries in the town and neighbourhood work up large quantities of ore in addition to the local supply. Steel, copper, and tin wares, steam-engines and general machinery, woollen goods, excellent saws and files, nails, needles, mirrors, clocks, leather, paper, and oil are among the products of the versatile industry of the place. Liége firearms have long enjoyed a wide reputation. They give employment to about 30,000 workmen, who for the most part work in their own houses, though in 1878 a large factory was erected in the American style for making all parts of the weapon by machinery. In 1878 183,806 single-barrelled guns, 113,121 double-barrelled guns, 403,649 revolvers, 19,395 saddle pistols, and about 85,000 army weapons, &c., were passed by Liége through the Government testing office. The trade of Liége is favoured by the fact that the town is an important junction on the Rhenish Belgian Railway, commands more than one navigable river, and has long been one of the leading cattle-markets in the country. The population was 115,956 in 1874.

About 720 the bishops of Tongres, after oscillating between Tongres and Maestricht, settled at Liége, though they did not take the title bishop of Liége for more than two centuries. Their church of St Lambert received large territorial endowments, and in the 14th century they became princes of the empire. For centuries the struggle was maintained between episcopal tyranny and civic independence; and ducal and imperial armies were called in to crush the insurrections. In this way Charles the Bold of Burgundy made himself master of the city in 1467, and again with much bloodshed and barbarity in 1468. Bishop Ferdinand in 1650 and Bishop Maximilian in 1684 were each imposed on the citizens by force of arms, and kept them down by means of a strong citadel and foreign soldiers. In 1691 Liége was bombarded for five days by Marshal de Boufflers; in 1702 Marlborough took the citadel by storm from a French garrison; and in 1792 the town was the scene of a great defeat of the Austrians by the French.

LIEGNITZ, the capital of a district of the same name in the Prussian province of Silesia, is picturesquely situated on the Katzbach, just above its junction with the Schwarzwasser, and 40 miles west-north-west of Breslau. It consists of an old town, surrounded by pleasant, shady promenades, and several well-built suburbs. The most prominent building is the palace of the former dukes of Liegnitz, rebuilt after a fire in 1835, and now occupied by the administrative offices of the district. The Ritter Academie, founded by the emperor Joseph in 1708, for the education of the young Silesian nobles, was reconstructed as a gymnasium in 1810. The Roman Catholic church, with two fine towers, contains the burial vault of the dukes. The principal Lutheran church dates from the 14th century. There are also several other churches and schools, and a number of benevolent institutions. The theatre, the barracks, the military hospital, and the town-house are the most noteworthy of the remaining buildings. The manufactures of Liegnitz are considerable, the chief articles being cloth, wool, leather, tobacco, and pianos. Its trade in grain and its cattle-markets are likewise important. The large market gardens in the suburbs grow vegetables to the value of £20,000 per annum. Population in 1880 37,168, about one-sixth being Roman Catholics.

Liegnitz is first mentioned in an historical document in the year 1004. In 1164 it became the seat of the dukes of Liegnitz, who greatly improved and enlarged it, especially in 1170 and 1175. The dukes were members of the illustrious Piast family, which gave so many kings to Poland. At Wahlstatt, near Liegnitz, the tide of Mongolian invasion was stemmed, in 1241, in a hard-fought battle between the Tartars and the Christian chivalry under the duke of Silesia. The victory, indeed, remained with the invaders, but the obstinate resistance deterred them from any further attack on Germany. During the Thirty Years' War Liegnitz was taken by the Swedes, but was soon recaptured by the Imperialists. The Saxon army also defeated the imperial troops near Liegnitz in 1634. On the death of the last duke of Liegnitz in 1675, the duchy came into the possession of Austria, which retained it until the Prussian conquest of Silesia in 1740–45. In 1760 Frederick the Great gained a decisive victory near Liegnitz over the Austrians under Laudon, and in 1813 the list of important battles in this neighbourhood was completed by Blucher's defeat of the French at the battle of the Katzbach. During the present century Liegnitz has been uniformly prosperous, and its population has increased fivefold since 1800.

See Schuchard, *Die Stadt Liegnitz* (Berlin, 1868); Sammter and Kraffert, *Chronik von Liegnitz* (Liegnitz, 1861–73).

LIEN, in English and American law, properly means a right of detaining goods of another in your possession until a debt due to you from the owner of the goods is paid. To the original or common law conception of a lien it would appear to be necessary that the goods over which lien is claimed should be actually in the possession of the creditor, and further that the debt should have been incurred with reference to the goods which are detained. Such is the lien of the workman to whom articles are delivered for the purpose of being operated upon by him in the way of his trade. He is entitled to keep the article he has worked at until remuneration for his labour has been made to him. Of precisely the same character is the lien of the carrier over the goods conveyed by him, for the fare; of the farrier over the horse which he has cured, for his fee; of blacksmiths, shipwrights, and other artificers for the wages they have earned by working at or on the thing detained. This, the true lien of the English law, is denominated a particular lien in contradistinction to a right of detainer exercisable over the property of another for a debt not incurred in relation to the thing detained. The latter is a general lien. The former is said to be favourably, the latter strictly, construed by the law. The former arises by implication of law from the relation of the parties; the latter requires a special contract either expressed in terms or to be inferred from the usage of trade. Again, as possession is the foundation of lien in common law, a parting with the possession would in general operate as a waiver or forfeiture of the lien. The same effect would follow of course from any agreement by the lien holder to give up his right while retaining possession of the property. Again as a general rule lien means only a right of detention, not a power of sale,—a fact which distinguishes it from a pledge of property in security for a loan. But in special cases powers of sale have by statute or judicial decision been added to liens. Thus innkeepers now have, in addition to their ordinary right of lien, power to sell goods and chattels left with them after six weeks (41 & 42 Vict. c. 38). In the United States the principle of the particular lien has been developed in a notable manner in protecting the rights of workmen employed in building. At common law, the building belongs absolutely to the owner of the soil; and accordingly, when a house is erected by contract, the contractor may receive payment from his employer and may fail to pay the labourers he has employed, who are consequently left without redress. The "mechanics' liens," created by statute in several of the American States, give labourers a lien over the building which they have erected for their unpaid wages. Notice having been filed in the prescribed manner, they acquire a right to have their wages paid out of the property, which may if necessary be sold for that purpose. A similar preferential charge, not depending on possession, is recognized by the law in various cases, and goes by the name of lien. Thus in equity an unpaid vendor has a charge for the amount of the purchase money, or the balance thereof, over the estate, although it may no longer be in his possession. Charges of this kind are sometimes denominated equitable liens. Of the same nature is the charge acquired over a ship by a person who has supplied her with necessaries for the voyage under a lawful contract with the master (maritime lien).

LIERRE, or LIER, a town of Belgium, in the province of Antwerp, 9½ miles south-east of Antwerp (on the railway to Malines), at the junction of the Great and Little Neethe. It is a busy place of 15,659 inhabitants (1874), and manufactures silk, lace, and shoes, beetroot sugar, and a peculiar kind of white beer known as *cavesse*. The church of St Gommarius (in plan a Latin cross with a lofty tower in front) is one of the most notable buildings of its class in Belgium. It was commenced in 1425, but not completed for more than a century. Of the fine stained glass windows three were presented by the emperor Maximilian.

Lierre, which dates from the 9th century, owed much to the favour of the dukes of Brabant, to whose territory it belonged. The more important facts in its annals are the celebration of the marriage of Philip the Fair with Joanna of Castile (1496); the residence in the town of Christian II. of Denmark during his exile; and the contests between the Dutch and Belgian forces in 1830. Joseph II. ordered the fortifications to be razed in 1784.

LIFE ASSURANCE. See INSURANCE.

LIFEBOAT. It will be convenient to consider here, not the lifeboat simply, but also other means of saving life at sea. When it is borne in mind that the vast commerce of such a country as Great Britain extends to every part of the world, that the arrivals and departures from the ports of the country in one year average six hundred thousand vessels, that these are manned by more than two hundred thousand men and boys, and carry goods to the estimated value of six hundred millions sterling, with unknown thousands of passengers, that its seaboard is nearly 5000 miles in extent, many parts of it being exceedingly dangerous to shipping, that about two thousand wrecks occur every year on its shores, and above seven hundred lives are lost, the necessity that exists for a well-organized system of life-saving apparatus becomes very apparent. It is satisfactory to be able to add that this well-organized system is most efficiently provided by the Royal National Lifeboat Institution, with its splendid fleet of two hundred and seventy-one lifeboats, and by the Rocket Service. The number of lives saved annually, either by the lifeboats or by special exertions for which the institution has granted rewards, averages in round numbers nine hundred, and by far the greater proportion of these (four-fifths) are saved by lifeboats. These lifeboats, too, are the means of saving every year from twenty to thirty vessels which, owing to stress of weather, exhausted men, &c., would almost certainly have been lost but for the aid afforded by the fresh and experienced lifeboat crews.

The qualities of the lifeboat first deserve our attention. These are such that this boat is able to live in seas, and go into positions of danger, that would overwhelm ordinary boats or insure their destruction. Eight important qualities are possessed by it in a very high degree:—(1) buoyancy; (2) great lateral stability, or resistance to upsetting; (3) the power to right itself if upset; (4) the power of immediate self-discharge when filled with water; (5) strength; (6) stowage room for a large number of passengers; (7) speed against a heavy sea; (8) facility in launching and taking the shore.

The *buoyancy* of the institution's lifeboat, or its inability to sink, be it ever so deeply laden, is secured chiefly by means of a watertight deck or floor, air-cases round the sides inboard, and two large air-chambers, one in the bow, the other in the stern. The "extra buoyancy" thus obtained cannot be too great so long as it does not interfere with the space necessary for working the boat and stowing shipwrecked persons. The air-cases round the sides serve also to confine any water shipped to the centre of the boat, a point of great importance. There is an air-tight space between the boat's floor and its bottom, filled partly with air partly with cork-ballast, which gives it additional buoyancy, but the air-chambers above the floor would float the boat even if she were stove in and this space filled with water. In a 33-feet boat the buoyancy obtained by all its chambers is equal to 11¼ tons.

Stability is obtained chiefly by means of ballast. Immense difficulty was experienced in arriving at the present form of the institution's splendid boat, because qualities of differing value had to be sacrificed to each other in due proportion. Thus, while breadth of beam secured stability, it seriously interfered with the self-righting quality. Ballast, therefore, in the form of a heavy iron keel, instead of breadth, became necessary to give the requisite stability.

Fig. 1 represents, let us say, the 33-feet, double-banked, ten-oared, self-righting, and self-emptying lifeboat of the institution on its transporting carriage, ready for launching; figs. 2 and 3, respectively, a section and a bird's-eye view of the same. The

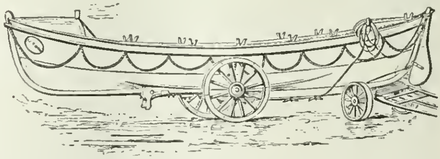

FIG. 1.—Ten-Oared Lifeboat.

breadth is 8 feet, with stowage room for forty-three persons—thirty passengers and thirteen of a crew. The festooned lines (fig. 1) enable people in the water to clamber inboard even without assistance. The shaded parts of figs. 2 and 3 show the position of the air-cases. The white oblong space in fig. 3 shows the free space available for crew and passengers. In fig. 2 are seen the depth to which the air-cases descend, and the height to which the bow and stern air-chambers ascend above the gunwale, also the ballast space between the floor and the keel.

The *self-righting* power is due to the large elevated air-chambers in bow and stern, coupled with great sheer, or rise fore and aft, of gunwale, to the iron keel, which weighs about 9 cwts. in a 33-feet boat, and to the air-cases and ballast, which latter weighs from 7 to 8 cwts. When the boat is upset it cannot rest on its two elevated air-chambers; it necessarily rolls on one side, then the heavy iron keel and ballast come into play and drag it back to its right position

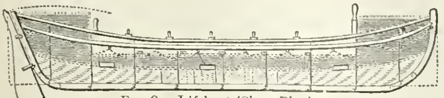

Fig. 2.—Lifeboat (Sheer Plan).

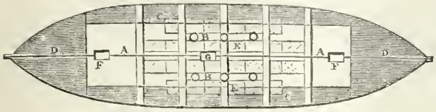

Fig. 3.—Lifeboat (Deck Plan).

in a few seconds. This principle of self-righting was discovered—at all events first exhibited—at the end of last century, by the Rev. James Bremner of Orkney, but was not finally adopted till the middle of the present century.

The *self-emptying* quality depends chiefly on the well-known physical fact that water must find its level. The floor of the lifeboat (fig. 2, the dotted double line extending from stem to stern), on which the men's feet rest when seated on the thwarts, is placed so as to be very slightly—2 or 3 inches—above the level of the sea when the boat is fully manned and loaded. In this floor there are six holes of 6 inches diameter, into which are fitted six metal tubes. These pass through the boat's bottom into the sea. The water of course enters them, but cannot rise above them into the boat, because it cannot rise above its own level. Valves at the upper ends of the tubes, opening downwards, prevent the annoyance of water spurting in, but allow it freely to run out. When, then, a billow overwhelms the boat, and fills it, the water rushes violently down the discharging tubes until it reaches the sea-level; by that time it has descended below the level of the floor and left the boat empty. So complete and swift is the process that a filled boat frees herself in about half a minute. This principle was first applied by the institution in 1851. Lifeboats devoid of the self-discharging quality become temporarily useless when filled by a sea, as they can be emptied only by the slow and laborious process of baling.

Strength, that will enable the lifeboat to suffer treatment which no ordinary boat could stand, is dependent on peculiarity of construction and material. The best Honduras mahogany is used, and the diagonal plan of construction adopted,—that is, the boat has two distinct "skins" of planking, both sets of planks being laid on in a position diagonal to the boat's keel and contrary to each other, besides passing round from gunwale to gunwale under the boat instead of from stem to stern as in ordinary boats. The skins have a layer of prepared canvas between them, and thus great strength and elasticity are combined.

The *carriage* of the lifeboat is an essential adjunct for the purpose of conveying it over any kind of road or beach to the place where it may be required. It can be run deep into a raging surf, and the boat, with its crew seated and oars ready out, can be launched at once, by blocks and tackle, so as to enable the men to dash forward and meet the incoming rollers with sufficient force to propel it through or over the seas, and thus avoid the risk of being hurled back on the beach. Each lifeboat is furnished with a set of spare oars, as these are frequently broken.

The institution's lifeboats are of various sizes—six, eight, ten, and twelve oared,—and they are placed at various points of the coast according to the necessities of each station. Some are called out at long intervals; others, such as those near the Goodwin Sands, are constantly on duty in rough weather—that of Ramsgate having a steamer to attend on it, which lies in harbour, with its fires banked up, ready for instant action night and day. The average cost of a lifeboat station is £1000,—the boat and equipments, including belts and carriage, costing £650, and the boat-house £350. The average annual expense of maintaining a station is £70, which is expended in paying the crew for going off and saving or attempting to save life from shipwreck, for exercising the lifeboat once a quarter, paying coxswain's salary, replacing gear, and repairs.

The *lifebelt* of the institution is a part of the equipment of the lifeboat which merits special attention, because it is a very efficient contrivance, and has been the means of saving many lives in time past. Fig. 4 shows its appearance and the manner in which it is worn. It was designed in 1854 by Admiral J. R. Ward, the institution's chief inspector of lifeboats. It is made of cork fastened on canvas, and combines great buoyancy with strength and flexibility. It not only floats a heavily-clothed man head and shoulders above water, but enables him to support a comrade easily—the extra buoyancy being 25 lb. One of its distinctive features is its division at the waist, by which means great freedom of action is allowed. It serves also as a species of armour to protect the wearer's most vital parts from blows against rock or wreck, while it affords some degree of warmth. No man may serve in the lifeboats of the institution without it, and it would be well if every British ship were obliged to carry lifebelts of this kind.

Fig. 4.

History.—The first lifeboat was conceived and designed by Lionel Lukin, a London coachbuilder, in 1785. Encouraged in his philanthropic plans by the prince of Wales (George IV.), Lukin fitted up a Norway yawl as a lifeboat, took out a patent for it, and wrote a pamphlet descriptive of his "Insubmergible Boat." Buoyancy he obtained by means of a projecting gunwale of cork and air-chambers inside—one of these being at the bow, another at the stern. Stability he secured by a false iron keel. The self-righting and self-emptying principles he seems not to have thought of; at all events he did not compass them. Despite the patronage of the prince, Lukin went to his grave a neglected and disappointed man. But he was not altogether unsuccessful, for, at the request of the Rev. Dr Shairp, Lukin fitted up a cobie as an "unimmergible" lifeboat, which was launched at Bamborough, saved several lives the first year, and afterwards saved many lives and much property.

Public apathy in regard to shipwreck was at length swept away by the wreck of the "Adventure" of Newcastle in 1789. This vessel was stranded only 300 yards from the shore, and her crew dropped, one by one, into the raging breakers in presence of thousands of spectators, none of whom dared to put off in an ordinary boat to the rescue. An excited meeting among the people of South Shields followed; a committee was formed, and premiums were offered for the best models of a lifeboat. This called forth many plans, of which those of William Wouldhave, a painter, and Henry Greathead, a boatbuilder, of South Shields, were selected. The committee awarded the prize to the latter, and, adopting the good points of both models, gave the order for the construction of their boat to Greathead. This boat was rendered buoyant by nearly 7 cwts. of cork, and had very raking stem and stern-posts, with great curvature of keel. It did good service in after years, and Greathead was well rewarded; nevertheless no other lifeboat was launched till 1798, when the duke of Northumberland ordered Greathead to build him a lifeboat which he endowed. This boat also did good service, and its noble owner ordered another in 1800 for Oporto. In the same year Mr Cathcart Dempster ordered one for St Andrews, where, two years later, it saved twelve lives. Thus the value of lifeboats began to be recognized, and before the end of 1803 Greathead had built no fewer than thirty-one boats—eighteen for England, five for Scotland, and eight for foreign lands. That these boats were lamentably insufficient to meet the necessities of England was shown year after year by the ever enlarging record of wreck and loss of life on her shores; nevertheless, public interest in lifeboats was not thoroughly aroused till 1823.

In that year Sir William Hillary, Bart., stood forth to champion the lifeboat cause. Sir William dwelt in the Isle of Man, had assisted with his own hand in the saving of three hundred and five lives, and felt the horrors of shipwreck so keenly that he resolved to stir up public men and the nation generally to a sense of their duty in regard to this matter. Eventually, in conjunction with two members of parliament—Mr Thomas Wilson and Mr George Hibbert—he founded the "Royal National Institution for the Preservation of Life from Shipwreck." This, perhaps the grandest of England's charitable societies, and now named the "Royal National Lifeboat Institution," was founded on the 4th of March 1824. The king and many of the nobility and gentry patronized it. The archbishop of Canterbury presided at its birth; the most eloquent men in the land—among them Wilberforce—pleaded the cause; the institution was launched under the most favourable auspices, and began its noble career with a sum of only £9826. In the first year twelve new lifeboats were built and placed at different stations, besides which thirty-nine lifeboats had been stationed on the British shores by benevolent individuals and by independent associations over which the institution exercised no control though it often assisted them. In its early years the institution placed the mortar apparatus of Captain Manby at many stations, and provided for the wants of sailors and others saved from shipwreck. The latter duty is now efficiently discharged by the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society." At the date of the institution's second report it had contributed to the saving of three hundred and forty-two lives, either by its own life-saving apparatus or by other means for which it had granted rewards. With fluctuating success, both as regards means and results, the institution continued its good work from year to year—saving many lives, and occasionally losing a few brave men in its tremendous battles with the sea. District or branch societies were established in most of the coast towns. Ultimately it began to be recognized that inland towns owed something to the lifeboat cause, as well as towns on the coast, and now such cities as Manchester, Liverpool, Glasgow, Edinburgh, &c., have presented lifeboats to the institution and become annual contributors. Since the adoption of the self-righting boats, loss of life in the service has been comparatively small and infrequent.

Towards the middle of this century the lifeboat cause appeared to lose interest with the public, though the life-saving work was prosecuted with unremitting zeal, but the increasing loss of life by shipwreck, and a few unusually severe disasters to lifeboats, brought about the reorganization of the society in 1850. The late Prince Albert became vice-patron of the institution in conjunction with the late king of the Belgians, and afterwards Her Majesty the Queen, who had been its patron since her accession, became an annual contributor to its funds. About the same time its present secretary, Mr Richard Lewis, barrister-at-law, was appointed. The following year (1851) the duke of Northumberland became its president, and from that time forward a tide of prosperity set in which is literally unprecedented in the history of benevolent institutions, both in regard to the great work accomplished and the pecuniary aid received. Its flow of prosperity has never since been checked. In 1850 its committee undertook the immediate superintendence of all the lifeboat work on the coasts, with the aid of local committees. Periodical inspections, quarterly exercise of crews, fixed rates of payments to coxswains and men, and quarterly reports were instituted, at the time when the self-righting self-emptying boat came into being. This boat was the result of a hundred-guinea prize, offered by the president, for the best model of a lifeboat, with another hundred to defray the cost of a boat built on the model chosen. In reply to the offer no fewer than two hundred and eighty models were sent in, not only from all parts of the United Kingdom, but from France, Germany, Holland, and the United States of America. The prize was gained by Mr James Beeching of Great Yarmouth, whose model, slightly modified by Mr Peake, one of the committee of inspection, became the foundation of the present boat, which, having been still further improved as time and experience have suggested, is now probably as near to perfection as can be attained.

The shortest way, perhaps, to exhibit the progressive work of the institution is to contrast the report of 1850 with that of 1880. In the former year the receipts had dwindled down to £84 of subscriptions and donations, which, with £270 of dividends (on a capital of £9000) and a balance of £476 on hand, gave an available income of £830. The expenditure was £590, and the lives saved were about one hundred. In 1880 donations and annual subscriptions amounted to £29,240; dividends and interest (on a capital of £231,000) amounted to £9266. The total income was £38,506, besides legacies in the same year to the amount of £40,782. The expenditure, including liabilities, was £40,586, and the number of lives saved was about seven hundred. In the past unusually disastrous year (1881), the institution has saved 966 lives by its boats, and granted rewards for the saving of 155 more, besides rescuing 33 vessels from destruction. The total number of lives saved either by the lifeboats, or by special exertions for which the institution has granted rewards, since its formation, is 28,724, for which services 95 gold medals, 939 silver medals, and £69,000 in cash have been granted as rewards. So highly are the services of the institution appreciated that donations of boats, gifts of money, acknowledgments, and legacies come in from nearly all quarters of the globe, in sums varying from a shilling to £10,000.

Rocket Apparatus.—This, next to the lifeboat, is the most important and successful means by which shipwrecked persons are rescued on the British shores. Many vessels are cast every year on the rocky parts of the coasts, under cliffs, where no lifeboat could be of service. In such places the rocket alone is available. It is worked by the men of the coastguard, with the aid, in a few places, of volunteer rocket brigades. The courage and skill displayed in its use are evinced by the saving of many lives every year, and by the fact that a large proportion of the medals given by the lifeboat institution for heroic conduct are awarded to the men of the coastguard, who, besides managing the rockets, frequently man the lifeboats and also effect rescues in their own boats. The number of lives saved by means of the rocket apparatus in the year ending 30th June 1881 was 657. This, however, is the greatest number saved in any one year since 1856, at which date the life-saving rocket apparatus was placed under the entire control and management of the Board of Trade. The rocket stations on the coast at the 30th June 1881 numbered 288. The Board of Trade now gives a sum of money for each life saved, besides awarding silver and bronze medals for acts of special gallantry.

The apparatus consists of five principal parts, viz., the rocket, the rocket-line, the whip, the hawser, and the sling lifebuoy. The mode of working it is as follows. A rocket, having a light line attached to it, is fired over the wreck. By means of this line the wrecked crew haul out the whip, which is a double or endless line, rove through a block with a tail attached to it. The tail-block, having been detached from the rocket-line, is fastened to a mast, or other portion of the wreck, high above the water. By means of the whip the rescuers haul off the hawser, to which is hung the travelling or sling lifebuoy. When one end of the hawser has been made fast to the mast, about 18 inches *above* the whip, and its other end to tackle fixed to an anchor on shore, the lifebuoy is run out by the rescuers, and the shipwrecked persons, getting into it one at a time, are hauled ashore. Sometimes, in cases of urgency, the lifebuoy is worked by means of the whip alone, without the hawser. A tally-board with instructions to wrecked crews, printed in English and French, is sent off with the whip, as ignorance in regard to the mode of working the apparatus has been the cause of much loss of life. Such ignorance is culpable, because the Board of Trade issues enamelled plates with instructions, which are supplied gratuitously to shipowners and masters to be placed on conspicuous parts of their vessels, and are fixed in public places along the British coast, while every certificated officer in the mercantile marine is required to understand the working of the rocket apparatus.

The late Captain G. W. Manby, F.R.S., in 1807 invented, or at least introduced, the mortar apparatus, on which the system of the rocket apparatus is founded. Previously, however, in 1791, the idea of throwing a rope from a wreck to the shore by means of a shell from a mortar had occurred to Serjeant Bell of the Royal Artillery, and about the same time, to a Frenchman named La Fère, both of whom made successful experiments with their apparatus. In the same year (1807) a rocket was proposed by Mr Trengrouse of Helston in Cornwall, also a hand and lead line as means of communicating with vessels in distress. The *heaving-cane*, a fruit of the latter suggestion, is now used at every station in the kingdom. In 1814 forty-five mortar stations were established, and Manby received £2000, in addition to previous grants, in acknowledgment of the good service rendered by his invention. Mr John Dennett of Newport, Isle of Wight, introduced the rocket, which was afterwards extensively used. In 1826 four places in the Isle of Wight were supplied with Dennett's rockets, but it was not till after Government had taken the apparatus under its own control, in 1855, that the rocket now in use was adopted. It was invented by Colonel Boxer, and its peculiar characteristic lies in the combination of two rockets in one case, one being a continuation of the other, so that, after the first compartment has carried the machine to its full elevation, the second gives it an additional impetus, whereby a great increase of range is obtained. The rocket has now entirely superseded the mortar in England.

The United States Life-Saving Service is chief among the lifeboat societies of other nations, both as regards the extent of coast embraced and the amount of work done. There are several points of difference between this service and that of England which are noteworthy. In the first place the whole or nearly the whole of its support is provided for by annual grants of money from Congress. Secondly, besides protecting its vast extent of seaboard it has to provide for the shores of its great lakes, or fresh-water seas. Then, the coasts of America, unlike those of England, are destitute of human habitations in many places, which renders necessary the constant employment of surfmen for the express purpose of looking out for vessels in distress and manning the surf-boats. It also necessitates the erection of houses of refuge, provisioned so as to afford shelter and food to shipwrecked crews for a considerable time, at places where, without such provision, those who escape the sea would probably perish from hunger and exposure.

The shores of the United States—lakes and sea—are over 10,000 miles in extent, embracing almost every variety of climate and formation of land. This vast extent of coast-line is divided into 12 districts, with a total of 179 stations. Of these 139 are on the Atlantic, 34 on the lakes, and 6 on the Pacific. Those on the desolate coast of Florida are houses of refuge only, without boats or apparatus. Many of the stations are closed during the fine months of the year, their crews being disbanded till the winter gales again summon them to the heroic and dangerous work of saving the shipwrecked. That they render noble service in this way may be gathered from the annual reports. The report for 1880 shows that the disasters to shipping in that year amounted to 300, that on board of the vessels thus endangered there were 1989 persons, of whom 1980 were saved and only 9 lost. The property imperilled at the same time was estimated at, in round numbers, £790,000, of which over £540,000 worth was saved, besides which, in one hundred and twenty-eight instances, stranded vessels were hove off, and piloted out of danger by the surfmen. The total number of lives saved by this service, since the introduction of the present system in 1871, to the close of the fiscal year in June 1881, was 11,864; the total number of persons sheltered 2610, and the number of days' shelter afforded 7350; the total value of property saved, $14,958,875.

Owing to the flat shores of the Atlantic coast, and the sparseness of the population, heavy boats are found unsuitable. Only a few boats on the English model exist in the service. The boats chiefly in use are surf-boats, incapable of self-righting, and liable to be swamped, but which nevertheless seem well suited for the work, and are admirably managed. They are very light, and can, on their transporting carriages, be easily dragged along the shore by their crews. The cork life-belts worn by the men are of the plan first designed in 1854 by Rear-Admiral Ward. For projecting a line over a stranded vessel, the Americans prefer the mortar, or other piece of ordnance, to the rocket. In addition to the travelling life-buoy, they use a metallic car, or small covered boat, which can hold three or four persons, who, entering it by a small manhole, are shut in and drawn ashore, safely protected from injury, even though overturned by the surf. This clever contrivance has been of great service in rescuing invalids, children, and aged persons. The total cost of the service is somewhere about £90,000 a year.

The history of the United States Life-Saving Service may be said to have begun in 1848, though half a century before that the Humane Society of Massachusetts had erected some huts of shelter and stationed some boats on the coast. In that year the United States Government was led to consider the subject of loss on their shores, chiefly through the energy of the Hon. W. A. Newell of New Jersey, a member of the House of Representatives. Captain Douglass Ottinger (the inventor of the life-car) was charged with the management and reconstruction of the service. The impetus given to it at this time was never quite lost. Again, in 1854, renewed efforts were made to improve the service, but no great progress was made till the year 1871, when the present effective system was organized; new stations were built; the patrol system between the stations was introduced; the regular keeping of journals and sending in of reports was ordered; libraries for the use of the men were sent to stations; uniformity in signals was arranged, and a thorough reform in all departments accomplished.

The French Society for Saving Life from Shipwreck, modelled on the basis of the English system, is a vigorous and healthy offshoot. It continues steadily to extend its operations along the coasts of France, besides introducing its life-saving apparatus into Algeria and other colonies. It was founded in the year 1865, and from that year onward has continued to do good and ever-increasing service in the saving of life and property. At the date of its report ending 30th June 1881, its lifeboat stations numbered 62, and its mortar or other projectile stations 391. During the year its lifeboats and gun apparatus had saved 209 lives and 16 ships, to which may be added 31 lives, for the saving of which the society had granted rewards. From the time of its commencement in 1865 to the above date it has rendered the following noble service:—

Lives saved by its own boats and apparatus	1,826
Lives saved by other means, for which the society granted rewards in gold, silver, and bronze medals, and cash	303
Total of lives saved from the beginning	2,129

Besides this it has saved 149 vessels and succoured 348, and has awarded 28 gold, 129 silver, and 319 bronze medals, 513 *diplômes d'honneur*, and about £20,400 in recompenses to those who have assisted in saving life in circumstances of unusual danger. It has also spent about £53,000 in the purchase and repair of its matériel. The receipts of the society show that its work is appreciated. At 31st December 1880 the subscriptions and donations together amounted to nearly £2600, and the legacies bequeathed to it the same year were about £1000. The boats chiefly used are built on the model of those of the English institution. The gun is preferred to the rocket in connexion with the life-saving apparatus. In addition to its direct work of saving life, the French society has accomplished much good indirectly by its influence. It has been instrumental in bringing about this result that, among the qualifications for a captain's certificate in the French mercantile marine, a thorough knowledge in detail of the means of saving life from shipwreck is required. It has also laboured to extend the usefulness and reduce the cost of the gun and rocket apparatus, besides securing that this apparatus, on Mr Delvigne's system, shall be supplied to every ship of the French navy.

The German Association for the Rescue of Life from Shipwreck, under the patronage of the emperor William, was founded at Kiel in May 1865, and is prosperous both in regard to its work and finances. It is maintained by voluntary contributions, and has 21 local branches on the coast and 27 in the interior, besides 149 agencies over the country. Previous to 1865 several private societies for saving life from shipwreck existed in the chief seaports of the North Sea and Baltic. These have been absorbed in the present association, the proceedings of which are reported in a paper entitled *From Shore and Sea*, published at Bremen once a quarter, and largely modelled on the *Lifeboat Journal* of the English institution. The association provides the whole extent of the German coast with life-saving apparatus. It has 74 lifeboat stations, 20 of which are provided with the mortar or rocket apparatus. With these means it has, in the year 1880–81, saved 122 lives and 2 ships. The total number of human lives saved by the association since its commencement is 1184. From May 1880 to May 1881 the amount subscribed by its members was £57,000. As in America, the heavy self-righting and self-emptying boats of England have been found unsuitable to the thinly peopled and flat sandy beaches of Germany. Lighter and shallower boats have therefore been adopted. These are iron-plated and not self-righting, but almost impossible to capsize. The stations are visited at least once a year by an inspector, and the whole system seems to be well regulated and thoroughly efficient.

In addition to the above, lifeboat societies or other lifeboat organizations—formed more or less on the basis of the National Lifeboat Institution of Great Britain—are to be found in Russia, Italy, and Spain.

Life-saving Hammocks, &c.—Various forms of buoyant mattresses, pillows, and india-rubber cloth life jackets and belts have been contrived. Among these may be specially mentioned the air lifebelt of Admiral Ward, which has four compartments, separately inflated, so that the puncture of one does not quite destroy the belt. Admiral Ryder's hammock also deserves notice. Its virtue lies simply in a cork mattress, which, when rolled up in its hammock, forms an efficient lifebuoy capable of supporting a man with his head and shoulders well above water, and it enables three men to float in an upright position. Cork mattresses are said to be cheaper and more comfortable than those stuffed with hair. Two such hammocks lashed together, about 20 inches apart, will enable two or three men to propel themselves easily through the water. The advantage of having such mattresses in a ship is obvious, for every one on board would be thus provided with a life-preserver.

It has also been suggested that the cushions of deck and cabin seats should, in a similar way, be made life-preservers, and that cabin furniture should be constructed so as to form rafts in cases of emergency. It is well to know, on the authority of the *Philosophical Magazine* (vol. xx. p. 362), that even a hat tied in a pocket handkerchief and held with the crown downwards may help to sustain a drowning man. It need scarcely be added that empty water-casks, tightly bunged, with ropes arranged for clinging to, form pretty good life-preservers. (R. M. B.)

LIFTS may properly be held to include all sorts of apparatus whose object is the lifting of weights. When the apparatus consists of comparatively small, separate, and portable pieces, it is called *lifting tackle*. When the lifting apparatus reaches that degree of size and complication that entitles it to be called *machinery*, there seems to be no general technical term that will include all kinds, but for the different classes of lifting machines there are such special names as *cranes*, *hoists*, *elevators*, *lifts*, *winding engines*, and *lift pumps*.

There is very little distinction made between hoists, elevators, and lifts. The word *hoist* refers more particularly to machines used in warehouses and factories for raising goods from one story to another. They are worked by hand or by power, and are for comparatively light loads. *Elevator* is used in two different senses. It refers to apparatus for lifting passengers to the upper stories of buildings. It also refers to the very different sort of apparatus used in grain-mills and storehouses for transferring the grain from one floor to another. The grain is drawn along channels or pipes, which are sometimes vertical and more often inclined, by means of a rotating archimedean screw, or of a strap continuously travelling upwards through the interior of the channel and carrying, fastened to it, a series of small buckets. Occasionally, if the inclination to the horizontal be small, a broad strap of the same width as the bottom of the channel runs along that bottom, and carries the grain with it simply lying on its upper surface. This latter method of transportation is more efficient, however, as a horizontal carrier or distributor than as a means of lifting. Grain might also easily be blown up a pipe by an air-blast, but the writer does not know any instance of this method having been used. *Lifts* are constructed either for raising passengers in buildings or for heavier loads, such as freighted trucks and waggons, or the superstructure of bridges and large roofs during their erection.

In lifts or elevators, the working force is either hand, steam, or hydraulic power. Gas-engines are unsuitable as direct sources of power for lifts, but they may be advantageously used to store hydraulic power in an accumulator from which water is supplied to work an hydraulic lift. Electricity has quite recently been used, but has not yet been tried sufficiently to allow of any valuable opinion being formed of its ultimate practical success.

The lift consists of (1) a box or "cage" to contain the persons or material to be raised; (2) a vertical square well or shaft, to the walls of which are attached guides to prevent the cage swinging to and fro; (3) a rope or chain by which to haul the cage upwards from above, or else a long rod or pillar by which to push it up from below; (4) a "barrel" or "sheave" over which to wind the chain or rope, and which is mounted on a shaft lying in bearings firmly supported by the building, or else a cylinder to contain water or steam to actuate the lifting rod; (5) mechanism through which the working power is transmitted to the barrel, or else water or steam piping connecting the cylinder above mentioned with the source of power; and (6) the driving engine or other source of power.

Most accidents happen to lifts through the hauling chain or rope breaking. For the sake of safety, therefore, particular care should be exercised in the choice of material for this part, and an appliance should always be attached to the cage whereby, if the rope breaks, the cage is caught immediately in whatever position it may be at the time of the breakage.

For light loads hempen ropes are sufficient and more convenient than chains, because they are noiseless in their action. If of the best quality (Manila) they are quite as reliable as ordinary chains, and an advantage claimed for them is that their gradual destruction by wear becomes easily apparent, and gives timely warning before they become dangerous, whereas the failure of a chain may take place without any easily visible previous sign having been given. For very heavy loads, however, chains or wire ropes should be used in preference to hempen ropes. Wire ropes may be made stronger for a given weight per foot of length than chains are, but unfortunately as commonly manufactured their quality cannot be certainly relied on. Like hempen ropes, they are almost noiseless. To insure smoothness and noiselessness in passenger lifts, the sheave over which the rope passes is lined in the groove with leather.

For the sake of safety, the rope by which the cage hangs is often duplicated. Sometimes even three or four are used. In order that these should give additional safety, each rope must be capable of supporting the load by itself. Generally the load is lifted by one or other kind of power, and descends by the weight of the cage itself. This weight is always much more than sufficient for the purpose, and therefore counterpoises are introduced to balance the greater part of it, thus lessening the work to be done during ascent by an amount equal to the product of the balance weight and the height of the lift. In the commonest arrangement, the balance weights are hung on the same rope as that by which the cage is suspended. This passes over a pulley whose diameter is half the width of the well, so that the cage end of the rope rises vertically from the centre of the roof of the cage. This pulley is keyed on a horizontal shaft, which is driven by power from below, either directly by means of a rope or chain passing over another pulley, or else through intermediate spur gearing. The actual working rope is in this case not attached to the cage. Less frequently the rope from the engine forms one of the suspenders of the cage, the balance weights being attached by separate ropes.

The rope or chain by which the load hangs has to be so strong that its own weight is very considerable. A large excess of strength being more in demand in this kind of machinery than in other kinds, a greater stress than about 1 ton per square inch cannot be put upon the chain or rope (supposed to be of iron). This would make the rope weigh 3·4 ℔ per foot of length for every ton of load carried. If the height of lift were, for example, 60 feet, then, comparing the top and bottom positions of the cage, there would be in the former 60 feet less of rope on the cage side of the pulley, and 60 feet more on the counterpoise side, than in the latter position, so that if the counter-weight just balanced the load when the cage was at the bottom, it, along with the rope, would outweigh the cage in its highest position by the weight of 120 feet of rope, that is 408 ℔ for every ton of load, or nearly $\frac{1}{5}$th of the whole load. Since the whole load—that is, that of cage, ropes, and passengers or goods—is three or four and sometimes five or six times as great as the net load, this is a very serious increase on the *unavoidable* loss of balance resulting from the fact that the cage is alternately loaded and unloaded. The difficulty can be got over by extending the rope downwards from the balance weight to pass underneath a grooved pulley at the bottom of the well, and up from this to the under side of the cage, where it is attached. There will then be an equal length of rope always hanging on each side of the top bearing pulley; but an extra amount of friction occurs at the bearing journals due to the weight of the extra rope. The lower half of the rope may be of cheap inferior material, since there is very little stress upon it.

A precisely similar difficulty occurs if the cage be lifted from below by an hydraulic ram or piston-rod. Occasionally the weight of the cage and ram is left unbalanced. In this case the water pressure on the ram or piston has to support the whole load. Suppose the pressure in the reservoir from which the water is drawn to remain steady during the ascent, then evidently at the top of its stroke the water pressure on the ram is less than at the bottom of its stroke, by the weight of a column of water, of section equal to that of the ram, and height equal to the lift. Suppose, for example, that the water pressure at the level of the face of the ram in its highest position is 200 ℔ per square inch. Then for every ton of total load there must be provided about 11 square inches of piston area. A column of water of this horizontal section and 1 foot high weighs about 4·75 ℔. This would give a difference of supporting pressure of 285 ℔ for every ton of total load in a lift of 60 feet,—that is, about $\frac{1}{8}$th of the total load. More commonly the weight f the cage and the ram is balanced by counterpoises on chains fastened to the top of the cage and passing over a pulley overhead, while the water pressure is used to overcome only the friction, and the additional load of passengers or goods. In this case again, owing to the passage of the chains over the pulleys, the balance is disturbed in a rise of 60 feet, by about $\frac{1}{5}$th the weight of the cage and the ram, while the upward water pressure on the ram is in the same rise diminished by $\frac{1}{8}$th. The former disturbance of balance is a *decrease* of the load resting on the base of the ram, while the latter is a *decrease* of the supporting pressure on the same base. If these were made equal, the cage and load would be perfectly balanced in every position. To make them equal, it would be necessary simply to adjust the ratio of the part of the load borne by the counterpoise to the part borne by the water. Let the former part be W_1 and the latter W_2, the total load being $W_1 + W_2$. Then for a water pressure of 200 ℔ per square inch, it would be necessary to have

$$\tfrac{1}{5}W_1 = \tfrac{1}{8}W_2, \text{ or } W_1 = \tfrac{5}{8}W_2 = \tfrac{5}{13}(W_1 + W_2).$$

For a pressure of 400 ℔ per square inch, the equation would be

$$W_1 = \tfrac{5}{16}W_2 = \tfrac{5}{21}(W_1 + W_2).$$

For 100 ℔ per square inch it would be

$$W_1 = \tfrac{5}{4}W_2 = \tfrac{5}{9}(W_1 + W_2).$$

This adjustment would necessitate a large unnecessary consumption of water, because the weight of cage and ram always bears a much greater ratio to the extra weight of passengers or goods than any of the above fractions $\frac{5}{16}$, $\frac{5}{8}$, or even $\frac{5}{4}$. The adjustment being attainable by other means, this waste can in no case be desirable.

If a second cylinder stand beside the lift-well and be connected by a pipe to the cylinder directly underneath the cage, so that there is a continually open passage between the two cylinders, then the supporting rod underneath the cage, together with the column of water leading from its base through the pipes to the second cylinder, is the exact counterpart in compression of the overhead ropes in tension in the other class of machine; and, as counterweights are hung upon these ropes, a balancing weight may be laid on the surface of the water in the second cylinder. The balance weight, equalling that of cage and ram, rests on a plunger or piston fitting this cylinder, and the rod is extended upwards into a third smaller cylinder, on the plunger of which is admitted, by means of the valve worked from the cage or landing-platforms, an extra amount of water pressure sufficient to elevate the extra load of passengers or goods. This is the arrangement in Tomassi's hydraulic balanced lift. The column of water which takes the place of the rope in the overhead arrangement passes from one cylinder to the other, and *vice versa*, in the same way as the rope passes from the cage side to the counterweight side of the overhead pulley. Thus the balance, which may be made correct for one position of the lift, becomes disturbed for other positions by a similar amount to that already investigated. A perfect balance of the constant part of the total load, namely, that of the cage and ram, is, however, obtained for all positions of the cage by the arrangement shown in figs. 1 and 2. This is the design of Mr Edward Ellington, described by him in a paper read before the Institution of Mechanical Engineers in January 1882. The whole load is borne by the rod a underneath the cage, which enters as a ram into the vertical cylinder A. This rod is made solid in order to reduce the size of the cylinder as much as possible, and, therefore, also the size of the well that has to be bored in the ground to contain this cylinder. This class of lifts is especially expensive on account of this boring, and the objection to them on the score of expense is lessened by making the well small. The rod is made only just strong enough to safely bear the load on it. Its section should be designed with reference to the height of lift, because the longer the free length of the supporting pillar the greater is its tendency to buckle under a given load. If k be the stress per square inch calculated to be admissible on its section, and if W be the weight of cage and ram together and W′ that of passengers or goods to be raised, the section is made equal to $\frac{W + W'}{k}$. Since this same load has to be supported by the water pressure on the lower end of this rod, that water pressure is made also equal to k. This cylinder A is kept always in open communication with the lower end of the cylinder B. In this moves a piston b fastened to the top of the thick piston rod d. This passes downwards into the third cylinder C, and to its lower extremity is fastened the large piston c. These pistons have a common stroke, which is much shorter than the lift of the cage. The cylinders are correspondingly shorter than A, and they stand above ground. The ratio of the strokes may range from 5 to 8, and is the same as the ratio of the annular area of the under side of the piston b to that of the rod a. If b and d be the areas of the piston and piston rod, and a that of the rod supporting the cage, the ratio of the strokes is $b - d : a$. Suppose the piston b to be at the top of its stroke and the cage to be consequently at the bottom of the lift-well, then, if in this position the piston b be at a height above the lower end of a equal to h inches, and if w be the weight of a cubic inch of water, then, the pressure per square inch on a being k, that on the *lower* side of piston b is $k - hw$. The whole upward pressure on this piston is therefore $(k - hw)(b - d)$; and a downward pressure equal to or rather more than this must be exerted on this piston in order to lift the cage. This is supplied by admitting the water from the main, or from the hydraulic accumulator if force-pumps are employed to provide water-pressure, into the upper ends of the cylinders B and C. The lower end of C is always kept in open communication with the atmosphere. The water is continually admitted to B, and the water pressure on the top surface of piston b is designed to balance the constant load of cage and ram when this piston is at the top of its stroke. During the ascent of the cage, the water is admitted into C by a valve moved from the cage or platforms by means of the rope t, and the water pressure on the annular top surface of piston c, when that piston is at its highest position, is designed to balance the extra load of passengers or goods. During the descent, the cage being empty, the connexion between C and the accumulator is shut by the valve actuated from the cage, and the water is allowed to escape freely to the drains, so that the pressure on c becomes equal to atmospheric pressure. If p be the pressure per square inch of the working water at the level of the piston b at its highest position, and c be the area of the cross-section of cylinder C, and if h' be the length of plunger d, then in this position the whole downward force that is borne by the water underneath the piston b, and distributed over its area $(b - d)$, is $pb + (p + h'w)(c - d)$, when the pressure is on piston c, and simply pb when this pressure is cut off from C. (To this should be added the weight of b, d, and c, but for our present purpose of explanation only this may be left out of account.) The former quantity has to equal $(k - hw)(b - d)$, and the latter should equal

$$\left(k\frac{W}{W + W'} - hw\right)(b - d).$$

These two equations serve to determine two of the quantities involved in terms of the others.

When the water pressure is admitted to the upper side of b alone, the intensity of pressure on the under side of b is evidently as many times greater than the intensity on its upper side as the area of its upper side is greater than that of its lower surface. Thus any increase of intensity on the upper surface will cause a correspondingly greater increase of intensity on the lower. Now if the pressure on the under side of b were to remain the same while the cage ascended, the pressure on the lower end of a would decrease by an amount proportional to the change in their difference of level. If, for example, the ratio of the strokes $b - d : a$ is 6 : 1, then, as the cage rises 6 inches, b will fall 1 inch, and h, the difference of level

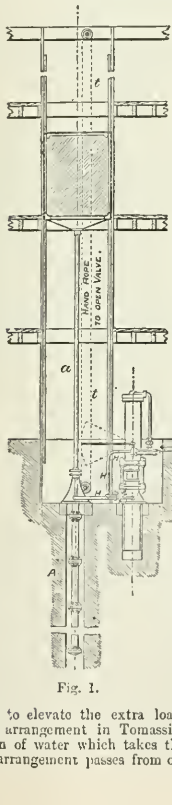

Fig. 1.

Fig. 2.

between b and a, will be decreased 7 inches. The pressure per square inch on a would decrease $7w$ if that on the under side of b kept constant. But, as the upper side of b also sinks 1 inch, the pressure per square inch on it will increase by w. If now the ratio of this upper area of b to its lower area be made 7, this increase of w on the top face will cause an increase of $7w$ on the lower face, and thus just neutralize the diminution of pressure on a due to the combined rise of the cage and fall of the lower side of b. Thus the unloaded cage will be in perfect balance, at whatever height it stands, if the areas b and $b-d$ are given the ratio

$$\frac{b}{b-d}=\frac{b-d}{a}+1 .$$

The ratio $b-d:a$ of the two strokes having been already chosen, this equation gives b directly. From the other two equations c and the necessary pressure p are found. This pressure p may be obtained by hydraulic pumps and an accumulator loaded to the right amount. If, however, the water from the mains is to be used, the ratio of the strokes or the size of a may be modified so as to suit the available working pressure p. If c be proportioned for the extra load at a given height, it will not be correct for all other heights, but this is of little consequence, because the extra load itself is variable from 0 upwards, so that no adjustment of c except to its maximum desired amount is possible. An excess of pressure on c above that needed for any given load has the effect simply of accelerating the speed of ascent, and this is modified roughly by partially closing the valve admitting water to C.

We have chosen this lift for description as the latest improvement in the design of hydraulic lifts. In it no water is wasted in raising or lowering the constant load.

When the hydraulic power is applied to the cage through a chain or rope passing over an overhead pulley, the hydraulic cylinder is usually laid horizontally for facility of setting and examination. Of course this arrangement involves much greater frictional resistance to the motion of the apparatus, but in it all the severely stressed parts may be in tension. There is greater security when they are so than when they are in compression. Tangye Brothers' hydraulic lift is arranged in this way.

Accidents to lifts occur in two ways. First, the suspending chain or rope may break, or, in those supported from below, the ram may break, or the cylinder or pipes enclosing the water may burst. To lessen the risk of such breakages the only method is to insist on good design in the details, good materials (which should be subjected to test before being used), and good workmanship. The connexion at both ends of the rope or chain to the load suspended from it, or the jointing of the different sections of the ram to each other and to the cage, is a point especially important. If such a breakage does actually occur, however, the cage is usually kept from falling by an automatic catch which grips it in whatever position it happens to occupy when the accident occurs. Tangye Brothers have for this purpose at each corner of the cage a toothed cam. The suspending rope sustains the cage through levers as shown in fig. 3. So long as there is a considerable pull on the rope, the levers keep the cams in the position shown. If the strain on the rope is relieved by accident to it, powerful spiral springs immediately force the cams outwards and the teeth become buried in the wooden guide-posts.

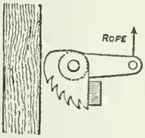

Fig. 3.

A toothed rack is sometimes bolted to the vertical posts and tooth-shaped prongs are forced forward by springs to engage with the rack when the rope breaks. Similar arrangements are not placed between the top of the ram and the cage of direct-acting hydraulic lifts, but it is a mistaken idea that they are not as necessary in this case as in the other. Such appliances should be examined and tested at regular frequent intervals. They are apt to get out of working order through disuse. A double rope is a greater safeguard against accident.

In chain or rope lifts the gearing or other machinery may break, and in consequence the cage might run down with dangerous rapidity without the rope either breaking, or being wholly relieved of tension, so that the above catches may not come into action. This may be prevented by a self-acting clutch on the shaft, which prevents the barrel rotating unless the clutch is specially released. The most perfect and mechanically beautiful of the many devices that have been invented for this purpose is Weston's frictional automatic coupling. Fig. 4 shows it as applied to a hand sack-hoist. To the shaft a is keyed a ratchet wheel b. A pawl gearing in this prevents the shaft from ever rotating except in one direction. The plate c is also keyed to the shaft. The hauling rope sheave d and the winding barrel e both run loose on the shaft. Their opposing end surfaces are cut helically, so that, according to the relative angular positions of d and e, they are either jammed against each other and between c and b, or are loose and free to rotate round the shaft. On pulling the sheave d in one direction all the parts are frictionally coupled together, and the barrel hauls up the load. The axial pressure producing friction between e and c and between d and b is greater than the load being hauled up in the ratio of the circumference of the barrel to the pitch of the helix. As there are two frictional surfaces, the whole friction is double this axial thrust multiplied by the coefficient of friction, and this friction must act at such a mean radius from the shaft as to have a moment greater than that of the load. If this is so for one load, it is so also for all others, as the friction is proportional to the load. To get sufficient friction for heavy loads with a diminished axial thrust, the very ingenious design shown in fig. 5 is adopted. Here the shaft a is driven by power, and is keyed to the boss d with a helix cut on one end.

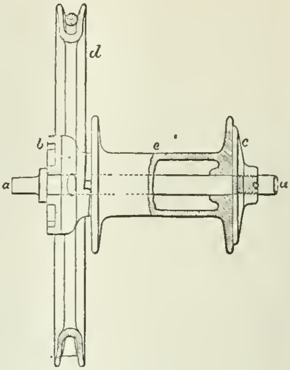

Fig. 4.

This helix abuts against a similar helix on the pinion e, which drives the hoisting barrel on a second shaft. The ratchet wheel b abuts against the collar f on the shaft a; b runs loose on the shaft and is cast on the end of a hollow drum containing three disks of hard wood, P, P, P. These disks can slide axially along the interior of the drum, but are prevented from turning except along with the drum. Intervening between these wood disks are two iron disks, O, O, which may slide axially along the boss of the pinion e, but are prevented from rotating except along with this pinion.

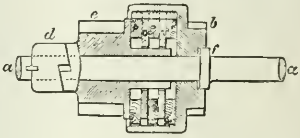

Fig. 5.

The axial pressure is transmitted from d to f, through the surfaces of the disks P and O, and, there being six pairs of surfaces between which this pressure is exerted, a very slight axial thrust produces sufficient friction at these surfaces to couple the ratchet wheel b to the pinion e. So long as this is exerted all the parts are jammed together, and the pawl engaging in b prevents the load lowering. When, however, the shaft a is rotated backwards, the helices disengage and the friction no longer binds e with b, so that e along with d and a can be rotated backwards and the load thus lowered. The weight of the load keeps e following d closely in its backward motion, and as soon as the operator or machine ceases to turn the shaft backwards the whole apparatus becomes once more frictionally bound together, and the ratchet wheel prevents further lowering. Fig. 6 shows another arrangement whereby the pinion e is uncoupled and allowed to lower the load by only a slight backward motion of the shaft a, it being unnecessary to rotate the shaft backward continuously. This last is obviously the most handy arrangement, and when worked carefully is as absolutely safe as the other. This device in a modified form is used in Tangye's lifts.

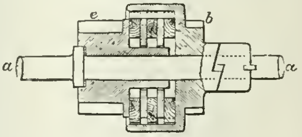

Fig. 6.

Thomas & Sons, of Cardiff, have a similar patent safety shaft coupling, which, although it has a very different form, is constructed on exactly the same principle as that of fig. 4.

Steam has been used as a motive power in long cylinders similar to those in hydraulic lifts. It has the great advantage of having very little weight, so that the difference of head occasioned by the rise of the piston is practically nil. The disadvantage is that the steam rapidly condenses, and thus the load could not be held up at any desired height for a length of time, without a continual fresh supply of steam to the cylinders. It is not likely to come into general use for passenger lifts, but may be used advantageously for goods lifts and heavy cranes. (R. H. S.*)

LIGHT

SOUND may be defined as any effect on the sense of hearing, and in the same way Light may be defined as any effect on the sense of sight. This is the purely subjective use of the terms. But both terms are quite as frequently used in the objective as in the subjective sense. Thus, as Sound may be defined in terms of the motion of the air in the cavity of the external ear, mechanically affecting the tympanum, so Light may be defined by the mechanical effect produced upon the extension of the optic nerve which forms the sensitive surface of the retina.

In treating of Light it will be convenient to use the term in a sort of mixed sense, at least until we come to discuss the different theories which have been devised to account for the propagation of the agent which causes vision. Then we shall have to use the term entirely in the objective sense. On the other hand, in Physiological Optics we are concerned chiefly with the subjective sense of the term.

The present article is intended to give a general sketch of the subject of Optics, so far as it can be treated by the help of elementary mathematics, but with sufficient detail to show the connexion of its various branches, and to enable the reader who desires further information on any point to judge for himself under what heading he will find it in this work. The subject is arranged in the following order:—

Early History of Optics.
Preliminary Statements with regard to Vision, Distinct Vision, the Colour-Sense, and the Duration of Visual Impressions.
Sources of Light.
General Reflexions on the Mechanism of Propagation of Light. Division of the Subject into Geometrical and Physical Optics.

GEOMETRICAL OPTICS.

Rectilinear Propagation of Light in Homogeneous Media, Shadows. Camera Obscura, &c.
Intensity of Illumination as depending on the Distance of the Source and the Obliquity of the Rays. Brightness and Intrinsic Brightness.
Photometry.
Velocity of Light.
Behaviour of Light at the Common Surface of Two Homogeneous Media.
Reflexion. Plane, Spherical, and Cylindrical Mirrors. Real and Virtual Images.
Single Refraction. Composite Nature of White Light. Refractive Index. Dispersion. Prisms; Fraunhofer's Lines. Irrationality of Dispersion. Achromatism. Lenses. Telescope, Microscope. Pure Spectrum. Refraction by Cylinder. Rainbow.
Refraction in a Non-homogeneous Medium. Hamilton's Characteristic Function. Mirage.
Absorption, Abnormal Dispersion, Fluorescence, Phosphorescence.

PHYSICAL OPTICS. UNDULATORY THEORY.

Nature and Propagation of Waves. Huygens's Principle. Explanation of Reflexion and Single Refraction. Disproof of the Corpuscular Theory.
Sketch of the History of the Undulatory Theory. Young's Discovery of Interference.
Interference Bands. Spectrum formed by Grating. Measure of Wave-Length. Loss of Semiundulation. Newton's Rings. Colours of Thin Plates and of Grooved Surfaces.
Relation between Wave-Length and Refractive Index.
Double Refraction. Wave-Surface in Iceland Spar.
Polarization. Transverse Vibrations. Nature of Unpolarized Light.
Plane, Circularly, and Elliptically Polarized Light. Nicol's Prism. Depolarization by Doubly-Refracting Plate. Fresnel's Rhomb.
Doppler's Principle. Measurement of the Relative Velocity of Luminous Source and Spectator.

Under OPTICS (GEOMETRICAL, PHYSICAL, and PHYSIOLOGICAL) further developments will be given; and the connexion between light and radiant heat will be discussed under RADIATION.

EARLY HISTORY OF THE SUBJECT.—It is to sight that we are mainly indebted for our knowledge of external things. All our other senses together, except under very special conditions, do not furnish us with a tithe of the information we gain by a single glance. And sight is also that one of our senses which we are able most effectively and extensively to aid by the help of proper apparatus—not merely (as by spectacles, invented *circa* 1300) for the cure of natural defects, but (as by the telescope and microscope) for the examination of bodies either too distant or too minute to be studied by the unassisted eye.

It is very remarkable, under these circumstances, to find how slowly men have reached some even of the simplest facts of optics. We can easily understand how constant experience must have forced on them the conviction that light usually moves in straight lines,—*i.e.*, that we see an object in the direction in which it really lies. But how they could have believed for ages that objects are rendered visible by something projected from the eye itself—so that the organ of sight was supposed to be analogous to the tentacula of insects, and sight itself a mere species of touch—is most puzzling. They seem not till about 350 B.C. to have even raised the question—If this is how we see, why cannot we see in the dark? or, more simply,—What is darkness? The former of these questions seems to have been first put by Aristotle.

Reflexion. The nature and laws of reflexion were, of course, forced on the ancients by the images seen in still water; and the geometers of the Platonic school were well acquainted with these laws. To Hero of Alexandria we owe the important deduction from them that the course of a reflected ray is the shortest possible.

Refraction. The general nature of refraction also was known, with some of its special applications, such as, for instance, to burning-glasses and to magnifiers. These were probably either spherical glass shells filled with water (Pliny, *H.N.*, xxxvi. 67 [25]; Lact., *De Ira Dei*, c. 10) or balls of rock crystal (Pliny, xxxvii. 10).

In the first century of our era Cleomedes pointed out how a coin at the bottom of an empty cup, where the eye cannot see it, can be made visible by filling the cup with water; and he showed that, in a similar way, the air may render the sun visible to us while it is still under the horizon. Shortly after this date Ptolemy (the celebrated astronomer) published his great work on *Optics*. He treats of vision, reflexion, the theory of plane and concave mirrors, and refraction. He measured, with considerable accuracy, the angles of incidence and refraction, for rays passing from air into water and into glass, and from water into glass; it was not, however, till more than fifteen hundred years had passed that the true relation between these angles was discovered. In addition to what has just been mentioned, the ancients' knowledge of optics was limited to a very superficial acquaintance with some of the properties of rainbows, halos, mirage, &c. But it was fragmentary in the extreme—though it far surpassed in amount as well as in accuracy their knowledge of the other branches of physical science.

It is not easy to understand the ideas of the ancients about colour. That it is a property of a body—just as its density, its hardness, or its smell is a property—was probably held by them. But they also imagined that a body could communicate its colour to light; thus, for instance, the clouds were, by some of them, supposed to communicate their colours to the sunbeams which form a rainbow.

Our next glimpse of real progress dates from the 11th or 12th century, when ALHAZEN (*q.v.*)[1] wrote a treatise on optics in Arabic, which for five hundred years or more was a recognized authority on the subject. It was, in many parts, founded on the work of Ptolemy, but with considerable additions and improvements. Alhazen gives an anatomical description of the eye, and points out, fairly enough, how with two eyes we see only one image. But he also points out that we see each object, however small, by a *pencil* of diverging rays,—not (as the ancients imagined) by a single ray. Alhazen accounts for twilight, and shows how by it to measure the height of the atmosphere. He also gives the now generally received explanation of the curious fact that the sun and moon appear larger when rising or setting than when they are high in the heavens.

The farther progress of the subject we need not now trace. From the end of 16th century that progress has been extremely rapid. The dates of the more important steps, and the names of their authors, will be given when we treat of these, in their turn, in the course of the article; and we will give them the additional interest of being presented, when this can readily be done, in the author's own words.

Vision.

PRELIMINARY STATEMENTS.—Before we commence a more rigorous treatment of the subject, it may be well to make a few preliminary statements as to the nature of *vision* and the conditions for *distinct vision*. Properly speaking, these belong to OPTICS (PHYSIOLOGICAL) (*q.v.*), but it is impossible to treat intelligibly any part of our subject without presupposing some, generally very slight, knowledge of other parts. And the few preliminary statements we have now to make are in no respect theoretical, while they are so simple that any one may at once test their truth for himself.

Distance of most distinct vision.

Except in the case of a very abnormal eye (extremely short-sighted or long-sighted as the case may be) there is a distance from it—usually somewhere about 10 inches—at which if an object be placed it is seen more distinctly than if placed at any other distance. Almost every one, perhaps without knowing it, habitually places at or about that distance from his eye an object which he wishes to examine carefully. When he places it at a smaller distance he becomes conscious of the *effort* required to see it distinctly. He has, in fact, to alter the form of the optical machinery of the eye, by a muscular effort, so that it may become capable of bringing to a focus on the retina rays more divergent than those for which the parts were in their unstrained state adapted. A corresponding effort, but usually much more slight, is commonly felt to be required if the object be at a distance greater than 10 inches.

Hence we arrive at the conclusion that, for the minimum of strain on the eye, rays should fall on it diverging as if they came from a point about 10 inches distant. But for all ordinary eyes any divergence from double of this (*i.e.*, divergence as if from a distance of 5 inches) to zero (*i.e.*, parallel rays) is consistent with the possibility of distinct vision. Rays either more divergent than the former limit, or convergent, are unfit to produce distinct vision. Hence every optical instrument, whatever be the reflexions or refractions to which light has been subjected in passing through it, must finally allow the light to escape either in parallel rays or with a divergence within the above specified limits, if it is to be employed by an ordinary eye. The comparatively slight differences which exist among ordinary eyes are easily compensated by the rack-work, or screw adjustment, which is invariably attached to the eye-piece of a good telescope and to the body of a good microscope. Every motion of this rack-work alters the divergence of the rays as they finally escape from the instrument. Any eye, however abnormal, if it be capable of producing distinct vision at all, has only to be furnished with suitable spectacles in order that it may behave exactly as does a normal eye. This statement, however, refers only to sharpness of definition, not in any degree to *colour*. The deficiency which causes *colour-blindness* cannot be supplied by any conceivable process. A definite part of the ordinary organ of vision is wanting (or inactive) in such cases—while the merely optical parts of the eye are usually in perfect order.

Inverted image on the retina.

Another fact which must be stated here is that, to produce vision of a body in its natural position, the image on the retina, as seen from the back, must be inverted—not merely as regards up and down, but also as regards right and left. Thus, in the ordinary astronomical telescope, the image on the retina is not inverted, and we therefore see an inverted image.

Judgment of distance.

A third is that our judgment of the relative distances of objects is formed mainly by the use of the two eyes simultaneously. One eye, kept still, can inform us only of relative distance in virtue of the greater or less effort to see distinctly (already spoken of). With both eyes, or with one eye moved from side to side, *parallax* comes in, and gives us the *stereoscopic* effect, as it is called. This power of judging distance is, of course, greater as the eyes are set more widely apart. There is, practically, no limit to the effective distance between the eyes when the proper instrumental methods (as with the telestereoscope) are employed.

It is also necessary to premise a few words about colour. The various homogeneous rays of the solar spectrum have each a colour of its own which no refraction can modify. But what about the many colours which do not occur in the spectrum? To such a question as "What is *yellow*"? the answer is, "*Each particular kind of yellow may be any one of an infinite number of different combinations of homogeneous rays.*" And the same is true, in general, of all other colours. Clerk Maxwell found that a yellow equivalent to that of the spectrum can be obtained by mixing in proper proportions certain homogeneous red and green rays. This single example is sufficient to show that the colour-sense is of a very singular nature. This question will be fully treated in OPTICS (PHYSIOLOGICAL); but for our present purpose it is only necessary to say that we now know (after Wünsch and Young) that the normal eye has only *three colour-sensations*—a red, a green, and a violet,—and that the apparent colour of any light which falls on it depends merely on the *relative intensities of the excitement* produced by the light on the three organs of sense corresponding to these sensations. This is true, however, only within certain limits of intensity; for extremely bright light, whatever be its real colour, seems to excite all the three sensations simultaneously, much as white light does; and with very feeble light (as, for instance, that of an ordinary aurora or of a lunar rainbow) we are sometimes scarcely conscious of

[1] The proper name of this geometer is El-Ḥasan (or by other accounts Moḥammed) ibn el-Ḥasan ibn el-Haitham, and it is as Ibn el-Haitham that he is commonly referred to. See Woepcke, *L'Algèbre d'Omar Alkhayyâmî* (Paris, 1851), p. 73 *sq.*, and Bar Hebræus, *Chron.*, p. 221 *sq.* Several of his mathematical treatises exist in English libraries (see the Catalogues of the Br. Mus., Bodl., and India Office MSS.); but the only copy of his great optical work—the *Kitâb el Manâẓir*—known to be in Europe is No. 1011 of the Leyden collection, with the commentary *Tanḳîḥ el Manâẓir* of Kemál ed-Din Abu'l Ḥasan (*Cat. Cod. Or. Lugd. Bat.*, iii. 61). A smaller work (Woepcke, *ut supra*) was based on the optical treatises ascribed to Euclid and Ptolemy, and Ibn el-Haitham claims to have restored the lost first book of the latter. The Arabs had Euclid's *Optics* (*Kitâb el Manâẓir*) in the version of Náṣir ed-Dín Tusy (*H. Khal.*, No. 10,532; Loth, *MSS. of India Office*, No. 743).

colours. In *colour-blindness* one or more of these organs of sense is wanting, or imperfect. The most common form, Daltonism, depends on the absence of the red sense. Great additions to our knowledge of this subject, if only in confirmation of results already deduced from theory, have been obtained in the last few years by Holmgren[1]; who has experimented on two persons, each of whom was found to have one colour-blind eye, the other being nearly normal. In this way was obtained, what could otherwise have been matter of conjecture only, a description of colour-blind vision in terms of (at least approximately) normal vision.

Finally, the sensation of sight is not limited to the duration of the mechanical action on the eye. It is known that we do not see a sudden flash (an electric spark for instance) until a measurable, though very short, period has elapsed. This depends on the rate at which an excitation is propagated along the optic nerve. But the familiar experiment of whirling a red-hot stick in a dark room shows that the sensation of sight lasts for a short period after the mechanical action which produced it has ceased. This period is probably different for different eyes, and for different amounts of excitement even in the same eye. (If the light be very intense the effect lasts much longer, but completely changes its character.) For our present purpose it may be assumed that the duration is somewhere about $\frac{1}{7}$th of a second. Thus, if the end of the red-hot stick describes a circle once in $\frac{1}{7}$th of a second, we see the complete circle; if in a longer period, we only see at once such a part of it as was described in $\frac{1}{7}$th of a second. Connected with this is the remarkable result obtained experimentally by Swan,[2] that the amount of sensation is, for flashes of short duration, directly proportional, not only to the brightness of the flash, but also to its duration. A flash which lasts for $\frac{1}{10}$th of a second produces the full effect on the eye; but an electric spark, as a flash of lightning, which certainly does not endure for more than $\frac{1}{1000000}$th of a second, produces at most only $\frac{1}{100000}$th of the effect it would produce if it lasted $\frac{1}{10}$th of a second. On this short duration of visual impressions depends the action of the *thaumatrope*, the *wheel of life*, &c. By various kinds of machinery a succession of views of an object in different positions or forms is presented to the eye, each for a brief interval. The result is that we fancy we see one and the same object going through a species of *continuous* motion, or of change of form, which would present it to the eye in these successive positions or forms. Thus, a tadpole may be represented as wriggling about, or as developing continuously into a frog, &c.

Sources of Light.—This subject will be fully treated in other parts of this work under various heads: from the purely scientific point of view under Radiation; from the more practical side under Lighting (Electric), &c. For our present purpose a very brief summary of the question will suffice; and we do not require to investigate the *process* by which, in any case, the light is produced.

1. The main source of light is *incandescence.* (It is usually understood that to be incandescent a body must be at a high temperature.) This may be due to any of a number of causes, such as the following:—

(*a*) *The Potential Energy of Gravitation of Scattered Fragments of Matter.*—When these fall together, as in the formation of the sun and stars, heat enough is generated by impact to render the whole vividly incandescent. It is probable that the light of nebulæ, and the *proper* light of comets, is due to this cause. The proximate cause, in all these cases, is the kinetic energy of the fragments before impact. To this class, therefore, can be reduced the light given out when a target is struck by a cannon shot.

(*b*) *The Kinetic Energy of Current Electricity or of an Electric Discharge.*—Here we have lightning, the electric light, and probably also the light of the aurora.

(*c*) *The Potential Energy of Chemical Affinity.*—The lime-light, gas-light, candle and lamp-light, fire-light, the magnesium light, &c.; also phosphorus, dead fish (?), &c., glowing in the dark.

(*d*) *Friction*, as in the trains of sparks from a grindstone or brake; though here, in general, chemical affinity also has a share.

(*e*) *Sudden great Compression of a Gas*, as of air by meteoric stones and falling stars.

2. Another very curious source, not (so far as is known) reducible to incandescence, is *the giving out* (*usually in an altered form*) *of light previously absorbed*:—fluorescence, phosphorescence, &c.

3. A third source is *physiological*:—fire-flies, glow-worms, *Medusæ*, dead fish (?), &c., the eye of a cat.

Any not black and not transparent body, exposed to any of these sources of light, becomes in its turn what may for our purpose also be treated as a source.

As will be shown in Radiation, the only bodies which, when incandescent, give *every* constituent of white light are bodies which are black in the sense of absorbing each and every ray which falls upon them. Such bodies are not *necessarily* solids—though the best examples we have of them are lamp-black, and (somewhat less perfect) charcoal and gas-coke.

Newton's speculations on these subjects, taken from the "Queries" at the end of his *Optics*, give an exceedingly interesting sketch of the state of this subject in his time. We quote a few of the more curious. There is a strange admixture of errors, but a still more strange anticipation of some of the most important of modern discoveries. Newton on sources of light

"Query 6. Do not Black bodies conceive heat more easily from light than those of other colours do, by reason that the light falling on them is not reflected outwards; but enters the bodies, and is often reflected and refracted within them, until it be stifled and lost?

"Query 8. Do not all Fixed bodies, when heated beyond a certain degree, emit light and shine; and is not this emission performed by the vibrating motions of their Parts. And do not all bodies, which abound with Terrestrial parts, and especially with Sulphureous ones, emit light, as often as those Parts are sufficiently agitated; whether that agitation be made by heat, or by friction, or percussion, or putrefaction, or by any vital motion, or any other cause? . . . .

"Query 9. Is not Fire a body heated so hot, as to emit light copiously? For what else is a red hot iron than fire? And what else is a burning coal than red hot wood?

"Query 10. Is not Flame a vapour, fume or exhalation heated red hot, that is, so hot as to shine? For bodies do not flame without emitting a copious fume, and this fume burns in the flame. The *Ignis Fatuus* is a vapour shining without heat; and is there not the same difference between this vapour and flame, as between rotted wood shining without heat and burning coals of fire? In distilling hot spirits, if the head of the still be taken off, the vapour, which ascends out of the still, will take fire at the flame of a candle, and turn into flame, and the flame will run along the vapour from the candle to the still. Some bodies heated by motion or fermentation, if the heat grow intense, fume copiously; and if the heat be great enough, the fumes will shine, and become flame. Metals in fusion do not flame for want of a copious fume, except spelter, which fumes copiously, and thereby flames. All flaming bodies, as oil, tallow, wax, wood, fossil coals, pitch, sulphur, by flaming waste and vanish into burning smoke; which smoke, if the flame be put out, is very thick and visible, and sometimes smells strongly, but in the flame loses its smell by burning; and, according to the nature of the smoke, the flame is of several colours; as that of sulphur, blue; that of copper opened with sublimate, green; that of tallow, yellow; that of camphire, white. Smoke passing through flame cannot but grow red hot; and red hot smoke can have no other appearance than that of flame. . . . .

"Query 11. Do not Great bodies conserve their heat the longest, their parts heating one another; and may not Great dense and Fixed bodies, when heated beyond a certain degree, emit light so

[1] *Proc. Roy. Soc.*, Jan. 1881.
[2] *Trans. Roy. Soc. Edin.*, 1849, 1861.

copiously, as by the emission and re-action of its light, and the reflexions and refractions of its rays within its pores, to grow still hotter, till it comes to a certain period of heat, such as is that of the sun? And are not the sun and fixed stars great earths vehemently hot; whose heat is conserved by the greatness of the bodies, and the mutual action and re-action between them, and the light which they emit; and whose parts are kept from fuming away, not only by their Fixity, but also by the vast weight and density of the atmospheres incumbent upon them, and very strongly compressing them, and condensing the vapours and exhalations which arise from them? . . . . And the same great weight may condense those vapours and exhalations, as soon as they shall at any time begin to ascend from the sun, and make them presently fall back again into him; and by that action increase his heat, much after the manner that in our earth the air increases the heat of a culinary fire. And the same weight may hinder the globe of the sun from being diminished, unless by the emission of light, and a very small quantity of vapours and exhalations."

Theories of Propagation of Light.—We may begin by assuming that the sensation of light is due to a mechanical action on the retina (see Eye). Now such a mechanical action must have a mechanical cause, and, as far as we can judge with our present knowledge, the latter must consist of impacts on the retina, due to moving matter. This matter may have travelled all the way from the source of light, or it may have been set in motion in the eye by a disturbance (analogous to a wave) which has travelled from the source. What is transferred, or what moves, is a quite independent question. Light must, as far as we can conceive, consist in the motion of particles of some kind from external objects to the eye, or in the propagation of some disturbance or wave-motion in an as yet unknown medium. Though it has been proved, as we will presently show, that some of the consequences of the first supposition are entirely inconsistent with observed facts, the nature of the propagation of the supposed luminous particles is still a very interesting study, and indeed many of the fundamental propositions in optics follow more easily from this hypothesis than from the other. We will therefore *not* at present dismiss this hypothesis, but will refer freely to it now and then, until its truth is shown to be inconsistent with experiment.

Corpuscular theory. This view, associated with the names of Newton, Laplace, and Biot, is known as the *corpuscular theory* of light. A formidable objection to it, *in limine*, will be easily seen to be furnished by the velocity of light. Since every point of every visible body must (on this theory) send such corpuscles to the eye, moving as we shall find at a rate of nearly 200,000 miles per second, their masses must be inconceivably minute in order that their united momentum may not amount to something comparable with that of a cannon shot, a supposition of course utterly destructive of all belief in the hypothesis. But, as we shall see, there are still higher grounds of objection, and such as no mere smallness of mass or size of each corpuscle can explain away.

The rival theory labours under considerable disadvantages, inasmuch as the theory of wave-propagation is very much more obscure and difficult than that of the motion of free particles; but the student, who has mastered the fundamental difficulties of sound (see Acoustics), which presents a fair although not an exact analogy, will find it comparatively easy to obtain a clear conception of the fundamental principles of the explanation offered by the *undulatory theory* of light.

The difference between these two theories of light may be illustrated by contrasting wind moving at the rate of 1100 feet per second (an inconceivably violent hurricane) and sound, gentle or violent, moving at precisely the same rate—yet how different in its effects!

Division of the Subject.—Optics, or the science of Light, is usually divided into two parts. A simple illustration of the nature of this division will be found in the different conditions of fluid equilibrium according as we do not or do introduce the idea of action between the fluid and the containing vessel (Capillary Action, *q.v.*). In the first or hypothetical case it is known that the free surface must be horizontal, and that all its separate parts must lie in the same plane; in the second, *i.e.*, the actual, case we find molecular action modifying these results, sometimes indeed to a very large extent, so that no part of the free surface is plane, and no two portions of it are at the same level. So in what is called Geometrical Optics it is assumed from experiment that light moves in straight lines in air, while Physical Optics, or the undulatory theory, agrees with experiment in showing that under certain circumstances a ray of light bends round an obstacle. But as, in obtaining the main facts of fluid equilibrium, capillary forces may be neglected, so, for the explanation of the ordinary phenomena of light, even with accuracy sufficient for the construction of the very finest telescopes and microscopes, it suffices that Geometrical Optics, based on laws *nearly* verified by experiment, be followed out to its consequences. The residual phenomena then came in to be treated by the undulatory theory. Pouillet divides the subject, in consequence of this distinction, into two parts, viz., (1) that in which we deal with the direction only of the rays, and (2) that in which we deal with the physical properties of the rays themselves.

In this order we will consider the subject, giving the explanations of the approximate experimental laws of Geometrical Optics, as we reach them, in the language of either theory. But before we come to the residual phenomena we shall have found that the corpuscular theory must be rejected, and we will therefore give, without detail, the principles of the undulatory explanation, which will be fully discussed in a special article.

Geometrical Optics.

Rectilinear Propagation of Light.

It is approximately true that, in any homogeneous medium, *light moves in straight lines.*

If an opaque body be placed anywhere in the straight line between the eye and an object, the object is concealed. Through a long straight tube no objects can be seen but those situated in the direction of its axis produced. This is so fundamental a fact, or it is so evident a result of experience, that it is the foundation of every process which involves the direction in space of one object as regards another,—whether it be for the aiming with a rifle, the pointing of a telescope, or for the delicate observations of a geodetic survey. But we must carefully observe the restrictions under which the statement is made. Not merely is it said to be only approximately true, but it is so only in a homogeneous medium. To both of these restrictions we will revert later.

(*a*) On this is founded the geometrical theory of *shadows*,—a subject of some importance, especially as regards eclipses. In this application the results may be considered as absolutely true, though, as we shall see in a subsequent page, the statement is liable in certain delicate cases to somewhat startling exceptions. When an opaque body is placed between a screen and a luminous *point*, it casts a shadow on the screen. (The sun's image formed by a lens or burning glass of short focus is our best mode of attempting to realize the conception of a luminous point; but a fair approximation may be made by piercing a very small needle-hole in a large plate of thin metal, and placing it close to any bright flame or incandescent body.) The outline of the shadow is, of course, to be found by drawing straight lines from the luminous point so as to touch the opaque body all round. These lines form a cone. The points of contact form a line on the opaque body separating the illuminated from the non-illuminated portion of its surface. Similarly, when these lines are produced to meet the screen, their points of intersection with it form a line which separates the illuminated from the non-illuminated parts of the screen.

This line is called the boundary of the *geometrical shadow*. A common but beautiful instance of it is seen when a very small gas-jet is burning in a ground-glass shade, near the wall of a room. In this case the cone, above mentioned, is usually a right cone with its axis vertical. Thus the boundary of the geometric shadow is a portion of a circle on the roof, but a portion of an hyperbola on the vertical wall. If the roof be not horizontal, we may obtain in this way any form of conic section. Interesting and useful hints in *projection* may be obtained by observing the shadows of bodies of various forms cast in this way by rays which virtually diverge from one point: *e.g.*, how to place a plane quadrilateral of given form so that its geometric shadow may be a square; how to place an elliptic disk, with a small hole in it, so that the shadow may be circular with a bright spot at its centre, &c.

When there are more luminous points than one, we have only to draw separately the geometrical shadows due to each of the sources, and then superpose them. A new consideration now comes in. There will be, in general, portions of all the separate geometrical shadows which overlap one another in some particular regions of the screen. In such regions we still have full shadow; but around them there will be other regions, some illuminated by one of the sources alone, some by two, &c., until finally we come to the parts of the screen which are illuminated directly by all the sources. There will evidently be still a definite boundary of the parts wholly unilluminated, *i.e.*, the true shadow or *umbra*, and also a definite boundary of the parts wholly illuminated. The region between these boundaries—*i.e.*, the partially illumined portion—is called the *penumbra*.

Fig. 1 shows these things very well. It represents the shadow of a circular disk cast by four equal luminous

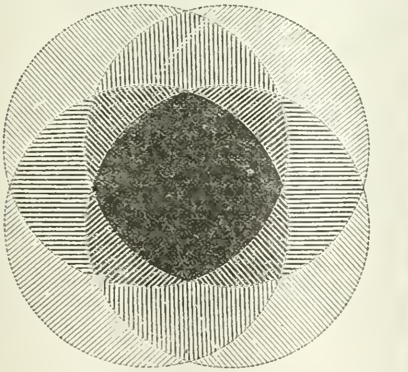

Fig. 1.

points arranged as the corners of a square,—the disk being large enough to admit of a free overlapping of the separate shadows. The amount of want of illumination in each portion of the penumbra is roughly indicated by the shading. The separate shadows are circular, if the disk is parallel to the screen. If we suppose the number of sources to increase indefinitely, so as finally to give the appearance of a luminous *surface* as the source of light, it is obvious that the degrees of darkness at different portions of the penumbra will also increase indefinitely; *i.e.*, there will be a gradual increase of brightness in the penumbra from total darkness at the edge next the geometrical shadow to full illumination at the outer edge. It is most instructive to contrast with the above figure that now given (fig. 2), in which the size of the disk is considerably diminished — everything else being unchanged. Here there is no true shadow—only four *equally bright* portions of the penumbra, each illuminated by three of the sources.

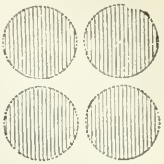

Fig. 2.

Thus we see at once why the shadows cast by the sun or moon are in general so much less sharp than those cast by the electric light (when it is not surrounded by a semi-opaque screen). For, practically, at moderate distances from the electric arc, it appears as a mere luminous point. But, if we place a body at a distance of a foot or two only from the arc, the shadow cast will have as much of penumbra as if the sun had been the source. The breadth of the penumbra when the source and screen are nearly equidistant from the opaque body is equal to the diameter of the luminous source. Simple as is the question from the point of view we have adopted, it may to some persons appear simpler to imagine themselves placed (as spectators) on the screen in different parts of the shadow or penumbra, and to consider what portions of the luminous source they would then be in a position to see.

This is what happens to us when we observe an eclipse of the sun. When the eclipse is total, there is a real geometrical shadow,—very small compared with the penumbra (for the *apparent* diameters of the sun and moon are nearly equal, but their distances are as 370 : 1); when the eclipse is annular, the shadow is all penumbra. In a lunar eclipse, on the other hand, the earth is the shadow-casting body, and the moon is the screen, and we observe things according to our first point of view. Eclipses.

Suppose, next, that the body which casts the shadow is a large one, such as a wall, with a hole in it. If we were to plug the hole, the whole screen would be in geometrical Light passing through an aperture.

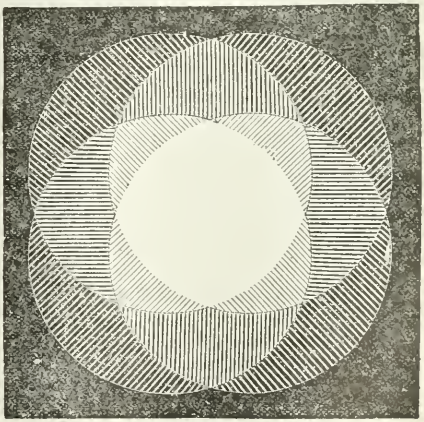

Fig. 3.

shadow. Hence the illumination of the screen by the light passing through the hole is precisely what would be cut off by a disk which fits the hole. Fig. 3, which is the complement of fig. 1, gives therefore the effect of four equal sources of light shining on a wall through a circular hole. And it is evident that, with the change of a word here and there, the previous reasoning may be applied to this case also. The umbra in the former case becomes the fully illuminated portion, and *vice versa*. The penumbra remains the penumbra, but it is now darkest where before it was brightest, and *vice versa*. For further information we subjoin the complement (fig. 4) of the second case above,—the same four sources, but the smaller hole. Here we have four *equally* bright, separate images

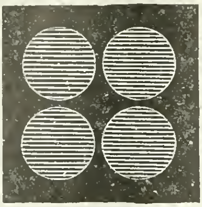

Fig. 4.

—one belonging to each of the sources. Thus we see how, when a *small* hole is cut in the window-shutter of a dark room, a picture of the sun, and bright clouds about it, is formed on the opposite wall. This picture is obviously inverted, and also perverted, for not only are objects depicted lower the higher they are, but also objects seen to the right are depicted to the left, &c. But it will be seen unperverted (though still inverted) if it be received on a sheet of ground glass and looked at from behind. The smaller the hole (so far at least as Geometrical Optics is concerned) the less confused will the picture be. As the hole is made larger the illuminated portions from different sources gradually overlap; and when the hole becomes a *window* we have no indications of such a picture except from a body (like the sun) much brighter than the other external objects. Here the picture has ceased to be one of the sun, it is now a picture of the window. But if the wall could be placed 100 miles off, the picture would be one of the sun. To prevent this overlapping of images, and yet to admit a good deal of light, is one main object of the lens which usually forms part of the camera obscura.

Images by small hole.

The formation of pictures of the sun in this way is well seen on a calm sunny day under trees, where the sunlight penetrating through small chinks forms elliptic spots on the ground. During a partial eclipse these pictures have, of course, a crescent form. When detached clouds are drifting rapidly across the sun, we often see the shadows of the bars of the window on the walls or floor suddenly shifted by an inch or two, and for a moment very much more sharply defined. They are, in fact, shadows cast by a *small* portion of the sun's limb, from opposite sides alternately. Another beautiful illustration is easily obtained by cutting with a sharp knife a *very small* T aperture in a piece of note paper. Place this close to the eye, and an inch or so behind it place another piece of paper with a fine needle-hole in it. The light of the sky passing through the needle-hole forms a bright picture of the T on the retina. The eye perceives this picture, which gives the impression of the T much magnified, but *turned upside down*.

Shadow image.

Another curious phenomenon may fitly be referred to in this connexion, viz., the *phantoms* which are seen when we look at two parallel sets of palisades or railings, one behind the other, or look through two parallel sides of a meat-safe formed of perforated zinc. The appearance presented is that of a magnified set of bars or apertures which appear to move rapidly as we slowly walk past. Their origin is the fact that where the bars appear nearly to coincide the apparent gaps bear the greatest ratio to the dark spaces; *i.e.*, these parts of the field are the most highly illuminated. The exact determination of the appearances in any given case is a mere problem of convergents to a continued fraction. But the fact that the apparent rapidity of motion of this phantom may exceed in any ratio that of the spectator is of importance,—enabling us to see how velocities, apparently of impossible magnitude, may be accounted for by the mere running along of *the condition of visibility* among a group of objects no one of which is moving at an extravagant rate.

(*b*) Another important consequence of this law is that *if the medium be transparent the intensity of illumination which a luminous point can produce on a white surface directly exposed to it is inversely as the square of the distance.*

The word transparent implies that no light is absorbed or stopped. Whatever, therefore, leaves the source of light must in succession pass through each of a series of spherical surfaces described round the source as centre. The same *amount* of light falls perpendicularly on all these surfaces in succession. The amount received in a given time by a unit of surface on each is therefore inversely as the number of such units in each. But the surfaces of spheres are as the squares of their radii,—whence the proposition. (We assume here that the velocity of light is constant in the medium, and that the source gives out its light uniformly and not by fits and starts.) When the rays fall otherwise than perpendicularly on the surface, the illumination produced is proportional to the cosine of the obliquity; for the area seen under a given spherical angle increases as the secant of the obliquity, the distance remaining the same.

As a corollary to this we have the further proposition that *the apparent brightness of a luminous surface (seen through a transparent homogeneous medium) is the same at all distances.*

The word brightness is here taken as a measure of the amount of light falling on the pupil per unit of spherical angle subtended by the luminous surface. The spherical angle subtended by any small surface whose plane is at right angles to the line of sight is inversely as the square of the distance. So also is the light received from it. Hence the brightness is the same at all distances.

The word brightness is often used (even scientifically) in another sense from that just defined. Thus we speak of a bright star, of the question—When is Venus at its brightest? &c. Strictly, such expressions are not defensible except for sources of light which (like a star) have no apparent surface, so that we cannot tell from what amount of spherical angle their light appears to come. In that case the spherical angle is, for want of knowledge, assumed to be the same for all, and therefore the brightness of each is now estimated in terms of the *whole* quantity of light we receive from it. It is in this sense only that we use the word when we speak of Venus at its brightest; for if we take the former definition of brightness the solution of this once celebrated problem would be very different from that usually given. As the question, however, is an interesting one both in itself and historically, we give an approximate solution of it. The approximation assumes what is certainly not true, that the illuminated portion of Venus always appears *uniformly* bright, and of the same degree of brightness in all aspects.

Maximum.

Let a be the radius of the earth's orbit, b that of the orbit of Venus, δ the distance between the planets when Venus is brightest.

Then if θ be the apparent angular distance of the earth from the sun as seen from Venus, the illuminated part of the disk of Venus as seen from the earth is

$$\frac{1+\cos\theta}{2}$$

of the whole disk. Hence

$$\frac{1+\cos\theta}{2\delta^2}$$

is a maximum,—with the obvious trigonometrical relation

$$a^2=\delta^2+b^2-2b\delta\cos\theta .$$

Substituting for $\cos\theta$, and putting the differential coefficient $=0$, we have a quadratic equation of which the only admissible root is the positive one·

$$\delta=\sqrt{3a^2+b^2}-2b.$$

From this the other quantities can be calculated.

But another matter has to be taken into consideration when we apply the above definition of brightness in practice. For the aperture of the pupil is usually very much contracted when we look at a brightly illuminated sky or cloud. Thus there is a rough compensation which, to a certain extent, modifies the effect on the retina.

Founded on the above is Cheseaux's celebrated argument about the finite dimensions of the stellar universe. For it is easy to see, as below, that if stars be scattered through infinite space, with average closeness and brightness such as is presented by those nearest us, and if stellar space be absolutely transparent, the whole sky should appear of a brightness like that of the sun. Cheseaux and Olbers endeavoured to show that, because the sky is not all over as bright as the sun, there is absorption of light in stellar space. This idea was ingeniously developed by Struve.

Consider a small spherical angle ω. The number of stars included in it whose distances are between r and $r+\delta r$ from the earth is proportional to

$$\omega r^2\delta r.$$

The whole amount of light received from such a portion of the sky must be therefore as

$$\omega\int_0^\infty dr,$$

provided that no star intercepts the light coming from another. This condition is unattainable, so that the conclusion is that the brightness is as great as it can be with the materials employed. Every portion of the background shines as if it were a star.

(c) A third very important fact, connected with our present subject, but not immediately deducible from our principle, is—*The brightness of a self-luminous surface does not depend upon its inclination to the line of sight.*

Thus a red-hot ball of iron, free from scales of oxide, &c., appears flat in the dark; so, also, the sun, seen through mist, appears as a flat disk. This fact, however, depends ultimately upon the second law of thermodynamics, and its explanation will be fully given under RADIATION.

It may be stated, however, in another form, in which its connexion with what precedes is more obvious—*The amount of radiation, in any direction, from a luminous surface is proportional to the cosine of the obliquity.*

The flow of light (if we may so call it) in straight lines from the luminous point, with constant velocity, leads as we have seen to the expression $\frac{\mu}{r^2}$ (where r is the distance from the luminous point) for the quantity of light which passes through unit of surface perpendicular to the ray in unit of time, μ being a quantity indicating the rate at which light is emitted by the source. This represents the illumination of the surface on which it falls. The flow through unit of surface whose normal is inclined at an angle θ to the ray is of course

$$\frac{\mu}{r^2}\cos\theta,$$

again representing the illumination. These are precisely the expressions for the gravitation force exerted by a particle of mass μ on a unit of matter at distance r, and for its resolved part in a given direction. Hence we may employ an expression

$$V=\Sigma\frac{\mu}{r},$$

which is exactly analagous to the gravitation or electric potential, for the purpose of calculating the effect due to any number of *separate* sources of light.

And the fundamental proposition in potentials, viz., that, if n be the external normal at any point of a closed surface, the integral

$$\iint\frac{dV}{dn}dS,$$

taken over the whole surface, has the value

$$-4\pi\mu_0,$$

where μ_0 is the sum of the values of μ for each source lying *within* the surface, follows almost intuitively from the mere consideration of what it means as regards light. For every source *external* to the closed surface sends in light which goes out again. But the light from an internal source goes wholly out; and the amount per second from each unit source is 4π, the total area of the unit sphere surrounding the source.

It is well to observe, however, that the analogy is not quite complete. To make it so, all the sources must lie on the same side of the surface whose illumination we are dealing with. This is due to the fact that, in order that a surface may be illuminated at all, it must be capable of *scattering* light, *i.e.*, it must be to some extent opaque. Hence the illumination depends mainly upon those sources which are on the same side as that from which it is regarded.[1]

Though this process bears some resemblance to the heat analogy employed by Sir W. Thomson for investigations in statical electricity (*Cambridge Mathematical Journal*, 1842) and to Clerk Maxwell's device of an incompressible fluid without mass (*Cam. Phil. Trans.*, 1856), it is by no means identical with them. Each method deals with a substance, real or imaginary, which flows in conical streams from a source so that the same amount of it passes per second through every section of the cone. But in the present process the velocity is constant and the density variable, while in the others the density is virtually constant and the velocity variable. There is a curious reciprocity in formulæ such as we have just given. For instance, it is easily seen that the light *received from* a uniformly illuminated surface is represented by

$$\iint\frac{dS\cos\theta}{r^2}$$

As we have seen that this integral vanishes for a closed surface which has no source inside, its value is the same for all shells of equal uniform brightness whose edges lie on the same cone.

We have said that light moves in straight lines in a homogeneous medium. This rectilinear path follows at once from the corpuscular theory, as well as from the undulatory theory of light: in the first case there is no deflecting cause, so each corpuscle moves in a straight line; in the second, the direction of propagation of a plane wave in an uniform isotropic medium is always perpendicular to its front. Looking along a hot poker or the boiler of a steamboat, we see objects beyond *distorted*; *i.e.*, we no longer see each point in its true direction. Here we have a non-homogeneous medium, the air being irregularly expanded in the neighbourhood of the hot body. To this simple cause are due the phenomena of mirage, the fata morgana, the reduplication of images of a distant object seen through an irregularly heated atmosphere, the scintillation or twinkling of stars, and the uselessness of even the best telescopes at certain times, &c. It is interesting to note here that Newton[2] says:—"Long telescopes may cause objects to appear brighter and larger than short ones can do; but they cannot be so formed as to take away that confusion of the rays which arises from the tremors of the atmosphere. The only remedy is a most serene and quiet air, such as may perhaps be found on the tops of the highest mountains, above the grosser clouds."

PHOTOMETRY.—The principle above explained suggests many simple methods of comparing the amounts of light given by different sources. If, for instance, a porcelain plate, or even a sheet of paper, of uniform thickness, have one half illuminated directly by one source of light, the other by a different source, and if one or other of these sources be moved to or from the plate till the halves appear equally illuminated, it is obvious that the amounts of light given out by the two sources are directly as the squares of their distances from the screen. This is the principle of Ritchie's photometer. Rumford suggested the comparison of the intensity of the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is

[1] From the formula of which the proof has been indicated Green's theorem and its consequences follow immediately. But we need not give these here.

[2] *Optics*, end of part i.

lit up by the other alone; and here again the amounts of light given out by the sources are as the squares of their distances from the screen when the shadows are equally intense. The shadow-casting object should be near the screen, so as to avoid penumbra as much as possible; yet not too near, so that the shadows may not overlap.

Bunsen has recently suggested the very simple expedient of making a grease-spot on white paper for photometric purposes. When the paper is equally illuminated from both sides, the grease-spot cannot be seen except by very close inspection. In using this photometer, the sources are placed in one line with the grease-spot, which lies between them and can be moved towards one or other. To make the most accurate determinations with this arrangement the adjustment should first be made from the side on which one source lies, then the screen turned round and the adjustment made from the side of the other source,—in both cases, therefore, from the same side of the paper screen. Take the mean of these positions (which are usually very close together), and the amounts of light are as the squares of the distances of the sources from this point. Wheatstone suggested a hollow glass bead, silvered internally, and made to describe very rapidly a closed path, for use as a photometer. When it is placed between two sources, we see two *parallel* curves of reflected light, one due to each source. Make these, by trial, equally bright; and the amounts of light from the sources are, again, as the squares of the distances. These simple forms of apparatus give results which are fairly accurate, so long at least as the *qualities* of the light furnished by the two sources are nearly the same. But, when we endeavour to compare differently coloured lights, the result is by no means so satisfactory. In fact, we cannot well define equality of illumination when the lights are of different qualities. In the undulatory theory, no doubt, we can distinctly define the intensity of any form of radiation. But the definition is a purely dynamical one, and has not necessarily any connexion with what we usually mean by intensity, viz., the amount of effect produced upon the nerves of the retina. Thus the theoretical intensities of a given violet and a given red source may be equal, while one may appear to the eye very much brighter than the other. Think, for instance, of a colour-blind person, who might, under conceivable circumstances, be unable to see the red at all. We are *all* as it were colour-blind as far as regards radiations whose wave-lengths are longer or shorter than those included in the range of the ordinary solar spectrum.

Wheatstone's.

Difficulties of photometry.

Other modes of measuring the intensity of light usually depend upon more recondite physical principles,—such as, for instance, the amounts of chemical action of certain kinds which can be produced by an exposure of a given duration to the light from a particular source. But all have the same grand defect as the simpler processes,—they are not adapted to the comparison of sources giving different qualities of light. And those last mentioned are liable to another source of error, viz., the action of radiations which are not called light, only because they are not visible to the eye; for in all other respects they closely resemble light, and are often more active than it is in producing chemical changes.

Velocity of Light.—Light moves with a velocity of nearly 186,000 miles per second. Of this we have four distinct kinds of proof, on each of which depends a method which is capable of giving pretty accurate results.

1. *Römer's Method.*—By this the finite velocity of light was discovered in 1676. Suppose, to illustrate this, that at a certain place a cannon is fired precisely at intervals of an hour while the weather is perfectly calm. A person provided with an accurate watch travels about in the surrounding district. When he first hears the cannon let him note the time by his watch, then on account of the non-instantaneous propagation of sound, if at the next discharge he be *nearer* the gun than before, the report will arrive at his ear *before* the hour's interval has elapsed; if he be farther from the gun, the interval between the discharges will appear longer than an hour; and the number of seconds of defect or excess will evidently represent the time employed by sound in travelling over a space equal to the difference of his distances from the gun at the successive observations.

Now the satellites of Jupiter are subject—like our moon, only much more frequently—to eclipse, and the interval between two successive eclipses can easily be observed. The almost sudden extinction of the light is a phenomenon similar to the discharge of the gun; and, if light take time to move from one place to another, we should find the interval between successive eclipses too short when we are approaching Jupiter, too long when we are receding from him. Such was found to be the case by Römer; and he also found that the shortening or lengthening of the interval depended upon the rate at which the earth was approaching to or receding from Jupiter. The inevitable conclusion from these facts is that light is propagated with finite velocity. Römer calculated from them that light takes about $16^{m}.5$ to cross the earth's orbit. The exact velocity deduced by this method is, after making all corrections, and assuming the most probable value of the solar parallax, about 186,500 miles per second.

2. *Bradley's Method.*—This depends on the *aberration of light*, discovered by Bradley in 1728. When in a calm rainy day one stands still he holds his umbrella vertical in order to protect himself. If he walk he requires to hold it forwards, and more inclined the faster he walks. In other words, to a person walking the rain does not appear to come in the same direction as to a person standing still.[1] Now the earth's velocity in its orbit is a very large quantity, some $18\frac{1}{2}$ miles per second, or about $\frac{1}{10000}$th of that of light. Hence the light from a star does not appear to come in the proper direction unless the earth be moving exactly to or from the star, and, as the direction of the earth's motion is continually changing, so the directions in which different stars are seen are always changing, and thus this phenomenon, called the "aberration of light," proves at once the finite velocity of light and the earth's motion round the sun.

As an additional illustration of the phenomenon, suppose a bullet fired through a railway carriage, in a direction perpendicular to the sides of the carriage. If the carriage be standing still, the bullet will make holes in the sides, the line joining which is perpendicular to the length of the carriage; if it be in motion, then the second side of the carriage will have moved through a certain space during the interval occupied by the bullet in passing from side to side, and thus the line joining the holes in the sides (*i.e.*, the line pursued by the bullet relatively to the carriage), will be inclined at an angle greater than a right angle to the direction of the train's motion.

It is evident that the path apparently described by each star during a year, in consequence of aberration, will be found by laying off from the star lines which bear the same ratio to the star's distance as the velocity of the earth does to that of light,—their directions being always the same as that of the earth's motion at every instant. This is precisely the definition of the Hodograph (*q.v.*) of the earth's orbit. Hence, on account of the finite velocity of

[1] In fact, to estimate the relative direction and velocity of two moving bodies we must subtract the vector velocity of the first from that of the second.

light, each star appears to describe in space a circle (not an ellipse) of fixed magnitude in a plane parallel to that of the ecliptic. As seen from the earth, therefore, stars will appear to describe paths which are the projections of these circles on the celestial sphere. These are in general ellipses, but circles for stars at the poles of the ecliptic and straight lines for stars in the ecliptic. This is found to be quite consistent with observation; and the major axes of these ellipses, the diameters of the circles, or the lengths of the lines subtend equally angles of about 41″ at the earth. Hence the velocity of light is to the velocity of the earth as 1 : tan ½ 41″; that is, about 10,000 : 1.

Both these methods depend, for their final result, upon a true knowledge of the earth's distance from the sun. But the most accurate measurements of this quantity are probably to be obtained from the velocity of light itself, this being independently determined by the physical processes next to be described. Thus the earth's distance from the sun will in future be measured rather by the constant of aberration, or by the acceleration or retardation of the eclipses of Jupiter's satellites, than by a transit of Venus, by the moon's motion, or by the parallax of Mars. Thus Römer's and Bradley's processes are now applied to the determination of solar parallax.

3. *Fizeau's Direct Measurement of the Velocity of Light.*—To illustrate the next and by far the most convincing *popular* proof of the finite velocity of light, suppose a person looking at himself in a mirror, before which is moving a screen with a number of apertures, the breadth of each aperture being equal to the distance between any two of them. If the screen be at rest with an aperture before the mirror, the light from the observer's face passes through the aperture and is reflected back, so that he sees himself as if the screen were not present. Suppose the screen to be moving in such a way that, when the light which passed through the aperture returns to the screen after reflexion, the unpierced part of the screen is in its way, it is evident that the observer cannot see himself in the mirror. If the screen pass twice as fast, the light that escaped by one aperture will, after reflexion, return by the next, so that he will see his image as at first. If three times as fast, the second unperforated part of the screen will stop the returning light; so he cannot see his image. To apply this practically a thin metallic disk had a set of teeth cut on its circumference so that the breadth of a tooth was equal to that of the space between two teeth. This disk could be set in very rapid rotation by a train of wheelwork, and the rate of turning could easily be determined by Savart's method (see ACOUSTICS, vol. i. p. 108). Light passed between two teeth to a mirror situated at 10 miles' distance, which sent it back by the same course, so that when the wheel was at rest the reflected light could be seen. On turning the disk with accelerated velocity the light was observed to become more and more feeble up to a certain velocity, at which it was extinguished; turning faster it reappeared, growing brighter and brighter till the velocity was doubled; then it fell off, till it vanished when the velocity was trebled, and so on. It is evident from the first illustration above that the velocity of light in air is to that of the tooth, at the first disappearance of the reflected light, as the distance of the mirror from the disk is to the half breadth of the tooth. It is not to be supposed that the description we have just given embodies all the details of this remarkable experiment. On the contrary, telescopes were used at each station to prevent loss of light as much as possible, and many other precautions were adopted which would be unintelligible without references to later parts of this article. This method and its first results were published in 1849 in the *Comptes Rendus*. The experiments gave, on their very careful repetition by Cornu in 1874, the value 186,700 miles for the velocity in vacuo (*Nature*, xi. p. 274).

4. *Foucault's Method.*—This was described in 1850 to the Academy of Sciences. It depends upon the principle of the rapidly revolving plane mirror introduced by Wheatstone to demonstrate the non-instantaneous propagation of an electric discharge. The mirror was made to revolve from 600 to 800 times per second, by means of a *siren* (see ACOUSTICS) driven by steam. A ray of sunlight fell upon it from a small aperture crossed by a grating of platinum wires. Between the wires and the mirror was placed an achromatic lens—the wires being farther from it than its principal focus, but *not twice as far*—so that the rays falling on the mirror were slowly convergent. They formed an image of the wires at a distance of about 4 metres from the mirror. In certain positions of the revolving mirror, the rays fell upon a concave mirror of 4 metres radius whose centre of curvature was at the centre of the revolving mirror. They were, therefore, reflected back directly to the revolving mirror, and, passing again through the lens, formed an image of the wire grating which, when the adjustment was perfect, coincided with the grating itself. This coincidence was observed by reflexion from a piece of unsilvered glass, placed obliquely in the track of the rays, the image in which was magnified by an eye-piece. It is obvious that, when the mirror is made to turn, the light which comes back to it after passing to the fixed mirror, finds it in a position slightly different from that in which it left it. That difference is due to the amount of rotation during the time of passage of the light to and fro along an air-space of 4 metres. Accordingly, as soon as the mirror began to rotate with considerable velocity, the coincidence between the wires and their images was destroyed; and the two were separated more and more widely as the velocity of rotation was increased. It was easy to calculate, from the measured dimensions of the apparatus, the amount of deflexion, and the rate of rotation of the mirror, the velocity of light. The rate of rotation was, of course, given by the pitch of the note produced by the siren.

Foucault's early results with this apparatus showed that the velocity of light which had been deduced from the old methods was too large; and he concludes his first paper by the statement that the determination of the distance of the earth from the sun must now be made by physical instead of astronomical methods. Foucault's process has recently been very considerably improved by Mitchelson, who, in 1879, found for the velocity of light in vacuo 186,380 miles per second (*Nature*, vol. xxi. p. 226).

By interposing a tube filled with water, and having flat glass ends, between the fixed and revolving mirrors, Foucault found that (for the same rate of rotation) the displacement of the image was greater than before in the proportion of the refractive index of water to unity. Thus it was at once evident, by a mode of experimenting exposed to no possible doubt, that light moves faster in air than in water, and, therefore, as will be seen later, that the corpuscular theory of light must be abandoned.

Other methods of determining the velocity of light in air, and for comparing the velocities of light in air and water (on which depends the most definite proof of the erroneousness of the corpuscular theory), and in still and moving water, will be afterwards explained. They give results of very great value, but we cannot introduce them here, as they depend upon somewhat more recondite principles of *physical* optics.

It is interesting to observe that, as the nearest fixed star is probably about 200,000 times farther from us than the sun is, we now see such a star by light which left it more than three years ago. If, as is now supposed, *variable* stars (such as Mira Ceti) owe their rapid periodical changes of brightness to eclipses, and if different homogeneous rays travel with different velocities in free space, it is evident that such stars would show a gradual change of colour as they wax, and an opposite change as they wane. Nothing of the kind has as yet been observed, though it has been carefully sought for. Hence we have every reason to conclude that, in free space, all kinds of light have the same velocity. It will be seen later that *dispersion* has been accounted for by the different velocities of light of different wave-lengths in the same refracting medium,—this being a consequence of the ultimate grained structure of ordinary matter, which is on a scale not incomparably smaller than the average wave-length.

Behaviour of Light at the Common Surface of Two Homogeneous Media.

Effect at a surface of separation between two media.

When a ray of light, moving in one homogeneous medium, falls on the bounding surface of another homogeneous medium, it is in general divided into several parts, which pursue different courses. These parts are respectively—(α) reflected; (β) refracted (singly or doubly); (γ) scattered; (δ) absorbed.

In the first two categories the result is two or three rays of light pursuing definite paths according to laws presently to be given. The fraction of the incident light which is reflected is in general greater as the angle of incidence is greater. In one important class of cases the reflexion is *total*. But at direct incidence the reflected portion is much greater for some bodies, such as mercury, than for others, such as water or glass. In bodies which give no scattering, the refracted portion of a ray consists of all the non-reflected portion, and therefore usually diminishes as the angle of incidence increases.

In the third category the common surface of the two media becomes illuminated, and behaves as if it were itself a source of light, sending rays in all directions. It may be objected to this, that in many cases the rays are scattered while penetrating the second medium. But in such cases the second medium cannot be called *homogeneous*. This will come up for discussion when we treat of absorption and colours.

In the fourth category the light ceases for an instant to exist as light; but its energy may either become heat in the absorbing body, or it may again be given out by the absorbing body in the form of light, but of a *degraded* character. This is called *fluorescence*, or *phosphorescence*, according as the phenomenon is practically instantaneous or lasts for a measurable time.

In category (α) the light is sent back into the first medium; in (β) it penetrates into the second; in (γ) it goes, in general, mainly to the first; in (δ) it is shared by both.

It is by scattered light that non-luminous objects are, in general, made visible. Contrast, for instance, the effects when a ray of sunlight in a dark room falls upon a piece of polished silver, and when it falls on a piece of chalk. Unless there be dust or scratches on the silver you cannot see it, because no light is given from it to surrounding bodies except in one definite direction, into which (practically) the whole ray of sunlight is diverted. But the chalk sends light to *all* surrounding bodies from which any part of its illuminated side can be seen; and there is no special direction in which it sends a much more powerful ray than in others. It is probable that if we could, with sufficient closeness, examine the surface of the chalk, we should find its behaviour to be of the nature of reflexion, but reflexion due to little mirrors inclined in all conceivable aspects, and at all conceivable angles, to the incident light. Thus scattering may be looked upon as ultimately due to reflexion. When the sea is perfectly calm, we see in it one intolerably bright image of the sun only. But when it is continuously covered with slight ripples, the definite image is broken up, and we have a large surface of the water shining by what is virtually scattered light,—though it is really made up of parts each of which is as truly reflected as it was when the surface was flat.

We have spoken above of the behaviour of light at the common surface of two media. Now we do not by this phrase necessarily mean two media different in their chemical composition. We mean merely media *optically* different. Thus water with steam above it, and in very special cases layers of water or air of different temperatures, give surfaces of separation at which reflexion and refraction may and do take place. But, except in such special cases, we rarely have an abrupt change, such as is necessary for reflexion, between two portions of the same substance *in the same molecular state*. In general the transition is gradual; and special mathematical methods must be applied for the purpose of tracing the behaviour of the ray, which is now really travelling in a *non-homogeneous* medium.

Reflexion of Light.—If light be reflected from a plane surface bounding two dissimilar isotropic media, *the incident and reflected rays are in one plane with, and are equally inclined (on opposite sides) to, the perpendicular to the reflecting surface at the point of incidence*. This is sometimes stated in the form—*The angles of incidence and of reflexion are equal to one another, and in one plane*. The best experimental proof of the truth of this statement is deduced from the use of a reflecting surface of mercury in observations with the mural circle. The graduation of such an instrument is the most perfect that human skill can accomplish, and no one has ever been able to find by it the slightest exception to the preceding statement.

The principle of Hadley's quadrant, and of the sextant as now used (an invention of Newton's), is founded on this fact. If a plane mirror on which a ray falls be turned through any angle about an axis perpendicular to the plane of reflexion, the reflected ray is turned through twice that angle. This is an immediate consequence of the above law. For, if the plane be turned through any angle θ, the perpendicular to it is turned through the same angle. Hence the angle between the incident ray and the perpendicular is increased or diminished by θ, and therefore that between the incident and reflected rays (which is double of this) is altered by 2θ. A plane mirror is now extensively used for the purpose of indicating, by the change of direction of a reflected ray, the motion of a portion of an instrument to which the mirror is attached. Thus the magnetometers of Gauss, the tuning-forks of Lissajoux, and the electrometers and galvanometers of Sir W. Thomson are all furnished with mirrors. The law of reflexion is also the basis of the goniometer, for the measurement of the angles of crystals and prisms.

It follows from this law that, if a ray pass from one point to another, after any number of reflexions at fixed surfaces, the length of its whole path from one point to the other is the least possible—subject to the condition that it shall *meet* each of the reflecting surfaces. For the point in a given plane the sum of whose distances from two given points (on the same side of the plane) is the least possible is that to which, if lines be drawn from the points, they are in one plane with the normal (or perpendicular) to the given plane and make equal angles with it. And, as the same is true of each separate reflexion, it is true for the whole course of the ray, since for any one of the reflecting surfaces may be substituted its tangent plane at the point of incidence.

It is to be remarked that there are exceptions to this form of the statement. The true form is that the actual path of a ray, under the given conditions, is less in length than any other path (satisfying the conditions) which is nowhere finitely divergent from it. This may be best seen by another method. Suppose a series of ellipses to be described whose foci are the source of light and an assigned point which is to be reached by the reflected ray. Let this system turn about the line joining the foci; it generates a series of prolate spheroids such that the time of light's passing from one focus to a point in any one of the surfaces, and thence to the other focus, is the same whatever point be chosen on that particular surface. If we take any point *without* that surface, for it the corresponding time is obviously greater. Hence to find the path of that one of a system of rays diverging from a given point which, after reflexion at a given surface, shall pass through a given point, we have only to imagine spheroids constructed as before. Of these one at least will *touch* the given surface. All points on the surface *in the neighbourhood of the point of contact* (mark this limitation) will in general be outside the spheroid. Hence this point gives the shortest path. But the spheroid and the reflecting surface have the same tangent plane, and therefore the parts of the ray are equally inclined to the surface.

Formation of Images by Reflexion at a Plane Surface.—We may assume here—what is indeed evident from the rectilinear propagation of light—that objects are rendered visible to the eye by rays *diverging* from them. Hence, if we have a set of reflected or refracted rays diverging from any point, or diverging as if they came from any point, they will convey to the eye the impression of the existence of a luminous source at that point. The eye, in fact, can only tell us what effect is produced upon it, *i.e.*, what sort of mechanical action it is subjected to. Its indications must therefore depend only upon what reaches it, and in no other sense whatever upon the source or the path of light. This point from which rays diverge, or appear to diverge, is called an *image.*

The image of any point in a plane mirror is found by drawing from the point a perpendicular on the mirror and producing it till its length is doubled.

The extremity of the line so drawn is the image of the point; or, in other words, rays proceeding from the point diverge after reflexion as if they came from the image so found. The image in this case is called *virtual*, to distinguish it from cases, subsequently to be mentioned, where it is *real*—the distinction being that the rays have actually passed through a real image, while they only appear to come from a virtual one.

To prove this it is only necessary to observe that, if A (fig. 5) be a luminous point or a point from which rays

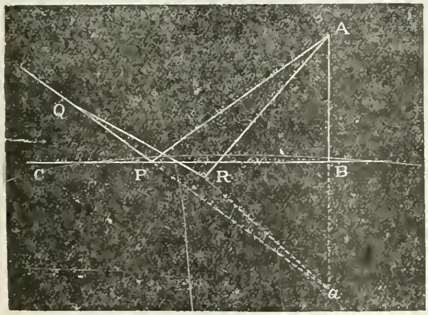

Fig. 5.

diverge, and CB any section of the mirror by a plane through AB, the perpendicular to it, and if we make $Ba = AB$, and take any point P, then, joining AP, aP, and producing the latter, the angles APB, aPB, and therefore CPQ are equal; also the plane of the paper contains the perpendicular to the mirror at P. Hence PQ is the reflected ray; or the ray, after reflexion, appears to come from a. Hence a is the image—a virtual one, as before noticed. Also, if R be any point whatever (not P) in the plane of the mirror, we have obviously $a\text{R} = \text{RA}$. Hence the path AR, RQ is equal to aR, RQ, two sides of the triangle aRQ, of which aQ, which is equal to the actual path (AP, PQ), is the third side.

Fig. 6 represents the pencils of diverging rays by which two points of the image are rendered visible to an eye placed in front of the mirror. From the requisite modification of this figure it follows that one can see his whole person in a mirror of only half his height and breadth.

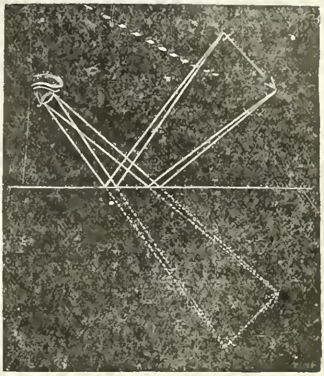

Fig. 6.

Dircks's *ghost*, which has played a prominent part in popular entertainments for some years back, is the image, in a large sheet of unsilvered plate glass hung at the front of the stage, of an actor or figure strongly illuminated, and concealed from the audience in a sort of enlarged prompter's box. Any one can see the phenomenon completely by looking into a plate-glass window on a sunny day, when he sees the passers-by apparently walking *inside* the house.

The principles already stated suffice fully for the explanation of the curious vistas of images formed by two *parallel* plane mirrors facing one another at opposite sides of a room. The only additional observation necessary on this subject is that, if the mirrors are silvered on the back, the light at each reflexion has to pass twice through the glass. Thus, if the glass be pinkish or greenish, the various images are more and more coloured as they are due to more numerous reflexions.

These principles also easily explain the KALEIDOSCOPE (*q.v.*) of Sir D. Brewster, where images are formed by two mirrors inclined to one another. It is easy to see that the series of images of a luminous point produced by such an arrangement after one, two, &c., reflexions must all lie on a circle; also that, if the angle between the mirrors be an aliquot part of four right angles, these images will form a finite number of groups, each consisting of an infinite number of images which have exactly the same position. Kaleidoscope.

The explanation of the law of reflexion which is furnished by the corpuscular theory is excessively simple. We have only to suppose that at the instant of its impact on the reflecting surface the velocity of a corpuscle *perpendicular* to the surface is reversed, while that *parallel* to the surface is unchanged. It bounds off, in fact, like a billiard-ball from the cushion. The undulatory theory gives an explanation, which is, in reality, quite as simple, but requires a little more detail for those who are not familiar with the common facts of wave-motion. We therefore reserve it for a time.

Reflexion at a Spherical Surface.—Let APB (fig. 7) be a section of a concave spherical mirror by a plane passing through its centre of curvature O, and through the luminous point U. Then, if any ray from U, as UP, meet the surface, it will be reflected in a direction PV, such that UP, PO, and PV are in one plane, and so that PO bisects the angle UPV. (This follows because OP, a radius of the sphere, is normal to the surface at P.) Hence it is

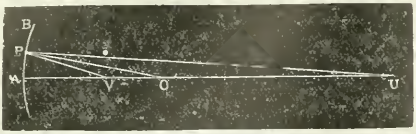

Fig. 7.

rigorously true that, if V be the intersection of PV with UOA,

$$\frac{VO}{VP}=\frac{OU}{UP}.$$

The full consequences of this *exact* statement will be developed under OPTICS (GEOMETRICAL). For our present purpose, an approximation will amply suffice. Let us suppose P to be so near to A that no sensible error is introduced by writing A for P in the above formula. This amounts to supposing the mirror's breadth to be very small in comparison with its radius of curvature. The formula now becomes

$$\frac{VO}{AV}=\frac{OU}{AU};$$

or, what is the same,

$$\frac{AO-AV}{AV}=\frac{AU-AO}{AU};$$

and V is, to the degree of approximation above stated, independent of the position of the point P. If we call r the radius AO of the mirror, $u=AU$ the distance of the source, and $v=AV$, the distance of the point V from the mirror, this becomes

$$\frac{r-v}{v}=\frac{u-r}{u}\,,\text{ or }\frac{1}{u}+\frac{1}{v}=\frac{2}{r}. \quad . \quad . \quad . \quad (a).$$

The formula, or the cut, shows at once that this relation between U and V is *reciprocal*; *i.e.*, all rays from V, falling on the mirror, will be made to converge at U. These points are therefore called *conjugate foci.*

Conjugate foci.

The simplicity of (a) is remarkable; so, also, is that of its interpretation. For the rays passing from a source to a given object, like the mirror, are less and less divergent as the source is farther off. Hence (a) signifies that the (algebraic) sum of the divergences of the incident and reflected rays is equal to that divergence which the mirror can convert into parallelism.

In fact the rigorous geometrical relation may be written in the obvious form AVP + AUP = 2AOP,—which, when all three angles are small, is simply (a). A similar statement may easily be made in the case of refraction.

Generalization of the formula.

Before we proceed to develop the consequences of this simple formula, we may point out that it is applicable to all cases,—to convergent rays falling on a concave mirror, to divergent rays falling on a convex mirror, &c., &c. The reader may easily verify this by trial for himself. But it follows at once from the necessary interpretation of the negative sign in geometry. Thus, if the mirror were convex, O would be to the *left* of A, as the figure is drawn; and AO, if formerly positive, would now be negative. Thus, for a convex mirror, the formula is

$$\frac{1}{u}+\frac{1}{v}=-\frac{2}{r}.$$

If the incident rays be *convergent*, U is to the left of A, and therefore AU, or u, is negative; and so on.

We must now study the *relative* positions of U and V, in order to find the size and position of the image for different positions of the object.

Returning to the formula (a) above, we see that the following pairs of values of u and v satisfy it:—

u	v
Infinite.	$\frac{1}{2}r$.
Greater than r.	Greater than $\frac{1}{2}r$, less than r.
r	r.
Less than r, greater than $\frac{1}{2}r$.	Greater than r.
$\frac{1}{2}r$.	Infinite.
Greater than 0, less than $\frac{1}{2}r$.	Negative.
0.	0.

Thus, when the source is at a practically infinite distance (as the sun or a star) the image is formed at a distance from the mirror equal to *half* its radius of curvature. It is then said to be in the *principal* focus. As the source comes nearer, the image comes out to meet it, and they coincide at the centre of curvature of the mirror. In fact, a ray leaving the centre of the mirror must meet the surface at right angles, and thus go back by the way it came. When the source comes still nearer, the image goes further off, until, when the source is at the principal focus, the image is at an infinite distance; that is, the rays go off parallel to one another. This is the mode in which a concave reflector is employed for lighthouse purposes. When the source comes still nearer, the image is behind the mirror, *i.e.*, the incident rays are so divergent that part of their divergence remains after reflexion. This remnant of divergence becomes greater and greater as the source is nearer to the mirror, *i.e.*, the (then *virtual*) image comes closer to the mirror, which finally behaves, for a very near source, almost precisely like a plane mirror.

All of these phenomena can be beautifully seen in a dark room by employing a beam of sunlight, rendered distinctly visible, in the fashion noted by Lucretius, by the motes in the air.

For further explanation pictures are given (figs. 8, 9), showing the course of the pencil of rays when (1) a *real*

Paths of rays forming an image

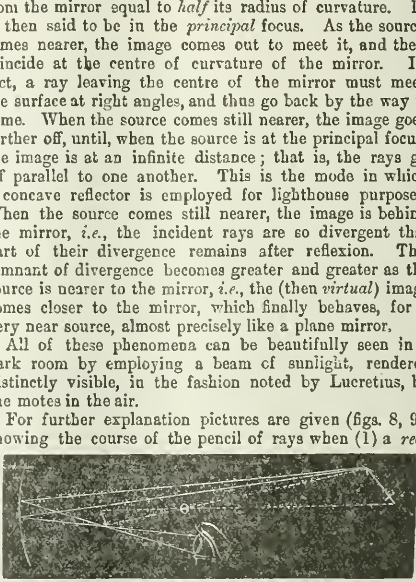

Fig. 8.

Fig. 9.

and (2) a *virtual* image is formed by a concave mirror. It will be seen at once that, in the cases figured, the *real* image is *inverted* and less than the object, the *virtual* image *erect* and larger. In fact the size of a small object is obviously to that of its image in proportion to their distances from O, the centre of curvature of the mirror. Also the image is erect when it lies on the same side of the centre of curvature with the object; inverted, if on the opposite. In other words, the image is inverted if the rays cross one another's path, erect if they do not.

When the breadth of the mirror is large compared with its radius, the approximation upon which all these results depend can no longer be made. There is then no definite image even of a luminous point. It becomes spread over what is called a *caustic*, a section of which is the bright curve familiar to every one who has looked at a cup of milk in sunshine.

Even when the approximation is close enough for ordinary purposes, it is not so for astronomical purposes, and the effect of its inexactness upon the image is known as *spherical aberration.* For the fine mirrors of reflecting TELESCOPES (*q.v.*) the spherical form cannot be employed; the surface of the mirror must be of *parabolic* section.

Cylindrical Mirrors.—As a simple example of the application of the law of reflexion at curved surfaces, when the rigorous solution is demanded, let us take the case of a vertical right cylinder, the object being a drawing on a horizontal plane. Such mirrors, with the frightfully distorted drawings necessary to give an image of natural proportions, were very common fifty years ago, but are now rarely seen. They are still, however, valuable as illustrations of our subject.

Let the plane of the object cut the axis OB of the cylinder at right angles in O (fig. 10), and let A be the position of the eye, and RQA a ray from a point R of the object, reflected at Q. Draw QP perpendicular to the axis. Then AQ and QR are in the same plane with QP (the normal to the surface) and make equal angles with it. Hence, when this figure is projected by vertical lines on the plane of the object, it takes the form in fig. 11; and AQ, QR now make equal angles with OQ. Also, if AB be drawn (in fig. 10) perpendicular to OP, the ratio of AQ to QR in fig. 11 is equal to that of BP to PO in fig. 10.

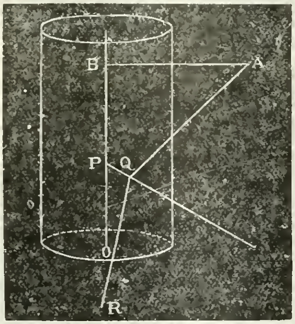

Fig. 10.

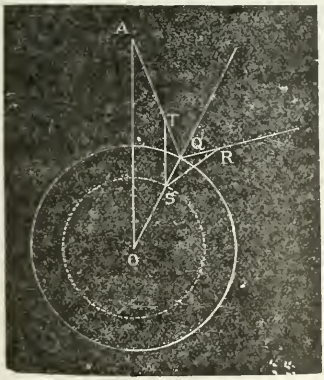

Fig. 11.

Take $QS : QO :: QR : QA$,

and draw ST parallel to OA. Then it is obvious that

$$SR = ST = \frac{QS}{QO} OA\ ;$$

and also that the angles QSR and QST are equal. Hence the following theorems, which enable us at once to draw a figure on the object plane such that its image shall appear of any assigned form.

1. Any line, such as QR, on the object plane, drawn from a point Q in the section of the cylinder so that the angles OQR and OQA are equal, is seen after reflexion as a generating line of the cylinder.

2. If an epicycloid be described by lines of fixed length OS, SR, turning about O with angular velocities 1 and 2, and both coinciding with OA at starting, its image will be a circular section of the cylinder.

Thus, if we imagine as drawn on the cylinder any number of vertical and horizontal sections, forming a network, the object corresponding to them can be traced as a number of intersecting straight lines and epicycloids. Thus we have a well-known means of drawing the required object. A similar process may be applied to other modes of using such mirrors.

When the cylinder has a small diameter, it may be usefully employed to intercept and reflect part of a beam of sunlight entering a dark room. It is easy to see, by a geometrical construction, that the reflected rays will, in this case, form a right cone, whose axis is that of the cylinder; and one of its generating lines will be parallel to the incident ray. Thus the angle of the cone becomes smaller as the inclination of the reflecting cylinder to the ray becomes less. If the ray, at the point of interruption, was at the centre of a spherical dome, after reflexion it will form on the dome a circle, small or great, which passes through its original point of incidence.

In the language of QUATERNIONS (*q.v.*), let α be the incident ray, β the axis of the cylinder, τ any normal to the cylinder, ρ the reflected ray. Then the law of reflexion gives

$$V.\tau\alpha\tau\rho = 0.$$

The property of the normal gives

$$S\beta\tau = 0.$$

Eliminating τ, we have at once

$$\frac{\rho^2}{\alpha^2} = \left(\frac{S\beta\rho}{S\alpha\beta}\right)^2,$$

the equation of a right cone.

Imitations, more or less perfect, of primary and secondary rainbows can easily be made by this process,—the sunbeam being led through a prism just before it falls on the cylindrical rod. This experiment is a very striking one; but, though capable of giving much information, it is of that dangerous kind which is liable to mislead instead of instructing an audience.

If we look at a great number of thin cylindrical rods, parallel to one another, and illuminated by sunlight, the rays which reach the eye must, by what we have already said, each form a side of some right cone (of definite angle) whose axis is parallel to each of the cylinders. The appearance presented will therefore be that of a luminous *circle*, passing through the sun. Its angular diameter becomes less as the axes of the cylinders are less inclined to the incident rays.

This phenomenon is beautifully shown by some specimens of crystals, especially of Iceland spar, which are full of minute tubes parallel to one another. In a plate of such a doubly-refracting crystal, however, there are necessarily four images. That which is *throughout* due to the ordinary ray (this term will be explained later) shows perfectly the phenomenon above described. The light of the luminous circle is white. The other three curves are not circles, and in them the colours are separated. One of them, which is elliptical, is usually very much brighter than either of the remaining two.

REFRACTION.—If homogeneous light be refracted at a plane surface separating two homogeneous isotropic media, *the incident and refracted rays are in one plane with the normal to the surface, and the sines of their inclinations to it are in a constant ratio.*

The law of single refraction was put in a form equivalent to this (all but one word) for the first time by Snell in Leyden, some time before 1626. It was first published in 1637 by Descartes, who undoubtedly obtained it from Snell; but he gave it without any mention of its author.

The one word referred to is *homogeneous* as applied to the incident light. For the fact that white light consists of innumerable different homogeneous constituents, which are separated from one another by refraction, was first established by Newton. We quote his own account of this important discovery from his letter to Oldenburg, dated Feb. , $167\frac{1}{2}$:—

"To perform my late promise to you, I shall without further ceremony acquaint you, that in the year 1666 (at which time I applied myself to the grinding of optick-glasses of other figures than spherical) I procured me a triangular glass-prism, to try therewith the celebrated phænomena of colours. And in order thereto, having darkened my chamber, and made a small hole in my window-shuts, to let in a convenient quantity of the sun's light, I placed my prism at its entrance, that it might be thereby refracted to the opposite wall. It was at first a very pleasing divertisement, to view the vivid and intense colours produced thereby; but after a while applying myself to consider them more circumspectly, I became surprised to see them in an oblong form; which, according to the received laws of refractions, I expected should have been circular. They were terminated at the sides with streight lines, but at the ends the decay of light was so gradual, that it was difficult to determine justly what was their figure, yet they seemed semicircular.

"Comparing the length of this coloured *spectrum* with its breadth, I found it about five times greater; a disproportion so extravagant, that it excited me to a more than ordinary curiosity of examining from whence it might proceed. I could scarce think, that the various thickness of the glass, or the termination with shadow or darkness, could have any influence on light to produce such an effect: yet I thought it not amiss, first to examine those circumstances, and so tried what would happen by transmitting light through parts of the glass of divers thicknesses, or through holes in the window of divers bignesses, or by setting the prism without, so that the light might pass through it, and be refracted, before it was terminated by the hole: but I found none of those circumstances material. The fashion of the colours was in all these cases the same.

"Then I suspected, whether by any unevenness in the glass, or other contingent irregularity, these colours might be thus dilated. And to try this, I took another prism like the former, and so placed it, that the light passing through them both, might be refracted contrary ways, and so by the latter returned into that course from which the former had diverted it: for by this means I thought the regular effects of the first prism would be destroyed by the second prism, but the irregular ones more augmented, by the multiplicity of refractions. The event was, that the light, which by the first prism was diffused into an oblong form, was by the second reduced into an orbicular one, with as much regularity as when it did not at all pass through them. So that whatever was the cause of that length, it was not any coutingent irregularity.

"I then proceeded to examine more critically, what might be effected by the difference of the incidence of rays coming from divers parts of the sun; and to that end, measured the several lines and augles belongiug to the image. Its distance from the hole or prism was 22 foot; its utmost length $13\frac{1}{4}$ inches; its breadth $2\frac{5}{8}$; the diameter of the hole $\frac{1}{4}$ of an inch. The angle which the rays, tending towards the middle of the image, made with those lines, in which they would have proceeded without refraction, was 44 deg. 56 min. and the vertical angle of the prism 63 deg. 12 min. Also the refractions on both sides the prism, that is, of the incident and emergent rays, were, as near as I could make them, equal; and consequently about 54 deg. 4 min. And the rays fell perpendicularly upon the wall. Now subducting the diameter of the hole from the length and breadth of the image, there remains 13 inches in the length, and $2\frac{3}{8}$ the breadth, comprehended by those rays which passed through the center of the said hole; and consequently the angle of the hole, which that breadth subtended, was about 31 min. answerable to the sun's diameter; but the angle which its length subtended, was more than 5 such diameters, namely, 2 deg. 49 min.

"Having made these observations, I first computed from them the refractive power of that glass, and found it measured by the ratio of the sines 20 to 31; and then by that ratio I computed the refractions of two rays flowing from opposite parts of the sun's *discus*, so as to differ 31 min. in their obliquity of incidence, and found that the emergent rays should have comprehended an angle of about 31 min. as they did before they were incident.

"But because this computation was founded on the hypothesis of the proportionality of the sines of incidence and refraction, which though by my own experience I could not imagine to be so erroneous, as to make that angle but 31 min. which in reality was 2 deg. 49 min. yet my curiosity caused me again to take my prism: and having placed it at my window, as before, I observed, that by turning it a little about its axis to and fro, so as to vary its obliquity to the light, more than an angle of 4 or 5 degrees, the colours were not thereby sensibly translated from their place on the wall; and consequently by that variation of incidence, the quantity of refraction was not sensibly varied. By this experiment, therefore, as well as by the former computation, it was evident, that the difference of the incidence of rays, flowing from divers parts of the sun, could not make them after decussation diverge at a sensibly greater angle, than that at which they before converged; which being at most but about 31 or 32 min. there still remained some other cause to be found out, from whence it could be 2 deg. 49 min.

"Then I began to suspect, whether the rays, after their trajection through the prism, did not move in curve lines, and according to their more or less curvity, tend to divers parts of the wall. And it increased my suspicion, when I remembered that I had often seen a tennis-ball, struck with an oblique racket, describe such a curve line. For, a circular as well as a progressive motion being communicated to it by that stroke, its parts, on that side where the motions conspire, must press and beat the contiguous air more violently than on the other, and there excite a reluctancy and re-action of the air proportionably greater. And for the same reason, if the rays of light should possibly be globular bodies, and by their oblique passage out of one medium into another acquire a circulating motion, they ought to feel the greater resistance from the ambient æther, on that side where the motions conspire, and thence be continually bowed to the other. But notwithstanding this plausible ground of suspicion, when I came to examine it, I could observe no such curvity in them. And besides (which was enough for my purpose) I observed, that the difference betwixt the length of the image and the diameter of the hole, through which the light was transmitted, was proportionable to their distance.

"The gradual removal of these suspicions at length led me to the *experimentum crucis*, which was this. I took two boards, and placed one of them close *behind the prism at the window*, so that the light might pass through a small hole, made in it for the purpose, and fall on the other board, which I placed at about 12 feet distance, having first made a small hole in it also for some of that incident light to pass through. Then I placed another prism behind this second board, so that the light trajected through both the boards might pass through that also, and be again refracted before it arrived at the wall. This done, I took the first prism in my hand, and turned it to and fro slowly about its axis, so much as to make the several parts of the image, cast on the second board, successively pass through the hole in it, that I might observe to what places on the wall the second prism would refract them. And I saw, by the variation of those places, that the light, tending to that end of the image towards which the refraction of the first prism was made, did in the second prism suffer a refraction considerably greater than the light tending to the other end. And so the true cause of the length of that image was detected to be no other, than that *light* is not similar or homogeneal, but consists of *difform rays, some of which are more refrangible than others*; so that without any difference in their incidence on the same medium, some shall be more *refracted* than others; and therefore that, according to their *particular degrees of refrangibility*, they were transmitted through the prism to divers parts of the opposite wall."

Refractive index.

The *constant ratio* mentioned in the above statement of the law of refraction is called the *refractive index*. Its numerical value depends upon the nature of the two media, and also upon the quality of the homogeneous light. It is usually greater for orange light than for red, for yellow than for orange, and so on,—so that the violet rays are often called the "more refrangible" rays.[1]

The following experimental facts are additions to the law.

When refraction takes place from a rarer into a denser medium, the angle of refraction is usually less than that of incidence.

If the refractive index for a particular kind of light from a medium A into another B be μ, that from B to A is $\frac{1}{\mu}$. In other words, a refracted ray may be sent back by the path by which it came.

If μ_1 be the refractive index for a particular ray from A

[1] This statement is, however, liable to some very singular exceptions, which will be mentioned later, when we are dealing with anomalous dispersion.

into B, and μ_2 that for the same ray from A into C, that from B into C is $\frac{\mu_2}{\mu_1}$.

These being premised, let us consider a source of homogeneous light in air shining on a surface of water. Here we may take μ as about equal to $\frac{4}{3}$.

Let MN (fig. 12) be the perpendicular to the water surface at the point where the incident ray AP meets it. In the plane APM make the angle QPN such that

$$\sin APM = \tfrac{4}{3} \sin QPN,$$

then PQ is the refracted ray. If QP be produced backwards to meet the vertical line BA in q, we may present this statement in the form

$$\frac{PB}{PA} = \frac{4}{3}\frac{PB}{Pq},$$

or

$$PA = \tfrac{3}{4}Pq.$$

If the rays fall *nearly* perpendicularly on the surface, we may put (approximately) B for P, and we have

$$Bq = \tfrac{4}{3}BA.$$

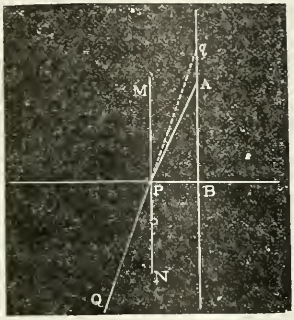

Fig. 12.

Hence, an eye placed under water and nearly in the vertical through A, sees a *virtual image* of A at q, one-third farther from the surface of the water.

As P is taken farther and farther from A, the angle of incidence becomes more nearly a right angle, and the sine of the angle of refraction becomes more nearly equal to $\frac{3}{4}$. *A ray cannot go from air into water so as to make, with the perpendicular to the surface, an angle whose sine is greater than* $\frac{3}{4}$. The true nature of this curious statement is, however, best seen when we suppose the source to be under water, and the light to be refracted into air. If APQ (fig. 13) be the course of a ray, we have as before

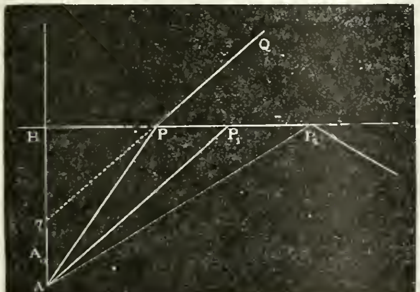

Fig. 13.

$$AP = \tfrac{3}{4}Pq.$$

Hence, if P_1 be taken so that

$$AP_1 = \tfrac{3}{4}P_1B,$$

it is clear that q coincides with B, or the ray AP_1, refracted at P_1, runs along the surface of the water. If AP_2 be less than $\frac{4}{3}$ P_2B, no point q can be found; so that the ray AP_2 *cannot get out of the water.* It is found to be completely reflected in the water. This reflexion unaccompanied by refraction is called *total reflexion.* The limiting angle of incidence (at P_1) which separates the totally reflected rays from those which (at least partially) escape into air is called the *critical angle.* When an equilateral triangular prism of glass is placed in a ray of sunlight, and made to rotate, we see (besides the spectra formed by refraction) beams of white light reflected alternately from the *outside* and the *inside* of each face. The totally reflected ray from the inside is seen to be very much brighter than that reflected from the outside.

To an eye placed nearly in the vertical of A, A appears at A_0, where

$$A_0B = \tfrac{3}{4}AB.$$

Thus a clear stream, when we look vertically into it, appears to be of only $\frac{3}{4}$ths of its real depth. But when we look more and more obliquely, seeing A for instance by the ray QP, the image appears nearer and nearer to the surface; or, if A be at the bottom, the water will appear more and more shallow; and all objects in it will appear to be crowded towards the surface. Thus the part of a stick immersed in water appears bent up towards the surface of the water.

Again, to an eye at A, all objects *above* the water will be seen within a right cone of which AB is the axis and AP_1 a side. The rest of the water surface, outside the cone just mentioned, shows us objects at the bottom by reflexion in a perfect mirror.

All this is on the supposition that the light is homogeneous. But when white light is emitted by A, the point A_0 will be nearer the surface for each constituent the greater is the refractive index. Thus a white point at A will appear drawn out into a coloured line whose lower end is red and upper end violet.

It is easily seen from the law of refraction that light, on passing through a plate of homogeneous material with parallel faces, finally emerges in a direction parallel to that at incidence, and therefore white light comes out from it still white. If the plate be water in a glass vessel with parallel sides, a body placed close to one side, while the eye is close to the other, appears to be at $\frac{3}{4}$ths of its real distance from the eye.

Corpuscular explanation of the law of refraction.

The explanation of the law of refraction, on the corpuscular theory, was given by Newton. It is still of importance, as the earliest instance of the solution of a problem involving molecular forces. Newton shows that, as the molecular forces on a corpuscle balance one another at every point inside either of the media, its velocity must be constant in each, but that in passing through the surface of separation of the two media the square of the velocity perpendicular to the surface undergoes a finite change.

Thus, if v be the velocity in air, α the angle of incidence, then in glass the velocity parallel to the surface is still $v \sin \alpha$, but that perpendicular to the surface is $\sqrt{v^2\cos^2\alpha + a^2}$. Thus the whole velocity is $\sqrt{v^2 + a^2}$; and, if α' be the angle of refraction,

$$\sqrt{v^2 + a^2}\,\sin \alpha' = v \sin \alpha.$$

Prisms.—When the surfaces are plane, but not parallel, we have what is called a *prism.*

The general nature of the action of a prism will be easily understood by the help of the previous illustrations, if we restrict ourselves to the case of a prism of very small angle and to rays passing nearly perpendicular to each of its faces. Thus, the rays falling nearly at right angles to its surface from a point A (fig. 14) will, after the first refraction, appear to diverge from a luminous line RV, red at the end next to A, violet at the other. This line is in the perpendicular AB from A to the first surface of the prism. Draw from R and V perpendiculars RS, VT to the second surface of the prism. Join BS, BT, and draw Ar, Av parallel to them so as to cut RS in r and VT in v. To an eye behind the prism, the bright point A will appear to be drawn out into a coloured line rv, red at the end nearest to A.

If A be a narrow bright line of light, parallel to the edge of the prism, it will appear to be drawn out into a rectangle consisting of images of the line ranged parallel to one another, and due to the various homogeneous constituents of white light in order of their refrangibility. If the light do not contain rays of every degree of refrangibility, some of these images will be wanting, and there will be corre-

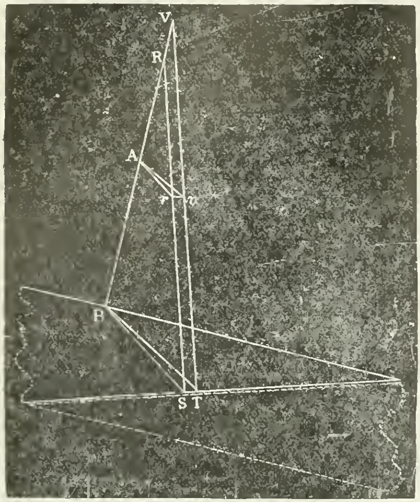

Fig. 14.

sponding dark lines or bands crossing this *spectrum* (as it is called). The amount by which any part of this spectrum is shifted from the true position of the bright slit depends (*cæteris paribus*) upon the amount of the refraction. It also depends on the angle of the prism. And, for a given angle, the length of the spectrum depends upon the difference between the refractive indices for the red and the violet rays. This is called the *dispersion*.

If a second prism, of the same glass, and of the same angle, as the first, be placed in a reversed position behind it (as indicated by the dotted lines in the figure), the effect of the two would be simply that of a *plate* of glass with parallel faces; the emergent rays would each be parallel to its original direction, and there would be no separation of colours. The reversed prism would therefore undo the work of the direct prism. Then we should have no dispersion, but we should also have no refraction. We have, however, as has already been shown, an increase of divergence, *i.e.*, the image is nearer to the eye than the object. Blair, Brewster, and Amici devised combinations of two pairs of prisms of the same glass, those of each pair having their edges parallel, such that the combination acted as a sort of achromatic telescope of low power.

Newton, from some rough experiments, hastily concluded that the amount of dispersion is in all substances proportional to that of the refraction. If such were the case it is easy to see that prisms of two differently refracting materials and of correspondingly different angles, combined (as above described) so as to annul the dispersion, would likewise annul the refraction. Thus Newton was led to suppose that refraction without dispersion is impossible.

It was found by Hall in 1733, and afterwards (independently) by Dollond, that this idea is incorrect—that, in fact, we have in certain media large refraction with comparatively small dispersion, and *vice versa*, and thus that the dispersion may be got rid of while a part of the refraction remains. James Gregory had previously conjectured that this might be done by using, *as is done in the eye*, more media than one. Thus we have for certain specimens of flint and crown glass, whose optical constants were carefully measured by Fraunhofer, the following values of the refractive index for three definite kinds of homogeneous light:—

	C	D	F
Flint glass	1·6297	1·6350	1·6483
Crown glass	1·5268	1·5296	1·5360

The rays C and F are in the red and greenish blue respectively, and are given off by incandescent hydrogen. D is the orange-yellow ray of sodium.

When the angle of the prism is very small (the only case we treat here), we may consider A*rv* as approximately a straight line, whose length is (*cæteris paribus*) proportional to the angle of the prism. Also the distances A*r*, A*v*, are to one another in the proportion of the refractive indices of red and violet rays, *each diminished by unity*. Hence, for a prism of flint glass such as was employed by Fraunhofer, the distances from A to its images formed by these three kinds of homogeneous light respectively are very nearly as

630, 635, 648.

When a prism of crown glass is used they are nearly as

527, 530, 536.

The differences between the numbers for C and F are

For flint glass 18
,, crown glass 9

or as 2 : 1. Hence if we make the small angle of the crown-glass prism twice that of the flint, and observe A through the two prisms, with their edges turned in opposite directions, the C and F images will coincide. Both, however, will be displaced from the real direction of A as if a prism had been employed, with its edge turned as that of the crown glass was, and to the same extent as that prism would have displaced them had its refractive index been about 1·21 and the same for the two kinds of light C and F.

In fact, the displacements by the flint prism are as

630, 648,

and those by the crown prism (to the opposite side) are as

1054, 1072.

The differences, in favour of the crown prism, are as

424, 424.

This combination of prisms is called *achromatic* or colourless, but is not perfectly so. For if we inquire into the displacement of the D image, we find that it is as Irrationality of dispersion.

635

for the flint prism; but as

1060

in the opposite direction, for the crown prism. Hence its whole displacement is as

425,

a little greater than that common to C and F. The reason for this is obvious from Fraunhofer's numbers given above. The interval from C to D is to that from C to F in a greater ratio in crown than in flint glass,—so that the spectra given by these media are not *similar*. The rays of higher refrangibility are more separated in proportion to those of lower refrangibility in flint than in crown glass. This is the *irrationality of dispersion*—which, so far as we yet know, renders absolute achromatism unattainable. Three lenses in combination give a better attempt at achromatism than can be made with two; and some remarkable results were obtained by Blair,[1] with two glass lenses enclosing a lenticular portion of a liquid.

By looking through a prism at a very narrow slit, formed by the window shutters of a darkened room, Wollaston (in 1802) found that the light of the sky (*i.e.*, sunlight) gives a spectrum which is *not continuous*. It is crossed by dark bands, as already hinted. These bands are due to the deficiency of intensity of certain definite kinds of homogeneous light. They were, independently, rediscovered, and their positions measured, by Fraunhofer[2] in 1817 with far more perfect optical apparatus. He also found similar, but not the same, deficiencies in the light from various fixed stars. The origin of these bands will be explained in RADIATION, along with the theory of their application in spectrum analysis. In optics they are useful to an extreme degree in enabling us to measure refractive indices with very great precision. Wollaston's own account of his discovery is as follows:—

"If a beam of day-light be admitted into a dark room by a crevice $\frac{1}{20}$th of an inch broad, and received by the eye at the distance of 10 or 12 feet, through a prism of flint-glass, *free from veins*, held near the eye, the beam is seen to be separated into the four following colours only, red, yellowish-green, blue, and violet, in the proportions represented in fig. . . . .

"The line A that bounds the red side of the spectrum is somewhat confused, which seems in part owing to want of power in the eye to converge red light. The line B, between red and green, in a certain position of the prism is perfectly distinct; so also are D and E, the two limits of violet. But C, the limit of green and blue, is not so clearly marked as the rest; and there are also on each side of this limit other distinct dark lines *f* and *g*, either of which in an imperfect experiment might be mistaken for the boundary of these colours.

"The position of the prism in which the colours are most clearly divided is when the incident light makes about equal angles with two of its sides. I then found that the spaces AB, BC, CD, DE occupied by them were nearly as the numbers 16, 23, 36, 25."[3]

The mode of formation of a spectrum which was employed by Newton, and which is still used when the spectrum is to be seen by many spectators at a time, differs from that just explained in this, that the light from a source A is allowed to pass through the prism, and to fall on a white screen at a considerable distance from it. In this case the paths of the various rays as they ultimately escape from the prism are found by joining the points $r, \ldots v$, with the prism and producing these lines to meet the screen. Unless one surface of the prism be covered by an opaque plate, with a narrow slit in it parallel to the edge of the prism, the spectrum produced in this way is very *impure*, *i.e.*, the spaces occupied by the various homogeneous rays overlap one another. To make it really pure an achromatic lens is absolutely requisite. This leads us, naturally, to the consideration of the refraction of light at spherical surfaces.

Refraction at a Spherical Surface.—Following almost exactly the same course as that taken with reflexion above, let O (fig. 15) be the centre of curvature of the spherical refracting surface AB. Let U be the point-source of homogeneous light, and let PV be the prolongation (backwards) of the path pursued, after refraction, by the ray UP.

[1] *Trans. R.S.E.*, vol. iii. (1791).

[2] Gilbert's *Annalen*, lvi.

[3] "The correspondence of these lines with those of Fraunhofer I have, with some difficulty, ascertained to be as follows:—

A, B, *f*, C, *g*, D, E, . . . Wollaston's lines.
B, D, *b*, F, G, H, . . . Fraunhofer's lines.

There is no single line in Fraunhofer's drawing of the spectrum, nor is there any in the real spectrum, coincident with the line C of Wollaston's, and indeed he himself describes it as not being 'so clearly marked as the rest.' I have found, however, that this line C corresponds to a number of lines half-way between *b* and F, which, owing to the absorption of the atmosphere, are particularly visible in the light of the sky near the horizon."—Brewster, *Report on Optics*, *Brit. Association*, 1832.

Then, *rigorously*, we have

$$\sin \mathrm{UPO} = \mu \sin \mathrm{OPV},$$

where μ is the index of refraction between the two media employed. This may be written (by omitting a common factor) as

$$\frac{\mathrm{OU}}{\mathrm{PU}} = \mu \frac{\mathrm{OV}}{\mathrm{PV}}.$$

If, as before, the breadth of the surface be small compared with its radius of curvature, we may approximate

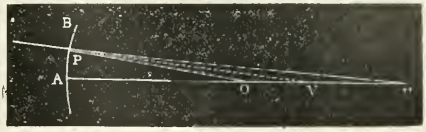

Fig. 15.

(sufficiently for many important practical purposes) by writing A for P. Thus we have

$$\frac{\mathrm{OU}}{\mathrm{AU}} = \mu \frac{\mathrm{OV}}{\mathrm{AV}}.$$

Retaining the same notation as in the case of reflexion, we get

$$\frac{u-r}{u} = \mu \frac{v-r}{v},$$

or

$$\frac{\mu}{v} - \frac{1}{u} = \frac{\mu - 1}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Notice that, if we put $\mu = -1$, this becomes the formula for *reflexion* at a concave mirror.

Lenses.—Suppose now that, after passing a *very short* distance into the refracting medium, the ray escapes again into air through another spherical surface whose centre of curvature also lies in the line OA. Let s be the new radius of curvature, w the value of the quantity corresponding to v for the escaping ray. Then, remembering that the refractive index is now $\frac{1}{\mu}$, we have (by the previous formula) Thin lenses

$$\frac{\frac{1}{\mu}}{w} - \frac{1}{v} = \frac{\frac{1}{\mu} - 1}{s}.$$

or

$$\frac{1}{w} - \frac{\mu}{v} = \frac{1-\mu}{s} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Adding (1) and (2) we get rid of v, which indicates the behaviour of the rays in the substance of the lens, and have

$$\frac{1}{w} - \frac{1}{u} = (\mu - 1)\left(\frac{1}{r} - \frac{1}{s}\right).$$

This contains the whole (approximate) theory of the behaviour of a very thin *lens*.

When the source is at an infinite distance, or $u = \infty$ we have

$$\frac{1}{w} = (\mu - 1)\left(\frac{1}{r} - \frac{1}{s}\right)$$

$$= \frac{1}{f} \quad \text{suppose.}$$

This quantity f, defined entirely in terms of the refractive index and of the curvatures of the two faces of the lens, is called the *principal focal distance*. If μ be greater than 1, *i.e.*, as in the case of a glass lens in air, f is *positive* if

$$\frac{1}{r} > \frac{1}{s}$$

be so; and it obviously retains the same value, and sign, if the lens be turned round. For, in the formula, r and s change places, and they also change signs; *i.e.*, we must Reversibility of thin lens put $-s$ for r and $-r$ for s. This leaves the result unchanged.

All lenses, therefore, whose sections are of any of the forms in fig. 16, whichever way they are turned, render

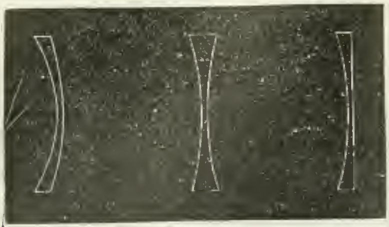

Fig. 16.

parallel rays which pass through them *divergent*. Their characteristic is that they are thinnest at the middle. But

$$\frac{1}{r}-\frac{1}{s}$$

is negative for lenses whose sections are of any of the forms shown in fig. 17. Such lenses, whichever way they are turned, render parallel rays *convergent*. Their characteristic

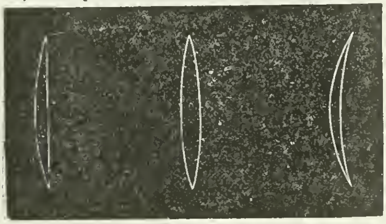

Fig. 17.

is that they are thickest at the middle. But these characters are interchanged when μ is less than 1; as, for instance, when the lens is an air-space surrounded by water. The similarity on reversal is *not* in general true in a second approximation.

The formula for a thin lens now takes the form,

$$\frac{1}{w}-\frac{1}{u}=\frac{1}{f},$$

and differs from that for a curved reflecting surface only in the sign of the second term. With the proper allowance for this, then, all that we have said of reflexion at spherical mirrors holds true of refraction through thin lenses with spherical surfaces.

We may now put the whole matter in the excessively simple form which follows:—

A thin lens increases or diminishes by a definite quantity the convergence or divergence of all rays which pass through it.

This quantity is the divergence or convergence of rays falling on the lens from or passing from it to its principal focus. Or it is the convergence or divergence which the lens produces in parallel rays. Thus, if the distance of an object from a convex lens is twice the focal length of the lens, the image is formed at the same distance from the lens, and is equal in size to the object.

Figs. 18 and 19 show the production of a real image and of a virtual image by lenses which produce *convergence* of parallel rays—along with the rays by which these are seen by an eye placed behind the lens. In either case it is obvious that the sizes of object and image are, respectively, as their distances from the centre of the lens. Fig. 18 shows how a lens produces a real inverted image of a body placed farther from it than its principal focus. This is the case in the camera obscura, in the solar

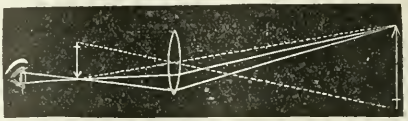

Fig. 18.

microscope, and in the object glass of a telescope. Fig. 19 shows how a virtual image is formed of a body placed nearer to a lens than its principal focus. This is the case of a single lens used as a microscope. In the former case the divergence of the incident rays is so small that the lens renders them convergent. In the latter the divergence is so great that the lens can only diminish, not destroy it.

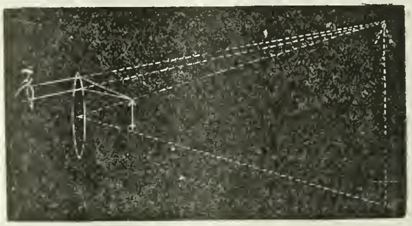

Fig. 19.

In using a hand-magnifier in this way, we so adjust it, by practice, that the enlarged image appears to be formed at the distance from the eye at which vision is most distinct. It is obvious that the amount of magnification must, then, be greater as the focal length of the lens is less.

We can now understand the working of the ordinary *astronomical telescope* (fig. 20). The object glass furnishes an inverted but real image of a distant body, *within our reach*. We can, therefore, place the eye-glass (like the single microscope above spoken of) so as to form a virtual magnified image of this real image treated as an object. It is still, of course, inverted. It is easy to see that the

Fig. 20.

angle subtended at the eye by the virtual image seen through the eye-piece is to that subtended by the object at the unaided eye approximately as the focal length of the object-lens is to that of the eye lens. These angles are, in fact, those subtended at the centres of the two lenses by the real image. This ratio is, therefore, called the *magnifying power* of the telescope.

The *compound microscope*, in its simplest form, is precisely the same arrangement as the astronomical telescope. The only difference is that the object, being at hand, can be placed near to the object-glass (still, however, beyond its principal focus), so that the real image formed is already considerably larger than the object, and is then still further magnified by the eye-glass.

The magnifying power of a single lens, when used as a hand microscope, is to be measured by the ratio of the angle under which the virtual image of an object is seen (at the distance of most distinct vision) to that at which the object itself would be seen (at that same distance); *i.e.*, it is the ratio of 10 inches to the focal length of the lens.

Combinations of Lenses in Contact.—From the formula

$$\frac{1}{f}=(\mu-1)\left(\frac{1}{r}-\frac{1}{s}\right)$$

we see that the focal length of a simple lens is less as μ is greater. Thus all that we have just said is true for homogeneous light alone. But if we combine two thin lenses, placing them close together, we may arrive at an approximately achromatic arrangement. For we have, for the first lens

$$\frac{1}{w}-\frac{1}{u}=\frac{1}{f}.$$

For a second, close to it, we have

$$\frac{1}{x}-\frac{1}{w}=\frac{1}{f'}.$$

For the two, considered as one, we have

$$\frac{1}{x}-\frac{1}{u}=\frac{1}{f}+\frac{1}{f'}.$$

Now

$$\frac{1}{f}+\frac{1}{f'}=(\mu-1)\left(\frac{1}{r}-\frac{1}{s}\right)+(\mu'-1)\left(\frac{1}{r'}-\frac{1}{s'}\right),$$

and there is an infinite number of ways in which r' and s' can be chosen, when r and s are given, such that the values of the right hand side shall be equal for *two* values of μ and the corresponding values of μ'. Any one of these gives an achromatic combination, of the necessarily imperfect kind described above in considering prisms. But, as we have now the curvatures of *four* surfaces to deal with, we can adjust these so as not only to make the best attainable approximation to achromatism, but also to reduce the unavoidable spherical aberration to a minimum.

These questions, however, are beyond the scope of this article. We can remark only that the adjustment for two rays, for which the refractive indices are μ and $\mu+\delta\mu$ in the first medium, and μ' and $\mu'+\delta\mu'$ in the second, requires the *one relation*

$$\frac{\delta\mu}{\mu-1}\,\frac{1}{f}+\frac{\delta\mu'}{\mu'-1}\,\frac{1}{f'}=0,$$

which involves only the ratio of the focal lengths of the two lenses—leaving their forms absolutely undetermined. But, if both μ and μ' be greater than unity, the signs of f and f' must be different;—*i.e.*, in an achromatic combination of two lenses one must be convex and the other concave.

The reader must, however, be reminded that we are dealing with a first approximation only, and that spherical aberration does not come in till we reach a second. The details for a proper achromatic combination will be given in OPTICS (GEOMETRICAL).

Before leaving this subject, we must find the behaviour of two thin lenses which are placed at a finite distance from one another. For the first lens we have, as before,

$$\frac{1}{w}-\frac{1}{u}=\frac{1}{f}.$$

If the second lens be placed at a distance a behind the first, the rays which fall on it appear to come from a distance $w+a$. Hence, for the light emerging from the second lens, we have

$$\frac{1}{x}-\frac{1}{w+a}=\frac{1}{f'}.$$

When u is infinite, we have from the last two equations

$$\frac{1}{x}=\frac{1}{f+a}+\frac{1}{f'}.$$

It is obvious that a combination of this nature offers the same kind of facilities for the partial cure of dispersion and of spherical aberration as when the lenses are in contact, with *one* additional disposable constant. Thus we have compound *achromatic eye-pieces*, which can be corrected for spherical aberration also.

Formation of a Pure Spectrum.—We may now go back to the formation of an image by a prism, and inquire how, by the use of an achromatic lens, we can project a pure spectrum on a screen. We have seen that a thin prism, for rays falling nearly perpendicular to it, forms a virtual and approximately rectilineal image of a luminous point, in which the colours are ranged in order of refrangibility. Suppose the light which passes through the prism to fall on an achromatic lens, placed at a distance greater than its focal length from the virtual image above mentioned. These rays after passing through the lens will proceed to form, at the proper distance, a real linear coloured image of the luminous point, in which (as in the virtual image) the colours do not overlap. Instead of a luminous point, rays diverging from a very narrow slit parallel to the edge of the prism are employed. It is usual to place the lens at *double* its focal distance from the virtual image, and thus the real image is formed at an equal distance on the other side of it, and is of the same size. It may now, if required, be magnified by means of an achromatic eye-piece. Or, in other words, it may be examined by means of a telescope. In fact a telescope, whose object glass is covered by a thin prism, has been usefully employed during a total eclipse in examining the light of the solar corona. A similar arrangement, made to have an exceptionally large field of view, is employed to find the nature of the spectra of meteorites or falling stars.

Refraction at a Cylindrical Surface.—A very simple, but interesting, case of refraction at a cylindrical surface is furnished by a thermometer tube. It is easily seen that the diameter of the bore appears, to an eye at a distance large as compared with the diameter of the tube, to be greater than it really is, in the proportion of the refractive index of the glass to unity. Thus in flint glass it appears magnified in about the ratio 5 : 3. Hence the mercury appears completely to fill the external surface of such a tube, if the bore be only $\frac{3}{5}$ths of the external diameter.

But a far more interesting case is that of parallel rays falling on a solid cylinder of glass or water. Its interest consists in the fact that by its aid we can explain the phenomena of the *rainbow*. We, accordingly, devote special attention to it. The problem, without losing any of its applicability to the rainbow, is much simplified by supposing the rays to be incident in a direction perpendicular to the axis of the cylinder; for in this case the whole course of each ray is in a plane perpendicular to the axis. We need not treat here of rays which pass *close to* the axis of the cylinder. For such the cylinder acts as a lens, and its focal length (to the usual first approximation) can easily be obtained by methods such as those given above.

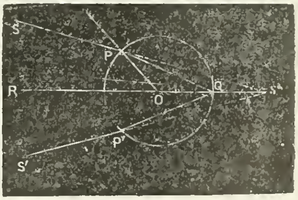

Fig. 21.

What we are mainly concerned with is the behaviour of the rays which escape into the air, after *one* or *two* reflexions at the inner surface of the cylinder.

Suppose first that we consider a ray once reflected in the interior of the cylinder. Let SP (fig. 21) be one of the set of incident parallel rays, and let its path be SPQP'S'. This involves refraction at P, reflexion at Q, and again refraction at P′. But it is obvious from the symmetry of the circular section, and from the laws of refraction and reflexion, that this path is symmetrical about the line OQ which joins the axis of the cylinder to the point at which the ray is reflected. Hence SP, S′P′ meet OQ in the common point s; and the amount by which the direction of the ray has been turned round by the refractions and the reflexion is twice the supplement of half the angle at s. But the angle POR is double OPQ the angle of refraction, while OPs is equal to the angle of incidence. Hence the half angle at s is the excess of twice the angle of refraction over the angle of incidence.

Turn now to fig. 22, in which we have two concentric circles whose radii are to one another as the refractive index of the cylinder is to unity. If A be any point on a diameter, and tangents Ap and Aq be drawn from it, we see at once that the sines of the angles at A are to one another as the radii of the circles. Hence, if OAp be the angle of incidence, OAq is the corresponding angle of refraction; and it is easy

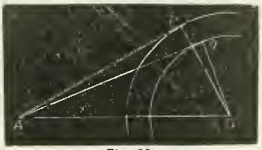

Fig. 22.

to see that the half angle at s (in fig. 21) will in fig. 22 be represented by the *excess* of OAq over qAp. Now when OA is large, both of these angles are small, and thus their difference is likewise small. As OA becomes less the difference of the angles becomes greater, but only up to a certain point, for when A is near the outer circle the angle OAp begins to increase much faster than does OAq. Hence there is a single definite position of A for which the difference is a *maximum*. In the first figure these changes in the angles of incidence and refraction, for the members of a group of parallel rays, correspond to the varying position of P in the circular section of the cylinder. Hence there is *one* position of P for which the angle at s is a maximum. Now one of the conditions of a maximum or minimum of any quantity is that, near it, the value of the quantity *changes very slowly*. Thus a number of issuing rays are crowded together near the direction corresponding to this maximum, the others being more widely scattered,—while for all of them the angle at s is smaller. Newton gives us as an illustration of this, the very slow change of length of the day when the sun is near one of the tropics.

Crowding of rays about a position of maximum or minimum deviation.

To find this Maximum Angle.—If θ be the angle of incidence, ϕ that of refraction, and μ the refractive index, we have to find the maximum value of

$$\tfrac{1}{2}s = 2\phi - \theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

with the condition

$$\sin\theta = \mu\sin\phi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

These give at once

$$2d\phi = d\theta,$$

and

$$\mu\cos\phi\, d\phi = \cos\theta\, d\theta.$$

Hence

$$\mu\cos\phi = 2\cos\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

From (2) and (3) we have

$$3\cos^2\theta = \mu^2 - 1\,;$$

which determines the requisite angle of incidence. The values of the other quantities are easily calculated from this; and we finally have, for the maximum value of the sine of the half angle at s, the expression

$$\frac{1}{\mu^2}\left(\frac{4-\mu^2}{3}\right)^{\frac{3}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

This is obviously smaller as μ is greater, at least up to the limit $\mu = 2$.

With the value $\frac{4}{3}$ for μ (which is nearly that for yellow rays refracted into water) we have

$$\mathrm{L}\sin\tfrac{1}{2}s = 9\cdot55462,$$

which corresponds very nearly to

$$\tfrac{1}{2}s = 21°\,1'.$$

Now suppose the diameter of the cylinder to be small compared with the distance of the eye from it. In this case the point s may be considered as being in the axis of the cylinder.

Let SsE$_1$ (fig. 23) be made equal to the maximum value of s; then an eye placed anywhere in the line sE$_1$ will receive the rays which are congregated towards the maximum. An eye *within* the angle SsE$_1$ (as at E$_2$) will receive some of the straggling rays, while an eye outside that angle (as at E$_3$) will see nothing. Let there now be imagined a great number of parallel cylinders; let E$_1\sigma$ be drawn parallel to the incident rays, and make the angle σE$_1s'$

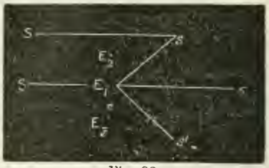

Fig. 23.

equal to σE$_1s$. Then the eye at E$_1$ will see the concentrated rays (already spoken of) in the directions E$_1s$ and E$_1s'$. From points within sE$_1s'$ some straggling rays will reach it, from points outside that angle none.

Now suppose cylinders to be placed in great numbers *in all directions* perpendicular to the incident rays. The eye at E$_1$ will see a bright *circle* of light whose centre is in E$_1\sigma$. Inside that circle there will be feeble illumination; outside it, darkness. This is obviously the case of the rainbow, where we have spherical drops of water instead of the cylinders above spoken of. For each spherical drop is effective only in virtue of a section through its centre, containing the incident ray and the eye; and such sections are the same as those of the cylinders.

Thus far we have been dealing with *parallel* rays of *homogeneous* light; and the appearance (to the degree of approximation we have adopted) is that of a bright circle whose centre is diametrically opposite to the source of light, whose radius is (for raindrops) about 42° 2′, and whose area is slightly illuminated.

Introduce the idea of the different kinds of homogeneous light which make up sunlight, and we find a circular (almost pure) spectrum—the less refrangible rays being on the outside. Next we introduce the consideration of the finite disk of the sun, and we have an infinite series of such arrangements superposed on one another, the centre of each individual of the series being at the point diametrically opposite to the point of the sun's disk which produced it. This leaves the *general* aspect of the phenomenon unchanged, but altogether destroys the purity of the spectrum.

If we next consider light which has been twice reflected within the cylinder, we have a figure like the diagram fig. 24; where the lettering is as nearly as possible the

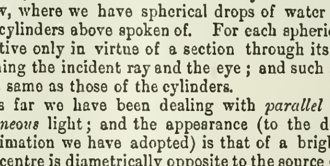

Fig. 24.

same as that in fig. 23. Everything is still symmetrical about the line Os, which obviously cuts at right angles the ray QQ′.

Reasoning precisely similar to that above given shows that the complement of half the angle at s is now equal to the excess of *thrice* the angle of refraction (OPQ) over that of incidence (the supplement of OPs), and that this also has a maximum value, *i.e.*, that s itself has a minimum value.

[To find it, we have

$$\frac{\pi}{2} - \tfrac{1}{2}s = 3\phi - \theta,$$

with

$$\sin\theta = \mu \sin\phi.$$

Differentiating, &c., as before, we find

$$8\cos^2\theta = \mu^2 - 1,$$

whence, finally,

$$\sin \tfrac{1}{2}s = \frac{\mu^4 + 18\mu^2 - 27}{8\mu^3}$$

This quantity increases with μ, for its differential coefficient is

$$\frac{1}{8}\left(\frac{9}{\mu^2} - 1\right)^2,$$

which is necessarily positive. (It vanishes, no doubt, for $\mu = 3$, but then so does θ.)

For $\mu = \frac{4}{3}$ the value of $\sin \frac{1}{2}s$ is

$$0{\cdot}4303 \text{ nearly},$$

so that

$$s = 50° \; 58'.$$

Carrying out the same steps of reasoning as before, and applying the result to raindrops, we find a second rainbow concentric with the first, but with a greater radius, viz., about 51° (for yellow light). All the above remarks about the impurity of the spectrum, &c., apply to this bow also. In this bow the less refrangible rays are on the *inner* side, and the straggling rays illuminate feebly the space *outside* it. Hence the space between the red boundaries of the two bows has no illumination from rays reflected either once or twice within the water drops.

What we have now given is nearly all that geometrical optics can tell us about the rainbow. It seems that the first really important steps in the explanation, viz., (1) that the primary bow is due to rays falling on the outer portions of the drops, which suffer two refractions and one reflexion before reaching the eye, and (2) that the secondary bow is due to rays falling on the inner side, and suffering two refractions and two reflexions, are due to Theodorich, about 1311. His work was not published, and its contents were first announced by Venturi[1] in the present century. These results were, independently, discovered by De Dominis[2] in 1611. Neither of these writers, however, pointed out the concentration of the rays in particular directions. This was done by Descartes in 1637, by the help of Snell's law. He calculated with great labour the paths of each of 10,000 parallel rays falling on different parts of one side of the drop, and showed that from the 8500th to the 8600th the angle between the extreme issuing rays is measured in *minutes* of arc,—thus discovering by sheer arithmetic the maximum which, as we have seen above, is so easily found by less laborious methods. Newton's addition to this theory consisted mainly in applying his discovery of the different refrangibilities of the different homogeneous rays. The explanation was then thought to be complete. For a long time this was held to be one of Newton's most brilliant discoveries. It is well to notice that he himself speaks of it in its true relation to the work of his predecessors. He merely says:—"But whilst they understood not the true origin of colours, it is necessary to pursue it here *a little further*." And he said well; for a full investigation conducted on the principles of the undulatory theory introduces, as was first pointed out by Young, certain important modifications in the above statements. Of these we need mention only one, viz., that in each bow there is more than one maximum of brightness for each homogeneous ray.

Spurious bows. The *spurious* bows, as they are called, which often appear like ripples, inside the primary and outside the secondary bow, and which depend upon the fact just mentioned, have no place in even Newton's theory. About them, in fact, geometrical optics has nothing to say. Young, in 1804, took the first step for their explanation. They were fully investigated, from the undulatory point of view, by Airy, in 1836–38; and his results were completely verified by the measurements of Hallows Miller in 1841.[3] Miller used a fine cylinder of water escaping vertically from a can. This is *one* of the reasons which induced us to treat the subject as a case of refraction and reflexion in a right cylinder.

The overlapping of the colours in the rainbow, due to the apparent size of the sun's disk, is occasionally so greatly exaggerated that only faint traces of colour appear. This may happen, for instance, when the sun shines on raindrops in the lower strata of the atmosphere through clouds of ice-crystals in the higher strata. By reflexion from the faces of these crystals, the source of light is spread over a much larger spherical angle, and there is no sharp edge to it as in the case of the unclouded disk. The rainbow is then much broader and fainter than usual, and nearly white. The size of the drops also produces modifications which are not indicated by the geometrical theory.

When the moon is the source of light, the rainbow is so faint that it is often difficult to distinguish the colours; but with full moon, and other favourable circumstances, it is easy to assure one's self that the colours are really present.

The refraction of sunlight, or moonlight, through ice-crystals forming cirrhus clouds, gives rise to coloured *halos*, *parhelia*, *paraselenæ*, &c. Their approximate explanation depends upon the behaviour of prisms with angles of 60° or 90°, and therefore does not come within the scope of the present article. They must not, however, be confounded with *coronæ*, those rings which encircle the sun or moon when seen through a mist or cloud. Halos have definite radii depending on the definite angles of ice-crystals; the size of a corona depends on the size of the drops of water in a mist or cloud, being smaller as the drops are larger. Thus their diminution in radius shows that the drops are becoming larger, and implies approaching rain. They are due to *diffraction*, and can only be explained by the help of the undulatory theory. Halos. Coronæ.

Refraction in a Non-Homogeneous Medium.—The principles already explained are sufficient for the purpose of treating this question also. But they require, for their application, the artifice of supposing the medium to be made up of layers, in each of which the refractive power is the same throughout the layer, but finitely differs from one layer to another, and then supposing these layers to become infinitely thin and infinitely numerous. In this case there will of course be only an infinitely small difference in properties between contiguous layers; and the abrupt change of direction which accompanies ordinary refraction is now replaced by a *continuous curvature* of the path of the ray. Non-homogeneous medium.

Glimpses of a more general method had been obtained even in the 17th century; and in the 18th these had become a consistent process so far as application to the corpuscular theory is concerned. But it was reserved for Sir W. R. Hamilton (*q.v.*) to discover the existence of what he called the *characteristic function*, by the help of which all optical problems, whether on the corpuscular or on the undulatory theory, are solved by one common process. Hamilton was in possession of the germs of this grand theory some years before 1824, but it was first communicated to the Royal Irish Academy in that year, and published in imperfect instalments some years later. The following is his own description of it. It is extremely important as showing his views on a very singular part of the more modern history of science.

"Those who have meditated on the beauty and utility, in theoretical mechanics, of the general method of Lagrange, who have felt the power and dignity of that central dynamical theorem which he deduced, in the *Mécanique Analytique* . . . , must feel that matho-

[2] Newton, in his *Optics*, says the work of De Dominis was written twenty years before it was published.

[3] Airy's paper is in vol. vi. of the *Cambridge Phil. Trans.*, Miller's in vol. vii.

matical optics can only *then* attain a coordinate rank with mathematical mechanics . . . , when it shall possess an appropriate method, and become the unfolding of a central idea. . . . It appears that if a general method in deductive optics can be attained at all, it must flow from some law or principle, itself of the highest generality, and among the highest results of induction. . . . [This] must be the principle, or law, called usually the Law of Least Action; suggested by questionable views, but established on the widest induction, and embracing every known combination of media, and every straight, or bent, or curved line, ordinary or extraordinary, along which light (whatever light may be) extends its influence successively in space and time: namely, that this linear path of light, from one point to another, is always found to be such that, if it be compared with the other infinitely various lines by which in thought and in geometry the same two points might be connected, a certain integral or sum, called often *Action*, and depending by fixed rules on the length, and shape, and position of the path, and on the media which are traversed by it, is less than all the similar integrals for the other neighbouring lines, or, at least, possesses, with respect to them, a certain *stationary* property. From this Law, then, which may, perhaps, be named the LAW OF STATIONARY ACTION, it seems that we may most fitly and with best hope set out, in the synthetic or deductive process and in the search of a mathematical method.

"Accordingly, from this known law of least or stationary action I deduced (long since) another connected and coextensive principle, which may be called by analogy the LAW OF VARYING ACTION, and which seems to offer naturally a method such as we are seeking; the one law being as it were the last step in the ascending scale of induction, respecting linear paths of light, while the other law may usefully be made the first in the descending and deductive way.

"The former of these two laws was discovered in the following manner. The elementary principle of straight rays showed that light, under the most simple and usual circumstances, employs the direct, and therefore the shortest, course to pass from one point to another. Again, it was a very early discovery (attributed by Laplace to Ptolemy), that, in the case of a plane mirror, the bent line formed by the incident and reflected rays is shorter than any other bent line having the same extremities, and having its point of bending on the mirror. These facts were thought by some to be instances and results of the simplicity and economy of nature; and Fermat, whose researches on maxima and minima are claimed by the Continental mathematicians as the germ of the differential calculus, sought anxiously to trace some similar economy in the more complex case of refraction. He believed that by a metaphysical or cosmological necessity, arising from the simplicity of the universe, light always takes the course which it can traverse in the shortest time. To reconcile this metaphysical opinion with the law of refraction, discovered experimentally by Snellius, Fermat was led to suppose that the two lengths, or *indices*, which Snellius had measured on the incident ray prolonged and on the refracted ray, and had observed to have one common projection on a refracting plane, are inversely proportional to the two successive velocities of the light before and after refraction, and therefore that the velocity of light is diminished on entering those denser media in which it is observed to approach the perpendicular; for Fermat believed that the time of propagation of light along a line bent by refraction was represented by the sum of the two products, of the incident portion multiplied by the index of the first medium, and of the refracted portion multiplied by the index of the second medium; because he found, by his mathematical method, that this sum was less, in the case of a plane refractor, than if light went by any other than its actual path from one given point to another, and because he perceived that the supposition of a velocity inversely as the index reconciled his mathematical discovery of the minimum of the foregoing sum with his cosmological principle of least time. Descartes attacked Fermat's opinions respecting light, but Leibnitz zealously defended them; and Huygens was led, by reasonings of a very different kind, to adopt Fermat's conclusions of a velocity inversely as the index, and of a *minimum time* of propagation of light, in passing from one given point to another through an ordinary refracting plane. Newton, however, by his theory of emission and attraction, was led to conclude that the velocity of light was *directly*, not *inversely*, as the index, and that it was *increased* instead of being *diminished* on entering a denser medium; a result incompatible with the theorem of the shortest time in refraction. This theorem of shortest time was accordingly abandoned by many, and among the rest by Maupertuis, who, however, proposed in its stead, as a new cosmological principle, that *celebrated law of least action* which has since acquired so high a rank in mathematical physics, by the improvements of Euler and Lagrange.

"Maupertuis gave the name of *action* to the product of space and velocity, or rather to the sum of all such products for the various elements of any motion,—conceiving that the more space has been traversed and the less time it has been traversed in, the more action may be considered to have been expended; and by combining this idea of action with Newton's estimate of the velocity of light as increased by a denser medium, and as proportional to the refracting index, and with Fermat's mathematical theorem of the minimum sum of the products of paths and indices in ordinary refraction at a plane, he concluded that the course chosen by light corresponded always to the *least possible action*, though not always to the least possible time. He proposed this view as reconciling physical and metaphysical principles which the results of Newton had seemed to put in opposition to each other; and he soon proceeded to extend his law of least action to the phenomena of the shock of bodies. Euler, attached to Maupertuis, and pleased with these novel results, employed his own great mathematical powers to prove that the law of least action extends to all the curves described by points under the influence of central forces; or, to speak more precisely, that if any such curve be compared with any other curve between the same extremities, which differs from it indefinitely little in shape and in position, and may be imagined to be described by a neighbouring point with the same law of velocity, and if we give the name of action to the integral of the product of the velocity and element of a curve, the difference of the two neighbouring values of this action will be indefinitely less than the greatest linear distance (itself indefinitely small) between the two near curves; a theorem which I think may be advantageously expressed by saying that the action is *stationary*. Lagrange extended this theorem of Euler to the motion of a system of points or bodies which act in any manner on each other; the action being in this case the sum of the masses by the foregoing integrals.

"Laplace has also extended the use of the principle in optics, by applying it to the refraction of crystals, and has pointed out an analogous principle in mechanics, for all imaginable connexions between force and velocity."

We give, first, a very brief indication of the nature of Hamilton's Varying Action method, as applicable directly to the corpuscular theory. Here the action of a corpuscle is the quantity which possesses the stationary property. Let v be the velocity at any point x, y, z of the medium, ds an element of the path, α, β, γ the direction cosines of ds, which are supposed to enter linearly and homogeneously into the expression for v. Then the action V is given by

$$V = \int v ds .$$

Hence, for a path nowhere finitely distant from the first,

$$\delta V = \int (\delta v ds + v d\delta s).$$

But

$$\delta v = \frac{dv}{dx}\delta x + \frac{dv}{dy}\delta y + \frac{dv}{dz}\delta z + \frac{dv}{d\alpha}\delta\alpha + \frac{dv}{d\beta}\delta\beta + \frac{dv}{d\gamma}\delta\gamma ,$$

the first three terms depending on the *translation* of the element ds, the others on its *change of direction*, and all the differential coefficients being partial. The homogeneity of v gives

$$\alpha\frac{dv}{d\alpha} + \beta\frac{dv}{d\beta} + \gamma\frac{dv}{d\gamma} = v .$$

Also

$$d\delta x = \delta dx = \delta . \alpha ds = \delta\alpha . ds + \alpha d\delta s,$$

with two similar equations in y and z.

By the help of these, and a partial integration of the factors $d\delta x$, &c., we have

$$\delta V = \frac{dv}{d\alpha}\delta x + \frac{dv}{d\beta}\delta y + \frac{dv}{d\gamma}\delta z + \int \left[\delta x\left(\frac{dv}{dx}ds - d\frac{dv}{d\alpha}\right) + \ . \ . \ . \ . \ \right] ,$$

where the integrated part is to be taken between proper limits.

If the initial and final points of the path be fixed, δx, &c., vanish in the integrated part, and the stationary condition shows that we must have

$$\frac{dv}{dx}ds - d\frac{dv}{d\alpha} = 0 ,$$

with other two similar conditions, only two of the three being independent because of the necessary relation

$$\alpha^2 + \beta^2 + \gamma^2 = 1 .$$

These may be regarded as the differential equations of the ray, or path of the corpuscle.

But the essence of Hamilton's method of *varying action* depends upon a change of the terminal point of the ray, and leads at once to the three equations

$$\frac{\delta V}{\delta x} = \frac{dv}{d\alpha} , \quad \frac{\delta V}{\delta y} = \frac{dv}{d\beta} , \quad \frac{\delta V}{\delta z} = \frac{dv}{d\gamma} ,$$

which follow directly from the general value of δV above, by taking account of the vanishing of the unintegrated part in consequence of the stationary condition. We may now write d for δ everywhere in these expressions.

In any *isotropic* body, homogeneous or not, it is clear that

$$dV = v(\alpha dx + \beta dy + \gamma dz);$$

and then we have, to determine V, the partial differential equation

$$\left(\frac{dV}{dx}\right)^2 + \left(\frac{dV}{dy}\right)^2 + \left(\frac{dV}{dz}\right)^2 = v^2.$$

The treatment of this equation is precisely the same as that of the corresponding one which will presently be derived from the undulatory view of the question.

We will now illustrate the application of Hamilton's method to the undulatory theory, in which the *time* of passage from one point of the path to another is the characteristic which fulfils the stationary condition. For the sake of limitation, we will confine ourselves to its application to single refraction in a non-homogeneous medium. In such a medium the velocity of light, at any point, is the same whatever be the direction of the ray. Hence it depends only upon the coordinates of the point, and upon some characteristic (say the wave-length) of the light considered.

If τ be this time of passage, ds an element of the path, and v the velocity of light in that element, we must have

$$\tau = \int \frac{ds}{v},$$

a quantity fulfilling the stationary condition. This gives

$$\delta\tau = \int \frac{d\delta s}{v} - \int \frac{ds\delta v}{v^2}.$$

Now, by what has just been said, if λ be the wave-length, we have an equation expressing the data of the problem,

$$v = f(\lambda, x, y, z),$$

where the form of f depends on the arrangement of the parts of the medium. Hence

$$\delta\tau = \int \frac{dxd\delta x + dyd\delta y + dzd\delta z}{vds} - \int \frac{ds}{v^2}\left(\frac{dv}{d\lambda}\delta\lambda + \frac{dv}{dx}\delta x + \ . \ . \ . \right)$$

$$= \left[\frac{1}{v}\left(\frac{dx}{ds}\delta x + \ . \ . \ . \ \right)\right] - \delta\lambda\int \frac{1}{v^2}\frac{dv}{d\lambda}ds - \text{\&c.}$$

The unwritten part consists of an integral which, by the stationary condition, vanishes if the ray be of a definite wave-length and the terminal points through which it passes be given, *i.e.*, if δx, δy, δz, be each equal to 0.

The rest of the expression depends on the terminal points of the ray, and on the wave-length, only. It gives the equations

$$\frac{\delta\tau}{\delta x} = \frac{1}{v}\cdot\frac{dx}{ds}, \quad \frac{\delta\tau}{\delta y} = \frac{1}{v}\frac{dy}{ds}, \quad \frac{\delta\tau}{\delta z} = \frac{1}{v}\frac{dz}{ds},$$

and

$$\frac{\delta\tau}{\delta\lambda} = -\int \frac{1}{v^2}\frac{dv}{d\lambda}ds.$$

Squaring and adding the first three, we have

$$\left(\frac{\delta\tau}{\delta x}\right)^2 + \left(\frac{\delta\tau}{\delta y}\right)^2 + \left(\frac{\delta\tau}{\delta z}\right)^2 = \frac{1}{v^2}.$$

It is easily shown, by a process similar to that used for *varying action* (see MECHANICS), that, if we can find a complete integral of this equation, containing therefore two arbitrary constants, in the form

$$\tau = F(x, y, z, \lambda, \alpha, \beta),$$

then

$$\frac{d\tau}{d\alpha} = \mathfrak{A}, \quad \frac{d\tau}{d\beta} = \mathfrak{B}$$

are the equations of two series of surfaces whose intersections give the paths of the rays. $\mathfrak{A}$ and $\mathfrak{B}$ here are also arbitrary constants. (These four constants are necessary, and sufficient, for the purpose of making the two intersecting surfaces pass each through any two given points.)

As an illustration, let us suppose the light to be homogeneous, and the medium to be arranged in concentric spherical shells such that the velocity at a distance r from their centre is expressed by

$$v = \frac{b^2 + r^2}{c},$$

where b and c are absolute constants. It is easy to see that, on account of the symmetry, the path of every ray is in a plane through the centre of the spheres. We may therefore restrict our work to the plane of x, y passing through that centre.

The equation is then

$$\left(\frac{d\tau}{dx}\right)^2 + \left(\frac{d\tau}{dy}\right)^2 = \frac{c^2}{(b^2 + r^2)^2};$$

or, by change to polar coordinates,

$$\left(\frac{d\tau}{dr}\right)^2 + \frac{1}{r^2}\left(\frac{d\tau}{d\theta}\right)^2 = \frac{c^2}{(b^2 + r^2)^2}.$$

What we require is a sufficiently general solution. Assume, therefore,

$$\frac{d\tau}{d\theta} = \alpha,$$

and we have

$$\frac{d\tau}{dr} = \sqrt{\frac{c^2}{(b^2 + r^2)^2} - \frac{\alpha^2}{r^2}}.$$

From these

$$\tau = \alpha\theta + \int dr\sqrt{\frac{c^2}{(b^2 + r^2)^2} - \frac{\alpha^2}{r^2}}.$$

The equation of the path is therefore

$$\mathfrak{A} = \frac{d\tau}{d\alpha} = \theta - \alpha\int \frac{dr}{r^2\sqrt{\dfrac{c^2}{(b^2 + r^2)^2} - \dfrac{\alpha^2}{r^2}}},$$

$$= \theta - \cos^{-1}\frac{b^2 - r^2}{r\sqrt{\dfrac{c^2}{\alpha^2} - 4b^2}},$$

or

$$\frac{b^2 - r^2}{r} = \sqrt{\frac{c^2}{\alpha^2} - 4b^2}\cos(\theta - \mathfrak{A}).$$

This is the equation of a series of circles, whose *one common characteristic* is that the rectangle under the segments of any chord which passes through the origin is b^2.

Hence every ray in any diametral plane describes a circle; and pairs of conjugate foci are situated on a line through the centre, the rectangle under their distances from the centre being b^2. The property holds therefore for all rays in the medium. This very singular ideal arrangement was suggested to Clerk Maxwell by the eye of a fish. He has given an investigation of it, by a totally different analysis, in the *Cambridge and Dublin Mathematical Journal*, vol. ix. As an illustration of those effects of want of homogeneity to which (as already stated) all the complex phenomena of *mirage*, &c., are due, it may be well to consider this simple case more closely. We will therefore consider how images are seen in such a medium. To get rid of the difficulty which would arise from finite change of density if an eye were supposed to be plunged in the medium, we will suppose it to be cut across by a crevasse whose surface is everywhere nearly at right angles to the rays by which the image is to be seen,—the eye being then placed (in air) close to such a cutting surface.

Let AB (fig. 25) be a small object, O the centre of the spherical layers of equal refractive index. Then every ray from A describes a circle which passes through A′, where AOA′ is a straight line, and

$$\text{AO} \,.\, \text{OA}' = b^2.$$

A similar construction gives B′ from B.

Fig. 25.

To an eye placed at E_1 (in a little crevasse as before explained), and looking towards the object, it will be seen erect,—A being seen in the direction of a tangent to the circle through AE_1A', and similarly for B. Here the rays have not passed through their conjugate focus. But if the eye be now turned away from the object, it (or rather its image) will be seen, A′ in the direction opposite to that in which A was seen, B′ in the opposite direction to B. The image will now be an *inverted* one, but it will easily be seen to possess a strange peculiarity. For what is now seen will be the *back* of the object, the side farthest from the eye. The reader may easily trace for himself the course of the rays which would fall on the eye in any other assigned position. Vision in such cases would usually be of a peculiar character from another point of view, viz., the amount of divergence in the plane of the figure will in general differ from that perpendicular to its plane, and therefore the rays would have different divergence for the height and for the breadth of the image. These would therefore appear at different distances from the spectator. This, however, could be cured by a proper cylindrical lens. It is clear from this example (which has been chosen for its special simplicity) that want of homogeneity in a refracting medium is capable of producing phenomena of the most extraordinary character.

It is difficult to ascertain exactly what is the condition of the atmosphere when multiple images, mirage, &c., are seen; and it is obvious from the remarks and illustrations already given that many very different arrangements will produce sensibly the same result to a spectator in a given position. Comparison of the appearances seen simultaneously by a great number of scattered observers is the only way in which we can expect to obtain definite information on such a point. But the following investigation suggests the general nature of the explanation.

If we suppose the refractive index of the air to depend only upon the vertical height above the earth's surface, rays will all travel in vertical planes, and Hamilton's equation (neglecting the curvature of the earth's surface) takes the very simple form

$$\left(\frac{d\tau}{dx}\right) + \left(\frac{d\tau}{dy}\right)^2 = f(y),$$

x being measured horizontally, and the refractive index being proportional to $\sqrt{f(y)}$.

This equation gives, as before,

$$\tau = \alpha x + \int dy\sqrt{f(y) - \alpha^2},$$

and the equation of the path of a ray is

$$\frac{d\tau}{d\alpha} = \mathfrak{A} = x - \alpha\int\frac{dy}{\sqrt{f(y) - \alpha^2}}.$$

Here, on the corpuscular theory, α is the horizontal velocity of the light, and $\sqrt{f(y) - \alpha^2}$ the vertical velocity. If the form of f and the value of α be such that we can have $f(\eta) - \alpha^2 = 0$, it is clear that at $y = \eta$ the ray is for a moment horizontal. The form of the equation of the ray shows that it has a *vertex* at this point, and that it is symmetrical about a vertical axis passing through the vertex. If ξ, η be the coordinates of the vertex for a ray passing through the point 0, b, we have the relation

$$\xi = \sqrt{f(\eta)}\int_b^\eta \frac{dy}{\sqrt{f(y) - f(\eta)}}.$$

This is the equation of the locus of the vertices of all rays which, starting from a given point, return again to the same level. To find, then, the various rays by which a distant object near the horizon can be seen, all that we have to do is to draw the curve of vertices which passes through the eye of the spectator, and to find the points in which it is intersected by a vertical line situated midway between the object and the eye. Each of these points is the vertex of a ray by which the object can be seen. When the curve of vertices leans forward towards the eye at one of these points, two contiguous rays cross one another, and an inverted image is seen; when it leans from the eye, they do not cross, and the image is erect.

Now, when the curve of vertices is traced, from the above formula, for an arrangement of the air such that the refractive index falls off through a horizontal stratum of air from a greater value below the stratum to a smaller value above it, it is found that the curve of vertices in the stratum can in general be cut by a vertical line in one point only. But if the refractive index have a nearly *stationary* value at the upper boundary of the stratum the curve of vertices can be cut twice, or not at all, by a vertical line. When there is no intersection we have only the direct image; but when there are two intersections a distant ship will be seen as usual through the lower uniform air, while there will be seen above it an inverted image, and then a direct image, both due to the stratum. This is a form of mirage very commonly seen at sea.[1] When there is no *stationary* value of the index at the upper boundary, the upper erect image is not given by the stratum. This arrangement, however, turned upside down, explains the ordinary mirage of the desert—where we see objects directly through the nearly uniform air at some distance above the sand, but also an inverted image (suggesting reflexion from a pool or lake) formed by the refraction in the hot layer of air near the sand.

Absorption, Fluorescence.—We must now take up the *third* and *fourth* of the categories under which light incident on the bounding surface of two media may fall —*scattering* and *absorption*. We take them together, because in the great majority of bodies, as we have already seen, scattering takes place not merely at the surface but within some distance below the surface, which in general is small, but in some cases considerable. And when the scattering takes place, even in part only, below the surface, the scattered light is usually modified by absorption.

[1] See especially Vince, in the Bakerian Lecture, *Phil. Trans.*, 1799.

An excellent instance of this scattering from below the surface is afforded by a mass of thin films or small particles of transparent bodies, such as glass, water, or ice. Thus pounded glass, froth or foam, snow, clouds, &c., appear brilliantly white in sunlight, and are, in consequence, opaque when in layers of sufficient thickness. Here the light is obviously scattered by reflexion. What passes through one film, crystal, or particle is, in part, reflected from the next, and so on.

Even when the froth consists of bubbles of a highly coloured liquid, such as porter for instance, it usually shows but slight traces of colour, for the great majority of the scattered rays have passed through very small thicknesses only of the liquid. In the same way, very finely pounded blue or red glass (unless it be exceedingly deeply coloured when in mass) appears nearly white. But when a mass of water is full of air bubbles, as, for instance, is the case in the neighbourhood of a breaker, the light reflected from the surfaces of these bubbles suffers a double absorption by the water before it reaches the eye. This is one of the causes of the exquisite colours of the sea. Near shore, or in shoal water, another cause sometimes comes into play, viz., fine solid particles suspended in the water. When such particles, whether in air or in water, are exceedingly small, they may produce colours due to their minuteness alone, and not to their own colour nor to the absorptive properties of the medium. This, however, is a question of physical optics.

In general, even the most highly coloured opaque or translucent solids, such as painted wood or stained paper, are visible by scattered light whatever portion of the spectrum falls on them. This is very well seen with highly coloured paper-hangings, when illuminated by homogeneous light, such as that of a sodium flame (a Bunsen flame, into which is thrust a platinum wire dipped in strong brine). The red, orange, and yellow parts usually appear very bright under such treatment, the blue parts appearing but slightly illuminated. The colour of all is, of course, that of the incident light. It appears, therefore, that *some* of the light is scattered from the surface. It is by this, for instance, that the blue parts are feebly visible. But that which is scattered from the portions coloured red, orange, &c., must come mainly from under the surface.

An excellent proof of this is furnished by mixing, in proper proportions, a yellow and a blue powder, or yellow and blue paints. It is commonly imagined that the green colour which is thus produced is a *mixture* of blue and yellow. Far from it! When a disk divided into alternate sectors, coloured with the same blue and yellow pigments, is made to rotate rapidly in its own plane, it of course produces on the eye the true result of a mixture of these blue and yellow colours. This depends for its exact tint on the pigments employed, and on the angles of the sectors, but is usually a faint pink or a muddy purple,—utterly different from the green produced by mixing the powders or the paints. Helmholtz was the first to point out the true source of the green. It is the *one colour* which is not freely absorbed either by the yellow or by the blue pigment. For the scattered light by which the mixture is seen comes chiefly from below the surface, and has thus suffered absorption by each of the component powders. The yellow powder removes the greater part of the blue, indigo, and violet rays; the blue, the greater part of the reds, oranges, and yellows. Thus the light which finally escapes is mainly green.

For the accurate study of the absorptive power of a solid or liquid medium, it is necessary to compare the spectrum of white light which has passed through a plate or layer of it with a normal spectrum. This is easily effected by placing the absorbing medium (if a fluid, it must be in a glass trough with parallel sides) in front of the narrow slit through which the light passes, and in such a position that one half of the slit only is thus covered. We have then side by side, under precisely similar circumstances, two spectra to be compared (one altered by absorption, the other not); and very minute differences between them can thus be detected. When the medium produces a general weakening of the whole spectrum, as well as particular local absorptions, the white light passing through the other half of the slit may be weakened to any desired extent by reflexion at the proper incidence from a plate of glass, before it falls on the slit.

To give a satisfactory representation of the phenomena of absorption spectra by the help of a woodcut is not easy. The highest artistic skill could not adequately represent the ordinary solar spectrum by the use of the finest pigments. All optical *colour* phenomena must be *seen*, they cannot be reproduced by painting. In such circumstances the simplest method of indicating the locality and amount of the absorption is the best. As we have already seen that we cannot by the eye judge of the relative intensities of lights which differ much in colour, we shall represent the normal spectrum (for our present purpose) as equally bright throughout, and indicate the absorption at different parts by shading of various degrees of depth. A few of the Fraunhofer lines are introduced to indicate (in the absence of colour) the parts of the spectrum which are attacked by the various absorbents. These lines are, of course, in the same absolute positions in all the various spectra; for the spectra are all supposed to be given by the same prism. The line B is in the red, D in the orange, E and F in the green, and G in the indigo. They correspond, as we have already said, to perfectly definite kinds of homogeneous light, and therefore adequately represent the distribution of colours in the spectrum, however much irrationality of dispersion may be shown by the material of the prism.

Absorption by blood.

In fig. 26 α represents the spectrum of light which has passed through diluted blood; β shows the spectrum when the blood has been acted on by a reducing agent; and γ the spectrum when the blood has been altered by acidulation with acetic or tartaric acid. These figures are taken from an important paper by Stokes (*Proceedings of the Royal Society*, 1864).

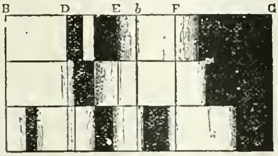

Fig. 26.

Absorption by cobalt glass.

Fig. 27 shows in a rude way the absorption by cobalt glass cut in wedge form, and corrected by an equal prism of clear glass.

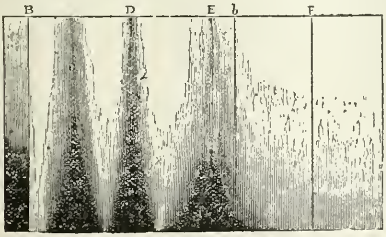

Fig. 27.

The commonly received method of calculating the absorption by layers of gradually increasing thickness is to suppose that, if a layer of unit thickness weakens in any ratio the intensity of any particular homogeneous ray, another unit layer will farther weaken in the same ratio that which reaches it, and so on. Thus the amount which passes through a number of layers diminishes in geometrical progression, while the number of layers increases in arithmetical progression. This is certainly true (neglecting the amount reflected), unless the *intensity* of the light have an effect on the percentage transmitted. And fig. 27 shows, in a very striking manner, the difference between similar terms of different geometric series as the common ratio becomes less and less. This ratio is not much less than 1 for certain red and blue rays, is smaller for yellow, and is very small for the rest of the red, for orange, and for green. The latter colours are therefore rapidly got rid of with increasing thickness; then the yellow becomes too feeble to be seen; while, even after the blue becomes almost insensible, the specially favoured red rays are still transmitted in sufficient quantity to be observed.

If r be the fraction of any species of homogeneous light which is transmitted by a layer of unit thickness, that transmitted by a layer of thickness x is r^x. The following little table will greatly assist the reader in understanding the relative rapidity of extinction of different rays passing through various thicknesses of an absorbing medium. It is a table of double entry, the first column giving various values of x, and the upper row various values of r, while the value of r^x is in the same column as that of r and in the same row as that of x.

100	1	0·366	0·00003	...	...

Thus a ray which loses 1 per cent. in unit thickness still preserves more than 90 per cent. after passing through ten units. But a ray which loses 10 per cent. in the first unit (and which, therefore, will thus far appear scarcely more weakened than the first) is reduced to 35 per cent. by passage through ten units. After passing through a hundred units the first ray has lost only 63 per cent., the second is practically invisible.

In thin plates cobalt glass is blue, because the particular red which it does not absorb freely forms only a small fraction of the whole transmitted rays; while in thick masses it is nearly red, for then little but this favoured red is transmitted. For a similar reason Condy's fluid (permanganate of potash) changes its tint in a very singular manner (even when preserved from the action of the air) by gradual dilution with water.

Defect of achromatism in the eye.

The imperfection of the achromatism of the eye is readily proved by looking through a plate of cobalt glass at a small hole in the window-shutter of a dark room. The hole at first appears red with a blue space round it; but, by an effort of the muscles of the eye, we can see the hole blue, and then there is a red space surrounding it. Rays of so widely different refractive index cannot be seen in focus simultaneously.

Very curious effects are produced when we examine a landscape through such a glass. Foliage of certain kinds scatters scarcely any blue rays, and therefore appears reddish. Bluish-greens, again, which scatter very little red, appear blue. The effects may be exaggerated in a very striking degree by combining the absorptions of two or more media, so as to allow of the free transmission of a few, far detached, portions of the spectrum.

Brewster made the very singular discovery that a solution of oxalate of chromium and potash produces one solitary, narrow, absorption band, almost resembling one of the broader lines in the solar spectrum.

Abnormal dispersion.

Closely connected with intense local absorption in certain parts of the spectrum is the phenomenon of *abnormal dispersion*, one of the most singular discoveries of modern times. It seems to have been first observed by Fox

Talbot; and he discovered its real nature. But the first published notice of such phenomena is due to Le Roux. Christiansen and others have since greatly extended our knowledge of the subject, and Helmholtz and Ketteler have given theoretical explanations of it. Fox Talbot's experiment, though the earliest on record, is one of the easiest to perform, and we therefore quote his own account. The experiment was made about 1840, and the following account is from the *Proc. Roy. Soc. Edin.*, 1870-71.

"I prepared some square pieces of window glass, about an inch square. Taking one of these, I placed upon it a drop of a strong solution of some salt of chromium, which, if I remember rightly, was the double oxalate of chromium and potash, but it may have been that substance more or less modified. By placing a second square of glass on the first, the drop was spread out in a thin film, but it was prevented from becoming too thin by four pellets of wax placed at the corners of the square, which likewise served to hold the two pieces of glass together. The glasses were then laid aside for some hours until crystals formed in the liquid. These were necessarily thin, since their thickness was limited by the interval between the glasses. Of course the central part of each crystal, except the smallest ones, was bounded by parallel planes, but the extremities were bevilled at various angles, forming so many little prisms, the smallest of them floating in the liquid. When a distant candle was viewed through these glasses, having the little prisms interposed, a great number of spectra became visible, caused by the inclined edges. Most of these were no doubt very imperfect, but by trying the glass at various points, some very distinct spectra were met with, and these could with some trouble be isolated by covering the glass with a card pierced with a pin-hole. It was then seen that each prism (or oblique edge of crystal) produced two spectra oppositely polarized and widely separated. One of these spectra was normal; there was nothing particular about it. The colours of the other were very anomalous, and, after many experiments, I came to the conclusion that they could only be explained by the supposition that the spectrum, after proceeding for a certain distance, stopped short and returned upon itself."

Le Roux in 1860 [1] discovered that vapour of iodine, which allows only red and blue rays to pass, refracts the red more than the blue. He, like Talbot, did not at first venture to publish his result, and it appeared only in 1862. Among the many convincing proofs of its accuracy he shows that the dispersion by an iodine-vapour prism can be nearly achromatized by a glass prism which gives refraction in the *same* direction. He also states that the dispersion in iodine-vapour is less as the temperature is higher.

Christiansen's [2] earliest determinations were made in 1870 upon an alcoholic solution of fuchsine (one of the powerful aniline colours). This solution gives a dark absorption band in the green; and it was found that the refractive index rises (as in normal bodies) for rays from the red to the yellow. But all the rest of the transmitted light, consisting of the so-called "more refrangible" rays, is less refracted than the red. Kundt and others shortly afterwards greatly extended these observations.

The explanation of this phenomenon, which has been advanced by Helmholtz,[3] depends upon an assumption as to the nature of the mutual action between the luminiferous ether and the particles of the absorbing medium, coupled with a further assumption connecting the absorption itself with a species of friction among the parts of each absorbing particle.

In 1879 De Klerker[4] made a very curious observation, which shows that the whole subject is still obscure. He employed two hollow prisms of equal angle, turned opposite ways, and filled with alcohol. Through such a combination light passes (as we have seen) without refraction or dispersion. When a few drops of the fuchsine solution were added to the contents of one of the prisms, the yellow, orange, and red rays (in the order named) began to separate themselves from the others. This process could be carried on until the solution was so strong that it transmitted no visible light. All this time the blue and violet rays remained apparently unrefracted—the yellow, orange, and red showing continually increasing refraction. The conclusion from this, on either theory of light, is that the addition of fuchsine to alcohol alters the velocity of propagation of the (so-called) less refrangible rays, but not perceptibly that of the more refrangible.

Fluorescence.—The singular surface appearances presented by "canary" glass, by some specimens of fluor spar, and by certain liquids, such as a solution of sulphate of quinine acidulated with sulphuric acid, had been the source of much speculation long before their true nature was traced by Stokes in 1852.[5] By a series of well-contrived experiments, one or two of which will presently be described, he put it beyond doubt that the cause of these phenomena lies in a change of refrangibility of the light which has been absorbed by the upper layers of the medium, and then given off again. In every case the fluorescent light appears to belong to a less refrangible part of the spectrum than does the incident light which gave rise to it, thus affording an instance of dissipation, or degradation of energy.

The yellowish-green surface-colour of canary glass (coloured with oxide of uranium) is well known, as the substance is, mainly on account of this property, very commonly used for ornaments. If we admit a ray of sunlight (or light from the electric lamp) into a dark room, through a cobalt glass so dark that the feeble violet-coloured light it transmits is scarcely visible, we find that the canary glass shows its yellow-green colour vividly when placed in the track of the ray. Striking as this experiment is, it is not quite conclusive as to the true cause of the appearance. But if we take another piece of glass, slightly tinged of a brownish-yellow (by oxide of gold), we find that it is quite transparent to the brilliant light from the canary glass; if, however, we place it in the track of the violet rays *before* they fall on the uranium glass, it prevents the production of the phenomenon altogether. That is, rays which cannot pass through the glass coloured with gold are rendered capable of freely passing through it after incidence on the canary glass. That the phenomenon is due to rays which are stopped by the uranium glass itself is proved by the fact that a second piece of the glass, placed in the track of the rays which have passed through the first, does not show the phenomenon. Unless, indeed, the source of light be very bright, the appearance is confined to a mere surface-layer of the first piece of canary glass. The phenomenon is very well shown by an aqueous infusion of horse-chestnut bark. Some specimens of paraffin oil exhibit it most brilliantly.

To find the rays which are most effective in producing the fluorescence of any substance, we have only to place it in a pure spectrum of sunlight (or, preferably, of the electric light),—prisms and lenses of quartz being used for producing the spectrum, because that material is found to be far less opaque than glass is to the violet and ultra-violet rays. When this is done with uranium glass we find scarcely a trace of effect until the substance reaches the blue rays, and the effect persists through all the higher colours, and even very considerably beyond the bounds of the visible spectrum. Stokes in fact used it as a means of studying the otherwise invisible, but far extending, spectrum of the ultra-violet rays of the electric spark.

The mechanism of the process by which these extraordinary results are produced is still somewhat obscure, and we cannot attempt to explain it here.

The duration of fluorescence is so very short that it is only by specially devised methods that we can make certain that it persists for any measurable time after the exciting Phos-pho-scop

light is cut off from the fluorescent body. Becquerel's ingenious *phosphoroscope* was invented for the purpose of inquiries of this kind. It consists essentially of a shallow drum, in whose ends two excentric holes, exactly opposite to one another, are cut. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and divided into the same number of sectors, the alternate sectors of each being cut out. One of these disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are made to rotate, the hole in one end is open while that in the other is closed, and *vice versa*. If the eye be placed near one hole, and a ray of sunlight be admitted by the other, it is obvious that while the sun shines on an object inside the drum the aperture next the eye is closed, and *vice versa*. If the disks be made to revolve with great velocity by means of a train of toothed wheels, the object will be presented to the eye almost instantly after it has been exposed to sunlight; and these presentations succeed one another so rapidly as to produce a sense of continued vision. By means of this apparatus we can test with considerable accuracy the duration of the phenomenon after the light has been cut off. For such a purpose we require merely to know the number of sectors in the disks and the rate at which they are turned. To guard against deception by the persistence of impressions on the retina, the eye should not be directed fixedly on the object, but should be kept travelling slowly round the position in which it is seen to lie.

Uranium glass shows, with rapid turning, nearly as vivid an effect as when exposed to continuous light, but fades rapidly when the speed of the rotation falls off. A pinkish kind of ruby, exposed to concentrated sunlight in the phosphoroscope, is seen to glow with a bright red like a piece of live coal. With very rapid turning, feeble fluorescence can be detected in a great many substances in which the ordinary methods will not show it. This is due in great measure to the fact that the phosphoroscope entirely does away with the scattered light, which in the ordinary mode of examining these substances overpowers their feeble fluorescence.

What is correctly termed phosphorescence has nothing to do with phosphorus (whose luminosity in the dark is due to slow oxidation), but it is merely a species of fluorescence which lasts for a much longer time after the excitation has ceased than does that just described. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of phosphorescent substances, such as are now so common, belongs to the early part of the 17th century. During that century the Bologna stone (sulphide of barium) and Homberg's phosphorus (chloride of calcium) were discovered. Canton's phosphorus (sulphide of calcium) dates from 1768. To the substances mentioned may now be added sulphide of strontium. Any of these sulphides, which must be carefully preserved from the air in sealed glass tubes, appears brilliantly luminous when carried from sunlight into a dark room, and for a long time after presents the general aspect of a hot body cooling. The rays which excite their luminosity are (as with the generality of fluorescent bodies) those of higher refrangibilities; but the colours of the phosphorescent light are of the most varied kind, even in specimens of almost precisely the same chemical composition, but prepared at different times. The causes of this strange diversity are as yet quite unguessed at; but the property has been taken advantage of for the production of what are called *luminous paints*. The behaviour of these substances is one of the most singular phenomena in optics. How they manage to store up so large a supply of energy during a short exposure to bright light, and to dole it out continuously for so long a time and mainly in the form of light, is exceedingly puzzling,—especially as no other physical or chemical change has yet been found to accompany the process. Another curious fact connected with their behaviour was discovered by Becquerel. He found that the less refrangible rays have in some cases the power of arresting the emission of light from these bodies when they have been previously excited by higher rays.

The chemical effects of light will be treated under PHOTOGRAPHY, so far as they are connected with decomposition. Its effects in causing combination, as of hydrogen and chlorine, have already been treated under CHEMISTRY.

UNDULATORY THEORY OF LIGHT.

The explanation of the fundamental laws of Geometrical Optics by the wave-theory requires some preliminary remarks. As the subject will be more fully discussed in a special article, we confine ourselves to what is strictly necessary for the immediate purposes of the present article.

(*a*) The essential characteristic of wave-motion is that a disturbance of some kind is handed on from one portion of a solid or fluid mass to another. In certain cases only, this disturbance is unaltered in amount and in kind as it proceeds.

(*b*) So far as light is concerned, the velocity with which each particular species of disturbance passes in any direction through a homogeneous isotropic medium is constant and is the same for all directions. When the medium is not homogeneous, the velocity may vary from point to point. If the medium be not isotropic, the velocity may depend upon the *direction* of propagation. Examples of each of these peculiarities will be met with presently. Velocity of propagation.

(*c*) When two or more separate disturbances simultaneously affect the same portion of a medium, the effect may be very complex. But, in the case of light, it has been found that a geometrical (or rather *kinematical*) superposition or composition agrees, at least to the degree of accuracy of the experiments, with all the observed facts. This would be the case, as a dynamical result, if the distortions due to wave-motion were always, even for the most powerful light, exceedingly small. On this is based the whole doctrine of *interference*, Young's grandest contribution to the wave-theory (1801). Interference.

(*d*) The disturbance at any point of a medium, at any instant, is that due to the superposition of all the disturbances which reached it at that instant from the various surrounding parts of the medium. This is (in a somewhat generalized form) what is commonly known as Huygens's principle, first enunciated in 1678.

(*e*) The *front* of a wave is defined at any instant as the continuous locus of all portions of the medium which, at that instant, are equally and similarly distorted. The word *continuous* is inserted because, in oscillatory wave-motion, such as that of light, a large number of successive waves are exactly equal and similar to one another. Thus we have a *series* of wave-fronts following one another, which are not to be considered as parts of one wave-front. The distance between two successive fronts in which the distortions are similar, measured in the direction in which the light is travelling, is called the *wave-length*.

(*f*) The *colour* of homogeneous light depends entirely on the *period* of a wave, *i.e.*, on the time of passage from one wave-front to the next. This is obviously the same thing as the time of a complete vibration of any one particle of the medium—whatever be the velocity of light in the medium, or the consequent wave-length.

These being premised, let us take the propagation of homogeneous light from a luminous point in a homo-

Wave-motion in homogeneous isotropic medium. geneous isotropic medium. Here we have simply a succession of concentric spherical wave-fronts, their radii differing by one or more whole wave-lengths. The disturbance in any portion of one of these fronts is propagated radially. But we may consider it from a different point of view, as hinted in (*d*) above. Simple as this particular case is, the reader will probably find that it will greatly assist him in understanding the more complex ones which follow.

Every disturbed portion of the medium may be looked upon as a centre of disturbance from which a new set of spherical waves is constantly spreading. Take then, as common radius, the space described by a disturbance in any very short interval; and, with centres at every point of any one wave-front, describe a series of spheres. The ultimate intersections of these spheres will lie on a surface which is the *envelop* of them all. In the case considered, it is obviously a sphere whose radius exceeds that of the wave-front from which we started by the common radius of the set of spheres. This is shown in a central section in fig. 28 below, which suffices to prove that we arrive *by this mode of construction* at the result which we know in this simple case to be the correct one. It will be seen that the centres of the construction-spheres lie on a certain part of one wave-front, while their ultimate intersections lie on the *corresponding* part of the future wave-front. This holds for spheres of all radii, and for continually increasing radii shows that a *plane* wave moves perpendicularly to its front. This is so important a part of Huygens's work that we give it in his own words (*Traité de la Lumiere*, 1690, pp. 18–20):—

"Pour venir aux proprietez de la lumiere; remarquons premierement que chaque partie d'onde doit s'étendre en sorte, que les extremitez soient tousjours comprises entre les mesmes lignes droites tireés du point lumineux. Ainsi la partie de l'onde BG, ayant le point lumineux A pour centre, s'étendra en l'arc CE, terminé par les droites ABC, AGE. Car bien que les ondes particulieres, produites par les particules que comprend l'espace CAE, se repandent aussi hors de cet espace, toutesfois elles ne concourent point en mesme instant, à composer ensemble une onde qui termine le mouvement, que precisement dans la circonference CE, qui est leur tangente commune.

"Et d'icy l'on voit la raison pourquoy la lumiere, à moins que ses rayons ne soient reflechis ou rompus, ne se repand que par des lignes droites, en sorte qu'elle n'éclaire aucun objet que quand le chemin depuis sa source jusqu'a cet objet est ouvert suivant de telles lignes. Car si, par exemple, il y avoit une ouverture BG, borneé par des corps opaques BH, GI; l'onde de lumiere qui sort du point A sera tousjours termineé par les droites AC, AE, comme il vient d'estre demonstré: les parties des ondes particulieres, qui s'étendent hors de l'espace ACE, estant trop foibles pour y produire de la lumiere.

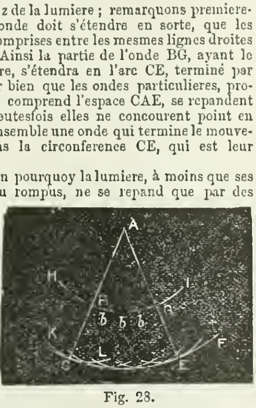

Fig. 28.

"Or quelque petite que nous fassions l'ouverture BG, la raison est tousjours la mesme pour y faire passer la lumiere entre des lignes droites; parce que cette ouverture est tousjours assez grande pour contenir un grand nombre de particules de la matiere etherée, qui sont d'une petitesse inconcevable; de sorte qu'il paroit que chaque petite partie d'onde s'avance necessairement suivant la ligne droite qui vient du point luisant. Et c'est ainsi que l'on peut prendre des rayons de lumiere comme si c'estoient des lignes droites.

"Il paroit au reste, par ce qui à esté remarqué touchant la foiblesse des ondes particulieres, qu'il n'est pas necessaire que toutes les particules de l'Ether soient égales entre elles, quoique l'égalité soit plus propre à la propagation du mouvement. Car il est vray que l'inégalité fera qu'une particule, en poussant une autre plus grande, fasse effort pour reculer avec une partie de son mouvement, mais il ne s'engendrera de cela que quelques ondes particulieres en arriere vers le point lumineux, incapables de faire de la lumiere: & non pas d'onde composeé de plusieurs, comme estoit CE.

"Une autre, et des plus merveilleuses proprietez de la lumiere est que, quand il en vient de divers costez, ou mesme d'opposez, elles font leur effet l'une à travers l'autre sans aucun empéchement. D'ou vient aussi que par une mesme ouverture plusieurs spectateurs peuvent voir tout à la fois des objets differens, et que deux personnes se voyent en mesme instant les yeux l'un de l'autre. Or suivant ce qui a esté expliqué de l'action de la lumiere, et comment ses ondes ne se détruisent point, ny ne s'interrompent les unes les autres quand elles se croisent, ces effets que je viens de dire sont aisez à concevoir. Qui ne le sont nullement à mon avis selon l'opinion de Des-Cartes, qui fait consister la lumiere dans une pression continuelle, qui ne fait que tendre au mouvement. Car cette pression ne pouvant agir tout à la fois des deux costez opposez, contre des corps qui n'ont aucune inclination à s'approcher; il est impossible de comprendre ce que je viens de dire de deux personnes qui se voyent les yeux mutuellement, ni comment deux flambeaux se puissent éclairer l'un l'autre."

We will now, for the purposes of this elementary article, assume that something similar holds in all cases, and will not trouble ourselves with the fact that our construction, if fully carried out, would indicate a retrograding wave as well as a progressive one. The obvious fact that a *solitary* wave can be propagated in water, or along a stretched string, may assist the reader in taking the bold step which we have proposed to him. And we will also assume that this mode of representation leads to correct results even when we do not choose a wave-front as the locus of the centres of disturbance,—that in fact we may choose for our purpose *any* surface through which the rays pass, provided always that the radii of the spheres are so chosen that the length of each ray from some definite wave-front to the centre of the sphere, together with the radius of that sphere, always corresponds to a path described in a given time.

Undulatory [explana]tion [of] plane reflex[ion]. We are now prepared to explain the reflexion of light, and we need do so for a plane reflecting surface alone, because the length of a wave, as we shall soon see, is an almost vanishing quantity in comparison with the radius of curvature of any artificial mirror, be it even the smallest visible drop of mercury.

Let a plane wave-front be approaching a plane mirror, and at any instant let fig. 29 represent a section by a plane perpendicular to each, cutting the wave-front in AB and the mirror in AC. From what has been already said, the motion of every part of AB is perpendicular to that line, and in the plane of the figure. During the time that the disturbance at B takes to reach C, the disturbance which had reached A will have (in part, for there is usually a refracted part also) spread back into the medium in the form of a spherical wave whose radius, AD, is equal to BC. Its section is of course a circle. That from any other point P will have reached Q, and then (in part) diverged into a spherical wave whose centre is Q and radius QT(=QT′) = BC − PQ. Obviously all the circles which can be thus drawn ultimately intersect in the straight line CD. This is a section of the reflected wave-front. A plane wave, therefore, remains a plane wave after reflexion, each part of it obviously moves in the plane of incidence, and the similarity of the triangles ABC and CDA proves the equality of the angles of incidence and reflexion, for the ray is everywhere perpendicular to the wave-front. It is to be particularly noted that this is independent of the velocity of the light, so that all rays are reflected alike. In this, as in the preceding and the immediately following instances, the diagram has been taken (with but slight change) from Huygens.

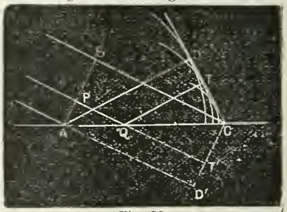

Fig. 29.

This being true of any *plane* wave-front, large or small in area, is necessarily also true of any wave-front of finite curvature. Thus, if a set of rays be drawn perpendicular to any wave-front, they will after reflexion be perpendicular to a new wave-front; and the lengths of all the rays, from wave-front to wave-front, will be equal.

This is merely another way of stating that if a set of rays can be cut at right angles by a surface (of finite curvature) they will always be capable of being cut at right angles by such a surface, even after any number of reflexions at surfaces of finite curvature, provided they move in a homogeneous isotropic medium.

This proposition will be seen to be capable of extension to refraction, provided always that both media are homogeneous and isotropic. For a plane wave, falling on a plane refracting surface, our construction (fig. 30) is as follows:—

Let AB be, as before, a plane wave-front in the first medium, and AC the plane surface of the second medium. As before, let BC be perpendicular to AB. Also let CD′ be drawn parallel to BA. With centre A and radius AD equal to the space described in the second medium while BC is described in the first, let a sphere be described. The disturbance at A will have diverged in this sphere, while that at B has just reached C. The disturbance at any other point, as P, will have passed to Q, and then have diverged into a sphere of radius QT such that

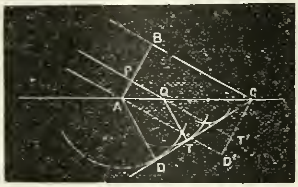

Fig. 30.

$$QT : QT' :: AD : BC.$$

Obviously all spheres so drawn ultimately intersect along CD, which is therefore the front of the refracted wave. The angles of incidence and refraction, being the inclinations of the incident and refracted rays to the normal, are the inclinations BAC and DCA of the incident and refracted wave-fronts to the refracting surface. Their sines are evidently in the ratio of BC to AD, *i.e.*, they are *directly* as the velocities of propagation in the two media.

Hence the law of refraction also follows from this hypothesis. But there will now be separation of the various homogeneous rays, because the ratio of their velocities in the two media is not generally constant.

Besides, it is clear from the investigation above that, in the refracting medium, the rays are still perpendicular to the wave-front. Thus the proposition lately given may now be extended in the following form:—

If a series of rays travelling in homogeneous isotropic media be at any place normal to a wave-front, they will possess the same property after any number of reflexions and refractions. And it is clear from the investigations already given that the *time* employed by light in passing from one of these wave-fronts to another is the same for every ray of the series.

We now see how crucial a test of theory is furnished by the simple refraction of light. On the corpuscular theory the velocity of light in water is to its velocity in air as 4 : 3 nearly; on the undulatory theory these velocities are as 3 : 4, since, as we have seen, the refractive index of water is about $\frac{4}{3}$. But Foucault's experimental method showed at once that the velocity is less in water than in air. This finally disposed of the corpuscular theory. Though it had been conclusively disproved long before, by certain interference experiments whose nature will presently be described, the argument from these was somewhat indirect and not well suited to convince the large non-mathematical class among optical students and experimenters. The true author of the undulatory theory is undoubtedly Huygens. Grimaldi, Hooke, and others had expressed more or less obscure notions on the subject, but Huygens in 1678 first gave it in a definite form, based to a great extent upon measurements of his own. It was read to the French Academy, but not published till 1690, when it appeared with the title *Traité de la Lumiere*. Huygens gives the explanation of the double refraction of Iceland spar, which had been described by Bartholinus in 1670. Unfortunately the remarkable step taken by Newton in explaining the law of refraction on the corpuscular theory—the earliest solution of a problem connected with molecular forces—had for some time been before the scientific world. The authority of Newton was paramount in such matters, and the work of Huygens produced no effect at the time. Even the genius of Young, who at the commencement of the present century recalled attention to this all-but-forgotten theory, and enriched it by the addition of the principle of interference, as well as by many important applications, failed to secure its recognition.

Opposition to the undulatory theory

It was not till 1815 and subsequent years that, in the hands of Fresnel, the undulatory theory finally triumphed, and, even then, the battle was won against determined resistance on the part of the upholders of the corpuscular theory. Witness what Laplace[1] said, in 1817, in the following excerpt from a letter to Young:—

"J'ai reçu la lettre que vous m'avez fait l'honneur de m'écrire, et dans laquelle vous cherchez à établir que, suivant le système des ondulations de la lumière, les sinus d'incidence et de réfraction sont en rapport constant, lorsqu'elle passe d'un milieu dans un autre. Quelque ingénieux que soit ce raisonnement, je ne puis le regarder que comme un aperçu, et non comme une démonstration géométrique. Je persiste à croire que le problème de la propagation des ondes, lorsqu'elles traversent différens milieux, n'a jamais été résolu, et qu'il surpasse peut-être les forces actuelles de l'analyse. Descartes expliquoit ce rapport constant, au moyen de deux suppositions; l'une, que la vîtesse des rayons lumineux parallèlement à la surface du milieu refringent ne changeoit point par la réfraction; l'autre, que sa vîtesse entière dans ce milieu étoit la même, sous toutes les incidences; mais comme il ne rattachoit aucune de ces suppositions aux lois de la mécanique, son explication a été vivement combattue et rejettée par les plus grand nombre des physiciens jusqu' à ce que Newton ait fait voir que ces suppositions résultoient de l'action du milieu refringent sur la lumière; alors on a eu une explication mathématique du phénomène dans le système de l'émission de la lumière: système qui donne encore l'explication la plus simple du phénomène de l'aberration, que n'explique point le système des ondes lumineuses. Ainsi les suppositions de Descartes, comme plusieurs aperçus de Kepler sur le système du monde, ont été vérifiées par l'analyse: mais le mérite de la découverte d'une vérité appartient tout entier à celui qui la démontre. Je conviens que de nouveaux phénomènes de la lumière sont jusqu' à présent très difficiles à expliquer; mais en les étudiant avec un grand soin, pour découvrir les lois dont ils dépendent, on parviendra peut-être un jour à reconnaître dans les molecules lumineuses des propriétés nouvelles qui donneront une explication mathématique de ces phénomènes. Remonter des phénomènes aux lois et des lois aux forces, est, comme vous le savez, la vraie marche des sciences naturelles."

Poggendorff remarks that there is no other instance, in the whole history of modern physics, in which the truth was so long kept down by authority. Poggendorff further remarks that of the six chief phenomena of light known in Huygens's time he fully explained three—reflexion, refraction, and the double refraction of Iceland spar—at least so far as concerns the *direction* of the reflected or refracted rays. Phenomena such as diffraction, and the colours of thin plates, required the principle of interference for their explanation, which was first given by Young; and dispersion (not yet quite satisfactorily disposed of) was first accounted for in comparatively recent times by Cauchy. Huygens himself was the discoverer of polarization, but he could not account for it. Even Young also, because like Huygens he supposed the undulations to be in the direction of the ray, failed to account for it; and it was not explained till Fresnel reintroduced with the

[1] Young's *Works*, ed. by Peacock, vol. i. p. 374. It is matter for curious remark that Laplace refers to Descartes only, and not to Huygens.

most brilliant success a guess of Hooke's (of date 1672), that the vibrations of light in an isotropic medium are *perpendicular* to the direction of the ray.

Taking the undulatory theory as the only one left possible by the experiments of Foucault, we will now consider the explanation it offers of various phenomena. It will be remembered that *we have as yet made no assumption whatever as to the precise nature of a wave*; and it will be found that a large class of important phenomena can be explained by it without our making any such assumption, but that other classes of phenomena compel us to adopt certain limitations of the very general hypothesis with which we started. As long as we deal with the first class of phenomena, we may take for granted those properties which are common to all ordinary forms of wave-motion, such as those in water or air. In ordinary water-waves the motion of a particle is partly to and fro in the direction in which a wave is travelling, partly up and down and therefore perpendicular to that direction. This is obvious to every one who watches a floating cork. In sound-waves, whether in air or in water, the displacement of each particle of the medium is wholly in the direction in which the wave is travelling. Directly connected with this there is another distinction between these classes of waves. In ordinary water-waves the water-elements change only their *form* as the wave passes; in sound-waves there is change of *volume* also. A third distinction, also directly connected with the first, is that sound-waves in water travel at a much greater rate than the swiftest, *i.e.*, the longest, of surface waves. But, in either case, when two similar and equal series of waves arrive at a common point they *interfere*, as it is called, with one another, so that the actual disturbance of the medium at any instant is the resultant of the disturbances which it would have suffered at that instant from the two series separately. Thus if crests, and therefore troughs, arrive simultaneously from the two series, the result is a doubled amount of disturbance. If, on the contrary, a crest of the first series arrive along with a trough of the second, the next trough of the first series will arrive along with the next crest of the second, and so on. One series is then said to be half a wave-length behind the other. In this case, the portion of the medium considered will remain undisturbed. Thus, at the port of Batsha in Tong-king, the ocean tide-wave arrives by two different channels, one part being nearly six hours, or half a wave-length, behind the other. As a result, there is scarcely any noticeable tide at Batsha itself, though at places not very far from it the rise and fall are considerable. This was known to Newton, and is noticed by him in the *Principia*, iii. 24. See also *Phil. Trans.*, vol. xiv. p. 677, for the observed facts and Halley's comments. Thus also (see ACOUSTICS) two sounds of the same wave-length and of equal intensity produce silence if they reach the external ear with an interval of half a wave-length, or any odd multiple of half a wave-length.

Tides of Batsha.

It is not remarkable that Young's Bakerian Lecture (1801), in which the principle of interference is for the first time described and applied, should consist in great part of extracts from the *Principia*. For there are many passages in Newton's works which might have been written by an upholder of the wave-theory. Unaccountably, however, Newton in the context almost always brings in a reference to the "rays of light" as something different from the vibrations of the ether, yet capable of being acted on by them so as to be put into "fits of easy reflexion or of easy transmission." These allusions are the most obscure parts of all Newton's scientific writings; and it is very difficult to form a precise conception of what he meant to express in them.

The following passage, extracted from Young's temperate reply (*Works*, vol. i. p. 202) to the violent but ignorant assault on him by Lord Brougham in the *Edinburgh Review*, is chosen as showing his own estimate of his own work and of its relation to what was already known:—

"It was in May 1801 that I discovered, by reflecting on the beautiful experiments of Newton, a law which appears to me to account for a greater variety of interesting phenomena than any other optical principle that has yet been made known. I shall endeavour to explain this law by a comparison.

"Suppose a number of equal waves of water to move upon the surface of a stagnant lake, with a certain constant velocity, and to enter a narrow channel leading out of the lake. Suppose then another similar cause to have excited another equal series of waves, which arrive at the same channel, with the same velocity, and at the same time with the first. Neither series of waves will destroy the other, but their effects will be combined: if they enter the channel in such a manner that the elevations of one series coincide with those of the other, they must together produce a series of greater joint elevations; but if the elevations of one series are so situated as to correspond to the depressions of the other, they must exactly fill up those depressions, and the surface of the water must remain smooth; at least I can discover no alternative, either from theory or from experiment.

"Now I maintain that similar effects take place whenever two portions of light are thus mixed; and this I call the general law of the interference of light. I have shown that this law agrees, most accurately, with the measures recorded in Newton's Optics, relative to the colours of transparent substances, observed under circumstances which had never before been subjected to calculation, and with a great diversity of other experiments never before explained. This, I assert, is a most powerful argument in favour of the theory which I had before revived: there was nothing that could have led to it in any author with whom I am acquainted, except some imperfect hints in those inexhaustible but neglected mines of nascent inventions, the works of the great Dr Robert Hooke, which had never occurred to me at the time that I discovered the law; and except the Newtonian explanation of the combinations of tides in the port of Batsha."

Interference experiments.

Young's first application of the principle of interference was made to the colours of *striated surfaces*, the next to the colours of *thin plates*. These, however, are not so easily intelligible as the application to an experiment devised by Fresnel several years later. We therefore commence with Fresnel's experiment, which gives the most simple arrangement yet contrived, but it must be understood that the explanation is really due to Young. BCD (fig. 31) is an isosceles prism of glass, with the angle at C very little less than two right angles. A luminous point is

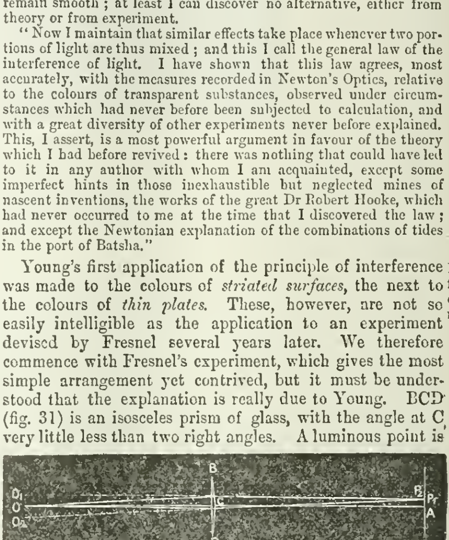

Fig. 31.

placed at O, in the plane through the obtuse edge of the prism and perpendicular to its base. If homogeneous light be used, the light which passes through the prism will consist of two parts, diverging as if from points O_1 and O_2 symmetrically situated on opposite sides of the line CO. Suppose a sheet of paper to be placed at A with its plane perpendicular to the line OCA, and let us consider what illumination will be produced at different parts of this paper. As O_1 and O are images of O, crests of waves must be supposed to start from them simultaneously. Hence they will arrive simultaneously at A, which is equidistant from them, and there they will reinforce one another. Thus there will be a bright band on the paper, parallel to the edges of the prism. If P_1 be chosen so that the difference between P_1O_2 and P_1O_1 is half a wave-length (*i.e.*, half the distance between two successive crests), the two streams of light will constantly meet in such relative conditions as to destroy one another. Hence there will be a line of darkness on the paper, through P_1, parallel to the edges of the prism. At P_2, where O_2P_2 exceeds O_1P_2 by a whole wave-length, we have another bright band; and at P_3, where O_2P_3 exceeds O_1P_3 by a wave-length and a half, another dark band; and so on. Hence, as everything is symmetrical about the bright band through A, the screen will be illuminated by a series of bright and dark bands, gradually shading into one another. If the paper screen be moved parallel to itself to or from the prism, the locus of all the successive positions of any one band will (by the nature of the curve) obviously be an hyperbola whose foci are O_1 and O_2. Thus the interval between any two bands will increase in a more rapid ratio than does the distance of the screen from the source of light. But the intensity of the bright bands diminishes rapidly as the screen moves farther off; so that, in order to measure their distance from A, it is better to substitute the eye (furnished with a convex lens) for the screen. If we thus measure the distance AP_1 between A and the nearest bright band, measure also AO, and calculate (from the known material and form of the prism, and the distance CO) the distance O_1O_2, it is obvious that we can deduce from them the lengths of O_1P_2 and O_2P_2. Their difference is the *length of a wave* of the homogeneous light experimented with. Though this is not the method actually employed for the purpose (as it admits of little precision), it has been thus fully explained here because it shows in a very simple way the possibility of measuring a wave-length.

The difference between O_1P_1 and O_2P_1 becomes greater as AP_1 is greater. Thus it is clear that the bands are *more widely separated the longer the wave-length of the homogeneous light employed.* Hence when we use white light, and thus have systems of bands of every visible wave-length superposed, the band A will be red at its edges, the next bright bands will be blue at their inner edges and red at their outer edges. But, after a few bands are passed, the bright bands due to one kind of light will gradually fill up the dark bands due to another; so that, while we may count hundreds of successive bright and dark bars when homogeneous light is used, with white light the bars become gradually less and less defined as they are farther from A, and finally merge into an almost uniform white illumination of the screen.

In this example, and in all others of a similar character which will be introduced into this elementary article, the solution is only *approximate.* The utmost resources of mathematics are in most cases required for the purpose of complete solution.

We are now in a position to prove that light moves slower in glass than in air, by the process which was merely *indicated* while we were discussing the velocity of light. For, if we could slightly lengthen the paths of the rays which come from O_1, leaving those from O_2 unaltered, the system of bands would obviously be shifted in the direction from A to P in the figure. This happens if a very thin film of glass be interposed in the path of the rays which appear to come from O_1. The best mode of making the experiment is to put a piece of very uniform plate glass, cut into two parts, between the prism and the screen, so that rays from O_1 pass through one part and those from O_2 through the other. So long as these pieces are parallel, no shifting takes place. But if *one* be slightly turned, so as to give the rays a longer path through it, the system of bands is at once displaced to the side at which it is situated.

Also, we can now see how it is possible to discover whether light has its velocity affected by that of the medium in which it is travelling. We know that sound travels faster *with* the wind, and slower *against* it, than it does in still air. We may, therefore, suppose a disposition of the interference apparatus such that the two rays which interfere have each passed through a long tube full of water. A rapid current may be established, in either direction, in one or other of the tubes, or in opposite directions in the two, and the shifting of the interference-bands will at once indicate the nature of the effect. We cannot describe the details of the process. The result, however, is analogous to that of wind on sound, but of course very much smaller; and it seems that the actual change of the velocity of light is *less* than the velocity of the current. See ETHER.

Let us next consider the effect of a *grating,* a series of fine parallel wires placed at small equal intervals, or a piece of glass or of speculum metal on which a series of equidistant parallel lines have been ruled by a diamond point. We take only the case in which plane waves of homogeneous light are incident in a direction perpendicular to the plane of the grating, and when the bars and openings of the grating are all equal in breadth.

Consider the effect on an eye or screen at a considerable distance, in the direction BE (fig. 32). If there were no grating, practically no light would reach the eye from the aperture AD unless ABE were very nearly a right angle.

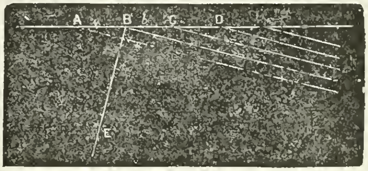

Fig. 32.

This is, of course, the statement of Huygens already quoted. But Young's principle enables us to say *why* this is the case. Let us divide AD into a series of equal parts by lines perpendicular to BE, and distant from one another by half a wave-length of the homogeneous light employed. The portions coming to the eye from any two adjacent parts AB, BC will be practically of the same intensity, and will exactly neutralize one another's effects on the eye. For if we take points a and b similarly situated with regard to A and B respectively, the distances of a and b from the eye differ by half a wave-length, and rays from a neutralize those from b. This is true wherever a be taken between A and B. Hence, under the conditions assumed, no light reaches the eye.

Now suppose the alternate parts AB, CD, &c., to be opaque. Similar reasoning will show that the remaining rays conspire to strengthen one another. Thus, when homogeneous light from a distant point falls perpendicularly on a grating in which the breadth of the bars is equal to that of the interstices, it will be seen brightly in a direction inclined at an angle θ (ABE) to the plane of the grating,—the angle θ being such that

$$AC \cos \theta = \text{wave-length}.$$

Similar reasoning shows that the light is reinforced whenever θ is such that

$$AC \cos \theta$$

is an integral multiple of the wave-length. The appearance presented when a long narrow slit is the luminous object, and the bars of the grating are placed parallel to it, is therefore (with homogeneous light) a central image with others equidistant from it on each side—their angular distances from it being the values of the angle corresponding to the sines

$$\frac{\lambda}{a}, \frac{2\lambda}{a}, \frac{3\lambda}{a}, \text{\&c.}$$

Here λ is the wave-length, and a is the sum of the breadths of a bar and an interstice. It is found in practice, and it is also deducible from the complete theory, that the *ratio* of the breadths of the bar and interstice has but little effect on the result, unless it be either very large or very small. Hence if λ be expressed as a fraction of an inch, and n be the number of lines per inch in the grating, the angular deviations of the bright bands have the sines

$$n\lambda,\ 2n\lambda,\ 3n\lambda,\ \&c.$$

The mean wave-length of visible rays in air is about $\frac{1}{50000}$th of an inch. Thus a grating with 5000 equidistant lines per inch will give with such light an angular deviation of about 6° for the first bright diffraction line.

If we notice that the sine of the deviation is proportional to the wave-length, it will be obvious that when white light is used the result will be a series of spectra on each side of the central white image, their more refrangible ends being turned towards that image. When the grating is a very regular one, and the appearances are examined by means of a telescope adjusted for parallel rays, the spectra formed in this way show the Fraunhofer lines with as great perfection as do the best prisms. And they have one special advantage, which prisms do not possess. The relative angular separation of the various colours depends solely on their wave-lengths, and thus the spectra formed by different gratings are practically similar to one another. There is, in fact, almost no *irrationality* in this kind of dispersion. In glass prisms and especially in those of flint glass, the more refrangible part of the spectrum is much dilated, while the less refrangible part is compressed.

Interference spectrum.

The counting of the number of lines per inch in a grating is not difficult, nor is the accurate measurement of the angle of deviation of any particular Fraunhofer line. Hence, by the help of the very simple formula given above, the wave-lengths of light corresponding to the various Fraunhofer lines have been determined with very great accuracy from the diffraction spectra of gratings. The following are, according to Angström,[1] a few of the chief values. λ is expressed in ten-millionths of a millimetre.[2]

A	Atmospheric	7604	...
B	Atmospheric	6867	1·3309
C	Hydrogen	6562	1·3317
D (double)	Sodium	5895 / 5889	1·3336
E	Calcium and Iron	5269	1·3358
F	Hydrogen	4861	1·3378
G	Iron	4307	1·3413
H (double)	Calcium and Iron	3968 / 3933	1·3442

For the sake of a discussion to be entered on later, we have appended the refractive index from air into water for each of these rays, as given by Fraunhofer himself.[3]

Complementary gratings.

If now we suppose AB, CD, &c., to be transparent, while BC, &c., become opaque, it is obvious that the new grating will be the *complement* of the old one, and will give precisely the same appearances at points outside the course of the direct beam. For when there is no grating there is practically no illumination at such points. This statement of course is equally true of any grating, whatever be the ratio of the breadths of the bars to those of the interstices.

Another very curious result of the theory of interference, fully verified by experiment, is furnished by the fact that the *central* spot of the shadow of a small circular disk, cast by rays diverging from a distant point in its axis, is as brightly illuminated as if the disk had not been interposed.

The final example of interference which we can give here is noteworthy on account of a peculiarity which it presents. Let us consider the case of homogeneous light reflected by a thin plate or film of a transparent material.

Ref from thi pla

Let AB (fig. 33) be the direction of the incident ray, BdE the direction in which part of it is reflected to an eye E at a considerable distance; and let DE be the direction in which another part escapes after refraction into the plate at B and partial reflexion at the second surface of the plate at C. Then if Dd be drawn perpendicular to BE, the retardation of the wave in DE as compared with that in BE will be $(2\mu BC - Bd)/\lambda$ wave-lengths, where μ is the refractive index into the plate.

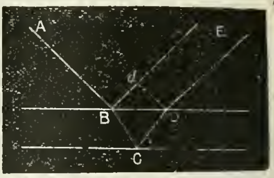

Fig. 33.

If α' be the angle of refraction, and t the thickness of the plate, it is easily seen that

$$BC \cos \alpha' = t,$$

and $$BD = 2BC \sin \alpha' = 2t \tan \alpha'.$$

Hence $$2\mu BC - Bd = 2\mu t \cos \alpha'.$$

Hence whenever, for a given thickness of plate, α' is such that

$$2\mu t \cos \alpha'$$

is an integral multiple of λ, the two rays should reinforce one another at E. The same will happen for a given angle of incidence when the thickness of the plate is such that

$$2\mu t \cos \alpha'$$

is an integral multiple of λ. When, on either account $2\mu t \cos \alpha'$ is an odd integral multiple of $\lambda/2$; the rays at E will weaken (perhaps destroy) one another.

Col of t pla

Hence, in homogeneous light, a thin plate, turned about, alternately reflects and does not reflect to an eye in a given position. And a fixed plate of non-uniform thickness reflects light from some parts and not from others. When white light is used there will in general be colours seen which vary with the angle of incidence, and also with the thickness. If the plate is infinitely thin it would appear that there should be infinitely slight retardation only, and the plate should thus be bright in homogeneous light (and of course white in white light) at all incidences.

Bla nes

In general this is *not* the case. Thus when a soap bubble, or a vertical soap-film, is screened from currents of air, and allowed to drain, the uppermost (*i.e.*, the thinnest) part becomes perfectly *black*. It can, in fact, be seen only by the feeble light scattered by little drops of oil or particles of soap or dust on its surface. Here, again, Young's sagacity supplied the germ at least of the explanation. It is given in the following extract from his *Theory of Light and Colours*, the Bakerian Lecture for 1801 already referred to:—

"Proposition IV.—*When an undulation arrives at a Surface which is the Limit of Mediums of different Densities, a partial Reflexion takes place, proportionate in Force to the Difference of the Densities.*

"This may be illustrated, if not demonstrated, by the analogy of elastic bodies of different sizes. 'If a smaller elastic body strikes against a larger one, it is well known that the smaller is reflected more or less powerfully, according to the difference of their magnitudes: thus, there is always a reflexion when the rays of light pass from a rarer to a denser stratum of ether, and frequently an echo when a sound strikes against a cloud. A greater body striking a smaller one propels it, without losing all its motion; thus, the particles of a denser stratum of ether do not impart the whole of their motion to a rarer, but, in their effort to proceed, they are recalled by the attraction of the refracting substance with equal force; and thus a reflexion is always secondarily produced, when the rays of light pass from a denser to a rarer stratum.' But it is not absolutely necessary to suppose an attraction in the latter case, since the effort to proceed would be propagated backwards without

[1] *Spectre Solaire*, 1863.

[2] As there are nearly 25 millimetres in an inch, these numbers each multiplied by 4 give the wave-lengths approximately in thousand-millionths of an inch.

[3] Gilbert's *Annalen*, lvi., 1817.

it, and the undulation would be reversed, a rarefaction returning in place of a condensation; and this will perhaps be found most consistent with the phenomena."

This idea, of a rarefaction returning by reflexion when a condensation is incident, is equivalent to a loss or gain of half a wave-length when light in a denser body is reflected at the surface of a rarer body. Whether, then, the plate be denser or rarer than the medium surrounding it, one or other of the two interfering rays loses half an undulation more than the other in the mere act of reflexion. This completely removes the difficulty. But Young went farther, and pointed out that if a thin plate be interposed between two media, one rarer, the other denser than the plate, this half wave-length effect should disappear. He verified this conjecture by direct experiment, founded on a modification of a process due to Newton.

Newton's rings. Newton had, long before, devised and carefully employed an excessively ingenious (because extremely simple and effective) method of studying the colours of thin plates. It consisted merely in laying a lens of long focus on a flat plate of glass. The film of air or other fluid between the spherical surface and its tangent plane has a thickness which is directly proportional to the square of the distance from the point of contact. When such an arrangement is looked at in homogeneous light, the lens having been pressed into contact with the flat plate, there is seen a central black spot, surrounded by successive bright and dark rings, whose number appears to be practically unlimited. The radii of the successive bright rings were found by Newton to be as the square roots of the odd numbers 1, 3, 5, &c. Hence the thicknesses of the film of air are directly as these numbers. When rays of higher refrangibility are used the rings diminish in diameter. Hence when white light is employed we have a superposition of coloured rings of all sizes, but it is no longer possible to trace more than four or five alternations of *bright* and *dark* rings—the colours being then more and more compound. This series of coloured rings is named after Newton, and the successive colours, gradually more and more composite, form Newton's *scale of colours*. Thus we read, in books more than thirty years old, of a red or blue of the *third order*, meaning those colours as seen in the third bright ring round the central dark spot.

Many of the most vivid colours of natural and artificial bodies are due to one or other of the forms of interference we have roughly explained. Thus Barton's *buttons* (once employed for ornament as they produce an effect very similar to that of diamonds) were simply polished metal plates stamped by a die of hardened steel, on whose surface a pattern had been engraved consisting of small areas ruled in different directions with close equidistant parallel grooves. That the colours of a pearl and of mother-of-pearl are due to a similar surface corrugation was proved by Brewster, who took impressions from such substances in black wax, and found that it was thus rendered capable of giving the same play of colours. The scales from the wings of butterflies owe their bright colours to a delicate ribbed structure. On the other hand, the thin transparent wings of the house-fly, earwig, &c., owe their colours to their thinness. The same is true of the temper colour of steel, Nobili's rings, &c. Very beautiful examples of thin plates scaled off from decayed glass (found in Roman excavations) have been figured, with their play of colours, by Brewster.[1]

Refractive index in terms of wave-length. Here we can only say a word or two about the probable relation between the wave-length of homogeneous light and its refractive index for any isotropic medium. The existence of dispersion was attributed by Cauchy to the fact that even the most homogeneous media, such as water, have grained or heterogeneous structure of dimensions not incomparably smaller than the average length of a wave of light. This grained structure has been recently proved to exist, by several perfectly independent processes arising from totally unconnected branches of physics; and its dimensions have been assigned, at least in a roughly approximate manner. See ATOM, and CONSTITUTION OF BODIES.

It appears from the theory of disturbances in such a medium that the velocity of a ray depends upon its wave-length in a manner which is expressed by a series of even inverse powers of that wave-length. Hence we have a relation such as

$$\mu = a + \frac{\beta}{\lambda^2} + \frac{\gamma}{\lambda^4} + \ldots\ldots,$$

in which, from our present ignorance of the precise connexion between matter and ether, we must be content to find the multipliers of the various terms by direct measurement. If we neglect all but the first two terms, we may determine a and β from the known wave-lengths of two of Fraunhofer's lines, and their refractive indices for a particular medium. We can then test the accuracy of the formula by its agreement with the corresponding numbers in the same medium for others of the fixed lines. Thus, taking the data for water given above, we have, from the numbers for the two hydrogen lines C and F, the values

$$a = 1\cdot3243,$$
$$\beta = 0\cdot00000000319.$$

Calculating from these, and the wave-length of H, we have for its refractive index 1·3447, instead of 1·3442 as determined by Fraunhofer. So far as we may trust this theory, which certainly accords fairly with the experimental data for substances of moderate dispersive powers, though by no means well with those for substances of high dispersive power such as oil of cassia, the value of the quantity a is the refractive index for the *longest possible waves*; *i.e.*, it is that of the inferior limit of the spectrum.

Double refraction. DOUBLE REFRACTION.—We now come to phenomena which cannot be even roughly explained by processes based on the vague analogies of sound and water waves which have hitherto sufficed for our elementary treatment of the subject.

Iceland spar. These phenomena were first observed in Iceland spar. They were described in a general way by Bartholinus, who showed that one of the two rays into which a single incident ray is divided by this substance follows the ordinary law of refraction. Huygens, who studied the subject only eight years later, verified the greater part of the results of Bartholinus, and added many new ones. From his point of view it was of course obvious that the ordinary ray is propagated by spherical waves, *i.e.*, its velocity is the same in all directions inside the crystal. To explain the extraordinary ray, he assumed that it was propagated in waves of the form of an ellipsoid of revolution, the simplest assumption he could make. To test its accuracy he first noticed that a rhombohedral crystal of Iceland spar behaves in precisely the same way whichever pair of parallel faces light passes through. Hence he acutely concluded that the axes of the ellipsoids of revolution (if such were the form of the waves for the extraordinary ray) must be symmetrically situated with regard to each of these planes. The only such lines in a rhombohedron are parallel to that which joins those corners which are formed by the meeting of three equal plane angles. In the case of Iceland spar these equal angles are obtuse. Huygens then verified, by experiments well contrived, though carried out by a very rough mode of measurement, the general agreement of his hypothesis with the fact; and he further tested it by comparing its indications as to the position of the two images for any position of the crystal

[1] *Trans. Roy. Soc. Edin.*, 1861.

with the results of direct observation. There can be no question that the whole investigation was, for the age in which it was made, of an exceedingly high order. But it must not be left unsaid that far more accurate measurements than those of Huygens were necessary before it could be asserted that the form of the extraordinary wave *is* an ellipsoid of revolution, and not merely a surface closely resembling such an ellipsoid. These improved measurements were made 1802 by Wollaston, and they have recently been repeated with far more perfect optical means by Stokes, Mascart, and Glazebrook. The result has been the complete verification of Huygens's conjecture. The generating ellipse of the extraordinary waves is found to have its minor axis, which is that of revolution, equal to the diameter of the corresponding sphere for the ordinary ray. Its major axis is to the minor nearly in the ratio 1·654 : 1·483.

We are now in a position to trace the paths of the two rays into which a ray falling in any direction on a surface of the crystal is divided by refraction.

Refraction by Iceland spar.

Let fig. 34 represent a plane wave front AB (in air) falling on the surface AC of a piece of Iceland spar cut in any way. The figure is a section perpendicular to the surface, and parallel to the incident ray. The wave-front AB cuts the surface of the spar in a line (not shown) at right angles to the plane of the paper. Draw from A the axis A*a* (not necessarily in the plane of the paper) and the sphere and ellipsoid of revolution which have A*a* for a common axis. Then, if C be taken such that BC is to A*a* as the velocity of light in air is to that of the ordinary ray in

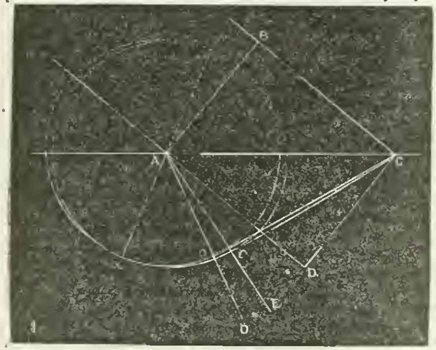

Fig. 34.

the crystal, the wave-front of the ordinary ray is found by drawing a tangent plane to the sphere, passing through C and perpendicular to the plane of the paper. This touches the sphere in a point *o* (in the plane of the paper) and A*o*O is the ordinary ray.[1] To find the direction of the extraordinary ray, a plane perpendicular to the paper, and passing through C, must be drawn so as to touch the ellipsoid. Let *e* be the point of contact, which will in general not be in the plane of the paper unless A*a* is in or perpendicular to that plane; then A*e*E is the extraordinary ray.

Thus, in general, the extraordinary ray is not in the plane of incidence. Also the ratio of the sines of the angles of incidence and refraction is generally different for different directions of incidence, in the case of the extraordinary ray.

Images seen through Iceland spar.

In an elementary article we cannot attempt more fully to study these phenomena; so we merely state that all the observed appearances, so far as the *directions* of the refracted rays are concerned, are explained by supposing the wave-surface in the crystal to be made up of the sphere and the ellipsoid of revolution above described. Thus, when both eyes are used, the two images of a plane object seen through a crystal of Iceland spar appear in general to be situated at different distances above the plane. One of them maintains its apparent position as the crystal is made to rotate about a perpendicular to the two faces employed; the other's position varies as the crystal is turned.

But we have now to inquire *why* the incident ray is divided into two, and why one of them follows the ordinary law of refraction. Here another experimental result of Huygens comes to our assistance. We paraphrase the author's description :—

'I will, before concluding, mention another remarkable phenomenon which I discovered after the above was written. For, although I have not yet been able to find the cause of it, I do not wish on that account to refrain from pointing it out, in order that others may have an opportunity of seeking to explain it. It appears that it will be necessary to make hypotheses additional to those already given,—though these will lose none of their probability, confirmed as they have been by so many tests. The phenomenon is that, taking two fragments of the crystal (Iceland spar) and laying them on one another, or even holding them apart, if all the faces of the one be parallel to those of the other, a ray of light divided into two by the first fragment will not be farther subdivided by the second. The ordinary ray from the first will be refracted ordinarily by the second, the extraordinary ray extraordinarily. And the same thing happens not only in this arrangement but in all others in which the principal sections[2] of the two fragments are in the same plane, whether the surfaces turned towards one another be parallel or not. It is, in fact, marvellous that these rays, falling on the second fragment, do not divide like the ray incident on the first. One would say that the ordinary ray from the first fragment *had lost* what is necessary for the production of extraordinary refraction, and the extraordinary ray that which is necessary for ordinary refraction; but there is something else which upsets this view. For when one places the fragments so that their principal sections are at right angles, whether the opposed surfaces be parallel or not, the ordinary ray from the first suffers only extraordinary refraction by the second, and *vice versa.*

"But in all the infinite number of positions other than those named, both rays from the first fragment are divided into two by the second. Thus the single incident ray is divided into four, sometimes equally sometimes unequally bright, according to the varying relative position of the crystals. But all together do not seem to have more light than has the single incident ray.

"When we consider that, the two rays given by the first crystal remaining the same, it depends upon the position of the second crystal whether they shall be divided into two or not, while the incident ray is always divided, it appears that we must conclude that the waves of light which have traversed the first crystal have acquired a form or disposition which in some positions enables them to excite the two kinds of matter which give rise to the two kinds of refraction, in other positions to excite only one of them. But I have not yet been able to find any satisfactory explanation of this."

So far Huygens. His statements are perfectly in accordance with fact; and they were reproduced by Newton[3] in very nearly the same form. Newton adds :—"The unusual refraction is, therefore, performed by an original property of the rays. And it remains to be enquired, whether the rays have not more original properties than are yet discovered. Have not the rays of light several sides, endued with several original properties?"

It is very curious to notice how near each of these great men came to the true explanation, and yet how long time elapsed before that explanation was found. The date of Huygens's work is 1690, that of Newton's 1704. It was not till 1810 that farther information on the subject was obtained. *Then* one brilliant observation opened the way for a host of discoveries in a new and immense field of optics.

[1] This is merely a repetition of the construction we have already given for singly refracting bodies.

[2] Defined as passing through the shorter diagonal of one of the rhombic faces of the crystal, and through the edge formed by the two adjacent faces.

[3] *Optics*, Queries 25, 26.

Polarization by reflexion. In the last-mentioned year Malus, while engaged on the theory of double refraction, casually examined through a doubly refracting prism of quartz the sunlight *reflected* from the windows of the Luxembourg palace. He was surprised to find that the two rays alternately disappeared as the prism was rotated through successive right angles, —in other words, that the reflected light had acquired properties exactly corresponding to those of the rays transmitted through Iceland spar. Even Malus was so imbued with the corpuscular theory of light that he named this phenomenon *polarization*, holding it as inexplicable on the wave theory, and as requiring a species of polarity (akin to the magnetic) in the light-corpuscles—a close reproduction of one of Newton's guesses.

But after a short time Hooke's old guess was independently reproduced, and in the hands of Young and others, but most especially of Fresnel, the consequences of the assumption, that the vibrations of the luminiferous medium take place *perpendicularly* to the direction of the ray, were the almost complete explanation of the cause of double refraction, and the discovery (often the prediction) of a long series of the most gorgeous phenomena known to science.

The real difficulty in the way of this conception probably lay in the fact that most of the familiar forms of wave-motion—such as sound-waves in air or in water, and ordinary water waves—are not of this character. In sound-waves the vibrations are wholly in the direction of the ray, while in surface-waves in water they are partly parallel to and partly perpendicular to the direction in which the wave is travelling. That a body may transmit waves in which the vibration is perpendicular to the direction of a ray, it must have the properties of an elastic *solid* rather than of a fluid of any kind. And our experience of the almost entire absence of resistance to the planetary motion seems, at first sight at least, altogether incompatible with the idea that the planets move in a jelly-like solid, filling all space through which light can be propagated.

Analogies. Without going into difficult dynamical details, we may obtain a notion of the nature of the motion now to be considered, by observing the propagation of a wave when a long stretched wire or string is struck or plucked near one end. Here the line of motion of each part of the wire is almost exactly perpendicular to the direction of the wire, *i.e.* to the line along which the wave travels. (When the string is extensible there may be another wave, due to extension; but this, which is analogous to sound, has its vibrations *along* the string, and it usually travels at a very different rate from the other, so that the two are not in any way associated).

Interference of polarized rays. Now it is clear that waves of this wholly transverse character can have, in Newton's language, *sides*. And it is also clear that they cannot interfere so as mutually to destroy one another unless their corresponding sides are parallel to one another; nor can they interfere *at all* if their sides are perpendicular to one another. Hence a very severe test of the theory will be furnished by examining various cases of interference of polarized light, which ought to present in general marked differences from those of ordinary light. It was by experiments of this kind that Fresnel and Arago first firmly established the bases of the theory of polarization. The important fact discovered by Malus was soon generalized into the following statement:—

Light reflected from the surface of substances so different as water, glass, polished wood, &c., at a certain definite angle, which depends on the nature of the substance, is found to possess all the properties of one of the rays transmitted through Iceland spar. If the plane of reflexion is parallel to the axis of the spar, the properties of the reflected light are those of the *ordinary* ray; if perpendicular to it, those of the *extraordinary* ray.

It was reserved for Brewster to discover, as the result of an extraordinary series of experimental measurements the very simple law which follows:—

The tangent of the polarizing angle is equal to the refractive index of the reflecting substance.

This may be put in another form, in which its connexion with theory is a little more evident:—

When the reflected ray is completely polarized, it is perpendicular to the refracted ray.

Bearing in mind Huygens's observations on light which has passed through two crystals of Iceland spar, we can now see that a ray of light polarized by reflexion is in general divided into two by a crystal of Iceland spar. But there is only one ray when the principal plane of the crystal is parallel to the plane of reflexion, and none when these planes are perpendicular to one another.

Polarizer and analyser. We may now much simplify matters by suppressing the Iceland spar, and using two reflecting plates of glass, so placed that a ray meets each of them in succession at the polarizing angle. It is then found that when the planes of reflexion are parallel the ray is reflected (almost without loss) from the second plate, but when they are perpendicular to one another there is complete extinction. In intermediate positions the intensity was found by Arago to be as the square of the cosine of the inclination of these planes.

This very simple experiment, which any one may easily make for himself, by putting two pieces of glass at the proper angle in the ends of two wooden tubes which fit into one another, enables us to form a general notion of the modification which is called polarization. The "sides" of the reflected ray are obviously in, and perpendicular to, the plane of incidence; for a ray can be reflected over and over again if the successive planes of incidence are parallel, but is stopped at once if one of them be perpendicular to the others.

Difficulties in the theory. Here, however, two new difficulties come in at once:—(1) Are the vibrations of the reflected ray in, or perpendicular to, the plane of reflexion? (2) As ordinary sun or lamp light, reflected at the proper angle from a polarizing surface, shows no variation of intensity when the azimuth of the plane of reflexion is changed, what can be then the direction of *its* vibrations? These questions have not yet been answered in a thoroughly satisfactory manner.

Plane of vibration and plane of polarization. Many important phenomena are explained in terms quite independent of the proper answer to (1); and, in others which do depend on the answer, the theoretical differences between the results of the two hypotheses are so small as to have hitherto remained undetected. In an important test, suggested by Stokes, the experimental results have been at variance in a way not yet explained. It is quite possible that, as is required by Clerk Maxwell's *electromagnetic theory* of light (see ETHER), there may be simultaneous displacements, but of different characters, in each of these planes, and then the question would be reduced to—Which of these displacements is the luminous one? But on this theory, *both* are probably essential to vision.

As to the second question, it may be said—*first*, that, so far as the test of double refraction can inform us, a polarized ray *whose plane of polarization is made to rotate rapidly* produces precisely the same effects as a ray of ordinary light; and, *secondly*, that, so great is the number of vibrations even of red light in one second, it would be impossible to make the plane of polarization rotate fast enough to affect the circumstances of any of the phenomena of interference, even when they take place between two portions of the same ray, one of which is retarded thousands of wave-lengths more than the other. But, *thirdly*, the fact that, when homogeneous light is used, Newton's rings have been *counted* up to the 7000th shows that, whatever be the actual nature of the vibrations of unpolarized light, they must for at least 7000 waves in succession be almost precisely similar to one another. Then, for other 7000 waves or so, we may have a totally different type of vibration. But, *fourthly*, in the course of $\frac{1}{7}$th of a second, at the very utmost, the vibrations must have been almost uniformly distributed over all directions perpendicular to the ray. Again, however, *fifthly*, another quite different view may be suggested. All common light has its origin from a practically infinite number of sources, consisting of the vibrating particles of the luminous body. The contributions from each of these sources (so far as one definite wave-length is concerned) may be and probably *are* at any one point as different in direction of vibration as they certainly must be in phase.[1] From this point of view, which we cannot develop here, the uniformity of optical phenomena becomes quite analogous to the statistical species of uniformity which is now found to account for the behaviour of the practically infinite group of particles forming a cubic inch of gas. The reader need only think of the fact that, so numerous are those particles, it is practically (though not theoretically) impossible that even a cubic millimetre of air should, even for $\frac{1}{10000}$th of a second, contain oxygen particles alone.

Reflexion not at the polarizing angle. When light is reflected at an incidence either less or greater than the polarizing angle, it behaves as if part of it only were polarized and the rest ordinary light; and it is said to be *partially polarized.* Tested by a crystal of Iceland spar, it gives two images in all positions of the crystal; but their brightness is unequal except in the special positions where they would be of equal brightness were the ray wholly polarized.

Polarization by ordinary refraction. From the fourth of the remarks made above regarding common light, and the facts of double refraction, it follows at once that, when light is to any extent polarized by reflexion, there must be an exactly equal amount of polarized light in the refracted ray, and its plane of polarization must be perpendicular to that of refraction. This was established by experiment soon after Malus's discovery. But as the reflected ray from glass, water, &c., is in general much weaker than the refracted ray, the percentage of polarized light is generally much greater in the former. It was found, however, by experiment that refraction at a second glass plate parallel to the first increases the proportion of polarized to common light in the transmitted ray, and thus that light may be almost completely polarized by transmission, at the proper angle, through a number of parallel plates. The experimental data of this subject were very carefully obtained by Brewster. He has found, for instance, how the angle of incidence for the most complete polarization varies with the number of plates. The plane of polarization of such a bundle is *perpendicular* to the plane of refraction.

This, however useful on many occasions, is at best a rough arrangement for producing polarized light. By far the most perfect polarizer for a broad beam of light is a crystal of Iceland spar, sufficiently thick to allow of the complete separation of the two rays. But such specimens are rare and costly, so that the polarizer in practical use is now what is called *Nicol's prism*, invented in 1828 (*Jameson's Journal*, p. 83). By cutting a rhomb of Iceland spar in two, and cementing the pieces together with Canada balsam (after carefully polishing the cut faces), Nicol produced an arrangement in which one only of the two rays is transmitted, the other being totally reflected at the surface of the balsam. The reason is simply that the refractive index of Canada balsam is intermediate to those of the ordinary and extraordinary rays in the spar. The ordinary ray, falling very obliquely on a medium of a smaller refractive index, is totally reflected; the extraordinary ray, falling on a medium of greater, but very little greater, refractive power, is almost wholly transmitted. The only defect of the Nicol's prism is that, to secure the total reflexion, its length must be considerably greater than its breadth; and thus it necessarily limits the divergency of the beam it allows to pass.

Certain doubly refracting crystals exert considerable absorption on one of the two rays they produce, and can therefore, when in plates of sufficient thickness, be employed as polarizers. This is the case with some specimens of tourmaline when cut into plates parallel to the axis of the crystal. It is also found in the flat crystals of several artificial salts, such as, for instance, iodo-sulphate of quinine.

Two Nico[ls]. Let us now suppose that by one or other of these pieces of apparatus, say a Nicol's prism, light has been polarized. If we examine this ray by means of a second Nicol, placed in a similar position to the first, it passes practically unaltered. As the second Nicol is made to rotate, more and more of the light is stopped, till the rotation amounts to a right angle. Two well-constructed Nicols, placed in this position, are practically opaque to the strongest sunlight. During the next quadrant of rotation the transmitted ray gradually increases in brightness, until at 180° of rotation it passes practically unaltered. Precisely the same phenomena occur in the same order during the next half of a complete rotation. The reader will observe that this is merely Huygens's original statement, limited to one of the four rays which are produced by passing common light successively through two crystals of Iceland spar.

Sym[metry of] pola[rized] ray. Whatever be the true mechanism of polarized light, there can be no doubt that its vibrations are *symmetrical* with respect to the ray, and also with respect to the plane of polarization. Hence we may, for many important purposes, symbolize them by simple harmonic vibrations taking place either in or perpendicular to the plane of polarization. But, if they be supposed to take place simultaneously in these two planes, their quality or nature must be essentially different in the two, else the symmetry above referred to would be violated. Hence it will be sufficient for the present to assume that they take place perpendicular to the plane of polarization. The nature of the resulting effects, so far as the eye is concerned, will not be different for the different hypotheses. Also, as no instance has yet been observed, even with the most intense beams of light, in which the joint effects observed are not those due to simple superposition, we may assume that the elastic force of the luminiferous medium, called into play by a displacement, is directly proportional to the displacement, and therefore that the vibrations for each wave-length follow the *simple harmonic law*, that of the cycloidal pendulum.

The subject of the composition of simple harmonic motions of equal period falls to be discussed as an important branch of *kinematics* (see MECHANICS). We will therefore here assume the following results,—referring to the above-quoted article for their proof:—

Prope[r]ties o[f] simpl[e] harm[onic] motio[ns]. 1. Two simple harmonic motions of the same period, in lines perpendicular to one another, give, in general, elliptic motion, which may be in the positive or negative direction of rotation.

2. The ellipse becomes a straight line, and the resultant motion therefore simple harmonic, when the phases of the

[1] A curious exception occurs in the case of light radiated from a body which polarizes by absorption. See RADIATION.

components are the same, or differ by an integral multiple of π.

3. It becomes a circle when the amplitudes of the components are equal, and their phases differ by an odd multiple of $\frac{1}{2}\pi$. The motion takes place in one direction (say right-handedly) in the circle when this multiplier is 1, 5, 9, 13, &c., and in the opposite (left-handed) when it is 3, 7, 11, 15, &c. . .

Now, suppose a plane polarized ray to fall on a plate of a doubly-refracting crystal (a thin plate of mica or selenite, for instance). Within the plate it will in general be divided into two, which are polarized in planes at right angles to one another. The directions of vibration in these rays are determined by the physical properties of the material. Let them be represented by the lines Ox, Oy in fig. 35. Then, if OA represents the semiamplitude of vibration in the incident ray, it may be looked on by (2) above as the resultant of two simple harmonic motions of the same period, whose semiamplitudes are OM and ON, and which are in the same phase. Each of these will pass through the plate of crystal *unchanged.* But one will, in general, travel faster than the other; for the essential cause of double refraction is the difference of velocities of the two rays. The portions of the two rays which simultaneously escape from the crystal, and which travel together outside it, will therefore *differ in phase.* Hence, to find the nature of the transmitted light, we must recombine the vibrations in OM, ON, taking account of this difference of phase. By (1) above the result will be in general elliptic motion. The ellipse will necessarily be one of the infinite number which can be inscribed in the rectangle AA'BB', whose construction is obvious. We have then, in general, what is called *elliptically polarized light.* This degenerates (by (2) above) into plane polarized light, whose vibrations are along OA or OA' according as the difference of phase is 0, 2π, 4π, &c., or π, 3π, 5π, &c. And it will become *circularly polarized light* if OM = ON (*i.e.*, if A O$x = \frac{1}{4}\pi$) and the difference of phase be an odd multiple of $\frac{1}{2}\pi$. By (3) above this will be right or left handed, according to the value of the odd multiplier.

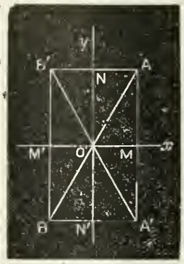

Fig. 35.

This conclusion from the assumption above made is fully borne out by experiment. When a plate of mica, of such a thickness as to retard one of the two rays a quarter of a wave-length more than the other, is interposed between two Nicols, we observe the following phenomena:—

If the Nicols were originally placed so as to extinguish the light, the introduction of the mica plate in general partially restores it. Now, let the mica plate be made to rotate in its own plane. The light vanishes for successive positions, differing by a quadrant of rotation, *i.e.* whenever the directions of vibration in the crystal coincide with the principal planes of the Nicols. In each of these positions the light from the first Nicol passes unchanged through the mica, and is therefore entirely stopped by the second Nicol. Half-way between these positions the light transmitted through the system is at its brightest; and in these cases it is not altered in brightness by rotating the second Nicol. It is then circularly polarized, and in whatever direction the second Nicol is placed the component of the circular motion which is ready to pass through it is of the same amplitude. Here, then, is a case in which a Nicol (the second) cannot enable us to distinguish between common light and light very seriously modified.

In what precedes, we have assumed that *homogeneous* light was used. In general, a doubly-refracting plate produces a difference of phase in its two rays which will depend on their wave-length; and thus when white light is used we have a display of colour, sometimes extremely gorgeous, and we may distinguish light thus circularly polarized from common light by slight changes of colour and intensity as the second Nicol is turned.

Hitherto we have spoken of the polarizing angle for light reflected in air from bodies such as glass, water, &c., which have a higher refractive index than air, and we have seen that an equal amount of light is polarized in the refracted beam. But what if there be no refracted beam? This is the case of total reflexion inside the denser body. Fresnel discovered that in this case the two kinds of polarized light (in planes at right angles to one another) co-exist in the totally reflected ray, but that they differ in phase, and therefore in general recombine into elliptically polarized light. Guided by peculiar theoretical considerations, he was led to construct a piece of glass (*Fresnel's rhomb*), inside which light is twice totally reflected at a certain angle with the result that, if it be originally polarized in a plane inclined at 45° to the plane of reflexion, the emergent light is circularly polarized. **Fresnel's rhomb.**

Metallic reflexion. Reflexion from the surface of metals, and of very highly refractive substances such as diamond, generally gives at all incidences elliptically polarized light. Attempts have been made to determine from such effects the refractive indices of metals and other opaque substances. These are all based upon theory, and cannot as yet command much confidence. With certain doubly-refracting substances the light reflected at a definite angle is differently polarized, and sometimes even differently coloured, for different azimuths of the plane of incidence.

Rings and cross in plate of uniaxal crystal. When a thin plate of doubly-refracting crystal, which gives a bright colour when placed between two Nicols, is slightly inclined to the ray, the colour changes as the difference of phase of the two refracted rays is increased. If, now, we take a plate of Iceland spar cut perpendicularly to the axis, no colour will be produced by parallel rays passing through it perpendicularly, because both rays have a common velocity parallel to the axis; but, if divergent light be used, there is a gorgeous display of circular coloured rings surrounding the axis, which depends upon the increasing retardation of the ordinary ray behind the extraordinary as their inclination to the axis increases. When the principal planes of the Nicols are at right angles, this system of rings is intersected by two black diameters, in these planes respectively. When the second Nicol is turned through a right angle, we have exactly the *complement* of the former appearance, *i.e.*, a figure such that, if superposed on the former, it would give an uniform field of white light.

It is to be noticed that none of these phenomena can be observed without the use of the second Nicol. This arises from the fact that, where the vibrations in any direction interfere so as to destroy one another, those in the direction perpendicular to the former interfere so as to strengthen one another. The second Nicol enables us to select one of these portions, and examine it independently of the other.

The only double refraction we have considered particularly is that of Iceland spar, where everything is symmetrical about the axis of the crystal. Such crystals, and they include as a rule all those of the second and third systems in CRYSTALLOGRAPHY (*q.v.*), are called *uniaxal.* Crystals of the first system are not doubly refractive. But it was one of the most valuable of Brewster's discoveries that the great majority of non-isotropic substances are doubly refracting, and in general are *biaxal*, *i.e.*, have two

Fresnel's wave. equally important axes inclined to each other at angles of all values from 0° to 90°. The form of the *wave-surface* in such bodies was, at least very approximately, assigned by Fresnel. This forms one of the most brilliant of his many grand discoveries; and it led to Hamilton's prediction of the existence of the two species of *conical refraction*, which was experimentally verified by Lloyd.

Fresnel also made the striking discovery that glass and other simply refracting bodies are rendered doubly refracting when in a state of strain. To this Brewster added the observation that the requisite strain might be produced by unequal heating instead of by mechanical stress, and also that unannealed glass is usually doubly refractive. Clerk Maxwell in 1873 (*Proc. Roy. Soc.*) showed that shearing stress in viscous liquids, such as Canada balsam, renders them temporarily doubly-refractive. This subject has been elaborately investigated by Kundt (*Pogg. Ann.*, 1879).

The details of these subjects, with those of the polarization of light reflected from small particles, the *rotatory polarization* produced by quartz, sugar, transparent bodies under the influence of magnetism, &c., must be deferred to Optics (Physical).

There is, however, one elementary point which must not be omitted here, as it is intimately connected with the wave-theory,—that is, the alteration which light undergoes in consequence of the relative motion of the source and spectator in the line of vision.

Döppler's principle. When a steamer is moving in a direction perpendicular to the crests of the waves, she will encounter more of them in a given time if her course is towards them than if she were at rest, while, if she be moving in the same direction as the waves, fewer of them will overtake her in a given time than if she were at rest. The same thing is true of sound-waves. When an express train passes a level crossing at full speed, the pitch of the steam whistle is higher during the approach to and lower during the recess from the listener at the gate than it would be if the engine were at rest. The successive sound-pulses are emitted at the same intervals as before, but from points successively nearer to or farther from the listener. Hence more or fewer reach his ear in a given time. The principle is precisely the same as that of Römer's observation of the frequency of eclipse of Jupiter's satellites, which we have already given: the number of light-waves which reach the eye per second is increased if the source is approaching, and diminished if it be receding. We are now dealing with a phenomenon which occurs some 600,000,000,000,000 times per second instead of once every forty-two hours. Now, increased wave-frequency, with unaltered velocity of light, certainly implies shorter wave-length and most probably greater refrangibility, and *vice versa*. There is, undoubtedly, a weak link in this reasoning, due to our ignorance of the true nature of the luminiferous medium and of the species of vibration on which light depends. If we knew something definite about the nature of the ether, and the mechanism of its vibrations, this weakness would be at least in part got rid of. Observation has not yet settled the question of the relative motion of bodies, the ether they contain, and the ether in free space.

This principle has been applied with success by Huggins and others to find the rate at which we are approaching to or receding from different fixed stars, and the rate of motion in solar cyclones; and it may even be applied, as was ingeniously suggested by Fox Talbot (*B. A. Report*, 1871), to determine (from the relative velocities of the components of a double star in the line of sight, measured by its aid) the distance of the star itself from our system.

The reader is advised to consult, in connexion with the whole of the second part of this article, the previous article Ether. (P. G. T.)

LIGHTFOOT, John (1602–1675), an eminent rabbinical scholar, was the son of Thomas Lightfoot, vicar of Uttoxeter, Staffordshire, and was born at Stoke-upon-Trent in that county, on March 29, 1602. His school education was received at Morton Green near Congleton, Cheshire, and in June 1617 he entered Christ's College, Cambridge, where he made great progress in Latin and Greek, and was reckoned the best orator among the undergraduates. After taking his bachelor's degree, he became for some time assistant master at Repton in Derbyshire; at the canonical age he received ordination, and shortly afterwards was appointed curate of Norton-under-Hales in Shropshire. There he attracted the notice of Sir Rowland Cotton, an amateur Hebraist of some attainments it would seem, who made him his domestic chaplain at Bellaport, and was the first to awaken his taste for rabbinical learning. Shortly after the removal of Sir Rowland with his family to London, Lightfoot followed him thither, but for some unexplained reason soon left the capital again, and, visiting his parents at Uttoxeter, took a solemn leave of them, having resolved "to travel beyond the seas." An unexpected and pressing invitation induced him to change his determination, and to accept a charge at Stone in Staffordshire, where he continued for about two years, and where, on May 21, 1628, he married Joyce, daughter of William Crompton of Stone Park, and widow of George Copwood of Delverne, Staffordshire. From Stone he removed to Hornsey near London, for the sake of the library of Sion College, which he often had occasion to consult; his first published work, entitled *Erubhin, or Miscellanies, Christian and Judaical, penned for recreation at vacant hours*, and dedicated to Sir R. Cotton, appeared at London in 1629. During the summer and autumn of 1630 he lived at Uttoxeter, and in September of that year he was presented by Sir R. Cotton to the rectory of Ashley in Staffordshire, where he continued to discharge his pastoral duties, and to prosecute his rabbinical studies, for the next twelve years. For the more uninterrupted pursuit of the latter he is said to have bought a small piece of land near his parsonage, and to have built upon it a small house "containing a study and withdrawing room below, and a lodging chamber above." "Here he closely followed his said studies with great delight and unwearied diligence, and did choose to lodge here very often, though it were so near to his family and parsonage house." In June 1642 he left Ashley for London; the precise occasion of the removal is not known, but probably it arose out of the necessity for personal superintendence of the publication of his next work, *A few and new Observations upon the Book of Genesis: the most of them certain; the rest, probable; all, harmless, strange, and rarely heard of before*, which appeared at London in that year with a dedication to "my dear and loving countrymen of the county of Stafford, and other my friends residing in the city of London." Soon after his arrival in the capital he became minister of St Bartholomew's church, near the Exchange; and in 1643 he was appointed to preach the sermon before the House of Commons on occasion of the public fast of March 29. It was afterwards published under the title of *Elias Redivivus*, the text being Luke i. 17; in it a parallel is drawn between the Baptist's ministry and the work of reformation which in the preacher's judgment was incumbent on the parliament of his own day. Lightfoot was also one of the original members of the Westminster Assembly, which held its first formal meeting on Saturday, July 1, 1643: his "Journal of the Proceedings of the Assembly of Divines from January 1, 1643 to December 31, 1644," now printed in the thirteenth volume of the 8vo edition of his *Works*, is a valuable historical source for the too brief period to which it relates. He was assiduous in his attendance from the first, and, though frequently standing almost or even quite alone, especially in the Erastian controversy, exercised a material influence on the result of the discussions of the Assembly. In 1643 Lightfoot published *A Handful of Gleanings out of the Book of Exodus*, dedicated to the inhabitants of Bartholomew Exchange, and in the same year he was made master of Catherine Hall by the parliamentary visitors of Cambridge, and also, on the recommendation of the Assembly, was promoted to the rectory of Much Munden in Hertfordshire; both appointments he retained until his death. In 1644 was published in London the first instalment of the laborious but never completed work of which the full title runs *The Harmony of the Four Evangelists among themselves, and with the Old Testament, with an explanation of the chiefest difficulties both in Language and Sense: Part I. From the beginning of the Gospels to the Baptism of our Saviour.* The second part *From the Baptism of our Saviour to the first Passover after* followed in 1647, and the third *From the first Passover after our Saviour's Baptism to the second* in 1650. On August 26, 1645, he again had the honour of preaching before the House of Commons on the day of their monthly fast; in the discourse, which was afterwards published (*A Fast Sermon*, on Rev. xx. 1, 2), after controverting as erroneous and false the doctrine of the Millenaries, he goes on to urge upon the parliament various practical suggestions for the repression with a strong hand of current blasphemies ("I do hold it a truer point in divinity that 'errans conscientia liganda' than 'ligat'"), for a thorough revision of the authorized version of the Scriptures, for the encouragement of a learned ministry, and for a speedy settlement of the church. "I rejoice to see what you have done in platforming classes and presbyteries, and I verily and cordially believe it is according to the pattern in the mount." In the same year appeared *A Commentary upon the Acts of the Apostles, chronical and critical; the Difficulties of the text explained, and the times of the Story cast into annals. From the beginning of the Book to the end of the Twelfth Chapter. With a brief survey of the contemporary Story of the Jews and Romans* (down to the third year of Claudius); and in 1647 he published *The Harmony, Chronicle, and Order of the Old Testament*, which was followed in 1655 by *The Harmony, Chronicle, and Order of the New Testament*, inscribed to Cromwell, with an epistle dedicatory to his highness's honourable council. In the last-named year Lightfoot, who in 1652 had commenced doctor of divinity, was chosen vice-chancellor of the university of Cambridge, but continued to reside by preference at Munden, in the rectory of which, as well as in the mastership of Catherine Hall, he was confirmed, through the influence of friends, at the Restoration. The remainder of his life was principally devoted to the production of the work by which his name now chiefly lives, the *Horæ Hebraicæ et Talmudicæ*, in which the volume relating to Matthew appeared in 1658, that relating to Mark in 1663, and those relating to 1 Corinthians, John, and Luke, in 1664, 1671, and 1674 respectively. Towards the close of 1675, while travelling from Cambridge to Ely (where he had been collated by Sir Orlando Bridgman to a prebendal stall), he caught a severe cold, upon which, by an indiscretion in diet it is said, fever supervened; falling afterwards into a lethargy which continued for about a fortnight, he died at Ely on December 6, 1675. The *Horæ Hebraicæ et Talmudicæ impensæ in Acta Apostolorum et in Ep. S. Pauli ad Romanos* were published posthumously.

The *Works* of Lightfoot were first edited, in 2 vols. fol., by Bright and Strype in 1684; the *Opera Omnia, cura Texelii*, appeared at Rotterdam in 1686 (2 vols. fol.), and again, edited by Leusden, at Franeker in 1699 (3 vols. fol.). A volume of *Remains* was published at London in 1700. The *Hor. Hebr. et Talm.* were also edited in Latin by Carpzov (Leipsic, 1675–79), and again, in English, by Gandell (Oxford, 1859). The most complete edition is that of the *Whole Works*, in 13 vols. 8vo, edited by Pitman (London, 1822–25). It includes, besides the works already noticed, numerous sermons, letters, and miscellaneous writings; and also *The Temple, especially as it stood in the Days of our Saviour* (London, 1650).

LIGHTHOUSE

I. LIGHTHOUSE CONSTRUCTION.

THE primary and most important consideration relating to the design and construction of a lighthouse tower which is to be built within the tide mark is the force of the waves which may be expected to assail it, and the directions and heights at which that force will act on the building. The great waves which are found in the open ocean cannot be generated in smaller seas, and, with a due regard to economy in construction, ought not therefore to be provided against. What is wanted is to ascertain in such shorter seas the height of waves in relation to the length of "fetch" in which they are generated, and next to determine their energy when on reaching the shore or a sunken rock, and so ceasing to be waves of oscillation, they enormously increase their destructive force by becoming waves of translation. Full information as to these points and as to the marine dynamometer—an instrument used for ascertaining the force of the waves on an exposed surface—will be found in the article HARBOURS, to which the reader is referred. It is enough here to state that the law of increase in the height of waves was found by Mr T. Stevenson to be proportional to the square root of the distance from the windward shore, and that the greatest force recorded on rocks exposed to the ocean was 3½ tons per square foot. The relative forces of summer and winter gales were found to be as 1 to 3, and the vertical force, after acting on a curved sea wall, was eighty-four times greater than the horizontal force at a height of 23 feet above high water.

The history of the ancient lighthouses is of so scanty a nature that we may pass at once to more modern works, commencing with Winstanley's Eddystone light.

Winstanley's Eddystone Light.—The Eddystone Rocks, which lie about 14 miles off Plymouth, are fully exposed to the south-western seas. The lighthouse was completed by Winstanley in four seasons. In 1698 it was finished at a height of 80 feet and the light exhibited; but in 1699, in consequence of damage by storms, the tower was increased by an outer ring of masonry 4 feet thick, and made solid from the foundation to nearly 20 feet above the rock. The height was increased to nearly 120 feet, and completed in 1700. During the well-known hurricane of 20th November 1703 the tower was destroyed. In general design as well as in details this work must be placed among the *vetanda* of maritime engineering. For example, in plan it was polygonal instead of circular. In his blind devotion to ornamentation Winstanley violated throughout the principles of uniformity of outer profile so as to present great obstructions to the action of the waves.

Rudyerd's Eddystone Tower.—This work was commenced in 1706 and completed in 1709, in the form of a frustum of a cone 92 feet high. The work consisted principally of timber, the lower part being oak carefully bolted together, and also to the rock. Above the lower structure of oak courses of stone, cramped together and fixed to the timber work and to the rock, were added in order to give weight to the structure. This lighthouse stood for forty-six years, and was destroyed by fire in 1755. In every respect the simplicity of the structure and the judicious character of the details of the design may be regarded as models of engineering. First, it rested upon a stepped level base, was circular in plan, did not wholly depend upon fixtures but upon weight, preserved a uniform external surface devoid of outside projections and ornamentation; and, above all, the engineer did not by splaying out the base needlessly throw away the small diameter which the rock afforded, but with much judgment adopted the conical form.

Smeaton's Eddystone Tower.—This justly celebrated work, which consisted entirely of stone, was commenced in 1756, and the masonry was finished in 1759. Smeaton was the first engineer who adopted a structure of masonry for a sea tower and dovetailed joints for the stones, which averaged a ton in weight. This work cannot be regarded as a safe model for general imitation in exposed situations, and Rudyerd's earlier tower was certainly as successful in resisting the forces to which it was exposed. Rudyerd unquestionably selected for so small a rock as the Eddystone a preferable form to that adopted by Smeaton. The sharply curved profile in Smeaton's design greatly reduced the diameter of the building at a small height above the rock, and so reduced its strength.

Fig. 1.

Smeaton's reasoning about the similarity of a tower exposed to the surf and an oak tree resisting the wind was very conclusively shown to be fallacious by the late Mr Alan Stevenson. The arching of the floors, as shown in fig. 1, was also a source of weakness which the introduction of the iron chains, shown black in the diagram, was intended to counteract. Mr Douglass in 1878 stated that "for several years the safety of the Eddystone had been a matter of anxiety and watchful care to the corporation of the Trinity House, owing to the great tremor of the building with each wave stroke." He also stated that the projecting cornice at the top had been lifted, and that the rock itself had been considerably undermined. A new tower has now (1882) been erected in place of Smeaton's by Mr Douglass.

Bell Rock Lighthouse Tower.—The Bell Rock, which lies 12 miles off the coast of Forfarshire, is fully exposed to the assaults of the German Ocean. The rock is of considerable extent but of a low level, the tower being covered about 16 feet at high water of spring tides. Mr R. Stevenson, of Edinburgh, when he first landed on the rock, decided to adopt a stone tower as Smeaton had done at the Eddystone, but he deviated largely from that design in the thickness of the walls, in raising the tower to 100 feet instead of 68 feet, and the level of the solid to 21 feet above high water instead of 11 feet.

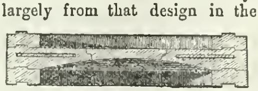

Fig. 2.

Instead of employing arched floors as at the Eddystone, he adopted lintel stones for the floors which formed part of the outward walls, and were feathered and grooved as in carpentry, besides having dovetailed joggles across the joints where they formed part of the walls. It will be seen on fig. 2 that the floors instead of being sources of weakness, as in Smeaton's tower, were converted into effective bonds tying the walls together. He also used a temporary beacon or barrack on the rock for the engineer and his workmen to live in while the tower was in progress. The bill introduced into parliament for this work in 1802 was not passed in consequence of financial difficulties. As the Bell Rock was scarcely dry at low water, while the Eddystone was scarcely covered at high water, the commissioners, in order to fortify Mr Stevenson's views, consulted Mr Telford, and before going to parliament for the second time they also, on Mr Stevenson's suggestion, obtained for the scheme the support of Mr Rennie, with whom he could afterwards advise in case of emergency during the progress of the work. The second bill was passed in 1806, and the works, which were begun in 1807, were finished in 1810, and the light was exhibited in 1811. The total weight of the tower is 2076 tons.

Skerryvore Lighthouse.—The Skerryvore Rocks, 12 miles off the island of Tyree in Argyllshire, which is the nearest land, are wholly open to the Atlantic. The works, designed and carried out by the late Mr Alan Stevenson, were commenced in 1838 and finished in 1843. The first temporary barrack was destroyed in 1838, and another erected on a more sheltered part of the rock. The tower, which is of a hyperbolic curve, is 138 feet high, 42 diameter at the base, and 16 at the top. Its weight is 4308 tons.

Bishop Rock.—The Bishop Rock, lying off the Scilly Islands, is fully exposed to the Atlantic. It was designed by the late Mr James Walker, and carried out by Mr J. N. Douglass. It is 100 feet above high water, 34 feet in diameter at the base, and 17 at top. The lowest part of the foundation of tower is covered about 19 feet at high water springs; the solid is 20 feet above high water, where the walls are 9 feet thick, and decrease to 2 feet at the top. Owing to the great tremor in this building, it has lately been found necessary to strengthen it by an internal structure of ironwork.

Wolf Rock.—This much exposed rock is about midway between Scilly and the Lizard Point, and is submerged to the depth of about 2 feet at high water. The first design for a lighthouse was in 1823, by Mr R. Stevenson, but it was not till 1862 that a lighthouse was commenced under the superintendence of Mr Douglass, from a design by the late Mr Walker. It is 116½ feet high, 41 feet 8 inches diameter at the base, decreasing to 17 at the top, and the walls are 7 feet 9½ inches thick, decreasing to 2 feet 3 inches. The shaft is a concave elliptic frustum, and contains 3296 tons. The lower part of the tower has projecting scarcements in order to break up the sea but, as has been already stated in the case of the Eddystone, such projections are not in accordance with the principle of uniformity of external surface, and are, therefore, more likely to produce disturbance of the masonry than to add to its stability.

Dhu Heartach Rock Lighthouse.—The Dhu Heartach Rock, which is 35 feet above high water, is 14 miles from the island of Mull, which is the nearest shore. The maximum diameter of the tower, which is of parabolic outline, is 36 feet, decreasing to 16 feet; the shaft is solid for 32 feet above the rock; the masonry weighs 3115 tons, of which 1810 are contained in the solid part. The temporary barrack for the workmen was made of malleable iron bars with an iron drum on the top in which the workmen lived. This tower was designed by Messrs D. & T. Stevenson, and occupied six years in erection, the length of the working season being only about two and a half months in each year.

Chickens Rock Lighthouse.—The Chickens Rock lies 1 mile off the Calf of Man. The curve of the tower, which is 123 feet 4 inches high, is hyperbolic, the diameter varying from 42 feet to 16 feet. The tower is submerged 5 feet at

high-water springs. The solid is $32\frac{1}{2}$ feet in height, weighing 2050 tons, the whole weight of the tower being 3557 tons. The walls decrease from 9 feet 3 inches to 2 feet 3 inches in thickness. The work was designed by Messrs D. & T. Stevenson, and was begun in 1869. and completed in 1874.

Great Basses Lighthouse near Ceylon.—Great Basses lighthouse lies 6 miles from the nearest land, and was designed by Mr Douglass. The tower has a cylindrical base 32 feet in diameter, above which is a tower 67 feet 5 inches high and 23 feet in diameter. The walls vary in thickness from 5 feet to 2 feet. The tower, including the base, contains about 2768 tons, and the work was finished in three years.

There are several other lighthouses in Ireland, India, and America which merit more attention than our space admits of, and we shall therefore conclude with directing the attention of the engineer to the important influence of the configuration of rocks in modifying the breaking of waves. It cannot but excite surprise that some of the structures which were erected on the Eddystone should have withstood the waves so long as they did. This fact seems to lead to the conclusion that the Eddystone Rock, at one time at least, acted to some extent as a shelter to the structures which were built on it. During a summer gale when Dhu Heartach lighthouse was being erected fourteen stones each of 2 tons weight, which had been fixed on the tower by joggles and Portland cement at the level of 37 feet above high water, were torn out and swept off into deep water, as shown on Plate VII. At the Bell Rock stones of 2 tons weight were several times swept away during the construction of the tower, while it is a remarkable fact that no stones were ever moved at the Eddystone. But what is more striking, the thin glass panes of Winstanley's first tower stood successfully through a whole winter's storms at the same level above the water as that at which the fourteen heavy blocks were swept away at Dhu Heartach, where it was found necessary from the experience acquired when constructing the lighthouse to raise the solid base of the tower to nearly the same height above the water as the glass panes in Smeaton's tower, which have hardly ever been broken during the storms of more than a hundred years.

The conclusion then which seems fairly deducible from these facts is that the level of the plane of dangerous impact of the waves above high water depends upon the relation subsisting between their height and the configuration of the rocks above and below high water, as well as perhaps on the configuration of the bottom of the sea near the lighthouse. Thus, while the rock at Dhu Heartach, from its height above high water, forms a great protection against the smaller class of waves, it operates as a dangerous conductor to the largest waves, enabling them to exert a powerful horizontal force at a much higher level than they would had the rock been lower. The lighthouse engineer must therefore beware of taking it for granted that Smeaton's Eddystone tower is a model for general imitation, and must carefully consider as best he can in what way the configuration of the rock may affect the stability of the tower which he has to design. Unfortunately in the present state of our information no specific directions can be laid down for his guidance in this matter, but the following general rules of construction may be given:—

(1) The tower should have a low centre of gravity, and sufficient mass to prevent its being upset by the waves. (2) It should be throughout circular in the horizontal plane, and either straight or continuously curved in the vertical plane, so as to present no abrupt change of outline which would check the free ascent of the rising waves, or the free descent of the falling waves, or the free vent of those passing round the tower. All external scarcements in the vertical plane, or polygonal outline in the horizontal plane, are therefore objectionable. (3) Its height, *cæteris paribus*, should be determined by the distance at which the light requires to be seen by the sailor. The rule for determining this height will be afterwards given. (4) Where the rock is soft, or consists of ledges which are easily torn up, the tower should spring from the foundation-course at a low angle with the surface of the rock, so as to prevent its being broken up by reaction of the waves from the building; or, in other words, the tower must have a curved profile. But special care should be taken to sink the foundation-courses below the surface of the rock, as the superincumbent weight decreases with the sine of the angle of inclination of the wall. If the rock overhangs, owing to the wearing action of the waves, the tower should, if possible, be built at a distance from the place where this dangerous action is in progress. (5) Where the rock is hard and of ample area, the tower may be of such a curved form as will best suit the economic arrangement of the materials, so as to avoid an unnecessary thickness of the upper walls. (6) When the rock is hard, but of small dimensions, the diameter above the base should not be suddenly reduced by adopting a curved profile, but a conical outline should be adopted; and if the rock be hard, but of yet smaller dimensions, a cylindric form of greater height should be adopted so as to thicken the walls, and to increase the weight and therefore increase the friction, which is directly proportional to the weight of the blocks of masonry. In all cases where the rock is small the thickness of the walls should be decreased by steps or scarcements *internally*, but never *externally*. (7) The level of the top of the solid part of the tower, and the thickness of the walls above it, should, in different towers having the same exposure, be determined in each case by the level and configuration of the rock and of the bottom of the sea. (8) The best position for the tower is not necessarily the highest part of the rock. It should, in each case, be selected so as to secure the greatest protection in the direction of the maximum fetch and deepest water near the reef. (9) The tower should not, if possible, be erected across any chasm which divides the rock, or in the direction of any gully which projects into it, especially if it be of converging form, which would concentrate wave action. (10) No permanent fixture of the tower to the rock is required for increasing the stability of the structure. The foundation-course (unless where a curved profile is adopted) becomes, indeed, in the end the most stable of all, because it has the greatest weight above it, to keep it in its place. (11) The stones should, however, be sufficiently connected together, and fixed to the rock, in order to prevent their being washed away during the construction of the work, when they have no superincumbent weight to keep them in their beds. (12) The tower should rest on a truly level base, or on level steps cut in the rock. (13) The pressure of all the materials within the tower should act vertically, so as not to produce a resolved force acting laterally as an outward thrust. (14) The tower should be of such height and diameter, with walls of such thickness, as to prevent the masonry being disturbed by the impact of the waves. (15) The entrance door should be placed on that side of the tower where the length of fetch is shortest, or where from the configuration of the reef and the depth of water, the force of the waves is least. This was determined at the Bell Rock by the distribution of the *fucus* which grew on the lower parts of the tower during the first winter, the vegetation being least where the waves were heaviest. (16) The materials should be of the highest specific gravity that can be readily obtained, and, in some special cases, lead, or dove-tailed blocks of cast iron set in cement, might perhaps be employed.

Plate VII. shows sections on the same scale of a number of the more remarkable lighthouse towers.

Fig. 3 shows an iron pile light erected at Haneda, in the Bay of Yedo, Japan.

II. LIGHTHOUSE ILLUMINATION.

What is required of every lighthouse apparatus is either the equal distribution of the rays constantly or periodically over the whole horizon, or else their unequal distribution over certain azimuths only.

The first of these two cases, viz., the equal distribution of the light, will be best understood by explaining the different manner in which the rays are operated on by the apparatus for a fixed light and by that for a revolving light. The characteristic of a *fixed* light, which is that of being seen constantly and always of the same power round the whole horizon, might no doubt be perfectly produced by a naked flame without any apparatus, but then all the rays which did not fall on the navigable track of shipping would be lost to the sailor. In order then to intercept and utilize those rays which, instead of falling on this navigable track, would either go upwards to the sky or downwards on the shore close to the lighthouse tower, and on that part of the sea which is very near the shore, we must have recourse to optical agents both for bending down the rays which naturally point too high, and for bending up those which point too low. It thus appears that the apparatus for a fixed light should bend the rays in the vertical plane only, but should not interfere with their natural horizontal divergence in azimuth.

The demands which are made on a light that has to *revolve* are not nearly so great as on one that is fixed, for the revolving light does not, like the fixed, require to illuminate the whole horizon simultaneously, but only each point of it at successive intervals of time. When the dark intervals occur, the rays from the flame which are then pointing in the direction of the dark spaces should therefore have their directions so altered laterally as to pass into the adjoining light spaces and thus to increase the power of the luminous flashes. A revolving light, though supplied by a flame of the same power as a fixed, will thus necessarily be far more intense, as it does not lose its power by diffusing the rays constantly over the whole horizon, but gathers them up into a number of separate bundles or beams of great intensity. The apparatus of a revolving light has consequently more optical work to do than that of a fixed, for the rays must be bent not only in the vertical plane but laterally in the horizontal and in all intermediate planes as well.

In the construction of lighthouse apparatus either metallic or glass agents may be employed, but it has been found by experiments that a great saving of light (about 25 per cent.) is effected when glass only is used. All kinds of apparatus may conveniently be ranged either under the *catoptric system*, where metallic reflexion only is used, the *dioptric* where the material employed is wholly glass producing refraction and total reflexion, or the *catadioptric*, in which both glass and metal are employed.

CATOPTRIC SYSTEM *of Illuminating every Azimuth with Light of equal Power either Constantly or Periodically.*

Passing over the early and rude expedients of such night marks as open coal fires or naked candles placed in glazed lanterns, we shall confine our attention to the gradual development of those optical designs which are now or were lately adopted for lighthouse apparatus.

Parabolic Reflectors.—In 1763, or at latest before 1777, parabolic reflectors were first used for lighthouse illumination by Mr Hutchinson, dockmaster of Liverpool. In his work on *Practical Seamanship*, published in 1777, he states that the Mersey lights were fitted with reflectors (figs. 5 and 6) formed of small facets of silvered

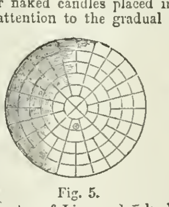

Fig. 5.

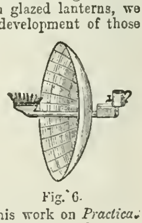

Fig. 6.

glass, and made, as he says "as nearly as they can be to the parabolic curve." This is unquestionably the earliest published notice of the use of parabolic reflectors for lighthouse illumination. Up to 1782 the wicks of the lamps were of a flat form, but in that year Argand introduced wicks and burners of a hollow cylindric form which admitted a central current of air through the burner so as to ignite the cone of gas issuing from the wick both within and without. Rumford afterwards split up the cone of gas into several concentric shells.

"It is remarkable," says Mr J. T. Chance in his excellent memoir (*Min. Ins. Civil Eng.*, vol. xxvi.), "how many inventors have contributed their respective parts to the multiple burner:—Argand, the double current; Lange, the indispensable contraction of the glass chimney; Carcel, the mechanism for an abundant supply of oil; and Count Rumford, the multiple burner, an idea made feasible by these contrivances, and finally realized by Arago and Augustin Fresnel."

Optical Properties of the Parabolic Reflector.—In the parabolic reflector all rays diverging strictly from the focus and falling on the paraboloid emerge in one beam of parallel rays. But as an oil light is not a mathematical point, but an object of considerable magnitude, the rays from the outside of the flame being exfocal will, after reflexion, emerge as a cone whose divergence is directly proportional to the radius of the flame and inversely to the focal distance of the reflector. Its intensity must consequently vary as the squares of the distances from the lighthouse. Optical apparatus does not then prevent that divergence which is due to the flame being of sensible magnitude.

Defects of the Paraboloid.—It will be seen from fig. 7 that the parabolic mirror a is at best but a very imperfect instrument, for even if the radiant were strictly a mathematical point, the cone of rays (shown undotted) escaping past the lips of the mirror must be lost.

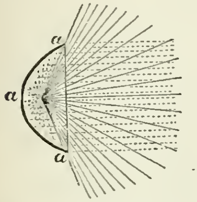

FIG. 7.—Vertical Section.

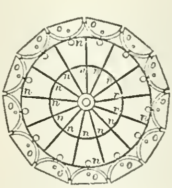

FIG. 8.—Plan.

Mode of Employing Reflectors for Fixed and Revolving Lights.—In order to produce, on the catoptric system, a fixed light showing all round the circle, a number of reflectors (o, o, o, fig. 8) are fixed round the outside of a stationary chandelier n. As the ordinary paraboloid has about 14° of divergence, twenty-five reflectors were needed to light up continuously (though not equally) the whole horizon. If again the light was to revolve, then a revolving chandelier (figs. 9 and 10) was employed having a certain number of flat faces, on each of which was fixed a number of separate lamps and reflectors with their axes parallel to each other. When the chandelier revolved, and one of the flat sides was turned towards the sailor, he would, when at some distance from the shore, receive a flash at once from each of the mirrors which were on that face, but when the face was turned away from him a dark period would intervene until the next face came round again.

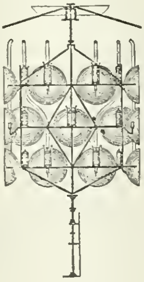

FIG. 9.—Elevation.

Bordier Marcet's Fanal Sidéral, 1819.—In order strictly to equalize a fixed light over the whole horizon, which could not possibly be done with separate reflectors, Marcet proposed this ingenious instrument, which is generated by the revolution of the parabolic profile pp' (fig. 11) round its parameter as a vertical axis, instead of round a horizontal axis, as in all former reflectors. The vertices of the parabola are cut off, so as to permit of a common focus for the flame. The rays will therefore be reflected parallel to the horizontal axis in the vertical plane, while the natural divergence of the light in azimuth will not be interfered with. By this excellent contrivance the light was for the first time spread equally round the horizon in one continuous zone. But even though the radiants were reduced to a mathematical point, very many of the rays (shown in hard lines in the elevation, fig. 11) are allowed to escape past the lips of the reflector, and this loss takes place all round the circle.

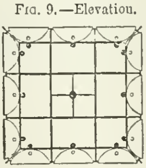

FIG. 10.—Plan.

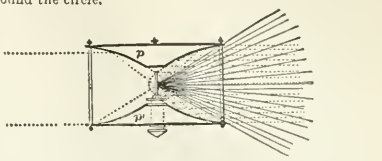

Fig. 11.

DIOPTRIC SYSTEM.

Beginning in 1822, Augustin Fresnel, the eminent physicist and mathematician, entirely revolutionized the previously existing lighthouse system by means of his annular lenses, cylindric refractors, and totally reflecting prisms. Before describing these and their combinations it is necessary to state that the size of the flame produces divergence with lenses as well as with reflectors. The measure of this divergence for any point of the lens is the angle whose sine is

$$\frac{\text{Radius of flame}}{\text{Distance of point from centre of flame}}$$

Fresnel's Optical Agents.

Annular Lens, 1748-1822.—Buffon in 1748 suggested a new form of lens for burning purposes in order to save the loss of heat by absorption of the sun's rays in passing through a thick lens of large size whose outer profile is continuously spherical. He proposed to grind out of a solid piece of glass a lens in steps or concentric zones in order to reduce the thickness to a minimum (figs. 12 and 13). Condorcet, in his *Éloge de Buffon*, in 1773 (Paris edition, 1804, p. 35) proposed the capital improvement of building up Buffon's stepped lens in separate rings, and pointed out that the cutting of the surface into steps had the effect of correcting to a large extent the spherical aberration, or divergence from the parallel, of the rays emitted by any continuously spherical lens. Sir D. Brewster, in 1811, also described the same plan. But both these writers designed their lenses for burning purposes only, and not for operating on light, while all the surfaces of their lenses were spherical. In 1822 Fresnel constructed a built-up lens for lighthouse purposes, in which the centres of curvature of the different rings receded from the axis according to their distance from the centre, so as practically to eliminate spherical aberration, the only spherical surface left being the small central part a (fig. 13). These lenses are used for revolving lights only.

Fresnel's annular lens.

FIG. 12.—Section.

FIG. 13.—Elevation.

Cylindric Refractor.—This instrument was introduced by Fresnel for effecting dioptrically by refraction in front of the flame what had been done before catoptrically by Marcet's reflector by reflexion from behind the flame. It consisted of a zone or hoop of glass (figs. 14 and 15) generated by the revolution round a vertical axis of the middle section of the annular lens just described, which lens, on the other hand, being generated by the same profile round a horizontal axis, parallelized the rays in every plane, whereas the cylindric refractor does so in the vertical plane only.

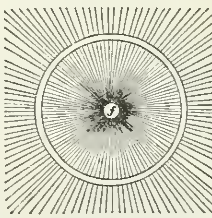

FIG. 14.—Plan.

Totally Reflecting Prisms.—Fresnel next conceived the admirable improvement of employing the principle of "total" or internal reflexion by glass prisms. The ray Fi (fig. 16) falling on a prismoidal ring, ABC, is refracted and bent in the direction iR, and falling on the side AC, at an angle of incidence greater than the critical, is totally reflected in the direction Re, and, impinging on the side BC at e, it undergoes a second refraction, and emerges horizontally. The highest ray FA after refraction by AB and reflexion by AC must (in order to avoid superfluous glass) pass

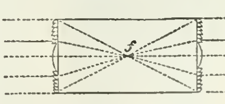

FIG. 15.—Vertical Section.

along AB, and after a second refraction at B emerge horizontally. The lowest ray FB after refraction by AB must, for like reason, pass along BC, and after reflexion by AC and a second refraction by BC also emerge horizontally. Every other ray incident on the prisms between A and B is, after one reflexion and two refractions, emitted horizontally.

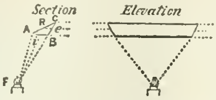

Fig. 16.

Straight Refracting Prism.—Fresnel's straight refracting prism which refracts the rays that fall on it, but in one plane only, requires no further explanation, as it is simply a straight prism of the same horizontal cross section as one of the prisms of his cylindric refractor, so as when placed in front of his fixed apparatus to produce a beam of parallel rays like a lens.

Great Central Lamp.—We will now go on to describe the manner in which Fresnel utilized the four new optical agents which he originated, by first referring to his central burner system. In all lighthouses prior to 1822 the mode of getting up the required power was by employing a sufficient number of separate reflectors, each of which (unless we except Bordier Marcet's mirror) required its own separate lamp. Instead of numerous independent lamps and reflectors, Fresnel used a single lamp which had four concentric wicks, and was fed with oil by a pump worked by clock work. Surrounding this burner was a stationary cylindric refractor for a fixed light, and annular lenses revolving outside of it for a revolving light

Fresnel's Combinations of his Optical Agents.

Cata-dioptric fixed light. *Catadioptric Fixed Light.*—This apparatus (figs. 17 and 18), in which a central burner is used, consists of a dioptric cylindric refractor with zones of silvered mirror above and below similar in profile to Bordier Marcet's reflector. By the adoption of the

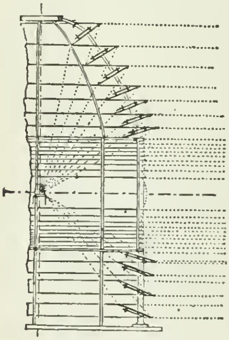

Fig. 17.—Section.

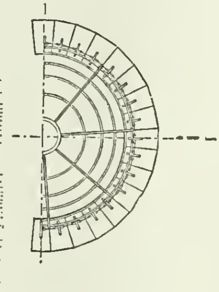

Fig. 18.—Plan.

refractor the whole of the wasteful divergence which occurs in Marcet's reflector is prevented. We have here a geometrically perfect combination, but it is not so physically, because metallic reflexion is used. This physical defect Fresnel obviated in his next design.

Dioptric Fixed Light.—First Application of Total Reflexion to Fixed Lights.—In this apparatus Fresnel substituted his totally

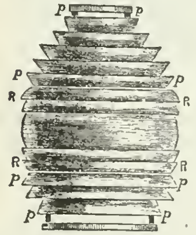

Fig. 19.—Elevation

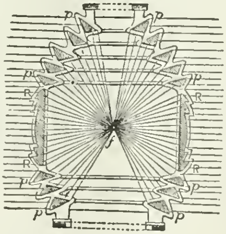

Fig. 20.—Vertical Section.

reflecting prism *p* and lens R for Marcet's reflector, and thus distributed the whole light equally over the horizon by means of dioptric agents alone. This was the first application of total reflexion to lighthouse apparatus, and this beautiful instrument continues till now in universal use. Figs 19 and 20 represent an elevation and section of this apparatus.

Fresnel's Revolving Light.—In this form of revolving light (fig. 21) the central burner is surrounded by annular lenses L, and a compound arrangement of inclined trapezoidal lenses L′ and plane silvered mirrors M. The inclined lenses fit closely to each other and form a pyramidal dome, and the light, intercepted by them, is sent upwards in inclined beams until, falling upon the plane mirrors M, it is sent outwards in horizontal parallelized beams. All these optical agents are made to revolve round the central lamp, and the sailor receives a full flash when the axis of one of the emerging beams passes his eye, and as soon as it passes him he is in darkness until the next beam comes round. This design, unlike that of his fixed light, is imperfect on account of the employment of metallic reflexion, and because two agents are employed for all except the central portion of the rays.

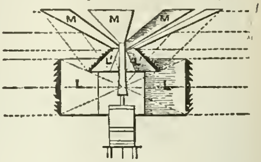

Fig. 21.—Vertical Section.

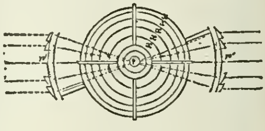

Fig. 22.—Plan.

Fixed light with flashes. *Fixed Light varied by Flashes.*—This distinction (figs. 22 and 23) Fresnel produced by placing his straight refracting prisms *r′* on a revolving frame outside of his fixed light apparatus *rr*, so that when the upright prisms come in line with the observer the light is increased to the power of the revolving light, a broad flash as in the annular lens being produced in place of a narrow strip of rays as in the unassisted fixed light.

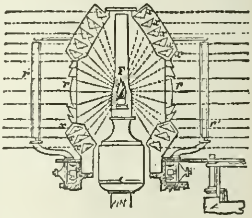

Fig. 23.—Vertical Section.

Alan Stevenson's Improvements.

Alan Stevenson's improvements. Mr Stevenson was the first to introduce the dioptric system into Britain, and in doing so he made the following improvements.

1. *Refractor of a Truly Cylindrical Form.*—Owing to difficulties in construction, Fresnel adopted a polygonal instead of a cylindric form for his refractor, but Mr Stevenson succeeded in getting Messrs Cookson of Newcastle to construct a first order refractor of a truly cylindric form.

2. *Helical Glass Joints for Fixed Lights.*—Mr Stevenson further improved the apparatus by constructing the refractor in rhomboidal instead of rectangular pieces (figs. 24 and 25), thus producing helical joints and preventing serious obscuration of the light in any azimuth.

3. *Helical Metallic Framings.*—The internal metallic frame work for supporting the upper cupola of prisms was also, for the same reason, made by him of a helical form.

4. *Diagonal Framed Lantern.*—The astragals or sash bars of the lantern were likewise made diagonal and constructed of bronze instead of iron in order to reduce their sectional area. A small harbour light with inclined astragals was made in 1836 by Mr E. Sang. Mr Stevenson also prepared a design in 1846 for Start Point, Orkney, in which he extended the helical arrangement to the astragals, but it was never carried out. Mr Douglass independently designed and afterwards carried into practice this form of lantern.

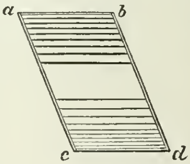

Fig. 24.—Elevation.

Fig. 25.—Vertical Section.

Alan Stevenson's Improved Revolving Light for Skerryvore.—In 1835 Mr Stevenson, in a report to the Northern Lighthouse Board, proposed to add fixed reflecting prisms *p* (fig. 26) below the lenses of Fresnel's revolving light, and he communicated this proposal to M. L. Fresnel, who approved of his suggestion, and assisted in carrying out the design in 1843. This combination added, however, but little to the power of the flash, and produced both a periodically flashing and constantly fixed light; but it must be remembered that the prism for fixed lights was the only kind of reflecting prism then known. The combination of trapezoidal lenses and mirrors was also, for the same reason, still used. The prisms for Skerryvore were the first that were made of the large size (first order), and were constructed by M. Soleil at Paris under the superintendence of Leonor Fresnel, the successor of his brother Augustin, then deceased.

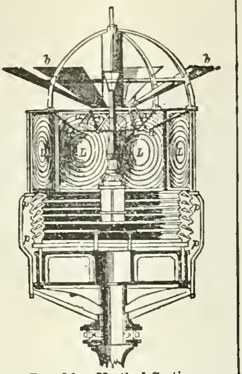

FIG. 26.—Vertical Section.

Besides the designs which have been described for improving Fresnel's revolving light, there were many others, among which may be mentioned those of Leonor Fresnel, Sir David Brewster, W. H. Barlow, F.R.S., A. Gordon, Lepaute, Letourneau, Reynaud, and Tabouret; but in all these, as well as in those which have been described, the rays were either not parallelized in every plane or else unnecessary agents were resorted to for that purpose.

T. Stevenson's HOLOPHOTAL *System.*

lo- tal tem. It was not till 1849-50 that the problem was first solved of condensing the whole sphere of rays diverging from a flame into a single beam of parallel rays without any unnecessary reflexions or refractions.

Catadioptric Holophote.—In figs. 27 and 28 part of the anterior hemisphere of rays is intercepted and at once parallelized by the

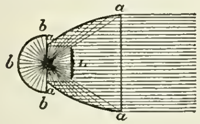

FIG. 27.—Vertical Section.

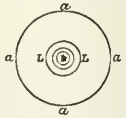

FIG. 28.—Front Elevation.

ta- ptric lo- ote. lens L, whose principal focus (*i.e.*, for parallel rays) is in the centre of the flame, while the remainder is intercepted and made parallel by the paraboloid *a*, and thus the double agents in Fresnel's design are dispensed with. The rays of the posterior hemisphere are reflected by the spherical mirror *b* back again through the focus, whence passing onwards one portion of them falls on the lens and the rest on the paraboloid, so as finally to emerge in union with and parallel to the front rays. This was the first instrument which intercepted and parallelized all the rays proceeding from a focal point by the minimum number of agents. It is therefore geometrically perfect, and was called by Mr Stevenson a holophote, but it is not physically so, for it employs metallic reflexion, and with an ordinary oil flame and burner some of the rays reflected by the spherical mirror would fall upon the burner and be lost. This instrument was first employed at the North Harbour of Peterhead in 1849.

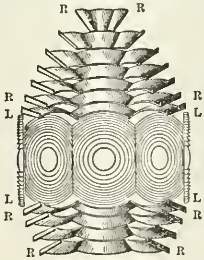

FIG. 29.—Vertical Section.

Holophotal Catadioptric Apparatus Revolving round a Central Flame.—If in place of Fresnel's compound arrangement of trapezoidal lenses and plane mirrors there are substituted mirrors R, R (fig. 29) generated by the revolution of a parabolic profile round a *horizontal* axis, all the light will be at once sent out in parallel beams by them and the lenses L, and the apparatus is therefore geometrically perfect, but metallic instead of glass agents are still employed.

T. Stevenson's Holophotal Dioptric Agents.

The agents for rendering the holophote purely dioptric fall next to be described.

Holophotal Prisms, 1850.—If prisms are generated by the revolution of sections of Fresnel's prisms round a horizontal instead of a vertical axis, as shown in fig. 30, rays incident upon them will be made parallel in every plane instead of in the vertical plane only as in Fresnel's prisms.[1] Holophotal prisms.

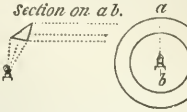

Fig. 30.

In 1852 it was stated that A. Fresnel, in 1826, tried prisms of this kind on lamp-posts for the quays of a canal in Paris, but their use was discontinued. They were not so arranged as to be applicable to lighthouses, and no account of them was published.

Double Reflecting Prisms giving Two Internal Reflexions instead of One, 1850.—The object of these prisms is to reflect the rays back through the focus. The rays from *f* (fig. 31) pass normally through

FIG. 31.—Vertical Section.

the surface *bc* and fall upon the surfaces *ab*, *ac*, by which they are totally reflected and sent back to the flame.[2]

Optical Combinations of Dioptric Holophotal Agents.

Dioptric Holophote with Dioptric Spherical Mirror.—If rings of holophotal prisms *p*, *p* (fig. 32), combined with a central refracting lens L subtending together 180°, be placed before a flame, the whole of the front half of the diverging sphere of rays will be at once condensed by refraction and total reflexion into one beam of parallel rays. Next, if there be placed behind the flame a dome of glass *a* formed of zones generated by the revolution of the cross section of the double reflecting prisms round a horizontal axis, the back hemisphere of rays will, after the double reflexion, be returned by it through the flame so as to diverge along with the front rays; for this dome is a perfect mirror, not only for the faint light that is superficially reflected by the first concave surface, but also for the main portion of the rays which enter the substance of the glass and are there totally reflected. Thus the whole light is parallelized entirely by glass agents. This combination should therefore produce the light of *maximum intensity*, being both geometrically and physically perfect when the radius is a luminous point. Still, some of the rays reflected by the upper and lower parts of the mirror will not clear the burner of an oil light, but falling on it will be lost. Dioptric holophote with mirror.

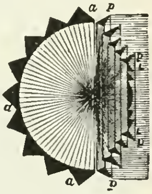

FIG. 32.—Vertical Section.

Dioptric Holophotal Revolving Light.—Application of Total Reflexion to Revolving Lights, 1850.—If sections of the front half of the dioptric holophote be arranged as a polygonal cage round a large central flame and made to circulate round that flame, a revolving light with its periodic flashes will be produced (fig. 33), which is therefore geometrically and physically perfect, and the double agents used in Fresnel's revolving light are thus wholly dispensed with. Mr J. T. Chance says, "on the whole the modern plan (holophotal) must give light five or six times more intense than that of the former (Fresnel's) arrangement." The greater simplicity and compactness of this light may be seen in comparing figs. 21 or 26 with fig. 33. Revolving light.

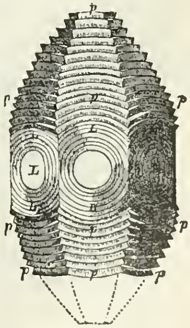

FIG. 33.—Elevation.

The holophotal revolving light is now the only one that is employed for all new lights. It was first introduced in 1850 on the small scale by Messrs Stevenson at Horsburgh Rock, Singapore, and on the larger scale at North Ronaldshay in Orkney, the prisms of which were most successfully made in 1851 by Letourneau of Paris.

[1] *Trans. Roy. Scot. Soc. of Arts*, 1850.
[2] *Ibid.*

Holophotal Fixed Light varied by Flashes.—Fresnel's double agents (figs. 22, 23) are here also dispensed with by the single agency of panels of fixed light apparatus p', p' (fig. 34) and cylindrical refractors L′, L′, alternating with panels of holophotal apparatus p, p, L, L, both of which revolve together round the central burner.

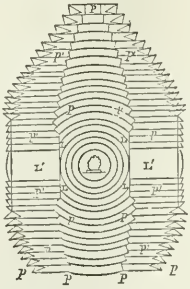

Fig. 34.—Vertical Section.

Back Prisms.—It will be noticed that, while perfection was attained by single agency in Fresnel's *fixed* apparatus and also in the holophotal revolving apparatus, a physical defect still attached to every form of holophote which compressed the light into a single beam where the rays require to be sent back through the flame. The defect is not a geometric one, and would be non-existent were the luminant a mathematical point. In order to remedy this objection, Mr T. Stevenson and Mr Brebner designed what they termed "back" prisms capable of deviating the rays through an angle of 130°, so that the engineer becomes virtually independent of the critical angle. Professor Swan of St Andrews also independently proposed the same kind of prism, accompanied by general formulæ for its construction. The ray ab (fig. 35) is refracted at b, totally re-

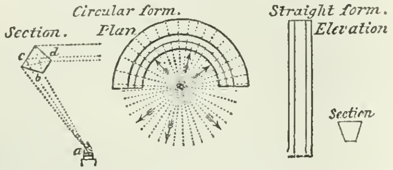

Fig. 35.

flected at c, and again refracted at d, so as to pass out parallel to the horizontal axis. These prisms may be formed by the revolution of the generating section round either a vertical or horizontal axis, or they may be made straight as shown in elevation and section in the diagram. The "back prisms" which were first used in Islay, Argyleshire, were made by Messrs Chance in accordance with Professor Swan's formula.

Perfect form of holophote.

Perfect Form of Dioptric Holophote for an Oil Flame.—By combining the back prisms ga, hc (fig. 36) just described with a semi-holophote abc subtending 180° and a portion of the dioptric spherical mirror ijk, no light is lost on the burner, and all the rays are parallelized, so that this apparatus, being all of glass, is both geometrically and physically perfect.

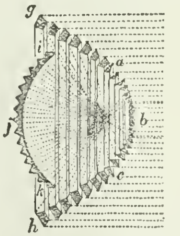

Fig. 36.—Vertical Section.

Chance's improvement.

J. T. Chance's Improvement of 1862 *on Stevenson's Dioptric Spherical Mirror.*—Mr Chance says, "The plan of generating zones round the vertical axis (instead of the horizontal) was introduced by the author, who adopted it in the first

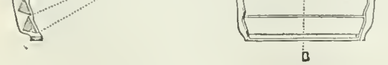

Fig. 37.

complete catadioptric mirror which was made and was shown in the exhibition of 1862 by the Commissioners of Northern Lighthouses, for whom it was constructed, in order to further the realizing of what Mr T. Stevenson had ingeniously suggested about twelve years previously. During the progress of this instrument the idea occurred to the author of separating the zones (fig. 37) and also dividing them into segments like the ordinary reflecting zones of a dioptric light; by this means it became practicable to increase considerably the radius of the mirror and thereby to render it applicable to the largest sea light without overstepping the limits of the angular breadths of the zones, and yet without being compelled to resort to glass of high refractive power."

Mr Stevenson states (*Min. Civ. Eng.*, vol. xxvi.) that he originally intended to generate the prisms round a vertical axis, but adopted the horizontal as more practicable where flint glass which was taken out of the melting pot on the end of a rod had to be employed for the most important and smaller central parts of the apparatus, which at that date were the only ones that could be constructed.

Professor Swan's Designs.—Among several ingenious arrangements and new forms of agents proposed by Professor Swan[1] is the mode of sending rays from prisms through interstices left between other prisms placed in front, and also a form of agent which he termed the triesoptric prism, in which the rays would undergo two refractions and three reflexions. In fig. 38 a are the front and b the triesoptric prisms. The two upper and lower prisms a are constructed of flint glass of high refractive power. It will be observed from the drawing that this ingenious arrangement is nevertheless open to objection, for cones of light of 30° in front and of 65° at the back are lost through the interstices.

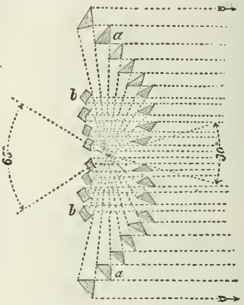

Fig. 38.—Vertical Section.

T. Stevenson's Azimuthal Condensing System *for Distributing the Light Unequally in Different Directions either Constantly or Periodically.*

Previous to 1850 all apparatus was designed to emit light of equal power in every azimuth either constantly or periodically, so that when applied to illuminate seas extending farther in some directions than in others, such, for example, as long narrow sounds, the power was either needlessly great in some azimuths or not nearly strong enough in others. The only exception was where a tower was placed on a long straight coast, when a spherical mirror was fixed behind the flame to prevent the light passing landward. The light that would have been lost on the land was, in this way, sent seawards, but no attempt was ever made to condense the light over a given arc or to allocate this auxiliary light in proportion to the varying lengths of the different ranges and the amplitudes of the arcs over which it had to be seen, nor, where a light had to show all round the horizon, to weaken its intensity in one arc and with the rays so abstracted to strengthen some other arc which from its range being longer ought to be of greater power. As the optical agents which we have described were insufficient for this purpose, it became necessary to devise new agents possessing special optical properties for distributing the rays not equally but equitably. Some of the more important of these agents and their combinations will be described, but before doing so it is necessary to make some preliminary explanations.

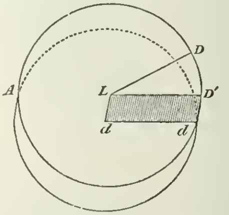

Fig. 39.

The form of the emergent light from condensing apparatus is neither a solid beam of parallel rays like that from an annular lens nor yet a zone of rays diverging naturally in azimuth all round like that from an ordinary fixed apparatus, but is intermediate between these, being a solid angle or wedge of light strengthened by those rays which would naturally diverge in other directions, but which are diverted and spread over the given sector as shown perspectively in plan in fig. 39, in which L represents the position of the lighthouse, LD

[1] "Professor Swan's Designs," *Trans. Roy. Scot. Soc. of Arts*, 1867-68.

the range, or distance at sea from which the light can be seen, and D'ddLD the solid horizontal angle that is to be illuminated and into which all the light DAD' which would naturally diverge over the rest of the circle must be compressed, and over which it must be uniformly spread.

Requirements for FIXED *Condensing Lights.*—1. Where a light has to be seen constantly over only one arc of the horizon, the apparatus must compress all the rays within that one arc whatever its amplitude may be, and spread them uniformly over it.

2. Where the whole horizon has to be constantly illuminated, but the light has to be seen at greater distances over some parts of the sea than over others, as much light must be abstracted as can be spared from the shorter ranges and diverted to the longer so as to allocate the rays in the compound ratio of the number of degrees and the squares of the distances from which the light has to be seen in each arc; and the light thus diverted from one arc to strengthen another must be spread uniformly over the one that has to be strengthened. By this mode of abstraction and addition there is produced a constant equitable distribution over the whole horizon of all the rays from any single flame. Where the whole horizon has not to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be diverted to and spread uniformly over these arcs in proportion to their amplitudes and ranges.

Requirements for REVOLVING *Condensing Lights.*—1. Where a light has to give its flashes periodically over only one arc of the horizon, all the rays must be collected and sent out periodically in solid beams of equal power over that arc.

2. Where the whole horizon has to be periodically illuminated, but where its flashes have to be seen at greater distances over some parts of the sea than over others, the apparatus must be made (as in number 2 of the fixed condensing light) to vary proportionally the power of the flashes whenever they begin to pass over those parts of the sea where the ranges are of different lengths so as to produce an equitable periodic distribution of all the rays.

3. Where the whole horizon has not to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be diverted to and spread uniformly over these arcs so as to strengthen the flashes in proportion to their amplitudes and ranges.

If n be the number of degrees in an arc to be illuminated, and d the distance in miles to be traversed by the light, then, neglecting atmospheric absorption, the quantity of light to be allocated to that arc will be proportional to nd^2; but if we take account of atmospheric absorption, supposing q to be the quantity out of a unit of transmitted light which escapes absorption after passing through a mile of air, then the whole light needed by the arc to be illuminated will be proportional to $m=nd^2q^d$. Supposing now that L is the whole 360° of available light from the apparatus, the quantity to be apportioned to the given arc will be $mL/\Sigma m$, where Σm denotes the sum of the several numbers m computed for the respective arcs of the horizon.

The Principal Optical Condensing Agents.

Condensing Straight Prisms.—These, either by reflexion or refraction or both, cause a ray fr (fig. 40) proceeding in any compass

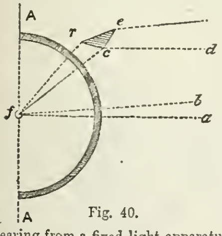

Fig. 40.

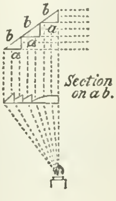

bearing from a fixed light apparatus AA to emerge in the direction, *e.g.*, parallel to the corresponding ray fb, which proceeds in the same compass bearing from another part of the apparatus and so of any other ray fc which is bent parallel to the ray fa.

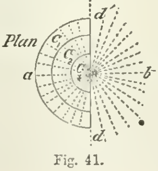

Fig. 41.

Right-Angled Expanding Prisms.—These (fig. 41) are right-angled vertically, while *in plano* two of them C_1C_2 are semi-rings, and the third C_3 a semi-cone. A semi-cylindric beam of parallel rays passing vertically upwards and falling normally on the bases a of the prisms enter the glass, are reflected by the sides b, and pass out horizontally and normally to the other sides; but, as the prisms are bent through a circular segment $d'ad$ *in plano*, the emergent rays will be spread over the same angle in azimuth, and this will be true of any angle in azimuth subtended by the prisms. As those in the diagram subtend 180°, the light will in this case be spread over half the horizon $d'ad$.

FIG. 42.—Section.

Twin Prisms.—These are for carrying out Professor Swan's mode of causing light coming from prisms behind to pass through spaces left for the purpose between others in front. The twin prisms (fig. 42) are formed by cutting out the apex (shown black on diagram) of a straight prism so as to leave a sufficient space between it and the next prism for the passage of rays coming from behind. The length of glass traversed by the rays is lessened by this arrangement, and the size of the apparatus and lantern can at the same time be very greatly reduced.

Differential Lens.—Horizontal divergence may be obtained to any required amount by varying the radius of curvature of the inner face of an annular lens. The outer face (fig. 43) is the same as that of an ordinary annular lens, while the other face (fig. 44), though straight in the vertical, is ground to the required curve in the horizontal plane. The rays $f'fc$ (fig. 45) falling upon the lens x converge to the vertical focal plane ff' and afterwards diverge through the smaller horizontal angle $x'f'x'$, and so for any other case.

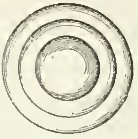

Fig. 43.

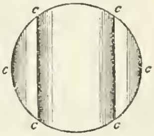

Fig. 44.

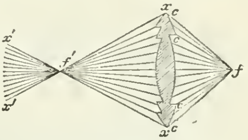

FIG. 45.—Horizontal Section.

Differential Refractor.—This is the application to the cylindric refractor of the same principle which has been described above for the ordinary annular lens.

Condensing Catoptric Spherical Mirror.—If a large arc of a spherical mirror be cut opposite to a short range of sea, and a smaller arc be cut in the mirror opposite to the longer range which has to be strengthened, then the light passing through the larger cut is received on an elliptic reflector placed behind, so as, with the help of an additional reflector and lens, to cause the larger cone of rays to be compressed into the smaller arc which has to be strengthened. Spherical mirror

Spherical Mirror of Unequal Area.—This mirror is cut down in height in such a way that its different heights represent inversely the different distances of the neighbouring land from the lighthouse, so as to reflect less light in the shorter and more in the longer ranges.

Application to Fixed Condensing Apparatus.

Fixed Condensing Light for a Single Sector, 1850.—The holophote pLp (fig. 46) throws its whole light on straight condensing prisms c, each of which distributes the rays over the required sector. Light for single sector.

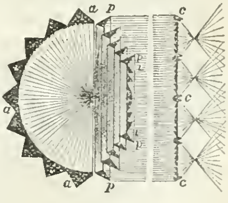

FIG. 46.—Vertical Section.

Condensing Apparatus for Steamers' Side Lights.—By means of this application of the condensing principle (figs. 47 and 48) all the light can be distributed with strict equality over 112° 30', which is the arc prescribed for steamers by the Board of Trade. Several of the Transatlantic and other steamers have adopted this kind of apparatus, which is hung on gimbals and placed in iron towers, having an entry from below the deck, which can be made use of in bad weather.

Condensing Quadrant.—The fixed apparatus bbb, with spherical mirror behind, throws its rays directly through the angle of 90° afa', while the supplementary rays falling on the straight condensing prisms p, p, p', p' (fig. 49) are sent out parallel to the corresponding rays in the unobstructed central quadrant of the main apparatus. The whole light will therefore be condensed equally over 90°. Condensing quadrant.

Condensing Octant.

Condensing Octant.—The central fixed apparatus *bb* (figs. 50, 51) with spherical mirror *dd* throws its rays directly over the angle of 45° *pgp*, while the supplemental rays fall upon the straight condens-

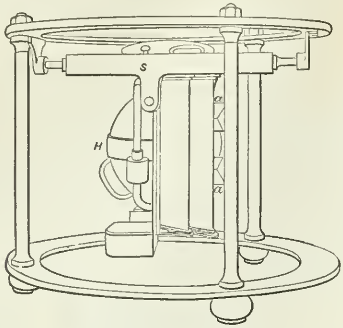

FIG. 47.—Side Elevation.

ing prisms *p*, each of which spreads the incident rays parallel to the corresponding rays in the central angle *pgp*. In this way the whole of the front hemisphere of rays is parallelized in the vertical

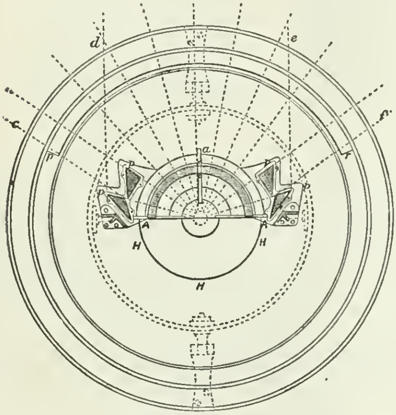

FIG. 48.—Horizontal Section.

plane and spread equally over the 45° in azimuth. The hemisphere of back rays is condensed into the same arc seawards by the dioptric spherical mirror, which returns the rays incident upon it through

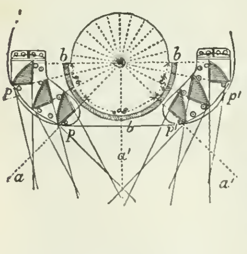

FIG. 49.—Horizontal Section.

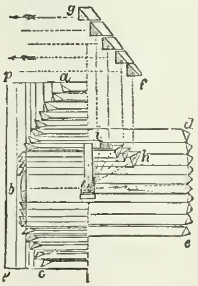

FIG. 50.—Vertical Elevation.

the flame, where mingling with the front rays they are finally distributed over the arc of 45°. The light passing above the spherical mirror is parallelized by a half holophote *ih* (fig. 50), and sent vertically upwards, when, falling on the expanding prisms *gfe*, it also is finally spread over the required arc. Thus the whole light is condensed and distributed with strict equality over the 45° by means of six different optical agents. Two apparatus of this kind form the leading lights to the River Tay.

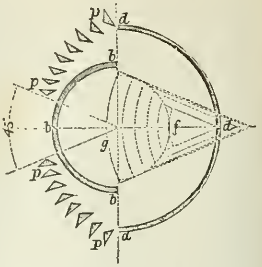

FIG. 51.—Horizontal Section.

Condensing Twin Prism Light.—Fig. 52 shows part of the Lamlash light in the Firth of Clyde. Its action will be easily understood by the numbers shown on the diagram.

Fixed Condensing Lights for more than one Sector of Unequal Range.—Fig. 53 is a chart of the Sound of Glenelg, in which the Isle Oronsay light has to be seen generally at a distance of 3 or 4 miles across the Sound, but in the direction AB down the sound an angle of 10° has to be seen about 15 miles and

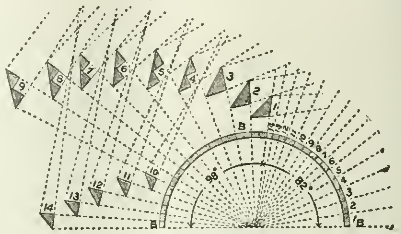

FIG. 52.—Horizontal Section.

another up the sound between C and D an angle of 10° has to be seen about 7 miles. Fig. 54 shows in plan the apparatus, which was for certain local reasons not constructed according to the

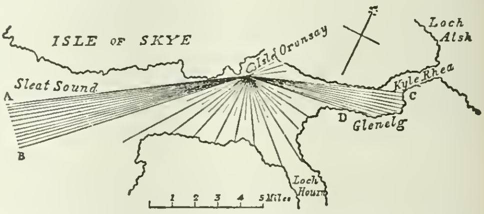

Fig. 53.

formula, but 193° of the spare light which would otherwise have fallen upon the land were allocated down Sleat Sound and 139 down the Sound of Glenelg. That for Sleat Sound was given

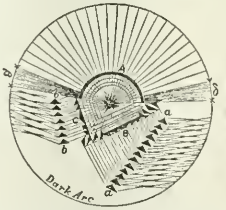

FIG. 54.—Horizontal Section.

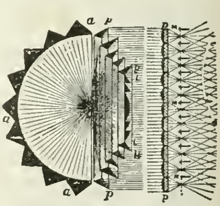

FIG. 55.—Vertical Section.

directly by the main apparatus through the arc δ, and that to Glenelg through the arc β, but these arcs were respectively strengthened by portions of the holophotes B and C, the light from which was condensed respectively over the arc δ by each of the straight prisms *a* and over the arc β by each of the prisms *b*. The condensed light at Isle Oronsay, which is of the fourth order, appears to be equal to that of a first order, so that with a lamp consuming annually only 170 gallons of oil a light is obtained in the only direction in which great power is required equal in effect to a lamp consuming 800 gallons per annum.

Fixed Condensing Lights of Unequal Range which constantly Illuminate the whole Horizon.—For this purpose the condensing spherical mirror or spherical mirror of unequal area will be found applicable.

Revolving or Intermittent Lights for Condensing the Rays into one Sector.—The holophote in fig. 55 throws its rays on straight condensing prisms P, each of which spreads the light over the prescribed sectors, while masks M turning horizontally on pivots cut off the light either slowly or suddenly so as to produce a revolving or an intermittent light, both of which condense all the rays uniformly over the one sector.

Application of Condensing Principle to Revolving Lights of Unequal Range, which do not Illuminate the whole Horizon.

Repeating Light.—Plane mirrors M (fig 56) revolve on an endless chain placed outside of the apparatus and alter the direction of the flashes after they pass into the dark arc on the landward side so as to cause the lenses L, L to repeat their flashes over the seaward arc which requires strengthening. The condensing spherical mirror and mirror of unequal areas will also be found applicable in cases where the flashes do not require to sweep over the whole horizon.

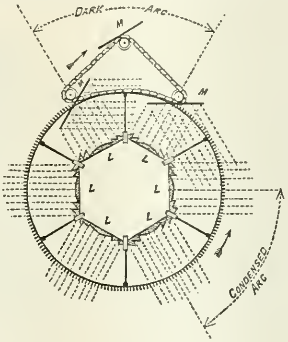

Fig. 56.—Horizontal Section.

olv- ts. ts. *Condensing Revolving Lights which Periodically Illuminate the whole Horizon, but which Vary the Strength of the Flashes in Passing over Certain Sectors.*—The spherical mirror of unequal areas and the condensing mirror are equally well suited for those that revolve.

er- tent its. *Condensing Intermittent Lights.*—Figs. 57 and 58 show straight refracting or reflecting prisms, which revolve and intercept as they pass round certain of the rays from a central fixed light apparatus so as to produce perfect darkness over the sectors which they subtend at the time, while they spread the rays which they intercept uniformly over and thus strengthen the intermediate sectors which are illuminated directly by the central apparatus. The peculiar property of this arrangement is that the power is increased in proportion to the duration of the intervening periods of darkness. Thus, neglecting the loss by absorption, &c., the power is doubled when the periods of light and darkness are equal, trebled when the dark periods are twice as long as the light, and so on in proportion, while in every case the rays are spread uniformly over each illuminated sector.

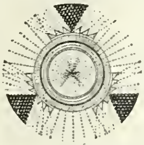

Fig. 57.—Horizontal Section.

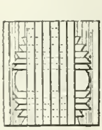

Fig. 58.—Elevation.

Intermittent Condensing Light with Differential Refractor.—Figs. 59 and 60 show the new apparatus of Mull of Galloway in which ABA is the differential refractor, by the compound horizontal and vertical action of which single agent the whole condensing intermittent effect is produced, so that condensing prisms are done away with opposite the central, which is the most important, part of the apparatus. The centre of the inner curve of the refractor is at O in fig. 60. Though there is no relative motion in this apparatus, every part of which revolves together, the parts may be arranged so that the condensers only move. This apparatus was constructed in the most satisfactory manner by Messrs Barbier & Fenestre, Paris.

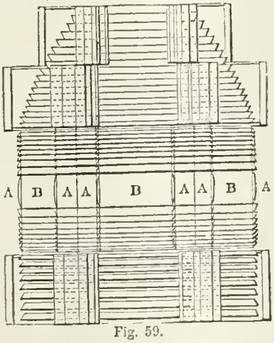

Fig. 59.

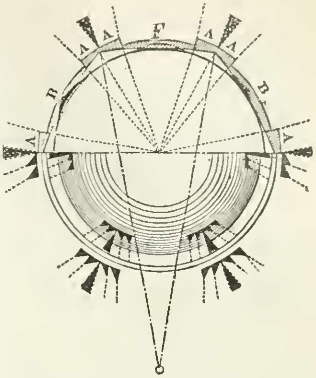

Fig. 60.

Alteration of Fixed to Intermittent Apparatus.—Any existing fixed light can at once be made intermittent so as to show either equal or unequal periods by simply causing condensing prisms to circulate round it, while the power will be increased in proportion to the ratio of the duration of light to dark periods.

Beacons and Buoys.

Beacons in exposed situations are constructed sometimes of stone, and cement-concrete or cement-rubble, but generally of cast-iron columns let into heavy base plates which are fixed to the rock by strong lewis bats. The small class iron beacons are generally of malleable iron and the larger of cast-iron, but steel or bronze might with advantage be used in very exposed places. Fig. 61 shows a first order cast-iron beacon as used in Scotland. Beacons

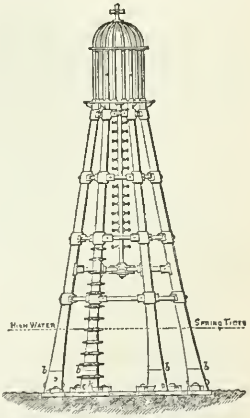

Fig. 61

T. Stevenson's Apparent Light.—This kind of light is specially useful at places where there is a sunk rock with little sea-room round it, and at the pierheads of harbours which must be closely hugged by vessels seeking entrance. It consists of certain forms of optical apparatus for reflecting and redistributing at a beacon placed on a submerged rock parallel rays which proceed from a lamp and apparatus placed on the land. An optical deception is thus produced, as the sailor naturally supposes that there is a lamp burning on the beacon itself. The first light of this kind, which has been in use since 1851, was placed in a beacon on a sunk reef in Stornoway Bay, and is shown pictorially in fig. 62. This light is 530 feet distant from the lighthouse where the lamp is placed. Others have since been established at Grangemouth, which is 535 feet from the light, and at lesser distances at the harbours of Ayr and Arbroath, at Odessa in the Black Sea, and at Gat Combo Head, Queensland. Apparent light.

Beacon Lights.—Lamps without glass chimneys, as used in the early experiments with paraffin, and as used with gas in Pintsch's buoy, having iron tubes placed at certain distances above the flame, and supplied with very large cisterns of crystal oil, have been kept continuously burning in Scotland for about a month without trimming. These lamps are for rocks at sea which can only be reached when the weather is moderate.

Illumination of Beacons by Gas to Produce a Fixed Light.—A light near Port-Glasgow has been illuminated by gas since 1861. The tower is about 300 feet from the shore, and the supply and pressure of gas are regulated by self-acting arrangements on the shore.

Pintsch's Gas Illuminated Buoy for Producing a Fixed Light.—These buoys are gas and water tight, and are charged to a pressure

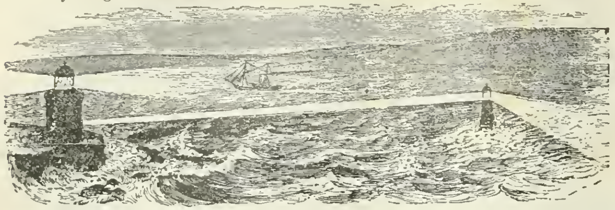

Fig. 62.

of ten atmospheres. The buoy is filled with gas sufficient to burn night and day for three or four months; the burning pressure is kept constant by Pintsch's regulator. These buoys promise to be of great service, and have now been in use for more than a year at several places both in England and Scotland.

Automatic Meter for Producing Intermittent Lights by the Flow of the Gas.—In order to distinguish one buoy or beacon from another, Mr T. Stevenson has proposed to make the flow of the gas itself produce automatic intermittent action without using clockwork. The full flame continues to burn until the action of the meter reduces the supply, but leaves a small jet still burning in the sockets of the burner till the full flame is again produced. This meter has been tried successfully on shore for twenty-eight hours consecutively.

Uniform system of beacons.

Uniform System of Beacons and Buoys.—The first proposal for dealing systematically with the colours of beacons and buoys was in 1828 when Mr R. Stevenson proposed for the navigation of the

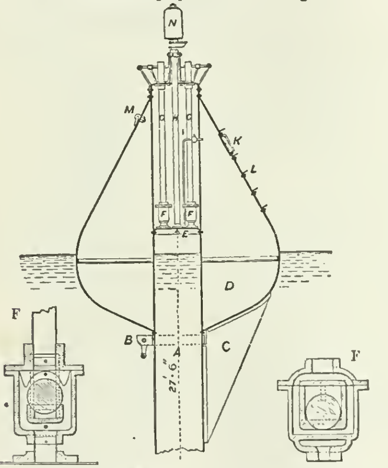

Fig. 63.—Courtney's Automatic Buoy. A, cylinder, 27 ft. 6 in. long; B, mooring shackle; C, rudder; D, buoy; E, diaphragm; F, ball valves; G, air inlet tubes; H, air (compressed) outlet tube to whistle; I, compressed air inlet to buoy; K, manhole; L, steps; N, whistle.

river Forth that red buoys should be taken on the starboard and black on the port side in going up the river. This system has since been adopted generally in the United Kingdom. In 1857 Admiral E. J. Bedford suggested a uniform system for all the coasts of the country, which was carried out in Scotland by Mr A. Cuningham. A different uniform system has been adopted in England by the Trinity House. In 1859 Mr J. F. Campbell suggested what is undoubtedly the best system, that a buoy shall indicate by its shape and colour the compass direction in which a vessel should sail after seeing the buoy.

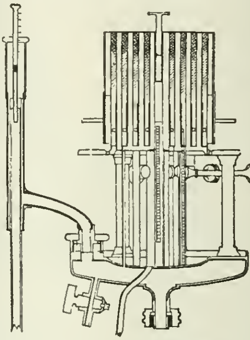
Courtenay's Automatic Buoy.—This useful form of buoy (fig. 63) first used in America, has a cylindric tube A projecting below the level of the water, on the upper part of which cylinder there is a whistle N and also two inlet valves F, F, so that the rising and falling of the buoy draws in and expels the air alternately which sounds the whistle. It is said that an undulation of even 12 inches is sufficient to sound the whistle.

Tolling bells by tide.

Tolling of Bells by the Hydrostatic Pressure of the Tide.—In 1810 Mr R. Stevenson designed apparatus for tolling a bell on the Carr Rock beacon, which was to have been effected by a float when ascending with the pressure of the flowing tide, when descending with the fall of the ebb tide and by means of a peculiar arrangement of weights for keeping the bell in action during the time of slack water.

Illuminants.

After Argand's ordinary single-wick oil burner, Fresnel still adhering to Argand's principle of the double air current introduced two, three, and four concentric wick burners, Mr Alan Stevenson the five, and Mr Douglass the six wick burner. These burners are suitable for the consumption of animal and vegetable oils, which were in use in the various lighthouse services of the world till within the last few years. These oils are, however, superseded by hydrocarbons, which at one half the cost give an increased luminous intensity for an equal consumption, but they require a larger supply of air for their combustion, and consequently an improved form of burner. M. Maris in 1856 devised a single-wick burner for this purpose which gave good results, but many and all attempts to construct a multiple-wick mineral oil burner failed till 1868, when Captain Doty's form was devised.



By a happy choice of proportions in the various parts of his burner (fig. 64), and by the addition of an exterior cylinder surrounding the outer wick, and a central disk, both placed in such a manner as to throw a current of air into the flame at the right place, Captain Doty succeeded in producing single and multiple-wick hydrocarbon burners, which carry a flame of great luminous intensity and regularity. The following table gives the details of these burners, and also the candle power and consumption, as determined by Dr Stevenson Macadam :—

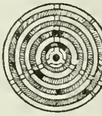


Fig. 64.

Number of Wicks.	Mean Diameter of Outer Wick in Inches.	Height of intense part of Flame, excluding Tails, in Inches.	Candle Power in Sperm Candles, each consuming 120 grs. Sperm per Hour.	Value of Light from Consumption of 1 Gallon in lb Sperm.	Consumption per Hour in Gallons.
1	·82	1	23·65	27·39	·0148
2	1·75	$1\frac{1}{2}$	80·13	27·04	·0508
3	2·5	$1\frac{3}{4}$	200·75	27·2	·1262
4	3·2	2	287·62	27·3	·1801

Mr J. N. Douglass has also introduced a mineral oil burner, which, however, Doty claims as similar in principle to his. By igniting only half the number of wicks (the outer in a six-wick for instance) the power of the burner can be diminished by one half. This is Mr Douglass's lamp of single and double power for use in clear and foggy weathers respectively.

The mineral oil employed most extensively in lighthouse illumination is Scotch paraffin. The specific gravity, which is a test of the relative richness of the oil, should be from 0·8 to 0·82 at 60° Fahr., and the flashing point or temperature at which it begins to evolve inflammable vapour should not be lower than 125° nor higher than 135° Fahr. The Board of Northern Lighthouses was the first lighthouse authority in Britain that adopted paraffin and Doty burners, and by doing so an annual saving of between £4500 and £5000 in the maintenance of the lights on the Scotch coast was effected.

Single-wick burners are supplied with oil from the cistern by the capillary action of the wick alone. But in the case of multiple-wick burners other methods must be employed to secure a sufficient supply. If the cistern be placed above the level of the top of the burner, the flow of the oil to the wick cases is effected by the direct action of gravity, regulated by a contrivance which maintains a constant head. If, however, the cistern be placed below this level, either a *mechanical* lamp is employed, in which the oil is forced into the burner by pumps worked by clockwork, or a *moderator* lamp, in which this is effected by the pressure exerted by a weighted piston descending in a cylinder forming the cistern.

Coal-Gas.—Coal-gas was first used as a lighthouse illuminant at Salvore, near Trieste, in 1817. For many years it has been used in the harbour lights of Great Britain when in the neighbourhood of gas-works. Mr J. R. Wigham has designed a compound or crocus burner consisting of a group of twenty-eight vertical tubes, each carrying an ordinary double fish-tail burner, and the ignited gases issuing from all these jets unite into one large flame. Additional groups of twenty jets each can readily be arranged around the first, which forms a central nucleus, and in this way, depending on the state of the atmosphere, the power of the burner can be made at will 28, 48, 68, 88, or 108 jets. Fig. 65 shows the arrangement

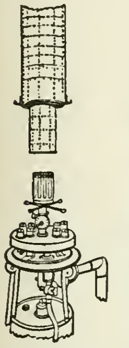

Fig. 65.

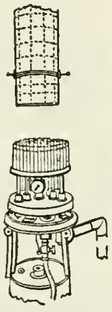

Fig. 66.

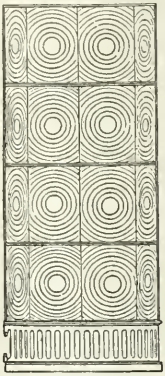

Fig. 67.

for 28 jets, and fig. 66 one for 108 jets. In his triform or quadriform systems Mr Wigham places two, three, or four of the burners already described vertically one above the other (fig. 67), with lenses opposite to each. The following table gives the candle powers, &c., of Mr Wigham's burners.

Number of Jets.	Consumption of Cannel Gas per Hour.	Candle Power in Sperm Candles, consuming 120 grs. per Hour.
28	51·4	429·8
48	93·2	882·0
68	146·3	1250·18
88	244·0	2408·0
108	308·0	2923·0

The diameter of the 108-jet burner is 12 inches.

Faraday and Holmes's Magneto-Electric Light.—In 1853 Professor Holmes made the first magneto-electric machine for lighthouses, which was tried by the Trinity House in 1857, and the electric light was first shown to the mariner in 1858. The Trinity House subsequently introduced it at Dungeness in 1862 and at Souter Point in 1871. The optical apparatus for these lights was designed by Mr J. T. Chance. In 1869 Holmes constructed for the Trinity House a dynamo-electric machine (in which no permanent magnet is used), giving a light of about 2800 candles. The magneto-electric light of Holmes as exhibited from a third order dioptric apparatus at the South Foreland light has been estimated at 152,000 candles, or twenty times that of the old first order dioptric fixed white light. The following table shows the results which have been obtained by Dr Tyndall and Mr Douglass by the magneto-electric and dynamo-electric machines, tried at the South Foreland, 1876–77 :—

Name of Machines.	Cost.	HP. absorbed.	Revolutions per Minute.	Light produced per HP. in Standard Candles.		Order of Merit.
	£			Max.	Mean.	
Holmes's Magneto-Electric............	550	3·2	400	476	476	6
Alliance do.	494	3·6	400	543	543	5
Gramme Dynamo-Electric (No. 1)..	320	5·3	420	1,257	758	4
Do. do. (No. 2)..	320	5·74	420	1,257	758	4

Do. do. (small, No. 58)	100	3·5	850	1,582	954	2
Do. do. (small, No. 68)	100	3·3	850	2,080	1,254	1
Two Holmes's Magneto-Electric	1,100	6·5	400	432	432	...
Two Gramme Dynamo................	640	10·5	420	1,085	654	...
Two Siemens's do. (small, Nos. 58 and 68)	200	6·6	850	2,141	1,291	...

It must be kept in view that in the electric as well as in every other light the following requirements must be fulfilled:—(1) it shall be constantly in sight during those periods of time at which it is advertised to the mariner as being visible; (2) it shall be seen as far as possible in a thick and hazy atmosphere; (3) it shall constantly maintain the distinctive character of the station where it is employed so as not to be mistaken for another light; and (4) when revolving, its flashes shall remain long enough in view to let the sailor take the compass bearing of the light. The electric light practically fulfils all these conditions, and, when we consider its transcendent intensity, and the smallness of the luminous radiant which enables the engineer to adapt it to any required conditions far more strictly than oil light, we may certainly conclude that the electric is the best though the most costly of all illuminants.

The only question which has not yet been decided is whether an electric light of equal initial power will penetrate a hazy atmosphere as far as an oil light. Experiments made at Edinburgh in 1866 seemed to show that the highly distinctive flash of the electric light when acted on by optical apparatus is perhaps not so much due to a greater amount of light as to the more complete parallelism of the rays arising from the smallness of the radiant. The apparatus of a small size which was first used both in England and France necessarily produced a wasteful vertical divergence, and has therefore been now justly discarded.

Allard's Statistics of Lighthouse Apparatus.

The following useful formulæ are taken from M. Allard's very valuable *Mémoire sur l'Intensité et la Portée des Phares*, Paris, 1876. Allard's statistics

Consumption of Oil in Relation to Diameter of Burner.—If c denote the consumption of mineral oil in grammes per hour, d the diameter of the burner in centimetres, then

$$c = 4{\cdot}9d^{2\cdot22}.$$

Luminous Intensities.—A Carcel burner consuming 40 grammes of colza oil per hour being taken as unity, if I denote the intensity for mineral oil in a burner of diameter d in centimetres, then

$$\mathrm{I} = 0{\cdot}22d^{2\cdot1}.$$

Luminous Intensities of Apparatus.—Loss due to Reflexion, Absorption, and Framing of Apparatus.—The loss due to surface reflexion on entering and leaving the glass may be valued at ·050, ·052, ·058, ·075, ·120, ·230, for angles of incidence respectively of 0°, 15°, 30°, 45°, 60°, 75°. In totally reflecting prisms the luminous ray suffers three deviations instead of two, therefore the above values should be multiplied by $\frac{3}{2}$.[1]

The loss by absorption in the glass, although properly given by an exponential formula, may, with sufficient accuracy, be taken as ·03 per centimetre of glass traversed.

The loss due to the horizontal joints of the lenses, and to the intervals between the reflecting rings, varies from ·02 to ·03, or from ·01 to ·04, in passing from the first to the fifth order.

Coefficients.—These are the ratios in which the intensity of the lamp is increased by the apparatus. Where m is the coefficient, f the focal distance, d the diameter, and h the height of flame in a fixed light apparatus, they can, if expressed in centimetres, be calculated from the formula—

$$m = \tfrac{2}{3}\left(\frac{f}{\sqrt{d}}\right)^{1\cdot15},\ \text{or}\ m = 2{\cdot}12\left(\frac{f}{h}\right)^{1\cdot15}.$$

Annular Lens.—The intensity of an annular lens is obtained by multiplying that of the corresponding fixed light by $\frac{3}{4}\frac{\phi}{a}$ where ϕ is the angle subtended by the annular lens, and a the horizontal semi divergence. The intensity of light from an ordinary fixed light apparatus is increased 38 per cent. by the use of the dioptric spherical mirror.

Distinctions of Lights.

The most important characteristic distinctions of lights are the following—(1) The *fixed light.* Two of these are sometimes shown at different heights from the same tower. (2) The *revolving light,* which at equal and comparatively long periods comes slowly and gradually into full power, and then as gradually disappears. (3) The *flashing light,* which at short periods (such as a few seconds) comes very quickly, though gradually, into full power, and as quickly and gradually fades away, was first introduced by the late Mr Robert Stevenson in 1825. (4) The *coloured light,* which is obtained by using coloured media, and was first employed by Mills of Bridlington. (5) The *intermittent light,* introduced by the late Mr R. Stevenson in 1830, which bursts instantaneously into full power, and after remaining as a fixed light for a certain length of time is as suddenly eclipsed and succeeded by a dark period. When the periods are very short the intermittent is now

[1] This result as to total reflexion is not in accordance with the experiments of Professor Potter, which, however, were made with a very finely polished prism made for optical purposes.

called an occulting light. (6) The *intermittent light of unequal periods*, first proposed by Mr R. L. Stevenson in 1871, showing from the same apparatus different durations of the dark periods with equal periods of light, such as fixed for 2″ eclipsed 5″, fixed 2″ eclipsed for 2″, and then, as at first, fixed for 2″. (7) *Group flashing light.* This distinction consists in giving a series of groups of two or more flashes separated by short eclipses, the groups being separated from one another by a larger eclipse. Mr Wigham of Dublin first proposed this distinction, and applied it to a dioptric revolving apparatus illuminated by gas, the effect being produced by raising and lowering the gas as Mr Wilson of Troon had done in 1827. Dr Hopkinson produced the same effect optically and for any illuminant by altering the arrangement of the ordinary revolving apparatus. (8) *Fixed lights illuminating the whole horizon, but showing revolving or intermittent characteristics over small arcs.* These can be produced by masks arranged like venetian house blinds placed opposite the arc where the characteristic is to be different from the main light. This arrangement and No. 9 were lately proposed by Mr T. Stevenson. (9) *Intermittent flashing light.* This is produced by condensing prisms revolving round a fixed light apparatus. The flashing light continues giving its rapidly recurring flashes for a certain period, which is succeeded by a dark period. The light which is not required during the dark periods is condensed by the prisms so as to strengthen the light periods.

Uniform System of Characteristics.—Various modes of distinguishing lights have been at different times proposed, such as Babbage's, which represented the stations by numbers, and Sir W. Thomson's by the Morse alphabet, or dots and dashes; but the following results seem to show that the present system is satisfactory, while it is free from many objections to which the other modes are liable. The Board of Trade records of shipwrecks show that during the space of twenty years (1857 to 1876) 2716 vessels were wrecked by stranding on the coasts and islands of Scotland and the Isle of Man, and that of all these there were only twenty-six, and the great majority of them were small vessels, in which it was even *alleged* that the cause was a failure in identifying the distinctive characteristic of some one of the Northern lighthouses, and in one-third of these cases the sailors were foreigners, and made such glaring mistakes as taking a fixed for a revolving light. It is surely more probable that in many of these cases they did not confound the characteristics at all, but really did not know what they were. But, waiving all these considerations, there were after all only about 1 per cent. of all the wrecks which were *alleged* to have been caused by mistaking one light for another.

Power of Coloured Lights.—Experiments, and particularly those of M. Reynaud, have shown that red of the same initial power as white penetrates a fog to a greater distance than the white, owing to the red rays not being so much dispersed by refraction. Experiments made at Edinburgh in 1868 show that a light should, before passing through red glass, have four and a half times the initial power of a white light. The same results have since been obtained by M. Allard of Paris.

An objection to all coloured lights is the fact that some persons are unable to detect any difference between certain colours. According to the experiments of Professor Holmgren on from sixty to seventy thousand persons in Europe and America, about 4·2 per cent. are congenitally colour-blind, and the commonest form of this defect is inability to distinguish between red and green, which are the only tints employed for lighthouse distinctions. This objection, however, must gradually lose its weight, as the Board of Trade has now adapted the "colours test" as part of their examinations for certificates in navigation.

Distribution of lights.

Distribution of Lights on a Coast.—Mr Alan Stevenson gives the following as a few of the chief considerations which should guide us in the selection of sites and characteristic appearance of the lighthouses to be placed on a line of coast.

"1. The most prominent points of a line of coast, or those first made on *over-sea* voyages, should be first lighted; and the most powerful lights should be adapted to them, so that they may be discovered by the mariner as long as possible before his reaching land.

"2. So far as is consistent with a due attention to distinction, revolving lights of some description, which are necessarily more powerful than fixed lights, should be employed at the outposts on a line of coast.

"3. Lights of precisely identical character and appearance should not, if possible, occur within a less distance than 100 miles of each other on the same line of coast which is made by over-sea vessels.

"4. In all cases the distinction of colour should never be adopted except from absolute necessity.

"5. Fixed lights and others of less power may be more readily adopted in narrow seas, because the *range* of the lights in such situations is generally less than that of open sea-lights.

"6. In narrow seas also the distance between lights of the same appearance may often be safely reduced within much lower limits than is desirable for the greater sea-lights. Thus there are many instances in which the distance separating lights of the same character need not exceed 50 miles; and peculiar cases occur in which even a much less separation between similar lights may be sufficient.

"7. Lights intended to guard vessels from reefs, shoals, or other dangers should, in every case where it is practicable, be placed *seaward* of the danger itself, as it is desirable that seamen be enabled to *make* the lights with confidence.

"8. Views of economy in the first cost of a lighthouse should never be permitted to interfere with placing it in the best possible position; and, when funds are deficient, it will generally be found that the wise course is to delay the work until a sum shall have been obtained sufficient for the erection of the lighthouse on the best site.

"9. The elevation of the lantern above the sea should not, if possible, for sea-lights, exceed 200 feet; and about 150 feet is sufficient, under almost any circumstances, to give the range which is required. Lights placed on high headlands are subject to be frequently wrapped in fog, and are often thereby rendered useless, at times when lights on a lower level might be perfectly efficient. But this rule must not, and indeed cannot, be strictly followed, especially on the British coast, where there are so many projecting cliffs, which, while they subject the lights placed on them to occasional obscuration by fog, would also entirely and permanently hide from view lights placed on the lower land adjoining them.

"10. The best position for a sea-light ought rarely to be neglected for the sake of the more immediate benefit of some neighbouring port, however important or influential; and the interests of navigation, as well as the true welfare of the port itself, will generally be much better served by placing the sea-light *where it ought to be*, and adding, on a smaller scale, such subsidiary lights as the channel leading to the entrance of the port may require.

"11. It may be held as a general maxim that the fewer lights that can be employed in the illumination of a coast the better, not only on the score of economy, but also of real efficiency. Every light needlessly erected may, in certain circumstances, become a source of confusion to the mariner; and in the event of another light being required in the neighbourhood, it becomes a *deduction* from the means of distinguishing it from the lights which existed previous to its establishment.

"12. Distinctions of lights, founded upon the minute estimation of intervals of time between flashes, and especially on the measurement of the duration of light and dark periods, are less satisfactory to the great majority of coasting seamen, and are more liable to derangement by atmospheric changes, than those distinctions which are founded on what may more properly be called the *characteristic appearance* of the lights, in which the times for the recurrence of certain appearances differ so widely from each other as not to require for their detection any very minute observation in a stormy night. Thus, for example, flashing lights of five seconds' interval, and revolving lights of half a minute, one minute, and two minutes, are much more characteristic than those which are distinguished from each other by intervals varying according to a slower series of 5″ 10″, 20″, 40″, &c.

"13. Harbour and local lights, which have a circumscribed range, should generally be fixed instead of revolving; and may often, for the same reason, be safely distinguished by coloured media. In many cases also, where they are to serve as guides into a narrow channel, the leading lights which are used should, at the same time, be so arranged as to serve for a distinction from any neighbouring lights."

Table of Distances at which Objects can be seen at Sea, according to their respective elevations, and the elevation of the eye of the observer.

Heights in Feet.	Distances in Geographical or Nautical Miles.	Heights in Feet.	Distances in Geographical or Nautical Miles.	Heights in Feet.	Distances in Geographical or Nautical Miles.
5	2·565	70	9·598	250	18·14
10	3·628	75	9·935	300	19·87
15	4·443	80	10·26	350	21·48
20	5·130	85	10·57	400	22·9
25	5·736	90	10·88	450	24·33
30	6·283	95	11·18	500	25·65
35	6·787	100	11·47	550	26·90
40	7·255	110	12·03	600	28·10
45	7·696	120	12·56	650	29·25
50	8·112	130	13·08	700	30·28
55	8·509	140	13·57	600	32·45
60	8·666	150	14·22	900	34·54
65	9·249	200	16·22	1000	36·28

Example.—A tower 200 feet high will be visible 20·66 nautical miles to an observer whose eye is elevated 15 feet above the water; thus, from the table:—

15 feet elevation, distance visible 4·44 nautical miles.

Floating Lights.

Prior to 1807 the only kind of floating light was a ship with small lanterns suspended from the yard-arms or frames. The late Mr Robert Stevenson introduced in that year a lantern which surrounded the mast of the vessel, and was capable of being lowered down to the deck to be trimmed. By his plan a lantern of much greater size could be used, and with this increase of size a larger and more perfect apparatus could be employed which admitted of gearing for working a revolving light, as adopted by the Trinity House. In fig. 68, *aa* is the mast, *b* tackle hook, *c*, *c* brass flanges for fixing parts of lantern together, *e* and *g* weather guards, *h* plate glass front of lantern, *i* shutter by which lamps are trimmed, *k* lamps, *l* silver reflector. Revolving catoptric apparatus was applied to floating lights in England, and M. Letourneau, in 1851, proposed to employ a number of sets of dioptric apparatus in one lantern; figs. 69 and 70 show elevation and plan of one of the Hooghly floating lights on the dioptric principle, designed for the Indian Government by Messrs Stevenson. It will be observed that not fewer than four of the separate lights are always in view from every part of the compass at once.

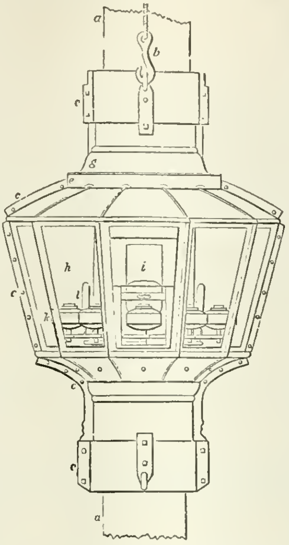

Fig. 68.

The "Seven Stones" lightship, which has all the recent Trinity House improvements, is moored off the Lands End in 42 fathoms. Her moorings consist of a 40 cwt. mushroom anchor, and 315 fathoms of $1\frac{1}{2}$ inch studded chain cable. The vessel is timber-built, copper-fastened throughout, sheathed with Muntz metal. Her length is 103 feet between perpendiculars; extreme breadth, 21 feet 3 inches; depth of hold from the strake next the timbers to the upper side of the upper deck beams, 10 feet 3 inches. In the event of the vessel breaking adrift, she is provided with sails, the mizzen being frequently used for steadying the vessel at her moorings. The cost of the vessel, fully equipped for sea, with illuminating and fog signal apparatus complete, was about £9500.

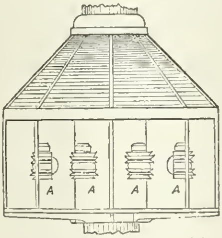

Fig. 69.—Dioptric Floating Light. Elevation.

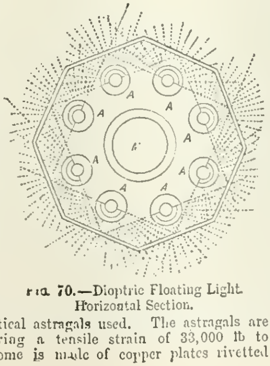

Fig. 70.—Dioptric Floating Light. Horizontal Section.

Lanterns are generally constructed of diagonally framed astragals (fig. 71) to avoid the obscuration of light in any one azimuth as would be the case with dioptric fixed light apparatus were vertical astragals used. The astragals are made of gun-metal, having a tensile strain of 33,000 lb to the square inch; the dome is made of copper plates rivetted together; and the glass is the best plate ¼ inch thick. *Storm panes* are kept at hand which can be applied in a few minutes in the event of a pane being broken, which sometimes occurs from large birds driving against the lantern and by stones thrown up from the face of cliffs by sea and wind during storms. Mr Douglass's cylindric or helical lanterns (fig. 72) have steel astragals, and the panes, which are also cylindrical, are ½ inch thick.

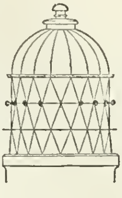

Fig. 71.—Diagonal Lantern.

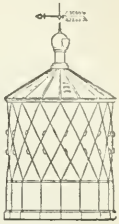

Fig. 72.—Helical Lantern.

Lightning Conductors.—Each lighthouse tower is furnished with a copper lightning conductor consisting of a ¾ inch copper rod or wire rope. These conductors terminate about 18 inches above the top of dome of lantern in a forked shape with two platinum points; the lower end bifurcated and furnished with large copper earth-plates is sunk into moist earth or into the sea. The conductor is put into metallic connexion with all large masses of metal outside or inside the lightroom. See Lightning Conductors.

Machinery. *Machinery.*—Revolving lights are propelled by clock-work machinery actuated by a falling weight. The machines are provided with a maintaining power which keeps the apparatus moving while the machine is being wound up, and a bell is attached which rings to warn the keepers when the machine requires winding up. A clock face is also attached which keeps time with the lightroom clock when the apparatus is revolving at the proper speed.

Masking screens. *Masking Screens.*—For the purpose of *cutting off* sharply the light proceeding from any fixed light apparatus, the late Mr J. M. Balfour devised what he called radial masking screens. These screens, which are in use at several lighthouses where the fairway for ships is narrow, consist of a series of thin plates placed with their edges towards the apparatus, and with such a distance between them, and of such a length as will secure that only rays having the desired divergence can pass through between them.

With revolving lights it is not possible to effect a "cut off" as in the case of fixed lights, on any particular bearing; for the direction of the axis of the luminous beam projected by the lens or reflector is being continually changed in the horizontal plane by the revolution of the frame on which it is fixed. Mr Stevenson's mode of overcoming this difficulty is by fixing a light metallic screen or coloured glass shade outside of the revolving apparatus and on the safety side of the danger arc. These screens are fitted with rollers for running on a slightly inclined plane or circular path. Small projecting rods or snugs fixed to the sides of each lens are, in revolving, brought against the edge of the screen, and gradually press the screen before it up the inclined plane. By the time the lens reaches the edge of the danger arc the screen has been pushed to the top of the inclined plane, and the full beam of light, coming from the now entirely uncovered lens, points in the required line of cut off, which is the border of the danger arc. But whenever the further revolution of the apparatus causes the snugs to pass clear of the edges of the screen so as to free it from their pressure it immediately runs back again to its original position in front of the lens, so as to prevent any of the light being now sent seawards. By this continued reciprocative movement of the screen, as lens after lens comes round, the same effect will be successively produced and the light will always be cut off on the lines of obscuration, so that the flashes can never be seen within the danger arc.

Mathematical investigations and formulæ for constructing the optical instruments for lighthouses will be found in the books undernoted by Alan Stevenson, Swan, Chance, Nehls, Reynaud, Allard, &c., to which the reader is referred.

LIGHTING, Electric. Artificial light is generally produced by raising some body to a high temperature. If the temperature of a solid body be greater than that of surrounding bodies it parts with some of its energy in the form of radiation. Whilst the temperature is low these radiations are not of a kind to which the eye is sensitive; they are exclusively radiations less refrangible and of greater wave-length than red light, and may be called infra-red. As the temperature is increased the infra-red radiations increase, but presently there are added radiations which the eye perceives as red light. As the temperature is further increased, the red light increases, and yellow, green, and blue rays are successively thrown off. On pushing the temperature to a still higher point, radiations of a wave-length shorter even than violet light are produced, to which the eye is insensitive, but which act strongly on certain chemical substances; these may be called ultra-violet rays. It is thus seen that a very hot body in general throws out rays of various wave-length, our eyes, it so happens, being only sensitive to certain of these, viz., those not very long and not very short, and that the hotter the body the more of every kind of radiation will it throw out, but the proportion of short waves to long waves becomes vastly greater as the temperature is increased. The problem of the artificial production of light with economy of energy is the same as that of raising some body to such a temperature that it shall give as large a proportion as possible of those rays which the eye happens to be capable of feeling. For practical purposes this temperature is the highest temperature we can produce. As an illustration of the luminous effect of the high temperature produced by converting other forms of energy into heat within a small space, consider the following statements. 120 cubic feet of 15 candle gas will, if burned in ordinary gas burners, give a light of 360 standard candles for one hour. The heat produced by the combustion is equivalent to about 60 million foot-pounds. If this gas be burned in a gas-engine, about 8 million foot-pounds of useful work will be done outside the engine, or four horse-power for one hour. This is sufficient to drive an "A" Gramme machine for one hour; the energy of the current will be about 6,400,000 foot-pounds per hour, about half of which, or only 3,200,000 foot-pounds, is converted into radiant energy in the electric arc, but this electric arc will radiate a light of 2000 candles when viewed horizontally, and two or three times as much when viewed from below. Hence 3 million foot-pounds changed to heat in the electric arc may be said roughly to affect our eyes six times as much as 60 million foot-pounds changed to heat in an ordinary gas burner.[1] Owing to the high temperature at which it remains solid, and to its great emissive power, the radiant body used for artificial illumination is nearly always some form of carbon.

The consideration of electric lighting naturally divides into two parts—the production of suitable electric currents, and the conversion of the energy of such currents into radiations. Although electric lights were first produced from currents generated by batteries, they have only attained commercial importance by the use of machines for converting mechanical energy into electric current.

Dynamo-Electric Machines.—In the widest sense a dynamo-electric machine may be defined as an apparatus for converting mechanical energy into the energy of electrostatic charge, or mechanical power into its equivalent electric current through a conductor. Under this definition would be included the electrophorus and all frictional machines; but the term is used in a more restricted sense for those machines which produce electric currents by the motion of conductors in a magnetic field, or by the motion of a magnetic field in the neighbourhood of a conductor. The general laws of electromagnetic induction need not be set forth here; as they are fully explained in the article Electricity, they will be assumed in all that follows. Since, if the current in a closed circuit be in one direction when the number of lines of force is increasing, it will be in the opposite direction when they are diminishing, it is clear that the current in each part of the circuit which passes through the magnetic field must be alternate in direction. Hence also the current in the wire outside the machine must also be alternate, unless something of the nature of a commutator be employed to reverse the connexions of the internal wires, in which the current is induced, and the external circuit. We have then broadly two classes of dynamo-electric machines:—the simplest, the alternate current machine,[2] where no commutator is used; and the continuous current, in which a commutator is used to change the connexions to the external circuit just at the moment when the direction of the current would change.

The mathematical theory of alternate current machines is comparatively simple.[3] Let τ be the period of the machine, that is, the time taken to move the armature from one position to the next exactly similar position, *e.g.*, in a Siemens alternate current machine of sixteen magnets on each side, one-eighth of the time of revolution; let γ be the coefficient of self-induction of the whole circuit, and R the resistance of the whole circuit; and let t denote the time at any instant counting from any epoch as initial, and I the magnetic induction at time t multiplied by the number of convolutions. The electromotive force in the circuit at time t will be

$$\frac{dI}{dt};$$

and the equation of the current will be

$$\gamma\frac{dx}{dt} + Rx = \frac{dI}{dt},$$

where x is the current. Now I may be expressed in the form

$$\Sigma_1^\infty A_s \sin 2\pi s\frac{t-t_s}{T},$$

where A_s and t_s are constants for the machine with given excitation of the fixed magnets. Hence

$$\gamma\frac{dx}{dt} + Rx = \Sigma_1^\infty \frac{2\pi s}{T} A_s \cos 2\pi s\frac{t-t_s}{\tau},$$

$$e = C\epsilon^{-\frac{R}{\gamma}t} + \Sigma_1^\infty \frac{2\pi s}{\tau} A_s' \frac{\cos 2\pi s\frac{t-t_s-\tau_s}{\tau}}{\sqrt{\left(\frac{2\pi s\gamma}{\tau}\right)^2 + R^2}},$$

where

$$\tan\frac{2\pi s\tau_s}{T} = \frac{2\pi s\gamma}{RT}.$$

The term $C\epsilon^{-\frac{R}{\gamma}t}$ is unimportant except just after closing the circuit. In the Siemens machine M. Joubert states that the only

Siemens: *Tel. Jour.*, vii. 284; Schellen, 315.

[3] *Journal de Physique*, x. 141; Joubert, "Théorie des machines à courants alternatifs," in *Phil. Mag.*, x. 298, 384.

important term is that of longest period. Hence, properly choosing the epoch, we write

$$x=\frac{2\pi A}{T}\frac{\cos 2\pi\frac{t-\tau}{T}}{\sqrt{\left(\frac{2\pi\gamma}{T}\right)^2+R^2}},$$

where

$$\tan\frac{2\pi\tau}{T}=\frac{2\pi\gamma}{RT}.$$

Hence we see the current is diminished either by increasing γ or increasing R, also that the moment of reversal of current is not coincident with that of no electromotive force, but occurs after that time by an amount depending on the relative magnitudes of γ and R. This explains in a general way what is known as the lead of the brushes in a continuous current machine. If we wished to apply a commutator to the Siemens alternate current machine for the purpose of producing an external current constant in direction, the change effected by the commutator should occur at an epoch after that of greatest electromotive force, an epoch which, with varying external resistance or varying speed, will depend on the resistance and speed.

The power of the current is Rx^2, and the energy in any considerable time, Θ, is

$$\Theta R\frac{2\pi^2A^2}{T^2}\frac{1}{\left(\frac{2\pi\gamma}{T}\right)^2+R^2},$$

which shows that most power will be required to drive the machine when

$$R=\frac{2\pi\gamma}{T}.$$

In what precedes it has been assumed that the copper wires are the only conducting bodies moving in the magnetic field. In most cases the moving wire coils of these machines have iron cores, the iron being in some cases solid, in others more or less divided. It is found that if such machines are run on open circuit the iron becomes hot, very much hotter than when the circuit of the copper wire is closed; in some cases the phenomenon is so marked that the machine actually takes more to drive it when the circuit is quite open than when the machine is short-circuited. The explanation is that on open circuit currents are induced in the iron cores, but that when the copper coils are closed the current in the latter by its induction diminishes the current in the iron. The effect of currents in the iron cores is not alone to waste energy and heat the machine; the current produced is also actually less for a given intensity of field and speed of revolution. The cure of the evil is to subdivide the moving iron as much as possible in directions perpendicular to those in which the current tends to circulate.

Continuous or Direct Current Machines.—It has been shown that to produce a continuous current a commutator is needed. If there is but a single wire in the armature, or if there are more than one, but all are under maximum electromotive force at the same time, the current outside the machine, though always in the same direction, will be far from uniform. This irregularity may be reduced to any extent by multiplying the wires of the armature, giving each its own connexion to the outer circuit, and so placing them that the electromotive force attains a maximum successively in the several circuits. A practically uniform electric current was first commercially produced with the ring armature of Pacinotti as perfected by Gramme. Suppose a straight bar electromagnet surrounded by a coil of copper wire from end to end. Let the electromagnet be bent with the copper wire upon it until its ends meet and it forms an annulus or anchor ring. Let the two ends of the copper wire be connected, so that the iron core is surrounded by an endless copper wire, and you have the Pacinotti or Gramme ring. This ring rotates about its axis of figure between two diametrically opposed magnetic poles of opposite name. The ring may at any instant be supposed divided in halves by a diameter perpendicular to the diameter joining the centre of the poles. Equal and opposite electromotive forces act on the copper wire of the two halves, giving two opposite electric poles half way between the magnetic poles. If electric connexions could be maintained with these two points as the ring revolves, a continuous current would be drawn off. In practice this is only approximated to. The copper wire is divided into a series of equal sections, and at the point of junction of each section with its neighbour a connexion is made with a plate of a commutator, having as many divisions as there are divisions of the copper coil. Collecting brushes bear upon the commutator plates, which are connected to the coil nearest to the point of maximum potential. Owing to the self-induction and mutual induction of the several coils of the armature, this point is displaced in the direction of rotation when a current is being drawn off, to an extent greater as the current is greater in relation to the strength of the magnetic field. The magnetic field in the Gramme and other continuous dynamo-electric machines may be produced in several ways.[1] Permanent magnets of steel may be used, as in the smaller machines now made, and in all the earlier machines; these are frequently called magneto-machines.[2] Electromagnets, excited by a current from a smaller dynamo-electric machine, were introduced by Wilde; these may be described shortly as dynamos with separate exciters. The plan of using the whole current from the armature of the machine itself for exciting the magnets was proposed almost simultaneously by Siemens, Wheatstone, and S. A. Varley.[3] For some purposes it is advantageous to divide the current from the armature, sending the greater part through the external circuit, and a smaller portion through the electromagnet, which is then of very much higher resistance, as the electromagnet is a shunt to the external circuit. Machines so arranged are sometimes called shunt dynamos.[4] The last two arrangements depend on residual magnetism to initiate the current, and below a certain speed of rotation give no practically useful electromotive force.

In discussing the comparative efficiency of dynamo-machines there are two points to be examined—(1) how much of the power applied is converted into energy of current in the whole circuit, whether external or in the wires of the armature or of the electromagnets, and (2) how much of the power is available outside of the machine. The

practical sources of loss are friction of bearings, and of the brushes on the commutator, electric currents induced in the iron of the machine, production of heat in the copper wire of the armature due to its resistance, and production of heat in the wire of the electromagnet due to its resistance. There is also a certain loss in sparks upon the commutator. The currents in the iron are reduced by dividing the iron by insulating surfaces perpendicular to the electromotive force tending to produce such currents. The loss by resistance of wire in armature and magnets greatly depends on the dimensions of the machine. For imagine two exactly similar dynamo-electric machines, the one being n times the dimensions of the other, we have the following relations between them, assuming the same magnetic field per square centimetre, and the same speed of rotation :—

The electric resistances of the several parts are as $1 : n$;
The electromotive force of the armature as n^2 ;
Current round magnets required to produce the field as n.

Thus the work wasted in heating the wire of the electromagnets varies as the linear dimensions of the machine. The current which the armature can carry with safety to the insulation will increase more rapidly than the linear dimensions of the machines, but less rapidly than the square of the linear dimensions. If the current vary as the linear dimensions n, the whole electric work done by the machine will vary as its weight n^3, and the work wasted in the coils both of the electromagnets and of the armature will only vary as n,—showing a great theoretic advantage in favour of the larger machines.

Electric Lamps. Incandescent Lamp.[1]—The simplest way of obtaining light from an electric current is by passing it through a considerable resistance in such small compass that the conductor becomes intensely hot. It is of course necessary that the conductor shall be able to endure a very high temperature without injury. Iridium and platinum-iridium wire have been employed, but are too expensive for commercial use. Hitherto the only available substance is carbon, in the form of a thread or filament. This carbon must be protected from the air by enclosing it in a glass globe from which every trace of air has been removed. An electric current passing through a carbon filament obeys Ohm's law, as through a metallic wire. But in metals the resistance increases as the temperature rises, in carbon it diminishes.[2] The filament or thread of carbon being enclosed in a vacuous space, the energy of current converted into heat in the filament only leaves it in the shape of radiations. To light economically, it is necessary to heat the filament to such a temperature that the greatest possible proportion of these radiations shall belong to that part of the spectrum to which the eye is sensitive, *i.e.*, to the highest temperature the filament will stand. The fundamental problem of incandescent electric lighting is to produce a carbon thread the substance of which shall permanently stand the highest possible temperature, to make good electrical connexion between the ends of the filament and the conducting wires, and above all to secure that the thread shall be uniform throughout its length, for the current which can be safely used is limited by the weakest point of the filament. Several inventors have recently succeeded in meeting these conditions, but their relative merit and priority cannot be discussed here.[3]

Semi-incandescent Lamp.—The lamps of Werdermann, Reynier, and Joel are intermediate between arc lamps and incandescent lamps, and present the distinctive advantages of neither.[4]

Arc Lights.—Sir Humphry Davy discovered that if two pieces of carbon were placed in contact with each other, and the current from a battery of a sufficient number of elements were passed from one piece to the other, the current did not cease when the carbons were slightly parted, but that the current passed across the intervening space, causing an intensely high temperature and consequently brilliant light. The pieces of carbon gradually burned away, the positive carbon being consumed more rapidly than the negative. When an electric current passes through a conducting solid body maintained at a constant temperature, the difference of potential on the two sides of the body has a constant ratio to the current passing through; this constant ratio is known as the electric resistance of the body at its then temperature. No such constant ratio exists in the case of the electric arc. If you increase the current passing between two carbons at a small distance apart, you do not materially change the difference of potential at the two ends of the electric arc. It is, therefore, not strictly appropriate to speak of the resistance of the electric arc; the appropriate constant, or approximate constant, for an electric arc is the difference of potential between the two sides of the arc.[5] However near the carbons approach without touching, this does not fall below a certain minimum value, and as the carbons are separated its value increases. In ordinary practice with continuous currents the potential of the electric arc may be taken as ranging from 35 to 45 volts. If the current in amperes be multiplied by the difference of potential in volts, and the product be divided by 746, we have the power used in the arc itself in horse-power, that is, the power effectively used in lighting. The mechanism of an electric lamp has two functions to perform, it has first to bring the carbons into contact and then part them, or simply part them if they are initially in contact when the light is started, or when it is accidentally extinguished (this is called striking the arc); it has also to bring the carbons together as they are consumed. The former function is always accomplished by an electromagnet or solenoid. In the electric candles, *e.g.*, those of Jablochkoff, Rapieff, Wilde, or Siemens, the carbons are approximately parallel, and they burn down as does a candle,—the arc being forced to the ends of the carbons by the repulsion of the current in the carbons on the electric arc.[6] In the ordinary arc lamps the carbons have their axes in the same line, and their approach or recession must be controlled by the current passing through, by the difference of potential, or by both combined. When the same current passes through a succession of lamps in series, it is clear that the regulation cannot be by the

current alone, as this is the same for all the lamps, and might be maintained constant by the adjustment of any one only of the lamps. When lamps are burned in series, it is essential that the difference of potential shall be an element in the control. This is done by using an electromagnet bound by fine wire so as to have a resistance of some hundreds of ohms, and connecting it to the two sides of the arc. In the Siemens differential lamp, and in some others, a potential or shunt coil and a current coil oppose each other; as the arc lengthens the current becomes less, and the potential greater, each acting to cause the carbons to approach. It will be seen that the possible combinations of mechanisms and electromagnets for adjusting an electric arc are endless; and so also are the patents for such combinations.[1] When an alternate current is used for an electric arc, the phenomena are much more complicated, owing to the difference of potential being a discontinuous function of the time. The difference of potential will be (say) 40 volts in one direction for a certain fraction less than half of the periodic time of the current; the current then entirely ceases, generally for a finite time, and is then reversed with a sudden reversal of difference of potential.[2] The work done in the arc is measured by the time integral of the product of difference of potential and current passing. A knowledge of neither the mean strength of the current, nor of the difference of potential, nor of both, gives the means of ascertaining the work done in an arc with alternate current. The only satisfactory electrical method is the quadrant electrometer suitably connected, and this is open to the objection that a considerable resistance must be introduced into the circuit.

Electric Light Measurements.—Under this head we content ourselves with a warning. A bare statement that an electric arc light is of so many candle power really conveys no accurate information at all. The light from an electric arc differs greatly in colour from that of a candle;[3] a given arc light may have three thousand times as much red of a certain wave-length as a standard candle has of the same wave-length, but ten thousand times as much green light. Any one will admit that green light is not measurable in terms of red light; a mixture of red and green is not measurable in terms of another mixture in which the proportions of the colours are wholly different. Again, the intensity of the light obtained from an arc light depends greatly on the direction in which it is viewed.[4] Neither of these considerations applies in the same degree to incandescent lamps. (J. HO.)

LIGHTNING. See METEOROLOGY and THUNDERSTORMS.

LIGHTNING CONDUCTOR, or LIGHTNING ROD (*Paratonnerre, Blitz-ableiter*), is the name usually given to apparatus designed to protect buildings or ships from the destructive effects of lightning. The title, alike in English, French, and German, is misleading; for, when properly constructed, lightning rods serve rather to prevent the occurrence than to ward off the effects of a flash of lightning. Damping the enemy's powder would be a most efficient precaution against cannon-shot, but it would be very inappropriately termed fortification. When a conductor charged with electricity is brought near to another conductor connected with the earth, it induces on it a charge of the opposite kind of electricity. The result is an attractive force which tends to bring the conductors nearer to one another, and to augment the electric density on their opposed surfaces. When the density is sufficiently great, there is rupture of the dielectric (air) between the conductors, and the disruptive discharge takes place as an electric spark. If one of the conductors have projecting points or angles, the electric density is usually much greater at such places than over the rest of the surface. But, though the density is great at such places, the charge on them is usually small, and the discharge takes place in an almost continuous manner by a brush or glow. When, for instance, a large conductor, connected with an electric machine, is giving a rapid succession of bright sparks to a ball connected with the ground, the sparks cease as soon as a pointed wire, connected with the ground, is held in the vicinity of the conductor. No discharge is heard, but in the dark a faint glow is seen at the end of the wire, which continues as long as the machine is turned. Remove the wire and the sparks instantly recommence. This glow is known to sailors as St Elmo's (San Telmo's) fire, in old days Castor and Pollux (Plin., *H. N.*, ii. 37). Suppose now one of the conductors to be a thundercloud, the other the surface of the earth, the discharge will usually take place between the places of greatest surface density; and it will in general be the more gradual as these are more pointed, and of less capacity. Hence Franklin's idea of furnishing buildings or other prominent objects with a projecting metal spike well connected with the ground, for the purpose of preventing a lightning discharge by substituting for it what is practically a continuous electric current.

To effect this object thoroughly, only three things are necessary:—(1) the points should so project from the building or ship to be protected as to prevent any great development of electric density elsewhere than on themselves; (2) they should be effectually connected with the earth; (3) the connecting rod ought to be so good a conductor as not to be injured even by a powerful electric discharge.

The first of these conditions is realized by making the rod branch out to all the salient portions of the building or ship, and furnishing it with points projecting beyond each of them. No general rule can be laid down as to the extent of the region protected by a single point, though it may usually be assumed with safety that the region extends throughout a vertical cone whose vertex is at the point,

and whose semivertical angle is about 45°. This is probably not true if the point be very high,—on the top of a tall chimney or tower, for instance. Objects not far from the base of such a protected tower, and within the cone just described, have occasionally been damaged by lightning.

The second condition is easily fulfilled in towns by connecting the lower end of the rod with the iron gas and water-mains, which form an excellent "earth," as it is technically called. Water-pipes, being usually jointed with metallic-lead-washers, are preferable to gas-pipes, which are usually put together with white lead. This condition is also easy to secure in ships and in lighthouses, where large metal plates (in the case of a ship, the copper sheathing is precisely what is required) can easily be permanently immersed in sea-water. In country houses it is usually more difficult to obtain a proper earth. Plates and tubes of metal, of large surface, buried in ground which is permanently damp, form usually the best arrangement. A well makes a good earth; a carefully constructed water tank (of stone or cement) is not an earth at all.

The third condition, so far as experience can guide us, seems to be effectually realized by making the conductor *throughout* of iron rod of an inch in diameter, or of copper rod not less in diameter than $\frac{3}{8}$ths of an inch Such rods of equal length have nearly the same conducting power, and therefore would have equal amounts of heat developed in them by a given discharge. But if such a discharge took place, the copper would be heated much more than the iron, in consequence of its smaller mass per foot (the specific heat being approximately the same in the two materials). Hence iron is, in this respect, preferable to copper, if the conducting powers of the rods are equal. Another advantage possessed by the iron rod is that it is much less likely to be wilfully damaged or stolen. Against this may be set the objections that it is easily injured by rust, and is not nearly so flexible as the equivalent copper rod. Conductors are now usually made of wire-rope, so that the question of flexibility is no longer of serious importance; but when iron is used it should always be protected by zinc, *i.e.*, be what is absurdly called "galvanized." Many fantastic forms of lightning rods were devised in consequence of the old erroneous notion that their efficiency depended on their surface and not on their cross section. In reality all conductors of equal length, and of the same material, are equally efficient if their cross sections be equal.[1] Thus, instead of stating the diameter of a rod, we may speak of its weight per foot, and say that a copper conductor should weigh at least about half a pound, and an iron one at least two pounds and a half per foot,—provided the materials be of good conducting quality.

The points need not be very sharp, but they ought to be protected by a coating of platinum or other non-oxidizable metal. And they should be in a group of two or three at the end of each branch of the rod, lest one of them should be fused and impaired in efficiency by an accumulation of electricity so rapid as to make the silent continuous discharge impossible. Joints should be avoided as far as possible; where they are unavoidable they should be made, not by screws or brazing, but by means of a large mass of solder completely enveloping the ends to be connected.

Another point to be carefully attended to is that all large metallic bodies, such as lead or zinc roofing, metal tanks, &c., should be in good conducting connexion with the rod, so as to prevent discharges of electricity inside the ship or building. In many buildings we see the lightning rods attached by means of glass or porcelain insulators, such as are employed for telegraph wires. This is a perfectly needless, expensive, and possibly dangerous practice.

The literature of this subject is very extensive, as may be seen from Ronalds's *Catalogue of Works on Electricity.* The reader may also consult Anderson on *Lightning Conductors* (1880), and the *Report of the Lightning-Rod Conference* (1882). In the latter work will be found abstracts of many valuable papers, especially the reports on lightning-rods made to the French Academy by some of its most distinguished members, including Coulomb, Laplace, Poisson, Gay Lussac, Fresnel, Pouillet, Cagniard de la Tour, Regnault, &c. There will also be found hints about some of the most ludicrous devices employed by men ignorant of the laws of electrical phenomena. One of the most singular of these was the so-called "Repeller." A lightning-rod, in all respects sufficient, was wont to be capped by a piece of glass like a thick soda-water bottle, inverted upon its point. The effect of this could only have been to prevent the possibility of the silent discharge, to produce which is the proper function of the rod, and to make probable a lightning flash, just as if the rod had been terminated by a ball instead of a point. One of these dangerous monuments of ignorance was removed from a British lighthouse within the last ten years. In an Irish lighthouse, which was recently examined after suffering serious damage, it was found that the lower end of the lightning-rod was jumped into the solid rock—a truly original form of "earth"!

In 1876 Clerk Maxwell suggested to the British Association the idea (based on Faraday's experiments) of protecting a building from the effects of lightning by surrounding it with a sort of cage of rods or stout wire. Here an "earth" would not be absolutely required. The present writer had some months previously suggested the same idea in a Report to the Board of Northern Lights. It is possible, though not certain, that this form of defence might be useful against globe-lightning, which undoubtedly occurs, and against which ordinary lightning-rods would probably be of little use.

These brief remarks contain all that is yet known to be necessary to the complete solution of an important practical problem about which many treatises have been written. (P. G. T.)

LIGUORI, LIGUORIANISM. The name Liguorianism has been popularly given in the present century to a particular school of moral and devotional theology in the Roman Catholic Church by the controversial opponents of that school, whether themselves Roman Catholics or not.. It is derived from the name of one of its principal and most influential exponents, Alfonso Maria de' Liguori, a theologian, saint, and doctor of the Roman Church. In strictness, the term is not accurate, for Liguori was in no sense the founder of the school, nor did he innovate upon, develop, or exaggerate its principles and maxims. He was simply a fair representative of the national type of piety of Italian devotees in his day; and, as a casuist, he was a diligent compiler, whose avowed design was to take a middle course between the two principal varieties of teaching in moral theology current in his own time, avoiding their extremes of severity or laxity. His own words, in the preface to his *Homo Apostolicus*, a work intended for the guidance of priests in hearing confession, explain clearly the intention of his bulkier treatise, the *Theologia Moralis.* He says:—"When compiling that work, I spent the labour of fifteen years in perusing and weighing the teaching of very many writers whom I examined, some of whom I found more lenient than is just; . . . while I found others who, strongly disliking such indulgence, fell into the other extreme of excessive rigour. And this was my principal task, to select from such a mass of opinions those decisions which, on the one hand, should uphold the obedience due to the precepts of God and of the church, and on the other should not add burdens which God has not imposed, by binding every one to that perfection which, through human weakness, is morally impossible to the general body of believers." A brief glance at the names of those casuists whom he cites most frequently, as Covarruvias, Soto, Lessius, Vasquez, Bonacina, the doctors of Salamanca, Sanchez, Diana, &c., shows them to belong mainly to the hundred years between 1580 and 1680, and

[1] Some curious modifications of this statement are introduced when we deal with magnetizable metals, but they are unimportant in practice.

therefore to the period of Jesuit predominance in moral theology, and of the prevalence of those maxims which Pascal lashed in the *Provinciales*, many of which were soon after condemned by Pope Innocent XI. in 1679. But, as Liguori embodies also in his materials the casuistical authors of the succeeding century, who were taught some caution by those mishaps of their predecessors, his works represent the final stage of casuistry in what is accounted a purified and moderate form, and have a yet greater importance, in that they have been accorded an official approval and authorization from the highest authorities of the Roman Catholic Church, such as those of no previous casuist of the post-Reformation era can allege. They are fully sanctioned, encouraged, and recommended for general use amongst the Roman Catholic clergy, and in fact only just fall short of being actually enjoined. Consequently they themselves, and the works based on them by Scavini and Gaume, as also the kindred manual of Gury, are all but universally found in use, and it is thus easy to learn from them what is now the accredited moral theology prevalent throughout the Latin obedience. So much being premised, we may now turn to the life of Liguori himself, and thence to the analysis of the system which he expounds.

Alfonso Maria de' Liguori, son of Giuseppe de' Liguori, a Neapolitan noble, and of Anna Cavalieri de Brindes, his wife, was born at Marianella, near Naples, on September 27, 1696. He was educated chiefly at home, though he attended an Oratorian school at Naples for a time; and, as his father desired that he should rise to office in the magistracy, he was especially directed to the study of jurisprudence, both civil and canonical. He took the degree of doctor in this faculty in January 1713, being then little more than sixteen years old. He was called to the bar in due course, and obtained considerable practice, while his biographers dwell much on the high moral tone of the rules he laid down for his guidance in the conduct of professional business. The loss of an important suit in which he was engaged as counsel for a Neapolitan noble against the grand-duke of Tuscany, and in which he had entirely mistaken the force of a leading document, so mortified him that, acting on a temper already disposed towards the monastic life, it induced his withdrawal from the legal profession, which he never resumed after this defeat. He soon adopted the ecclesiastical dress as a candidate for orders, which he received in December 1724, when he entered as a novice into the Congregation of Missions, being ordained priest in December 1726.

He soon became popular as a preacher and as a confessor, obtaining much influence in Naples and its vicinity. In 1732 he founded the "Congregation of the Most Holy Redeemer," usually known as Redemptorists, or, as they are often named, Liguorians, whose special object is the religious instruction of the rural poor and other uneducated classes, establishing the first house of the society, in the force of much opposition, at the little town of Scala, about 8 miles from Salerno. The headquarters were transferred somewhat later to Ciorani, and in 1743 to Nocera dei Pagani, which is still the chief house. The confirmation of the rule and institute was obtained from Benedict XIV. in February 1749, and in the following year Liguori, who had previously made some minor literary ventures, published one of his most famous and popular books, *Le Glorie di Maria*, a book intended to promote the cultus of the Blessed Virgin; and in 1753 he issued his yet more celebrated *Moral Theology*, dedicating it to Pope Benedict XIV., expressly as a "via media" treatise. An Italian version of this book, somewhat abridged, recast, and adapted for the use of the clergy, was his next task; and, on this shorter treatise becoming popular, and a demand for it arising outside of Italy, he translated it into Latin, and issued it in 1755 as the *Homo Apostolicus*.

In 1762, being then sixty-six years of age, he accepted the bishopric of Sant' Agata dei Goti, a small town in the province of Benevento, at the express desire of the pope (though he had several years before refused the archbishopric of Palermo, offered him by the king of Naples), and by a very unusual concession was permitted to retain his superiorship of the Redemptorists, governing them by means of a vicar-general. He worked diligently in this sphere of labour for thirteen years, busying himself with practical reforms of various kinds in his diocese, notably in trying to raise the standard of clerical life and work, while not intermitting either his literary pursuits or his efforts to promote the growth of his Redemptorist institute. In 1775, being then seventy-nine years of age, he obtained permission from Pius VI. to resign his bishopric, on the plea of enfeebled health, and retired to the Redemptorist house at Nocera dei Pagani, where he died August 1, 1787, aged nearly ninety-one. He was decreed the rank of "Venerable" very speedily, being so named by Pius VI. in 1796, was beatified by Pius VII. in 1816, canonized by Gregory XVI. in 1839, and finally declared a "Doctor of the Church" by Pius IX., March 11, 1871. He is one of the most copious of the later Roman theologians, and his productiveness extended over a period of thirty years, from the issue of his *Visits to the Blessed Sacrament* in 1747 till the appearance of no fewer than eleven treatises in 1777; but his only writings necessary to be added here to those already named are his treatises *De Usu Moderato Opinionis Probabilis*, 1754, recast and reissued in 1756; *Praxis Confessarii*, 1756; six apologies in defence of his views on probabilism and of his *Moral Theology*, in the same year, followed by three more in 1768; *Verità della Fide*, against Helvetius and the deists, 1767; *Storia delle Eresie*, directed chiefly against the Jansenists and Molinists, 1772; *Dissertazioni teologiche morale*, 1772; and *Vindiciæ pro suprema Pontificia potestate, adversus Justinum Febronium*, in the same year.

He was a man of naturally amiable and gentle disposition, ascetic and self-denying in his personal habits, indefatigably diligent in many forms of activity, and of more than respectable abilities, though with the emotional side of his character in greater relief than its intellectual side. He was learned, as learning was understood amongst the Italian clergy of the 18th century, though altogether lacking in critical faculty, whence he is quite untrustworthy as a controversialist, not only as habitually quoting spurious or interpolated authorities, but by adding matter of his own to amplify genuine quotations which fall short of proving his case. In estimating the nature of his moral teaching, not only have these personal characteristics to be steadily kept in mind, but also the fact that his life exactly synchronizes with that epoch of European history which was the seed-time of the Revolution, and when, owing to reaction from the fervid theological controversies of the 16th and 17th centuries, a general languor, coldness, and indifference towards religious questions reigned in all parts of Western Christendom. It was Liguori's firm belief that only the most lenient and gentle treatment could win back the alienated laity; and consequently, though he professed to steer a middle course between errors of laxity and severity in moral teaching, and fully believed himself to have done so, yet in fact such a treatment was impossible to one who viewed the question as he did. For, while he regarded errors on the side of laxity as pardonable mistakes committed through excess of zeal in winning over penitents, contrariwise he looked on the stricter method of the rigorists, who upheld a loftier morality, as not merely inexpedient, but as positively and intentionally evil, as designed to make religion odious by making it impossible, and so to prepare the way for the triumph of unbelief. He identified all teaching of the sort with Jansenism, and Jansenism, from its resistance to various pontifical decrees, seemed to him all but equivalent to atheism.

Hence the opinions of rigorist theologians find almost no place in his writings, save for the purpose of censure, since he did not regard them as authorities to be relied on; and accordingly the line he draws is not, what he probably thought it, an intermediate one between rigorism and laxity, but between a greater and a lesser degree of laxity, depending on the working of the principle known as "Probabilism." The meaning of this principle (due to the scholastic form of the Aristotelian dialectic, and thus visible in germ as early as St Thomas Aquinas, though not taking final shape till the writings of Medina, Valencia, Vasquez, and others, mainly, but not exclusively, Jesuits, at the close of the 16th century) is simply this:—when a doubt arises as to the binding force of some divine or human precept in any given case, it is permissible to abandon the opinion in favour of obedience to the law—technically known as the "safe" (*tuta*) opinion—for that which favours non-compliance, provided this laxer opinion be "probable." And by "probable" is meant any judgment or opinion based on some reasonable grounds, though with some doubt that the opposite view is perhaps the true one (Gury, *Theol. Mor.*, vol. i. n. 51). It may be probable in two chief ways,—intrinsically, because of reasons drawn from the nature of the thing itself, or extrinsically, because supported by one or more theologians of repute; and its degree of probability may vary according to a variety of conditions. Casuists are divided into six classes according to their mode of regarding probability:—(1) Rigorists, who lay down that the safer way, that of obedience to the law, is always to be followed; (2) Mitigated Rigorists, or "Tutiorists," who, holding that the law is always the safer and better way, yet allow that an opinion of the highest intrinsic probability in favour of liberty may sometimes be followed; (3) Probabiliorists, who hold that the law is always to be obeyed unless an opinion clearly very probable (*probabilior*) is opposed to it; (4) Equiprobabilists, who teach that in a balance of opinions the less safe opinion may be lawfully followed, provided it be as probable, or nearly as probable, as its opposite; (5) Moderate Probabilists, according to whom it is lawful to follow the less safe and somewhat less probable opinion, provided it have some degree of real probability, even if the opposite opinion be clearly more probable; (6) Laxists, who hold that even slightly probable opinions may be followed; but, as they were condemned by Innocent XI., they no longer exist as an avowed school, but are still latent under classes 4 and 5.

On further examination, it appears that the right of judging of the *intrinsic* probability of an opinion is restricted to persons of considerable learning, and specially versed in moral theology, since they alone can know that there is not any certain argument in opposition. All other inquirers must fall back on *extrinsic* probability, that is, on what may be called "counsel's opinions." And, in forming a judgment on this basis, the following rules are laid down by F. Gury:—a moderately educated person may accept as probable any opinion which he finds asserted by distinguished theologians of the present day, and may follow even a single author of repute, though teaching contrary to the commonly received view, provided he brings forward some fresh argument, and can urge reasonable pleas against former solutions; while an ignorant man may take the word of any person whom he thinks trustworthy, able, and learned, that a particular opinion is probable (*Theol. Mor.* vol. i. n. 54). Some classes of things are, however, excluded by Roman casuists from the operation of this principle; as, for example, all questions relating to matters of faith, in which the very highest degree of probability is not sufficient to excuse from following the safe opinion, which is that of the Roman Church. Liguori's own position is that of an equiprobabilist, and he therefore, as a rule, leans to the laxer side.

Before proceeding to illustrate the exact nature of his teaching by extracts from his works, it is desirable to ascertain what degree of authority attaches to those works in virtue of the position now accorded to him. In the first place, one of the earliest steps in the process of canonization is a strict review of every writing of the candidate proposed, whether published or unpublished. Every single proposition therein must be separately considered, and be judged on its own merits, without taking the author's probable intention into account, and if even one passage be found which fails to stand this test, as containing any moral or theological error, the process is stopped at once, unless proof be adduced that the author had in his lifetime formally and fully retracted the erroneous opinion. But a decree of the Congregation of Rites, confirmed by Pius VII. in 1803, declared that in none of the writings of Alfonso de' Liguori was anything found meriting censure, and the testimony of Artico, bishop of 'Asti, and prince-prelate of the papal household, is that the examination had been unusually severe, that Liguori's system of morality had been discussed more than twenty times, and that the approval of the congregation was perfectly unanimous. Next, in the year 1831, Cardinal Rohan-Chabot, archbishop of Besançon, submitted a case to the cardinal grand penitentiary, desiring to know, whereas the teaching of Liguori's *Moral Theology* was resisted by some persons in his diocese, as too lax, dangerous to salvation, and contrary to the moral law, whether a professor of theology might safely follow and teach the opinions in that work, and further, whether a confessor should be molested for following those opinions in the confessional, solely on the ground that they had been pronounced free from censure by the apostolic see, and without having examined them independently himself. To the former of these questions an affirmative reply was given, to the latter a negative one. Thirdly, in the bull of canonization, issued by Gregory XVI. in 1839, the entire absence of error in Liguori's writings is once more asserted.

So far, no more is implied than the entire orthodoxy and moral soundness of Liguori's writings, vouched for to the ordinary Roman Catholic by the fact of his canonization. And, though the liberty is thereby taken away of directly censuring any proposition in the writings of a saint as doctrinally or morally untenable, yet there is no precise obligation to follow all things contained therein. It is still lawful to challenge the opinions of a saint, if it be done modestly and with the production of strong reasons (Bened. XIV., *De Canoniz.*, ii. 32, 12); but this liberty is very seriously abridged if the saint be also a "Doctor of the Church." For the meaning of that title is that the person who bears it is one who has not merely transmitted the teaching of the church to others, but has taught the church itself (Bened. XIV., *De Canoniz.*, iv. ii. xi. 11), and whose doctrine has consequently been generally followed and authorized by the church. The number of these doctors of the church is very small; and, in the special case of Liguori, he is not only the latest so named, but the only post-mediæval casuist who has yet been canonized. Accordingly, it is not merely permissible, as heretofore, to follow his teaching, but it is now clothed with so high a degree of authority that it becomes matter of grave doubt whether even such a modified expression of dissent from his teaching as occurs in the *Apologia* of Cardinal Newman in 1864 be now feasible without risk of censure. For the letters apostolic of Pius IX. declare that the works of Liguori may be used publicly in the same manner as the writings of other doctors of the church, such as Augustine, Gregory the Great, and Thomas Aquinas; with, however, this notable difference that, whereas the teaching of those earlier doctors is necessarily qualified and conditioned by the subsequent development of theology, and by the successive glosses which they have received, on the other hand, Liguori's recent date makes him the sole authoritative interpreter of all moral theologians earlier than himself, while no writer has yet appeared to modify authoritatively, much less to supersede, his own moral teaching.

It may seem, at first sight, that a great advantage is gained by having thus a standard text-book on morals, even if some exceptions may be taken to its rulings in certain cases, because it may be expected to check serious divergency of opinion, and to put, indirectly at least, a high ethical ideal before the body of religious teachers. This, however, can be the case only when such a text-book expressly repudiates the principle of probabilism, and so comes to be ranked amongst rigorist works. For once probabilism is conceded as part of the system, as is the case with Liguori, then every opinion not officially condemned by authority, which is set down in the text-book itself, and is fortified with the names of any casuists of repute, becomes thereby probable and sanctioned, even though it be not the one professed by Liguori himself. Thus it may freely be followed by any priest in the confessional; and, what is yet more startling, it is the common and preferable doctrine that a penitent in confession can require absolution to be given him as a right, if he claim to have followed a probable opinion as to the act involved, even though not only the opposite opinion may be the more probable in the confessor's judgment, but that of the penitent seem absolutely false, and the confessor is therefore bound *sub gravi* to absolve in such a case (Lig., *Theol. Mor.*, vi. 605); nor is it necessary that the opinion which the penitent advances should really convince or satisfy his own conscience. It is enough that it stands in the books, and is citable. Accordingly, the only practical effect of such a text-book as Liguori's is to undermine all rigorist propositions, and to make tenable every lax proposition, except the very few which have been specifically condemned.

As regards Liguori himself, his usual method is to begin with taking very high ground, and to state in unexceptionable terms the moral obligation of the precept with which he is concerned, but then to evacuate it of all real force by exceptions and qualifications. That such was felt to be the case, even in the relaxed society of his own day, appears from the frequency with which, even before his death, his moral teaching was impugned in Italy and France as of dangerous consequences, and from the number of apologies he was obliged to put forward in its defence.

He lays down broad general propositions, such, for example, as that all voluntary departure from the divine rule, whether of human and natural law or of revealed law, is sin (*Theol. Mor.*, ii. 1, 1); that nearly all sins against the decalogue are mortal sins (*Ibid.*, ii. 52, 2); that all sins, whether mortal or venial, deserve punishment (*Ibid.*, ii. 51, 1, 2); and, specifically, that all lying and falsehood is a breach of one precept of the decalogue (*Ibid.*, vi. 1, *procem.*), and all theft and dishonesty a breach of another (*Ibid.*, iv. 518); but the favourable impression which such unimpeachable rulings produce is not maintained on further inquiry.

In the first place, he lays down that, to make any act sinful, three conditions must be fulfilled:—(1) it must be done with consent of the will; (2) it must be free, that is, it must be in the power of the will to do it or leave it undone; (3) there must be intellectual consciousness (*advertentia*) of its evil nature. These look specious enough, and against the first no objection can be raised. But Liguori then alleges that violent gusts of passion or desire, which disturb the reason, and take away liberty of action, sometimes excuse from sin (*Ibid.*, ii. 1, 2). He is not speaking of actual insanity, which is not under consideration; and he adds that evil acts done by a drunken person are either not sinful at all, or are at most venial sins (*Ibid.*, ii. 1, 4), because the effect cannot be more sinful than the cause. And as to the degree of advertence necessary as a condition of sin, he first mentions the stricter view, that actual and immediate attention to the nature of the act is not required, but that a virtual knowledge of its character suffices, by which a man might reasonably be expected to recognize it, since otherwise all evil-doers who are blinded by their passions, or by a long course of malpractices, may go on taking no notice, and continue to commit sins with moral impunity. He then states the laxer and commoner view, that some direct advertence of the sinful nature of the act is necessary to constitute sin in doing it, and proceeds to reconcile these two opinions by ruling that voluntary ignorance, whether due to conscious neglect, to deliberate following of passion, to a course of evil habit, or to omission of the degree of consideration which the act demands, does not excuse from sin; but that all other forms of it do acquit the offender. The obscurity inseparable from some of these qualifications complicates a sufficiently simple matter, and in any case the doubter is at liberty to fall back on the laxer opinion. But there is one exception;—unbelievers and heretics cannot plead ignorance as their excuse. All their errors, of whatever kind, are imputed to them as sin (*Ibid.*, ii. 1, 4). A further difficulty is created by the distinction made between mortal and venial sins, and by the inferences drawn from this distinction. "A mortal sin is that which, by reason of its gravity, dissolves grace and friendship with God, and merits eternal punishment. It is called mortal, because it takes away the principle of spiritual life, that is, habitual grace, and brings death on the soul. A venial sin is that which, by reason of its slightness, does not take away grace and friendship, though it abates the warmth of charity, and deserves temporal punishment. It is called venial, because, without damage to the principle of spiritual life, that is, grace, it brings on the soul an easily curable weakness, and easily obtains pardon" (*Ibid.*, ii. 51). This seems at first merely a recognition of the broad practical distinction between serious and trifling offences acknowledged by every sound ethical thinker and by every civilized penal code. But its consequences go much further, for in the Roman system of casuistry the aim is as a rule to attenuate mortal sins into venial ones; while these latter are regarded as of such little moment as scarcely to deserve the very name of sin. This appears from the fact that, whereas the canon (xxi.) *Omnis utriusque sexus fidelis* of the council of Lateran (1215), which first made private confession compulsory, enjoins the confession of all one's sins at least yearly, on the other hand, the council of Trent (Sess. xiv. c. 5) lays down that only mortal sins need be so disclosed, while venial sins, though they may be named in confession, according to the practice of devout persons, can be passed over in silence without any fault. And Liguori gives his own sanction to the proposition that a Christian does not sin gravely who proposes to commit *every one* of the venial sins (*Theol. Mor.*, v. 1, 12). Such being the light estimate of these sins, it might be fairly supposed that great care would be taken to mark them off so clearly from mortal sins that even the least instructed conscience could not confuse them with each other. But every sin which, considered in itself, is mortal, becomes venial if any one of these three conditions be absent:—full advertence and deliberation; entire consent; for the most part, gravity of the subject matter. Insufficient deliberation may be known in three ways:—imperfect consciousness of the sinfulness of the act, as if one were half asleep; subsequent regret, and a conviction that you would not have done the act had you fully apprehended it; such disturbance, through passion, alarm, or distraction, as to confuse the sense of what you were doing. Imperfect consent is established by the presence of a doubt in any one's mind whether he did really consent; by the habitual disposition being that of regarding mortal sin as a worse evil than death; by consciousness of having proceeded very timidly and hesitatingly in the action; by being half asleep, so as to be only doubtfully conscious, and being of opinion that the act would not have been done in case of full possession of the senses. And gravity of the subject matter is to be decided, not merely on the merits of the thing in itself, but in its relation to the end proposed by the agent. If it make but little for this end, it is trifling; if much, then it becomes serious (*Theol. Mor.*, ii. 54, 55, 56).

It is obvious that each of these subdivided qualifications admits of indefinite hair-splitting, and so that the security apparently provided by the general distinction between mortal and venial sins is elusive. It is true that there are also causes which will raise a venial sin to the rank of mortal; but the ascending process is more uncertain and difficult than the descending one. A venial sin, committed deliberately as a stepping-stone to a mortal sin, is to be judged in respect of this its object, and so becomes mortal. A venial sin, so passionately clung to as to make its votary ready to commit a mortal sin rather than forego its indulgence, also becomes mortal. But in neither of these cases is it necessary to confess the venial sin, only the mortal sin to which it has led up. The third mode of a venial sin becoming mortal is when it is committed with the formal and express purpose of disobedience to a superior, or to a precept, just because it is a precept. And in this case alone, because of the supreme place given to obedience in the Roman system, wherein it is not only the first and highest of virtues, but practically almost the only one insisted on for all, there is no manner of withdrawal from the category of mortal sins (*Theol. Mor.*, ii. 59, 60, 61).

So far, only the general principles on which Liguori's system is based have been explained. It next remains to exhibit their practical application, both as regards his own statements and also as regards those opinions of other casuists which, though not accepting them for himself, he yet embodies without censure in his work, thereby giving them the character and sanction of probability. It will simplify the inquiry to limit it mainly, though not exclusively, to the teaching on falsehood and theft.

Both of these are declared by Liguori to be sins of grave character, and in regard to the former he cites, amongst other authoritative condemnations, these words of Pope Innocent III.: "Not even to defend our life is it lawful to speak falsely." He adds that persons who are being lawfully questioned by such as have a right to interrogate as judges in court, or a priest in the confessional, are bound to disclose truly all that they know of the matter inquired into. Those who are questioned by such as have no right to interrogate them, or are questioned irregularly by lawful authority, are not bound to communicate their knowledge, and may set aside and avoid such questioning by any lawful means,—such means, however, not including falsehood, nor answers made with mental reservation, making the words actually spoken false, this latter mode of evasion having been formally condemned by Innocent XI. in 1679, though it was permitted by the casuists of the immediately preceding period. This is all tenable enough, but its apparent force is easily reduced by a little ingenuity.

In the first place, he distinguishes amphibology or equivocation from mental reservation, and names three varieties of equivocation: (1) that of a word having two quite different senses, as *volo* in Latin means to "wish" and to "fly,"—to which may be added the frequent English ambiguity of two distinct words having the same sound, as *air* and *heir*; (2) a sentence having two main meanings, as "This book is Peter's," which may signify his ownership or his authorship; (3) that of words having two senses, one more common than the other, or one literal and the other metaphorical. The example he gives of this last form is the phrase "I say No," uttered by a person who wishes to conceal something as to which he is questioned. The words seem to his hearer to denote express denial of the fact; the meaning in which he uses them is merely "I utter the word 'No,'" this sentence being complete in itself. "It is certain," adds Liguori, "and the common opinion of all, that it is lawful for a just cause to use equivocation in the manners described, and to confirm it with an oath. . . . And the reason is because we do not then deceive our neighbour, but for a just cause permit him to deceive himself; and besides, we are not bound, if there be a just cause, to speak so that others may understand. And any honest object for retaining any good things that are useful to our body or spirit may be a just cause" (*Theol. Mor.*, iv. 151).

But suppose that it is impossible to allege a just cause, is it then mortal sin to swear with such equivocation? Some of the stricter casuists say so, but Liguori sides with the laxists, and declares it merely venial, except in a court of law or in formal contracts,—alleging that, save in these two cases, any reasonable cause, such as desire to be quit of troublesome and irregular questioning, is sufficient to mitigate the sin. He adds, however, two cautions—that a more serious cause is required to justify equivocation with an oath than without one, and that, in proportion as the equivocal words employed give greater occasion for mistake, a graver cause is required for their proper use, a qualification instantly modified by the next clause, which lays down that, when words which are in themselves equivocal, having two equally valid meanings, are used, then they give little or no cause for error, and may be used on the very lightest grounds.

Next, as to mental reservation, or "restriction," which is the technical name, this was expressly condemned in three propositions by Innocent XI., forbidding it in all cases. According to the analogy of all prohibitory laws, this general prohibition of the genus should include prohibition of all the species also. But the casuists, unable to oppose direct resistance to the papal decree, have turned its flank by inventing a new distinction which was unknown in 1679. They have now divided mental restriction into two main heads, the first of which, absolute or "pure" mental restriction (by which is meant such reservation as cannot possibly be observed by the hearers, or conjectured from the attendant circumstances), is always illicit, whether with or without an oath. But "non-pure" mental restriction (that is, such as may conceivably be observed and inferred from attending circumstances, such as an inaudible whisper, or a qualifying gesture) does not, they allege, fall under the ban of Innocent XI., and is always lawful for a just cause. "The reason of this opinion is that, if it were not permissible to use non-pure mental restriction, there would be no lawful means of concealing a secret, which one could not disclose without loss or inconvenience, which would be as hurtful as lying to human intercourse. And therefore the condemnation passed by the pope on mental restriction is rightly to be understood of a restriction taken absolutely and strictly, for that alone can be called true mental restriction which takes place in the mind alone, and so remains hidden, and can in no wise be recognized from external circumstances" (*Theol. Mor.*, iv. 152). And the following illustrations are supplied. (1) A confessor may affirm with an oath that he is ignorant of a crime which he has heard in confession, secretly meaning thereby that he is ignorant of it as a mere man, though not as a minister of religion. (2) An accused or a witness, if *irregularly* questioned by the judge in court, may swear that he knows nothing of a crime which he does in fact know of, understanding thereby that he does not know it so as to be legally bound to answer or depose concerning it. This alarming proposition is apparently corrected by the warning that, when the interrogation of the judge is in due form, then the person questioned is bound to obedience, and barred from all equivocation. But this safeguard is at once fatally weakened by the further provisions that, if the act be not a crime in the witness's opinion, he need not disclose it, and that if the crime be altogether hidden (*i.e.*, where only the criminal himself and the witness know the facts), the witness is not merely permitted, but is actually bound, to say that the accused did not commit it. And the accused is equally free to do so, unless there be already "half-full" proof against him, because, in the absence of such a degree of presumption, the judge has no legitimate right to question him as to his guilt. Those who have deceived the court by such sworn equivocation are, Liguori rules, entitled to absolution without the declaration of the truth being imposed as a condition.[1] (3) A needy man, who has made

[1] Akin to this teaching is the maxim laid down in another place, that it is lawful to procure the giving of perjured evidence, "if you have a great interest in employing perjury to expose the fraud of another person in order to obtain your own rights" (*Theol. Mor.*, iii. 3, 77), with which may be coupled the permission for suitors to offer and for judges to take bribes for expediting causes, so long as the bribing is not expressly for delivering false judgment (*Ibid.*, v. 196, 212).

away, for his maintenance, with property due to his creditors, may affirm to the judge that he has nothing. (4) A witness asked by the judge whether he has had any conversation with the accused may deny it, meaning that he has not talked with him so as to co-operate in the crime. (5) An adulteress, questioned by her husband as to her guilt, may deny it in any of these four ways: (*a*) that she has not broken the marriage-tie, because it is not voided by adultery; (*b*) if she have gone to confession, she may say that she is innocent of the crime, because it has been remitted in confession; (*c*) that she has not committed adultery, using the word in its frequent Biblical sense of "idolatry"; (*d*) that she has not committed it so as to be bound to tell him of it (*Theol. Mor.*, iv. 153–162).

Promises are no safer than assertions under this code. As usual with Liguori, a broad statement of their binding character is prefixed to the qualifications which leave nothing but the outer shell remaining. For we are told (*a*) that "the whole obligation is commonly understood as depending on the intentions of the promisers, and not binding unless that be confirmed with an oath or a formal document, in the absence of which it may be considered a mistake or a jest"; and (*b*) that "it is certain that every promise, even an accepted one, does not bind, if after the date of the promise it becomes impossible, or very hurtful, or unlawful, or useless, and generally speaking, when there has been a serious change of circumstances, which, if foreseen, would have prevented the promise; such a promise is always presumed to have been made under some such tacit condition" (*Theol. Mor.*, iv. 720).

Theft is treated in a very similar fashion. A broad general rule is laid down as to its sinfulness, and this is at once traversed by the following doctrine: "It is certain that a man who is in extreme necessity may purloin other people's goods, enough to relieve himself from such necessity. So the doctors in common say, agreeing with St Thomas." Extreme necessity is defined as meaning risk of loss of life, or of some limb or other important bodily member, peril of perpetual captivity, or of any serious disease or discredit. And Liguori, contradicting the stricter casuists, includes under the same heading the case of a man of rank ashamed to work or to beg, who may then lawfully steal to maintain himself. Then the case is put whether a poor man in extreme need is free to steal before asking. One rigorist lays down that it is a mortal sin to do so, because no man can be held to be in extreme necessity who can get what he wants by asking. But the laxer casuists rule that, though he is bound to ask first, he sins only venially by omitting to do so; and Liguori solves the difficulty by saying that the robber sins mortally if what he takes is not absolutely necessary to relieve his want, but that, if he does so need it that the owner, if aware of the fact, would be bound by the laws of charity to give it him, then he does not sin even venially by stealing it, because he has in that case an absolute right to take it (*Theol. Mor.*, iv. 520).

Some of these rulings are contrived so as to evade the condemnation passed by Innocent XI. on the proposition that "it is allowable to steal, not only in extreme necessity, but also in grave necessity." But a more direct conflict with the papal ruling appears in respect of another censured proposition, that "men and women servants may secretly pilfer from their employers to compensate themselves for their work, which they account as of more value than the wages they receive." This is explicit enough, but it is at once set aside by the casuists, who allege that the rule holds good only in the case of a servant who has of his free will contracted to accept a low salary, as he thereby bars himself from compensation; but if he has made the bargain under any sort of constraint, as, for instance, being in great poverty, and thus glad to take any situation, he is at liberty to steal to the amount of what he considers his just additional wages. Some casuists do, indeed, question the servant's right to be judge and assessor in his own cause, but the point is ruled practically in his favour (*Theol. Mor.*, iv. 522, 523, 524). Again, servants may purloin such eatables and drinkables as are not locked up, provided they do so for their own consumption, and not to sell out of doors, and so long as each such theft is singly trifling (*Ibid.*, iv. 54). Even when restitution is enjoined, there is a notable provision in favour of the thief. If he is uncertain who it is he has robbed, he is to make restitution in one or other of certain ways, one of which is that if he be poor he may apply the proceeds of the theft to himself or to his family (*Prax. Confess.*, ii. 44).

In addition to these glosses on the decalogue, there is one element of doubtfulness introduced into nearly all questions of theft, which is, as to the "gravity of matter," constituting the offence mortal or venial according to the degree of this factor, and a comparison of the various places where Liguori employs the term "gravitas materiæ" shows that in all cases where numerical expression can apply he means *quantity*. Accordingly, he, in common with many other casuists, constructs a sliding tariff of guilt, depending, as a rule, on the amount stolen (*Theol. Mor.*, iv. 526–528).

A few brief citations from other decisions will show that the same principles applied to questions of lying and theft extend to the remaining forms of sin. (1) A man of high position may lawfully kill any one who attempts to slap his face, if there be no other way of warding off the insult (*Theol. Mor.*, iv. 38). (2) He who kills A, meaning to kill B, is not bound to make compensation, because the homicide is casual and inadvertent as regards A; and similarly if a man burns down the house of his friend, meaning to burn that of an enemy (*Ibid.*, iv. 628, 629). (3) Though we are bound to love our enemies, we are not bound to salute them, to speak to them, to visit them if sick, to comfort them in any trouble, to receive them into our house, or to hold any kind of familiar intercourse with them (*Ibid.*, v. 3, 28). (4) A servant may help his master, by lifting him on his shoulders, or by providing him with a ladder, to enter a house, even forcibly, for immoral purposes; for the act is innocent and colourless in itself, nay, even an act of charity or good-will, and the servant is not responsible for the subsequent conduct of his employer (*Ibid.*, iii. 3, 66).

For all practical purposes, the probabilism which is at the base of all this casuistical method, and which is simply the substitution of an external authority for the dictates of conscience, is now in absolute possession throughout the Latin obedience, having finally conquered the resistance it has encountered at intervals since its first formulation as a working theory. Although it owes its chief development to the Jesuits, yet some of its ablest opponents were members of that company, such as Comitolus, Rebellus, Gisbert, and even two of the generals, Mutio Vitelleschi and Tirso Gonzales; while the Sorbonne and the Dominicans were also engaged in frequent controversy against its upholders, and in censuring the teaching of several of Liguori's favourite authorities, such as Lessius, Escobar, Tamburini, Bauny, Viva, Busembaum, and Diana.

Alfonso de Liguori*, London, 1857; *Charge of Archdeacon Sinclair*, in 1867. (R. F. L.)

LIGURIA, in ancient geography, was the name given to a portion of the north-west of Italy, including the districts, on both sides of the Maritime Alps and the Apennines, which border on the Tyrrhenian Sea from the frontiers of Gaul to those of Etruria. Along the sea-coast it extended from the river Varus or Var, which separated it from Gaul, to the Macra (Magra), which formed its limit on the side of Etruria, thus comprising the whole district between the mountains and the sea, now known as the Riviera of Genoa. But besides this it comprehended a broad tract to the north of the same range, formed by the underfalls of the Apennines and the hilly tract adjoining them, extending to the plains of the Padus or Po,—that river itself constituting its northern limits under the Roman administration. But at an earlier period the term had a much wider signification,—all the tribes on the south slopes of the Alps, in the north-west of Italy, being apparently of Ligurian origin. This we are expressly told by ancient authors in the case of the Taurini, who dwelt around Turin, and of the Lævi and Libici, who extended from thence to the Ticinus; and there can be little doubt that it was true also of the Salassi, who occupied the modern Val d'Aosta. But to the west of the Maritime Alps also the Ligurians were undoubtedly widely spread in ancient times, and occupied a considerable extent of what was afterwards included in Gaul. Thus the Salyes, who held all the southern part of Provence from the Var to the Rhone, are distinctly termed a Ligurian tribe, as well as the minor tribes of the Oxybii and Deciates, near Frejus and Nice. All the early Greek writers speak of the important colony of Massilia as founded in Liguria.

Of the origin or affinities of the Ligurians (or Ligyans, as they are termed by Greek writers) we know absolutely nothing. All ancient writers concur in representing them as a distinct people from the Gauls on the one hand, and from the Iberians on the other; and the attempts of some modern writers to assign them to a Celtic stock rest upon no adequate foundation. In the absence of all remains of their language, all such speculations must be matters of mere conjecture. They appear in the historical period as a rough and hardy race of mountaineers, cultivating a rugged territory with much industry, and opposing a stubborn resistance to the efforts of the Romans to reduce them to subjection. They first came in contact with the Roman arms in 235 B.C., but it was not till after the Second Punic War—in which the Ligurians had openly espoused the cause of Hannibal—that a serious struggle began, which, commencing in 200 B.C., was continued with little intermission for more than eighty years. While the Roman generals in the East were overthrowing, with comparative ease, the powerful monarchies of Macedonia and Syria, one of the consuls was generally engaged in inglorious hostilities with the hardy mountaineers of the Ligurian Apennines. Even after these were reduced to subjection, the tribes which held the still more rugged fastnesses of the Maritime Alps long maintained their independence, and it was not till the reign of Augustus that they were finally subdued. The construction by that monarch of a Roman highway along the coast, which followed almost exactly the same line as the modern road of the Corniche, marked the period of their complete subjection.

The physical geography of Liguria has been already described in the article of ITALY. All the rivers which take their rise on the northern slope of the mountains ultimately discharge their waters into the Po; of these by much the most considerable is the Tanaro, which receives the tributary streams of the Stura and the Bormida, while to the east of it flow the Scrivia and the Trebia, celebrated by the victory of Hannibal over the Romans. This last stream, according to the division of Augustus, formed the boundary between Liguria and Gaul south of the Po. The streams which flow from the Apennines southward to the sea are for the most part inconsiderable, and mere mountain torrents. But the Magra, which forms the limits of the province on the east, is an important stream, and brings with it the waters of its tributary, the Boactes or Vara. On the west also the Var is a river of considerable magnitude, which forms a natural boundary on this side between Liguria and Gaul, as it long constituted their political limit. The Rutuba or Roya, a little farther east, is also a considerable river, descending through a deep mountain valley from the Col di Tenda.

The principal Ligurian tribes were (1) the Apuani, inhabiting the valley of the Magra, including the district known in modern times as the Lunigiana; (2) the Friniates, on the northern slope of the Apennines towards Modena; (3) the Briniates, in the valley of the Vara; (4) the Genuates, around Genoa; (5) the Veturii, immediately west of the preceding; (6) the Ingauni, whose capital was Albium Ingaunum, still called Albenga; (7) the Intemelii, whose chief city still retains the name of Vintimiglia; and (8) the Vediantii, extending thence to the Var. North of the Apennines the most important tribes were the Vagienni, who held the whole mountain tract from the Monte Viso and the sources of the Po to the Tanaro; and the Statielli, east of them, whose chief town was Aquæ Statiellæ or Acqui.

The chief city on the Ligurian sea-coast was, in ancient as in modern times, that of Genoa, which combined an excellent natural port with a central position, and easy communications with the interior. West of it, along the coast, were Vada Sabbata (Vado, near Savona), Albium Ingaunum (Albenga), Albium Intemelium (Vintimiglia), the Portus Herculis Monœci (Monaco), and Nicæa (Nice), which was founded by a colony from Massilia. In its immediate vicinity was the Roman town of Cemenelium (Cimiez). On the northern slope of the Apennines were several considerable towns, almost all of them of Roman origin. The chief of these were Augusta Vagiennorum (Bene), Alba Pompeia, Asta, Aquæ Statiellæ, Dertona (Tortona), and Iria (Voghera), but none of them attained to anything like the same prosperity and importance as the great cities of Cisalpine Gaul. The towns on the eastern Riviera, between Genoa and the Gulf of Spezia, were inconsiderable places; and even on the shores of that gulf, forming the magnificent port called the Portus Lunæ, there was never any town of importance, Luna itself being some distance inland, and within the confines of Etruria. (E. H. B.)

LILAC, *Syringa vulgaris*, L., belongs to the olive family, *Oleaceæ*. The common lilac is said to have come from Persia in the 16th century, but according to Heuffel it is indigenous in Hungary, the borders of Moldavia, &c. (De Candolle, *Prod.*, viii. p. 282). Two kinds of *Syringa*, viz., *alba* and *cærulea*, are figured and described in Gerard's *Herball* (1597), which he calls the white and the blue pipe privets. The former is the common privet, *Ligustrum vulgare*, L., which, and the ash tree, *Fraxinus excelsior*, L., are the only members of the family native in Great Britain. The latter is the lilac, as both figure and description agree accurately with it. It was carried by the European colonists to North-East America, and is still grown in gardens of the Northern and Middle States. There are several varieties of lilac, *e.g.*, "Dr Lindley," which bears large clusters of reddish lilac flowers, *alba*, *violacea*, *rubra insignis*, and *rosea grandiflora*. *S. dubia*, Pers., or *chinensis*, Willd., the Siberian lilac, is a closely allied species, if it be really distinct. The variety *Rothomagensis*, Mirb., or *Lilas Varin* of the French, probably belongs to this species. Of other species, there is *S. Josikæa*, Jack., from Transylvania, with scentless bluish-purple flowers, *S. Emodi*, Wall., a native of the mountains of India, and *S. persica*, L., the Persian lilac, rarely exceeding 4 or 5 feet, the flowers of which vary from rosy carmine to white.

LILBURNE, JOHN (1618–1657), an English sectary and prolific pamphleteer, was the younger son of a gentleman of good family in the county of Durham, and was born in 1618. At the age of twelve he was apprenticed to a clothier in London, but he appears to have paid only slight attention to business, and to have early addicted himself to the "contention, novelties, opposition of government, and violent and bitter expressions" for which he afterwards became so conspicuous as to provoke the saying of Marten that, "if the world was emptied of all but John Lilburn, Lilburn would quarrel with John, and John with Lilburn." He appears at one time to have been law-clerk to Prynne. In February 1638, for the part he had taken in importing and circulating the *Merry Litany* and other publications of Bastwick and Prynne, offensive to the bishops, he was sentenced to be publicly whipped from the Fleet prison to Palace Yard, Westminster, there to stand for two hours in the pillory, and afterwards to be kept in jail until a fine of £500 had been paid. Though gagged at the pillory, and confined in prison, he was not the man to give up his opinions or forego the pleasure of expressing them, and in the following year he did not improve his prospects of a speedy release by the kind of literary activity to which he devoted his enforced leisure.[1] In point of fact he did not regain his liberty until November 7, 1640, when one of the earliest recorded speeches of Oliver

[1] *Come out of Her, My People: or An Answer to the Questions of a Gentlewoman, a professor in the Anti-Christian Church of England, about Hearing the public Ministers; where it is largely discussed, and proved to be unlawful. Also a Just Apology for the way of Total Separation, commonly but falsely called "Brownism"; that it is the truth of God though lightly esteemed in the eyes of the world. With a challenge to dispute them publicly before King and Council, to prove whatsoever I have said at the pillory against them: viz., that the calling of them is* jure Diaboli, *even from the Devil himself. By me John Lilburne, close prisoner in the Fleet for the cause of Christ. Printed in the year of hope of England's Purgation and the Prelates' Dissolution*, 1639.

Cromwell was made in support of his petition to the House of Commons. In 1641 he received an indemnity of £3000. He now entered the army, and in 1642 was taken prisoner at Brentford and tried for his life; sentence would no doubt have been executed had not the parliament by threatening reprisals forced his exchange. He soon rose to the rank of lieutenant-colonel, but in April 1645, having become dissatisfied with the general conduct of affairs, and especially with the predominance of Presbyterianism, he resigned his commission, presenting at the same time to the Commons a petition for considerable arrears of pay. His violent language in Westminster Hall about the speaker and other public men led in the following July to his arrest and committal to Newgate, whence he was discharged, however, without trial, by order of the House, in October. In January 1647 he was again committed to the Tower for accusations which he had brought against Cromwell, but was again set at liberty in time to become a disappointed spectator of the failure of the levelling or ultrademocratic party in the army at the Ware rendezvous in the following December. The scene produced a deep impression on his mind, and in February 1649 he along with other petitioners presented to the House of Commons a paper entitled *The Serious Apprehensions of a part of the People on behalf of the Commonwealth*, which he followed up with a pamphlet, *England's New Chains Discovered* (March 1, 1649), criticizing Ireton, and another exposing the conduct of Cromwell, Ireton, and other leaders of the army since June 1647 (*The Hunting of the Foxes from Newmarket and Triploe Heath to Whitehall by Five Small Beagles*, the "beagles" being Lilburne, Overton, Walwyn, Prince, and another). Finally, the *Second Part of England's New Chains Discovered*, a violent outburst against "the dominion of a council of state, and a constitution of a new and unexperienced nature," became the subject of discussion in the House, and led anew to the imprisonment of its author in the Tower on April 11. His trial in the following October, on a charge of seditious and scandalous practices against the state, resulted in his unanimous acquittal, followed by his release in November. In January 1652, for printing and publishing a petition against Sir Arthur Hasilrig and the Haberdasher's Hall for what he conceived to have been an injury done to his uncle George Lilburne in 1649, he was sentenced to pay fines amounting to £7000, and moreover to be banished the Commonwealth, with prohibition of return under the pain of death. In June 1653 he nevertheless came back from the Low Countries, where he had busied himself during the interval in pamphleteering and such other agitation as was possible, and was immediately arrested; the trial, which was protracted from July 13 to August 20, indeed issued in his acquittal, to the great joy of London, but it was nevertheless thought proper to keep him in captivity for "the peace of the nation." He was detained successively in the Tower, in a castle at Jersey, and in Dover Castle. At Dover he came under Quaker influence, and signified his readiness at last to be done with "carnal sword fightings and fleshly bustlings and contests"; and in 1656, on giving security for his good behaviour, he was set free. He now settled at Eltham in Kent, frequently preaching at Quaker meetings in the place and neighbourhood during the brief remainder of his troubled life. He died on August 29, 1657.

See Masson, *Life of Milton*, who refers (iv. 120) also to Walker (*History of Independency*, ii. 247), Godwin (*Commonwealth*, iii. 163–177), and Bisset (*Omitted Chapters of the History of England*, 191–251), and adds, "Mr Bisset relates Lilburne's trial (in 1649) at length, with copious extracts, and makes John more of a hero than Godwin does, though Godwin is not unfavourable. On the whole, I like him myself, and am glad that he is in the history of England, but think he was an ass."

LILLE, capital of the department of Nord, France, and the ancient capital of Flanders, is situated about 155 miles by rail north of Paris, and at an elevation of 75 feet, in a low plain on the Deule, which flows to the Scheldt by the Lys. It is the chief fortress of the north of France, and headquarters of the first army corps, and is defended by a rampart and by a pentagonal citadel situated to the west of the town beside the Deule. The water of the river fills the moat, and the environs of the citadel can be laid under water. Prior to 1858 the town occupied an elliptical area of about 2500 yards by 1300, with the church of Notre Dame de la Treille in the centre, but the ramparts on the

south side have since been demolished and the ditches filled up, their place being now occupied by the great Boulevard de la Liberté, which extends in a straight line from the goods station of the railway to the citadel. The new enceinte is much more extensive, and encloses the old communes of Esquermes, Wazemmes, and Moulins-Lille, the area of the town being thus more than doubled; in the new quarters fine boulevards and handsome squares, such as that De la République, have been laid out in pleasant contrast with the sombre and dirty aspect of the old town. The district of St André to the north, the only elegant part of the old town, is the residence of the Lille aristocracy.

At the demolition of the old fortifications, the Paris gate, a triumphal arch erected in 1682 in honour of Louis XIV., after the conquest of Flanders, was preserved, as also the Ghent and Roubaix gates, which date from the time of the Spanish domination, and are built in the Renaissance style, with bricks of different colours. The present rampart is pierced by eleven gates, besides a special gate for the railway, and two water gates for the canal of the Deule. The goods station has also its special outlet, and a line from it, after making the round of the new quarters, passes within the enceinte to the quays of the river. Crossing the bridges which span the different arms of the Deule, we reach the citadel, the glacis of which, planted with trees, form a public walk. Within the citadel are extensive barracks and a considerable arsenal. The church of Notre Dame de la Treille, in the style of the 13th century, which has been in process of building since 1855, occupies the site of the old Château du Buc, the original nucleus of the city. The town-house, on the site of the old palace of the duke of Burgundy, Philip the Good, was built in 1846. The exchange, which dates from the period of the Spanish domination, is in an original style. It is surmounted by a graceful campanile, and contains a statue of Napoleon I., made from cannon taken at Austerlitz. In the middle of the great square stands a column, erected in 1848 commemorating the defence of the town in 1792 There are several large hospitals, faculties of medicine and of science, a Catholic institute, comprising the five faculties of theology, letters, law, science, and medicine, an academy of music affiliated to the Conservatoire at Paris, several learned societies, and a large number of various kinds of schools. The picture gallery, with upwards of eight hundred works, is one of the richest in the provinces, and the Wicar museum contains a unique collection of original designs of the great Italian masters. Lille possesses also an ethnographical museum (Musée Moillet), as well as museums of archæology, numismatics, the industrial arts, and natural history. The communal library is also worthy of mention; it includes numerous MSS., and particularly a valuable *Evangeliarium* of the 12th or 13th century. On the front of the building where the departmental archives are kept are to be seen medallions of all the sovereigns who have successively possessed Lille from Baldwin of the Iron Arm to Louis XIV. Lille, which is pre-eminently a manufacturing and commercial town, enjoys exceptional advantages as regards means of transit. The lower Deule is canalized to its junction with the Lys, and there is continuous water communication with the Scheldt in Belgium, and with Paris by way of Douai and St Quentin. The town is at the same time an important railway junction, and is also provided with tramways.

The principal industry is flax-spinning, in which thirty-five mills, with 190,000 spindles, give employment to 14,000 persons (of whom 9000 are females), the annual turnover being £1,800,000. Forty thread mills employ 2000 persons, and produce thread to the annual value of £240,000. Fifteen factories, with 1000 operatives, produce woollen goods worth from £120,000 to £160,000 per annum; 5000 persons are engaged in cotton-spinning (115,000 spindles), to the amount of £800,000. There are besides eighty factories in which damasks, tickings, and the usual staples of the linen trade are manufactured; quilts and packsheets occupy from 6000 to 7000 persons, and 4000 are employed in producing the fabric out of which the smock frocks of the peasantry are made. Connected with these industries are dye-works, bleachfields, and establishments for the production of engines, looms, and combing and carding machines; and there are also chemical works, sugar-works, breweries, and oil-works.[1] The state manufacture of tobacco in Lille gives employment to 1200 persons. The total population of Lille in 1876 was 162,775.

Lille is said to date its origin from the time of Count Baldwin IV., who in 1030 surrounded with walls a little town which had arisen around the castle of Buc. At the end of the 12th century Lille, which had developed rapidly, obtained communal privileges. Destroyed by Philip Augustus in 1212, it was rebuilt by Johanna of Constantinople, but besieged and retaken by Philip the Fair in 1297. After having taken part with the Flemings against the king of France, it was ceded to the latter in 1312. In 1369 Charles V. gave it to Louis de Male, who transmitted his rights to his daughter Margaret, wife of Philip the Bold, duke of Burgundy. Under the Burgundian rule Lille enjoyed great prosperity; its merchants were at the head of the London Hansa. Philip the Good made it his residence, and within its walls held the first chapters of the order of the Golden Fleece. With the rest of Flanders it passed from the dukes of Burgundy to Austria, and then to Spain. After the death of the Philip IV. of Spain, Louis XIV. reclaimed the territory, and besieged Lille in 1667. He forced it to capitulate, but preserved all its laws, customs, privileges, freedoms, and liberties. In 1708, after an heroic resistance, it surrendered to Prince Eugene and the duke of Marlborough. The treaty of Utrecht restored it to France. In 1792 the Austrians bombarded it for nine days and nights without intermission, but had ultimately to raise the siege. (G. ME.)

[1] The old commune of Moulins, now annexed to the town, derived its name from the windmills in which the oil was pressed.

LILLEBONNE, capital of a canton in the department of Seine-Inférieure, France, 131 miles west-north-west by rail from Paris, and 20 miles due east from Havre, is a pretty little town, picturesquely built at the foot of wooded hills, in the valley of the Bolbec, which falls into the Seine 3 miles lower, at Port Jérôme. The principal industries are cotton-spinning and the manufacture of calico. The population in 1876 was 5400.

Lillebonne was the capital of the Caletes, or inhabitants of the Pays de Caux, in the time of Cæsar, by whom it was destroyed. It was afterwards rebuilt by Augustus, who called it Juliobona after his daughter; and before it was again ruined by the barbarian invasions it had become a very important centre, whence Roman roads branched out in all directions. Some forty years ago the remains of ancient baths and of a theatre capable of containing 3000 persons were brought to light. Statues, tombstones, all sorts of articles in iron, bronze, ivory, marble, stone, glass, &c., have been found in the course of excavation, and deposited, for the most part, in the museum at Rouen. The most beautiful object yet discovered is a large mosaic found in 1870 (some 28 feet by 21). In the Middle Ages the fortifications of the town were constructed out of the materials supplied by the theatre. William of Normandy built at Lillebonne a castle whence he dates several charters. It is now a ruin within a charming park. The 13th century donjon, with walls over 12 feet in thickness, is in admirable preservation. The church of Notre Dame, of the 16th century, had a fine porch, formerly adorned with rich sculptures, which have mostly disappeared. The graceful tower is about 180 feet high.

LILLY, WILLIAM (1602–1681), an astrologer somewhat famous in his day, was born in 1602, at Diseworth in Leicestershire, his family having been settled as yeomen in the place for "many ages." He received a tolerably good classical education at the school of Ashby-de-la-Zouche, but he naively tells us what may perhaps have some significance in reference to his after career, that his master "never taught logic." In his eighteenth year, in consequence of his father having fallen into great poverty, he went to London, and was employed in a sort of menial situation in attendance on an old citizen and his wife, with whom he so managed to ingratiate himself that his master, at his death in 1627, left him an annuity of £20; and, Lilly having soon afterwards married the widow, she, dying in 1633, left him property to the value of about £1000. Having now a good deal of leisure on his hands, he began to dabble in astrology, reading all the books on the subject he could fall in with, and occasionally trying his hand at unravelling mysteries by means of his art. The years 1642 and 1643 were devoted to a careful revision of all his previous reading, and in particular having lighted on Valentine Naibod's *Commentary on Alchabitius*, he "seriously studied him and found him to be the profoundest author he ever met with." Him he "traversed over day and night," and so "advanced his judgment and knowledge" to the utmost height he ever arrived at. He characterizes him as "a most rational author and the sharpest expositor of Ptolemy that hath yet appeared." About the same time he tells us that he "did carefully take notice of every grand action betwixt king and parliament, and did first then incline to believe that as all sublunary affairs depend on superior causes, so there was a possibility of discovering them by the configurations of the superior bodies." And, having thereupon "made some essays," i.e. "found encouragement to proceed further, and ultimately framed to himself that method which he ever afterwards followed." He then began to issue his prophetical almanacs and other works, and it is a curious illustration of the state of intelligence even among educated people at the time that trash of this kind really seems to have met with serious attention from some of the most prominent members of the Long Parliament. If we may believe himself, Lilly lived on friendly and almost intimate terms with Bulstrode Whitlock, Lenthall the speaker, Sir Philip Stapleton, Elias Ashmole, and others. Even Selden seems to have given him some countenance, and probably the chief difference between him and the mass of the community at the time was that, while others believed in the general truth of astrology, he ventured to specify the future events to which its calculations pointed. Even from his own account of himself, however, it is evident that he did not trust implicitly to the indications given by the aspects of the heavens, but like more vulgar fortune-tellers kept his eyes and ears open for any information which might make his predictions safe. It appears that he had correspondents both at home and in foreign parts to keep him conversant with the probable current of affairs. He was evidently a proficient in all the unscrupulous cunning, adroitness, and plausibility which go to make up the successful quack and impostor, and not a few of his exploits indicate rather the quality of a clever police detective than of a profound astrologer. After the Restoration he very quickly fell into disrepute. His sympathy with the parliament, which his predictions had generally shown, was not calculated to bring him into royal favour, and the frivolons and sceptical character of the age could scarcely be expected to fall in with transcendentalism either in the shape of sense or nonsense. He came under the lash of Butler, who, making allowance for some satiric exaggeration, has given in the character of Sidrophel a probably not very incorrect picture of the man; and, having by this time amassed a tolerable fortune, he bought a small estate at Hersham in Surrey, to which he retired, and where he diverted the exercise of his peculiar talents to the practice of medicine. He died in 1681, in the eightieth year of his age.

Lilly's life of himself, published after his death, is still worth looking into as a remarkable record of credulity and successful imposture. Superstition dies hard; and it is a curious evidence of the inveteracy of popular delusions that so lately as 1852 a prominent London publisher put forth a new edition of Lilly's *Introduction to Astrology*, "with numerons emendations adapted to the improved state of the science."

LILY, *Lilium*, the typical genus of *Liliaceæ*, embraces nearly fifty species, all confined to the northern hemisphere, about fifteen being natives of Japan and China, six of the mountains of India, eight of south Europe, five of the east and nine of the west coasts of North America. The earliest in cultivation were described in 1597 by Gerard (*Herball*, p. 146), who figures eight kinds of European (true) lilies, viz., *L. album* (*L. candidum*, L.), and a variety, *L. bizantinum*, two umbellate forms of the type *L. bulbiferum*, Park., named *L. aureum* and *L. cruentum latifolium*, and three with pendulous flowers, apparently forms of the martagon lily. Parkinson, in his *Paradisus* (1629), described five varieties of martagon, six of umbellate kinds—two white ones, and *L. pomponium*, *L. chalcedonicum*, *L. carniolicum*, and *L. pyrenaicum*—together with one American, *L. canadense*, which had been introduced in 1629. For the ancient and mediæval history of the lily, see M. de Cannart d'Hamale's *Monographie historique et littéraire des Lis* (Malines, 1870). Since that period many new species have been added. The latest authorities for description and classification of the genus are J. G. Baker ("Revision of the Genera and Species of Tulipeæ," *Journ. of Linn. Soc.*, xiv. p. 211, 1874) and J. H. Elwes (*Monograph of the Genus* Lilium, 1877-78), who first tested all the species under cultivation, and has published every one beautifully figured by W. H. Fitch, and some hybrids. With respect to the production of these latter, the genus is remarkable for its power of resisting the influence of foreign pollen, for the seedlings of any species, when crossed, generally resemble that which bears them. For the hardier kinds in cultivation, reference may be had to Hemsley's *Handbook of Hardy Trees*, &c., p. 501. The structure of a lily is of simple type, consisting of two whorls, of three free parts each, six free stamens, and a consolidated pistil of three carpels, ripening into a three valved capsule containing many winged seeds. In form, the flower assumes three types:—trumpet-shaped, with a more or less elongated tube, *e.g.*, *L. longiflorum* and *L. candidum*; an open form with spreading perianth leaves, *e.g.*, *L. auratum*; or assuming a pendulous habit, with the lips strongly reflexed, *e.g.*, the martagon type. All have scaly bulbs, which in three west American species, as *L. Humboldti*, are remarkable for being somewhat intermediate between a bulb and a creeping rhizome. *L. bulbiferum* and its allies produce aerial reproductive bulbils in the axils of the leaves. The bulbs of several species are eaten, such as of *L. avenaceum* in Kamchatka, of *L. Martagon* by the Cossacks, and of *L. tigrinum*, the "tiger lily," in China and Japan. Medicinal uses were ascribed to the species, but none appear to have any marked properties in this respect. See HORTICULTURE, vol. xii. p. 257.

The white lily, *L. candidum*, the λείριον of the Greeks, was one of the commonest garden flowers of antiquity, appearing in the poets from Homer downwards side by side with the rose and the violet. According to Hehn, roses and lilies entered Greece from the east by way of Phrygia, Thrace, and Macedonia (*Kulturpflanzen und Hausthiere*, 3d ed., p. 217). The word λείριον itself, from which *lilium* is derived by assimilation of consonants, appears to be Eranian (*Ibid.*, p. 527), and according to ancient etymologists (Lagarde, *Ges. Abh.*, p. 227) the town of Susa was connected with the Persian name of the lily *sûsan* (Gr. σοῦσον, Heb. *shôshan*). Mythologically the white lily, *Rosa Junonis*, was fabled to have sprung from the milk of Hera. As the plant of purity it was contrasted with the rose of Aphrodite. The word κρίνον, on the other hand, included red and purple lilies, Plin., *H. N.*, xxi. 5 (11, 12), the red lily being best known in Syria and Judæa (Phaselis). This perhaps is the "red lily of Constantinople" of Gerarde, *L. chalcedonicum*, L. The lily of the Old Testament (shôshan) may be conjectured to be a red lily from the simile in Cant. v. 13, unless the allusion is to the fragrance rather than the colour of the lips, in which case the white lily must be thought of. The "lilies of the field," Matt. vi. 28, are κρίνα, and the comparison of their beauty with royal robes suggests their identification with the red Syrian lily of Pliny. Lilies, however, are not a conspicuous feature in the flora of Palestine, and the red anemone (*Anemone coronaria*), with which all the hill-sides of Galilee are dotted in the spring, is perhaps more likely to have suggested the figure. For the lily in the pharmacopœia of the ancients see Adams's *Paul. Æginета*, iii. 196. It was used in unguents and against the bites of snakes, &c. In the Middle Ages the flower continued to be common, and was taken as the symbol of heavenly purity. The three golden lilies of France are said to have been originally three lance-heads.

LILYE, WILLIAM (*c.* 1466-1523), one of the introducers of a knowledge of the Greek language into England, was born at Odiham, in or about the year 1466. He entered the university of Oxford in 1484, became a demy of Magdalen in 1486, and after taking his first degree in arts went on a pilgrimage to Jerusalem. On his return he put in at Rhodes, which was still occupied by the Knights, under whose protection many Greeks had taken refuge after the taking of Constantinople by the Turks. Here he laid the foundation of a knowledge of the Greek language. We next hear of him in Italy, following the lectures of John Sulpitius and Pomponius Lætus at Rome. From this he passed on to Venice, from which place he writes to his friend and patron Thomas Starkey, that "he is assiduously attending the lectures of Egnatius in Latin, but that he finds no one in Venice who can assist him in the study of Greek. He reads, however, Greek by himself, and has read seven plays of Sophocles, five of Euripides, three of Aristophanes, besides extracts from Xenophon and Plutarch, by himself without a teacher." After his return he settled in London, as a private teacher of grammar, and is believed to have been the first who taught Greek in that city. In 1510 Colet, dean of St Paul's, who was then founding the school which afterwards became famous, appointed Lilye the first highmaster. He held this office only twelve years, dying of the plague in February 1523.

Lilye's name deserves commemoration, not only as one of the pioneers of Greek learning, but as one of the joint authors of a book, familiar to many generations of students, down to the present century, the old Eton Latin grammar. The *Brevissima Institutio*, a sketch by Colet, corrected by Erasmus, and worked upon by Lilye, contains two portions, the authorship of which is indisputably Lilye's. These are the lines on the genders of nouns, beginning "Propria quæ maribus," and those on the conjugation of verbs, beginning "As in præsenti." The "Carmen de moribus" bears Lilye's name in the early editions; but Hearne asserts that it was written by Leland, who was one of his scholars, and that Lilye only adopted it. Besides the *Brevissima Institutio*, Lilye wrote a variety of Latin pieces both in prose and verse. Some of the latter are printed along with the Latin verses of Sir Thomas More in *Progymnasmata Thomæ Mori et Gulielmi Lylii Sodalium*, Basel, 1518. Another volume of Latin verse directed against a rival schoolmaster and grammarian, Whittington, whose grammar that of Lilye superseded, is entitled *Antibossicon ad Gulielmum Hormannum*, 1521.

The only authority for the few facts which make up the above life of Lilye is a short sketch furnished by his son George to Paulus Jovius, who was collecting for his history the lives of the learned men of Great Britain. All the other names, such as Bale, Pits, Fuller, Wood, which figure in the dictionaries as authorities, are only transcripts of George Lilye. To these scanty memoranda the present article adds an extract from three letters of Lilye's preserved in the British Museum, Cotton. Nero, B. vi. fol. 157, now printed for the first time.

LIMA, capital of the republic of Peru, as also of the department and province of Lima, is situated on an extensive plain, 500 feet above the sea-level, and 7 miles east from its port Callao on the Pacific coast, in 12° 2′ 34″ S. lat., 77° 7′ 36″ W. long. The general configuration of the main portion of the city, previous to 1870 surrounded by walls, is that of an irregular triangle, whose base rests on

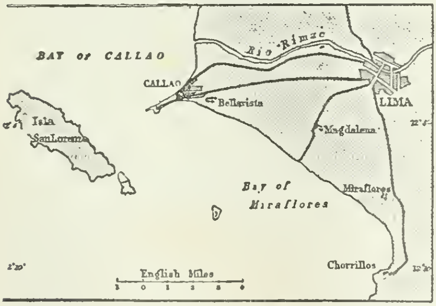

Fig. 1.—Neighbourhood of Lima and Callao.

the river Rimac, which separates the city from its offshoot or suburb of San Lazaro. Sheltered on the north and east by the spurs of the Andes, the city is exposed to the winds prevailing from the south-east, as also to those from the south and west. Although the atmosphere is moist, and the transitions of the seasons are rapid, the climate is not unhealthy, the rainfall being slight, and the variations of temperature not excessive. The summer commences in December, and the winter in June, and the mean temperature for the year is about 73° Fahr. The city is divided into five quarters or parishes, and is well laid out with broad and regular thoroughfares, the streets intersecting one another at right angles. The houses are spacious, but generally of only two stories, and are approached by portals leading into an open court or yard. In the principal square, which covers an area of 9 English acres in the centre of the city, stands a fine fountain of bronze. Here also are the cathedral, a stone structure with two lofty towers and a broad façade, the archiepiscopal palace, the Government house, and the Portal de los Escribanos, containing the municipal offices and archives. Besides the cathedral there are five chief parochial and sixty-two other churches and chapels, and numerous monasteries and convents. Of the churches, the largest is that of San Pedro (1598), which has seventeen altars; of the religious houses that of the Dominicans is the finest, and that of the Franciscans the most extensive. The university, built in 1576, is the oldest in America; it contains the hall and offices

used by the chamber of deputies. Lima has more than seventy schools, a public library containing upwards of forty thousand volumes, and many charitable institutions, several of them connected with the religious orders. The principal place of amusement is the amphitheatre for bullfights in the Plaza del Acho, accommodating nine thousand spectators. In the Plaza de la Exposicion is a marble statue of Columbus unveiling a figure of America. Of the many other monuments in Lima the most famous is the bronze equestrian statue of Simon Bolivar in the Plaza de la Independencia (or de Bolivar), 11 tons in weight, commemorating the battle of Ayacucho, which secured the independence of Peru. Among the public promenades are reckoned the cemetery outside the Maravillas gate, and the Paseo de la Alameda de los Descalzos, in the centre of which is a gorgeous garden. As the capital of Peru, Lima is one of the most important trading centres in South America. It has, however, but few home industries, its manufactured goods being chiefly imported from Europe *via* Callao, the medium of nearly all its foreign commerce. Several attempts have from time to time been made to establish factories, but the high price of labour has hitherto prevented any efforts on a large scale being permanently successful. There are, however, manufactories for tallow, soap, sperm candles, glue, gold lace, gilt leather, and silver filigree work, and the capital supplies the towns of the republic with coarse woollen fabrics. The market is attended daily by about a thousand dealers. Fish is supplied from Callao, and vegetables partly from gardens in the city and environs, and partly from the native villages. Since 1857 the water for drinking purposes has been obtained filtered from the Rimac, and supplied by pipes to the houses. The imports are various; the exports include guano, cinchona, Indian wool, raw cotton, hides, sugar, saltpetre, gold, silver, and other minerals. Under ordinary conditions the imports and exports together exceed £5,000,000 annually. There are railways from Lima leading to Callao, Chancay, Chorrillos, and Oroya; the construction of several other lines has been stopped by the war with Chili. In 1780 the population of Lima was 50,000; in 1860 it had reached 100,341, and in 1868 121,362, of whom 38,761 were foreigners. A recent estimate (1877) gives the number at about 200,000, but, considering the vicissitudes the city has since then endured, these figures must be considered at the present time (1882) as far too high. The Spanish natives have the reputation of being courteous, affable, and generous, but at the same time fond of pleasure, improvident, and superstitious. By confession they are mostly Roman Catholics.

Lima was founded 18th January 1535, by Francisco Pizarro, who named it *Ciudad de los Reyes* in honour of the emperor Charles V. and Doña Juana his mother, or, according to some authors, from its site having been selected on the 6th January, the Feast of the Epiphany. The name afterwards gave place to that of *Lima*, a Spanish corruption of the Quichua word *Rimac*. In 1548 Lima received its first archbishop, and in 1582 the earliest provincial council for the state was held there. Remaining under Spanish rule during the 17th, 18th, and early part of the 19th centuries, the city continued to increase in prosperity, though often visited by terrible earthquakes, of which the most disastrous was that of the 28th October 1746, when 5000 of the inhabitants perished and the port of Callao was destroyed (see CALLAO, vol. iv. p. 107). On the 12th July 1821, after a siege of some months, Lima was entered by a Chilian force under General San Martin, who on the 28th was proclaimed protector of Peru as a free state, but its independence was not finally secured until after the victory of Ayacucho (9th December 1824). In March 1828 the city again suffered from an earthquake, and in 1854–55 the yellow fever carried off a great number of the inhabitants. On the 11th of August 1857, Mr Sullivan, British minister to Peru, was assassinated. In November 1864 a congress of plenipotentiaries from Chili and other South American states was held here to concert measures of mutual defence. Of the various revolts which have during the last few years taken place at Lima may be mentioned that of November 1865, when President Pezet was displaced for Canseco; the riots against religious toleration, 15th April 1867; and the military insurrection, 22d July 1872, when Gutierrez, minister of war, arbitrarily assumed power, had President Balta imprisoned and shot, but himself soon fell a victim to the popular fury; order being afterwards with difficulty restored by Vice-President Zavallos. In consequence of the ill-success of the war with Chili, Lima towards the close of 1879 was again in an unsettled condition; President Prado fled, and on the 22d December, after a sanguinary coup d'état, Pierola was proclaimed dictator. In April 1880 Callao was blockaded by Chilian war ships, and Lima had to be placed in a state of defence. On the 20th of November the Chilian army effected a landing at Pisco, a fortified place about 100 miles south of Lima, and, having afterwards advanced upon the capital, forcibly occupied it upon the 17th of January 1881.

See Mariano F. Paz Soldan, *Diccionario geográfico estadístico del Perú*, Lima, 1877, pp. 513–27; Mateo Paz Soldan and M. F. Paz Soldan, *Geografía del Perú*, Paris, 1862, vol. i. pp. 290–320; M. A. Fuentes, *Lima, or Sketches of the Capital of Peru, Historical, Statistical, Administrative*, &c., London, 1866; C. R. Markham, *Cuzco . . . and Lima*, London. 1856. Prescott, *Hist. of the Conquest of Peru*; F. de Xeres, *Conquista del Perú*; A. de Zarate, *Hist. de la Conq. del Perú*; and J. de Ferreras, *Hist d'Espagne* (French translation by Hermilly), Paris, 1751. (E. D. B.)

LIMA, capital of Allen county, Ohio, U.S., on the Ottawa river, and at the intersection of four railway lines, 130 miles north of Cincinnati It is pleasantly situated in a fine farming country, and has two large railway repairs shops, extensive car works, and other smaller manufactories. The population in 1850 was 757; in 1860, 1989; in 1870, 4464; and in 1880, 7567.

LIMBORCH, PHILIP VAN (1633–1712), a prominent Remonstrant theologian, was born June 19, 1633, at Amsterdam, where his father held a good position in the legal profession. He received his education at Utrecht, at Leyden, in his native city, and finally at Utrecht university, which he entered in 1652. In 1657 he became a Remonstrant pastor at Gouda, and in 1667 he was transferred to Amsterdam, where, in the following year, the office of professor of theology in the Remonstrant seminary was added to his pastoral charge. He died there on April 30, 1712.

His most important work, *Institutiones theologiæ christianæ, ad praxin pietatis et promotionem pacis christianæ unice directæ* (Amsterdam, 1686, 5th ed. 1735), remains unrivalled as a full and clear exposition of the system of Episcopius and Curcellæus. The fourth edition (1715) included a posthumous "Relatio historica de origine et progressu controversiarum in fœderato Belgio de prædestinatione." Limborch also wrote *De veritate religionis Christianæ amica collatio cum erudito Judæo*, Gouda, 1687; *Historia Inquisitionis* (1692), in four books prefixed to the "Liber Sententiarum Inquisitionis Tolosanæ" (1307–1323), and *Commentarius in Acta Apostolorum et in Epistolas ad Romanos et ad Hebræos*, Rotterdam, 1711. His editorial labours included the publication of various works of his predecessors, and of *Epistolæ ecclesiasticæ præstantium ac eruditorum virorum* (Amsterdam, 1684), chiefly by Arminius, Uytenbogardus, Vorstius, Vossius, Grotius, Episcopius (his grand-uncle), and Barlæus; they are of great value for the history of Arminianism. An English translation of the *Theologia*, "with improvements, from Wilkinson, Tillotson, Scott, and others," was published in the beginning of last century by W. Jones (*A Complete System or Body of Divinity, both Speculative and Practical, founded on Scripture and Reason*, London, 1702); and a translation of the *History of the Inquisition*, by S. Chandler, with "a large introduction concerning the rise and progress of persecution and the real and pretended causes of it" prefixed, appeared in 1731.

LIMBURG, or LIMBOURG, one of the nine provinces of Belgium, is bounded on the N. and E. by Holland, on the S. by the province of Liége, and on the W. by those of Brabant and Antwerp; the area is 932 square miles, with a population, in 1880, of 211,694. The surface is for the most part flat, but rising somewhat towards the south-east. Most of the province is included in the barren and marshy district of sandy heath known as *La Campine* (Flem., *Kempen*). The Meuse, with a tolerably fertile valley, is its chief river. The soil is metalliferous; the chief vegetable products are cereals, leguminous plants, flax, hemp, and beetroot; and stock-breeding is largely carried on. Industries are less developed in Limburg than in the rest of Belgium; but the distilleries of the province are very considerable and noted. Limburg is divided for administrative purposes into three arrondissements, of which the capitals are Hasselt (population 11,500), Tongres (7600), and Maeseyck (4400). The last-named is the birthplace of Hubert and John van Eyck, the Flemish painters. One of the most interesting towns of the province is ST TROND (*q.v.*), thought to be the ancient *Atuaticum Oppidum*, the oldest town in Belgium. Near Tongres is a mineral well, described by Pliny.

The territory of Limburg was that of the *Eburones*, whom the Romans exterminated, and was afterwards inhabited by the *Tungri* and *Taxandri*. It was one of the first conquests of the invading Franks, who established themselves and proclaimed their first kings there. In the Middle Ages it constituted the county of Looz, holding of the bishop of Liége; afterwards it became the duchy of Limburg, which was taken possession of in the 13th century by the duke of Brabant. From the 12th to the end of the 18th century the duchy included only a small portion of the present province; it extended eastward from the Meuse as far as to Aix-la-Chapelle, and southward to the Vesdre. In the 16th century Limburg remained in the possession of Spain, and it passed to Austria in 1713. After the treaty of Campo Formio (1797) it became a French department, Meuse-Inférieure, with Maestricht as capital. By the treaty of

Vienna (1815) it formed one of the nineteen provinces of the kingdom of the Netherlands, and by that of London (1831) the eastern portion was ceded to Holland, becoming a Dutch province, the remainder constituting the present province of Belgium.

LIMBURG, or LIMBOURG, one of the eleven provinces of Holland, is bounded on the W. by Belgium (Limburg) and North Brabant, on the N. by North Brabant and Guelderland, on the E. by Rhenish Prussia, and on the S. by Belgium (Liége), and has an area of 851 square miles, with a population in 1876 of 235,135 (97 per cent. being Roman Catholics). The surface, which is flat, is partly covered with heaths and fens; of the latter the most considerable is the "peel" or marsh in the north, which extends into North Brabant. The province is traversed by the Maas, of which the chief affluents here are the Geule, the Geleen, and the Roer, all on the right; means of water communication are also supplied by the Zuid Willem's canal and its branches. The agricultural products are similar to those of Belgian Limburg; bee-keeping is also engaged in. Coal occurs within the province, and there is a mine at Kerkrade. The arrondissements are two in number,—Maestricht and Roermonde,—Maestricht being the capital. For the history of the province see the preceding article.

LIMBURG, a town in the circle of Unterlahn and district of Wiesbaden, Prussia, is situated 360 feet above the sea-level, on the Lahn, here crossed by a bridge dating from 1315, and on the Nassau Railway midway between Coblentz and Wetzlar. A local branch line connects it with Hadamar. It is the seat of a Catholic bishop, and has one evangelical and four Catholic churches. The only prominent architectural feature is the small seven-towered semi-Byzantine cathedral, picturesquely situated on a rocky site overhanging the river; it was founded by Conrad Kurzbold, count of Niederlahngau, in 905, and finally consecrated in 1235 (restored 1872–78). Limburg has a seminary for the education of priests, and a variety of schools; the industries, which are unimportant, include manufactures of cloth, tobacco, machinery, pottery, and leather. The population in 1875 was 5161.

Limburg, which was a flourishing town during the Middle Ages, passed in 1404 into the possession of the archbishops of Treves after the extinction of its own line of counts, and in 1803 fell to the duke of Nassau. It was the scene of a victory of the archduke Charles of Austria over the French under Jourdain on September 16, 1796. It possesses an interesting MS. fragment of its chronicles, the *Fasti Limpurgenses*. The original writer is supposed to have been the recorder Tillmann (ob. 1400), additions being made by subsequent copyists; the document, which has been more than once printed, is valuable especially for the ancient rhymes it embodies, and for its notices of old German poets.

LIMBUS. The *Limbus Infantum* or *Puerorum* in mediæval theology is the "margin" or "border" (limbus) of hell to which human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included, not unbaptized infants merely, but also idiots, cretins, and the like. The word "limbus," in the theological application, occurs first in the *Summa* of Thomas Aquinas; for its extensive currency it is perhaps most indebted to the *Commedia* of Dante (*Inf.*, c. 4). The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period, and received very various answers. Generally speaking it may be said that the Greek fathers inclined to a cheerful and the Latin to a gloomy view. Thus Gregory of Nazianzus (*Orat.* 40) says "that such children as die unbaptized without their own fault shall neither be glorified nor punished by the righteous Judge, as having done no wickedness, though they die unbaptized, and as rather suffering loss than being the authors of it." Similar opinions have been expressed by Gregory of Nyssa, Severus of Antioch, and others,—opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost, and taught that there are only two alternatives,—to be with Christ or with the devil, to be with Him or against Him. Following up, as he thought, his master's teaching, Fulgentius declared that it is to be believed as an indubitable truth that, "not only men who have come to the use of reason, but infants dying, whether in their mother's womb or after birth, without baptism in the name of the Father, Son, and Holy Ghost, are punished with everlasting punishment in eternal fire." Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell, but otherwise inclined with practical unanimity to take the mildest possible view of the destiny of the irresponsible and unbaptized. Thus the proposition of Innocent III. that "the punishment of original sin is deprivation of the vision of God" is practically homologated by Thomas, Scotus, and all the other great theologians of the scholastic period, the only outstanding exception being that of Gregory of Rimini, who on this account was afterwards called "tortor infantum." The first authoritative declaration of the Latin Church upon this subject was that made by the second council of Lyons (1274), and confirmed by the council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." Perrone remarks (*Præl. Theol.*, pt. iii. chap. 6, art. 4) that the damnation of infants and also the comparative lightness of the punishment involved in this are thus *de fide*; but nothing is determined as to the place which they occupy in hell, as to what constitutes the disparity of their punishment, or as to their condition after the day of judgment. In the council of Trent there was considerable difference of opinion as to what was implied in deprivation of the vision of God, and no definition was attempted, the Dominicans maintaining the severer view that the "limbus infantum" was a dark subterranean fireless chamber, while the Franciscans placed it in a lightsome locality above the earth. Some theologians continue to maintain with Bellarmine that the infants "in limbo" are affected with some degree of sadness on account of a felt privation; others, following Sfrondati, hold that they enjoy every kind of natural felicity, as regards their souls now, and as regards their bodies after the resurrection, just as if Adam had not sinned. In the condemnation (1794) of the synod of Pistoia (1786), the twenty-sixth article declares it to be false, rash, and injurious to treat as Pelagian the doctrine that those dying in original sin are not punished with fire, as if that meant that there is an intermediate place, free from fault and punishment, between the kingdom of God and everlasting damnation.

The *Limbus Patrum*, *Limbus Inferni*, or *Sinus Abrahæ* is defined in Roman Catholic theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding the locality, and its pleasantness or painfulness, nothing has been taught as *de fide*, and opinions have been various. It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the *limbus infantum*. The whole idea, in the Latin Church, has been justly described as the mere caput mortuum of the old catholic doctrine of hades, which was gradually superseded in the West by that of purgatory.

LIME is the name of the strongly basic monoxide CaO of the metal calcium. This base is widely diffused throughout the three kingdoms of nature in the form of salts, of which the carbonate $CaCO_3$ and the hydrated sulphate $CaSO_4.2H_2O$ are by far the most abundant. Both are found in the mineral kingdom in a variety of forms. Of native carbonates of lime, *calc-spar* (Iceland spar), though comparatively rare, may be mentioned first as representing the purest native form of the compound. It generally presents itself in the form of well-developed transparent colourless rhombohedra, which possess to a remarkable degree the property of producing double refraction of light, whereupon is founded its application in the construction of certain optical instruments. Of the varieties of massive or crystalline carbonate of lime, those which, through the fineness of their grain and other qualities, lend themselves for the purposes of the sculptor go by the name of marble, while the remainder are embraced under the generic term of limestone. This name, however, is understood to exclude chalk, a soft, amorphous variety which, according to Ehrenberg, consists mainly of *Foraminifera* shells. All limestones contain at least traces of magnesia. When this foreign base is present in considerable proportion the rock is termed "dolomite" (see MAGNESIUM). Among the native forms of (hydrated) sulphate of lime the mineral "selenite" (glacies Mariæ) corresponds to Iceland spar among the carbonates. It forms colourless transparent clino-rhombic prisms, generally united into "twins," and flattened down into plates readily cleavable along planes parallel to the surface. Hardness ranges from 1·5 to 2; the specific gravity is 2·3. Far more common than selenite are the massive varieties known as ALABASTER (see vol. i. p. 439) and ordinary GYPSUM (vol. xi. p. 337).

Both sulphate and carbonate of lime, apart from their occurrence as independent minerals, are almost universally diffused throughout the earth's crust, and in the waters of the ocean. Now the sulphate is appreciably soluble in even pure water, while the carbonate, though practically insoluble in pure, is quite decidedly soluble in carbonic acid water. As all atmospheric water must necessarily hold carbonic acid gas in absorption, most natural waters, and certainly all deep-well waters, are contaminated with more or less of bicarbonate or sulphate of lime, or with both. When such a water is being boiled, there is an escape of the free and the loosely combined carbonic acid, and the carbonate of lime comes down as a loose precipitate or as a "crust"; and, when the water is sufficiently concentrated by evaporation, the sulphate likewise is partly deposited. The decomposition of the "bicarbonate" in fact takes place, though slowly, even at ordinary temperatures, when the water in which it is held in solution is exposed to the atmosphere. It is in this manner that stalagmites and stalactites frequently seen within rock-caverns are produced, and there is no difficulty in accounting for the grotesque and fantastic forms which the latter often exhibit.

Quicklime.—The native carbonate always serves as the starting-point in the preparation of calcium compounds. From it the oxide CaO, known as quicklime or caustic lime, is produced industrially by heating limestone or marble in kilns, between layers of fuel, which in the United Kingdom is generally coal. The carbonic acid goes away with the gaseous products of combustion, and the oxide remains in unfused lumps of the form of the original stones. Lime, when pure, is an amorphous white solid, which is absolutely infusible and non-volatile; and on this account, when raised to high temperatures, it emits a brilliant white light ("lime-light"). The commercial article is generally grey or otherwise discoloured by the presence of foreign metallic oxides.

The decomposition that goes on in a limekiln is not brought about by the effect of heat alone. Gay-Lussac found long ago that carbonate of lime, when heated to intense redness in a closely covered crucible, loses its carbonic acid only very slowly, while the acid goes off readily even at somewhat lower temperatures when a current of steam is passed over the heated limestone. This may be accounted for by assuming that the steam, in the first instance, produces hydrate—from the carbonate—of lime, which latter then at once breaks up into its two components. More probably, however, the steam acts only by producing a *quasi* vacuum, that is, by clearing out the carbonic acid which, if allowed to stagnate even at high temperatures, would react on the quicklime produced, thus preventing the decomposition of a portion of the carbonate.

Quicklime acts readily and energetically on water, with evolution of much heat (269 units per unit weight of lime; Berthelot) and formation of a bulky white powder of the hydrate $CaOH_2O$ or $Ca(OH)_2$. This powder readily mixes with water into a smooth paste, which may be diluted to a milky liquid—milk of lime. This, when filtered through paper, yields "lime-water," a strongly alkaline liquid containing about $\frac{1}{700}$th of its weight of lime (calculated as CaO). When boiled it deposits a part of its dissolved lime as such, and when exposed to ordinary air it quickly draws a skin of carbonate of lime. Hence its application as a reagent for carbonic acid, and the extensive use of milk of lime (whitewash) as a cheap white pigment in wall-painting. Lime paste, as every one knows, is most extensively used as a mortar or cement for bricks and stones in building. For this purpose it is always mixed with a certain proportion of sand. This admixture in all probability was originally intended only to save lime and prevent shrinking. But it is now generally assumed to have a chemical function, causing the formation of a hard silicate of lime pervading and thus strengthening the mortar. Some chemists deny the practical importance though not the occurrence of this silication; what admits of no doubt is that the hardening of mortar involves the very gradual conversion of the original hydrate into carbonate of lime. Under the name of plaster, a fine smooth paste of lime and sand, with short hair to increase the tenacity of the mixture, is a most important material for coating the internal walls and roofs of ordinary buildings.

Hydraulic Cements.—Ordinary mortar, on account of the solubility of lime in water, is unfit for aquatic masonry; for this purpose hydraulic cements must be used. Of these there are a great variety, which, however, mostly agree in this that they consist of calcined mixtures of limestone and clay (preferably alkaliferous clay) and other silicates. By calcining such mixtures at temperatures short of that at which a glass would be produced, the lime becomes caustic, and part of the caustic lime, by uniting with the clay (and silicate generally), forms a silicate sufficiently basic to be disintegrable by acids and even by water. When such cement, as a powder, is mixed with water, the lime acts upon the silicate of alkali and the gelatinous silica-hydrate transitorily produced, and with the silica and alumina and oxide of iron unites into a hard, waterproof, very complex silicate mixture.

H. Ste Claire Deville having found that magnesia has hydraulic properties, hydraulic cements have been made by calcining dolomites of the proper composition so far as to decompose only the carbonate of magnesia (into MgO and CO_2). See CEMENT, vol. v. p. 328.

Lime, being the cheapest of powerful bases, is largely used in chemical manufacturing. It serves for the causticizing of soda, for the preparation of ammonia from ammonia salts, and for the manufacture of bleaching powder. It also enters into the composition of certain kinds of glass, and is used (as lime or as carbonate), in the making of soda ash.

Lime Salts.—These can in general be prepared by the saturation of the respective acids with lime hydrate. Thus the (pure) *car-*

bonate $CaCO_3$ may be prepared by passing carbonic acid into lime-water. But a more convenient method is to decompose a solution of pure chloride of calcium with excess of carbonate of ammonia, preferably at 70–80° C., when the carbonate assumes the form of a crystalline precipitate which settles readily and is easily washed with hot water. The *sulphate* (artificial gypsum) appears as a voluminous white precipitate, consisting of minute colourless needles, when sulphuric acid is added to a not too dilute solution of chloride of calcium or other lime salt. The precipitate $CaSO_4.2H_2O$ is appreciably soluble in water, 1000 parts of which at 0°, 35°, and 100° C. dissolve 2·05, 2·54, and a little over 2 parts respectively of gypsum. The hydrated sulphate at temperatures exceeding 110° C. loses its water. The anhydrous sulphate, if formed below about 200° C., readily recombines with water into compact gypsum (plaster of Paris). By exposure to high temperatures (500° C. and upwards) sulphate of lime loses its power of recombining with water; at very high temperatures it fuses. A naturally anhydrous sulphate of lime (anhydrite) occurs in association with rock salt, and otherwise, as a not very common mineral.

The well-known favourable action of gypsum as a manure, more especially for clover (see AGRICULTURE), has lately been explained by Déherain on the strength of analyses and vegetation experiments of his own, by assuming that it converts the carbonate of potash of the soil into sulphate, which, being less obstinately retained by the soil, more readily finds its way into the roots of the plants.

Chloride of Calcium (muriate of lime), $CaCl_2$, is prepared by dissolving marble or limestone in aqueous muriatic acid. The iron and manganese generally present as impurities can be eliminated, after peroxidation by chlorine water, by digestion with hydrate of lime, which also, if allowed sufficient time, removes the magnesia. The filtrate is acidified with hydrochloric acid and concentrated by evaporation, so far that, on cooling, it deposits part of the dissolved salt as crystals. These have the composition $CaCl_2.6H_2O$. They are very easily soluble in water and alcohol, and highly hygroscopic. Hence the salt is used occasionally to keep textile fibres moist and in a fit state for being woven. The crystals when kept in a basin at about 200° lose about two-thirds of their water, and leave that porous kind of chloride of calcium which analytical chemists prefer for the drying of gases. This substance, when heated to redness—which must be done in platinum to prevent contamination—loses the rest of the water and (at 723° C., Carnelley) fuses into the anhydrous salt $CaCl_2$, which on cooling hardens into a stone-like mass. In this final process of dehydration, however, part of the chlorine goes off as hydrochloric acid, so that the product obtained is contaminated with some oxychloride. This can be prevented by igniting the salt with sal-ammoniac or—more surely—by effecting the dehydration in a current of anhydrous hydrochloric acid gas. Anhydrous chloride of calcium is much used in laboratories as a powerful dehydrating agent. It combines with ammonia gas into a solid compound. It dissolves in methyl alcohol and in ethyl alcohol, forming crystallizable "alcoholates" (Graham), compounds of $CaCl_2$ with "crystal alcohol."

Nitrate of Calcium, $Ca(NO_3)_2$, crystallizing with $4H_2O$, is a very hygroscopic salt, soluble in even absolute alcohol. It is mentioned here as a material for the convenient preparation of *pure* lime—by simple ignition of the salt in a platinum crucible. Regarding *bleaching powder*, a double salt of hypochlorite and chloride of calcium Cl – Ca – (ClO), see CHLORINE, vol. v. p. 678.

Fluoride of Calcium, CaF_2, obtainable by precipitation of chloride of calcium with an alkaline fluoride, occurs in nature as FLUORSPAR (*q.v.*). Fluoride of calcium is widely disseminated throughout the mineral kingdom as an admixture with other minerals. All native forms of phosphate of lime contain it; some in considerable quantity. Traces of it are found in bones and in the ashes of most plants.

Metallic Calcium cannot be prepared by the reduction of the oxide with charcoal. It may be produced, however, by the electrolysis of the fused chloride or—more conveniently—by heating the iodide CaI_2 (seven parts) with sodium (one part) in an iron crucible. The metal has a yellow colour; it is somewhat harder than lead, and very malleable and ductile (Liès-Bodart and Jobin). The specific gravity is 1·578 (Bunsen and Matthieson). It does not tarnish in *dry* air, but readily decomposes water, with evolution of hydrogen and formation of hydrate of lime. It is practically non-volatile. When heated in air or oxygen it burns with a most brilliant light into oxide, CaO.

Tests.—Solutions of ordinary calcium salts are not affected visibly by sulphuretted hydrogen, sulphide of ammonium, or pure ammonia. Carbonate of ammonia, even in the presence of sal-ammoniac, precipitates the carbonate. So far calcium behaves like barium and strontium. From the former it is distinguished by its not being precipitated by either hydrofluosilicic acid or bichromate of potash, and from both by its spectrum and the relatively large solubility of its sulphate in water. The latter is obtained from any calcium solution by addition of sulphuric acid and alcohol. The sulphate is washed with alcohol on a filter. When then boiled with water it yields a solution which, dilute as it is, gives a very distinct precipitate with oxalate of ammonia (barium and strontium sulphates in these circumstances give negative results). Oxalate of ammonia is the most delicate precipitant for calcium; the precipitate is insoluble in water, in ammonia and ammonia salts, and in acetic acid. From solutions (in acids) of phosphate or oxalate of calcium ammonia and likewise sulphide of ammonium precipitate the metal as phosphate or oxalate. To detect it in such a precipitate, dissolve in hydrochloric acid and add sulphuric acid and alcohol. The calcium is precipitated as sulphate, which can be identified as just explained.

For the phosphates of lime, see PHOSPHATES. (W. D.)

LIME, or LINDEN. The lime trees, species of *Tilia*, are familiar timber trees with mellifluous flowers, rarely if ever maturing their fruit in England, which are borne on a common peduncle proceeding from the middle of a long bract. *T. europæa*, L., is indigenous to Europe, excepting the extreme north, and extends eastwards across Russian Asia to the Altai. The lime is much planted in Britain, and is probably wild in south and west England, and perhaps in Ireland. The truly indigenous form in north Europe is always a small-leaved one. The large leaved variety (*T. grandifolia*, Ehrh.) is of South-European origin (Bentham, *Handbook of the British Flora*, i. 157); *T. parvifolia*, L., is perhaps the English wild form of the Continental *T. europæa*, L.; while *T. intermedia*, D. C., probably a sub-species of *T. europæa*, L., is the so-called common lime (Hooker, *Student's Flora of the British Isles*, p. 76). For a full description of the European and American forms, see Loudon, *Arboretum*, i. p. 364, and De Candolle, *Prod.*, i. 513. The lime sometimes acquires a great size: one is recorded in Norfolk as being 16 yards in circumference, and Ray mentions one of the same girth. The famous linden tree which gave the town of Neustadt in Würtemburg the name of "Neustadt an der grossen Linden" was 9 feet in diameter.

The economic value of the tree chiefly lies in the inner bark or liber, called bast, and the wood. The former was used for paper and mats and for tying garlands by the ancients (*Od.*, i. 38; Pliny, xvi. 14, 25; xxiv. 8, 33). *T. grandifolia* and *T. parvifolia* have been found in the debris of lake dwellings in Switzerland. Bast mats are now made chiefly in Russia, the bark being cut in long strips, when the liber is easily separable from the corky superficial layer. It is then plaited into mats about 2 yards square; 14,000,000 come to Britain annually, chiefly from Archangel. The wood is used by carvers, being soft and light, and by architects in framing the models of buildings. Turners use it for light bowls, &c. The flowers, alone, are used for an infusion in Austria and elsewhere, with much success in vertigo and spasms, producing perspiration, and alleviating coughs; but the bracts and fruit are astringent.

The common lime was well known to the ancients. Theophrastus says the leaves are sweet and used for fodder for most kinds of cattle. Pliny alludes to the use of the liber and wood, and describes the tree as growing in the mountain valleys of Italy (xvi. 30). See also Virg., *Geo.*, i. 173, &c.; Ov., *Met.*, viii. 621, x. 92. The φιλύρα (Hdt., 4. 67) was the lime of the Greeks, perhaps *T. argentea* (see Pickering's *Chron. Hist. of Plants*, pp. 214, 227, 418). Allusion to the lightness of the wood is made in Aristoph., *Birds*, 1378.

For the sweet lime (*Citrus Limetta*) and lime juice, see LEMON.

LIMERICK, a maritime county of Ireland, in the province of Munster, is bounded on the N. by the estuary of the Shannon and the counties of Clare and Tipperary, on the E. by Tipperary, on the S. by Cork, and on the W. by Kerry. Its greatest length from north to south is 35 miles, and its greatest breadth east and west 54 miles. The total area comprises 662,973 acres, or 1036 square miles.

The greater part of the county is comparatively level, and rests on limestone, but in the south-east the picturesque Galtees, which extend into Tipperary, and are composed of Silurian strata overlaid by Old Red Sandstone, attain in Galtymore a height of 3015 feet, and on the west stretching into Kerry there is a circular amphitheatre of less elevated mountains composed of volcanic rocks. The Shannon is navigable to Limerick, above which are the rapids of Doonas and Castleroy. The Maig, which rises in the Galtees, and flows into the Shannon, is navigable as far as the town of Adare. Limerick includes the greater part of the Golden Vale, the most fertile district of Ireland, which stretches across the centre of the county from Cashel in Tipperary to near the town of Limerick. Along the banks of the Shannon there are large tracts of flat meadow land formed of deposits of calcareous and peaty matter, and possessing extraordinary fertility. The soil in the mountainous districts is, for the most part, thin and poor, and incapable of improvement. In 1880 there were 176,774 acres under tillage, 415,107 pasture, 8407 plantations, and 62,465 waste. The total number of holdings in 1880 was 16,286, of which 1937 were less than one acre, and 11,273 between 15 and 100 acres in extent, 1019 between 100 and 200 acres, 259 between 200 and 500 acres, and 29 above 1000 acres. The large farms occupy the low grounds, and are almost wholly devoted to grazing. The following table shows the area under the principal crops in 1855 and 1881:—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1855	17,149	45,455	12,057	35,723	11,394	2,771	243	71,292	196,084
1881	7,257	21,440	3,003	23,035	5,520	3,994	6	112,578	176,833

The table shows a remarkable increase in the area under meadow, notwithstanding which the total area under tillage has considerably decreased. The number of horses has, since 1855, declined from 17,206 to 15,389, of which 10,228 were used for agricultural purposes. Cattle have increased from 159,710 to 201,456, an average of 28 to every 100 acres under cultivation, the average for Ireland being 25·8. The number of cows was 95,225. Sheep have diminished from 80,914 to 50,599, and pigs from 61,733 to 48,801. The number of goats was 10,012, and of poultry 428,398.

According to the corrected return of 1878, the land, exclusive of that in the county of the city of Limerick, was divided among 1676 proprietors, possessing 660,386 acres, of the annual value of £461,213, or 13s. 11d. per acre. Of the owners nearly 40 per cent. possessed less than 1 acre, the average extent being 394. The following were the largest proprietors:—Earl of Devon, 33,026; Earl of Dunraven, 14,298; Lord Ashton, 11,273; Archdeacon Goold, 10,966; Lady Louisa Fitzgibbon, 10,316; Sir Croker Barrington, 9485.

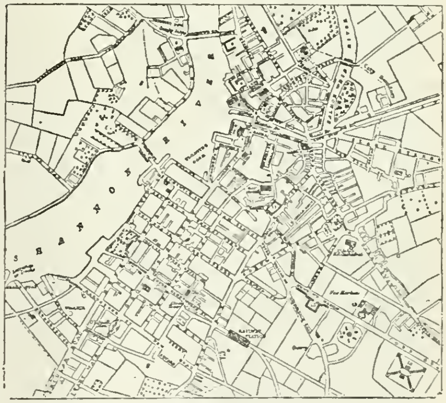
Manufactures.—The inhabitants are employed chiefly in agriculture, but coarse woollens are manufactured, and also paper, and there are a considerable number of meal and flour mills. At one time there were a number of flax-spinning and weaving mills, but that industry is now almost wholly extinct.

Administration and Population.—The county includes 14 baronies, 131 parishes, 2067 townlands, and the city and parliamentary borough of Limerick. The number of members returned to the Irish parliament was eight, two being returned for each of the boroughs of Askeaton and Kilmallock, in addition to the two returned as at present for the county, and the two returned for the county of the city of Limerick. There are three poor-law unions wholly within the county, and portions of four others. Assizes are held at Limerick, and quarter sessions at Bruff, Limerick, Newcastle, and Rathkeale. The county is within the Cork military district, with a brigade depôt at Tralee. The population, estimated in 1760 at 92,376, had increased in 1821 to 277,477, and in 1841 to 331,003, but since that period it has been gradually diminishing, being 217,277 in 1861, and in 1881 only 177,203, of whom 86,541 were males and 90,662 females. The decrease since 1871 has been 7·7 per cent., the decrease per cent. in Ireland being 4·7. Besides the city of Limerick, with a population in 1881 of 48,246, only two other towns, Rathkeale and Newcastle, had a population of over 2000. From 1st May 1851 to 31st December 1880 the number of emigrants from the county was 130,333, a proportion of 60 per cent. of the population in 1861.

History and Antiquities.—Limerick, originally inhabited by the Coriondi, was included in the kingdom of Thomond. Afterwards it had a separate existence under the name of Aine-Cliach. From the 8th to the 11th century it was partly occupied by the Danes. By Henry II. it was granted to Henry Fitzherbert, but his claim was afterwards resigned, and subsequently various Anglo-Norman settlements were made. About 100,000 acres of the estates of the earl of Desmond, which were forfeited in 1586, were situated in the county, and other extensive confiscations took place after the Cromwellian wars. In 1709 a German colony from the Palatinate was settled by Lord Southwell near Bruff, Rathkeale, and Adare.

There are only slight remains of the round tower at Ardpatrick, but that at Carrigeen is much better preserved. There are important remains of stone circles, pillar stones, and altars on Loch Gur. In several places there are remains of old moats and tumuli. Besides the monasteries in the city of Limerick, the most important monastic ruins are those of Adare Abbey, Askeaton Abbey, Kilshane Abbey, Galbally Friary, Kilflin Monastery, Kilmallock Abbey, and Monaster-Nenagh Abbey. See the *History of Limerick* by Fitzgerald and M'Gregor, 1826–27.

Limerick, a county of a city, parliamentary borough, and the chief town of the county of Limerick, is situated on both sides of the Shannon, at the head of its estuary, and on an island of the river, 120 miles west-south-west of Dublin by rail. The western bank of the river is occupied by Irish Town, the island by English Town, and the eastern bank by Newtown Pery,—the two former divisions consisting chiefly of mean houses occupied by the poorer classes, and Newtown Pery including the principal streets, shops, and public buildings. The different parts of the town are connected by several bridges, the most important of which is Wellesley bridge, erected in 1827 at a cost of £85,000. The cathedral of St Mary, founded in 1180, and rebuilt in



Plan of Limerick.

1490, is a cruciform structure in the Gothic style, with an embattled tower 120 feet in height. A Roman Catholic cathedral in the First Pointed style was erected in 1860. The other principal public buildings are the court-house, the custom-house, the exchange, the chamber of commerce, the town-hall, the county jail, the city jail, the infirmary, and Barrington's hospital. There are barracks for cavalry, artillery, and infantry. Limerick as a port occupies the fourth position in Ireland, and, while possessing secure and open communication with the Atlantic, is included in a vast network of inland navigation. Vessels of 1000 tons can unload at the floating dock, and vessels of 500 tons at the quays. A graving dock, admitting vessels of 1500 tons for repair, has lately been constructed. The value of the imports in 1880 was £837,269, the average for the four years 1876–79 being £940,279, and, for 1872–75

£873,533. For the same dates the value of the exports was £26,569, £9552, and £12,516. The principal industries are flax spinning and weaving, and the manufacture of lace and gloves. There are also breweries, distilleries, tanneries, and flour-mills. The population in 1851 was 48,961, which in 1871 had increased to 49,980, but in 1881 had diminished to 48,246.

Limerick is said to have been the ancient *Regia* of Ptolemy and the *Rosse-de-Nailleagh* of the Annals of Multifernan. There is a tradition that it was visited by St Patrick in the 5th century, but it is first authentically known as a settlement of the Danes, who in the middle of the 9th century made it one of their principal towns, but were expelled from it in the 11th century by Brian Boroimhe. From 1106 till its conquest by the English in 1174 it was the seat of the kings of Thomond or North Munster, and, although in 1179 the kingdom of Limerick was given by Henry II. to Herbert Fitzherbert, the city was frequently in the possession of the Irish chieftains till 1195. By King John it was committed to the care of William de Burgo, who founded English Town, and for its defence erected a strong castle. The city was frequently besieged in the 13th and 14th centuries. In the 15th century its fortifications were extended to include Irish Town, and until their demolition in 1760 it was one of the strongest fortresses of the kingdom. In 1651 it was taken by General Ireton, and after an unsuccessful siege by William III. in 1690 its resistance was terminated in October of the following year by the treaty of Limerick. The town first obtained municipal privileges in 1199, and these were confirmed and extended by Edward I. and other sovereigns. In 1609 it received a charter constituting it a county of a city, and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford. The powers of the corporation were remodelled by the Limerick Regulation Act of 1823. The prosperity of the city dates chiefly from the foundation of Newtown Pery by Mr Sexton Pery in 1769. It returns two members to parliament. See the *History* by Linahan, 1866.

LIMITATION, STATUTES OF, are Acts of Parliament by which rights of action are limited to a fixed period after the occurrence of the events giving rise to the cause of action. This is one of the devices by which lapse of time is employed to settle disputed claims. There are mainly two modes by which this may be effected. We may say that the active enjoyment of a right—or possession—for a determined period shall be a good title against all the world. That is the method known generally as PRESCRIPTION (*q.v.*). It looks to the length of time during which the defendant in a disputed claim has been in possession or enjoyment of the matter in dispute. On the other hand, the principle of the statutes of limitation is to look to the length of time during which the plaintiff has been out of possession. The point of time at which he might first have brought his action having been ascertained, the lapse of the limited period after that time bars him for ever from bringing his action. In both cases the policy of the law is expressed by the maxim *Interest reipublicæ ut sit finis litium.*

The principle of limitation was first adopted in English law in connexion with real actions, *i.e.*, actions for the recovery of real property. At first a fixed date was taken, and no action could be brought of which the cause had arisen before that date. By the Statute of Westminster the First (3 Edward I. c. 39), the beginning of the reign of Richard I. was fixed as the date of limitation for such actions. This is the well known "period of legal memory" recognized by the judges in a different class of cases to which a rule of prescription was applied. Possession of rights in *alieno solo* from time immemorial was held to be an indefeasible title, and the courts following the statutes above mentioned held time immemorial to begin with the first year of Richard I.

A period absolutely fixed became in course of time useless for the purposes of limitation, and at last the method of counting back a certain number of years from the date of the writs was adopted in the Statute 32 Henry VIII. c. 2, which fixed periods of thirty, fifty, and sixty years for various classes of actions named therein. A large number of statutes since that time have established periods of limitation for different kinds of actions. Of those now in force the most important are 21 James I. c. 16 for personal actions in general, and 3 & 4 Will. IV. c. 27 relating to actions for the recovery of land. The latter statute has been repealed and virtually re-enacted by the Real Property Limitation Act, 1874, which reduced the period of limitation from twenty years to twelve, for all actions brought after the 1st January 1879. The principal section of the Act of Will. IV. will show the *modus operandi*:—"After the 31st December 1833, no person shall make an entry or distress, or bring an action to recover any land or rent *but within twenty years next after the time* at which the right to make such entry or distress or to bring such action shall have first accrued to some person through whom he claims, or shall have first accrued to the person making or bringing the same." Another section defines the times at which the right of action or entry shall be deemed to have accrued in particular cases; *e.g.*, when the estate claimed shall have been an estate or interest in reversion, such right shall be deemed to have first accrued at the time at which such estate or interest became an estate or interest in possession. Thus suppose lands to be let by A to B from 1830 for a period of fifty years, and that a portion of such lands is occupied by C from 1831 without any colour of title from B or A—C's long possession would be of no avail against an action brought by A for the recovery of the land after the determination of B's lease. A would have twelve years after the determination of the lease within which to bring his action, and might thus, by an action brought in 1891, disestablish a person who had been in quiet possession since 1831. What the law looks to is not the length of time during which C has enjoyed the property, but the length of time which A has suffered to elapse since he might first have brought his action.

It is to be observed, however, that the Real Property Limitation Act does more than bar the remedy. It extinguishes the right, differing in this respect from the other Limitation Acts, which, while barring the remedy, preserve the right, so that it may possibly become available in some other way than by action.

By section 14 of the Act of Will. IV., "when any acknowledgment of the title of the person entitled shall have been given to him or his agent in writing signed by the person in possession, or in receipt of the profits or rent, then the right of the person (to whom such acknowledgment shall have been given) to make an entry or distress or bring an action shall be deemed to have first accrued at the time at which such acknowledgment, or the last of such acknowledgments, was given. By section 15, persons under the disability of infancy, lunacy, or coverture, or beyond seas, and their representatives, are to be allowed ten years from the termination of this disability, or death (which shall have first happened), notwithstanding that the ordinary period of limitation shall have expired.

By 21 James I. c. 16, actions of trespass, detinue, trover, replevin, or account, actions on the case (except for slander), actions of debt arising out of a simple contract, and actions for arrears of rent not due upon specialty, shall be limited to six years from the date of the cause of action. Actions for assault, menace, battery, wounds, and imprisonment are limited to four years, and actions for slander to two years. Persons labouring under disabilities are allowed the same time after the removal of the disability. When the defendant is "beyond seas" (*i.e.*, outside the United Kingdom and the adjacent islands) a similar extension of time is allowed.

An acknowledgment, whether by payment on account or by mere spoken words, was formerly sufficient to take the case out of the statute. The Act 9 Geo. IV. c. 14 (Lord Tenterden's Act) requires any promise or admission of liability to be in writing and signed by the party to be charged, otherwise it will not bar the statute.

Contracts under seal are governed as to limitation by 3 & 4 William IV. c. 42, which provides that actions for rent upon any indenture of demise, or of covenant, or debt, or any bond or other specialty, and on recognizances, must be brought within twenty years after cause of action. Actions of debt on an award (the submission being not under seal), or for a copyhold fine, or for money levied on a writ of *fieri facias*, must be brought within six years.

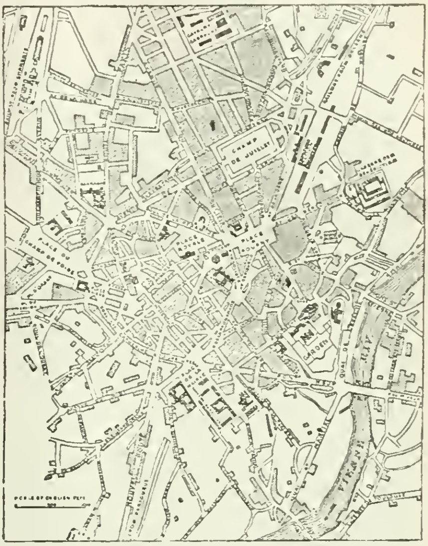
Of the miscellaneous limitations fixed by various Acts, the following may be noticed. Suits and indictments under penal statutes are limited to two years if the forfeiture is to the crown, to one year if the forfeiture is to the common informer. Penal actions by persons aggrieved are limited to two years (3 & 4 Will. IV. c. 42). Actions brought against a justice of the peace for acts done in the execution of his office are limited to six calendar months (11 & 12 Vict. c. 44). Acts done under any local or personal Act of Parliament can only be sued upon within two years (5 & 6 Vict. c. 97).

A defence under the statutes of limitations must in general be specially pleaded. Limitation is regarded strictly as a law of procedure. The English courts will therefore apply their own rules to all actions, although the cause of action may have arisen in a country in which different rules of limitation exist. This is also a recognized principle of private international law.

United States.—The principle of the statute of limitations has passed with some modification into the statute-books of every State in the Union except Louisiana, whose laws of limitation are essentially the prescriptions of the civil law drawn from the *Partidas*, or "Spanish Code." As to personal actions, it is generally provided that they shall be brought within a certain specified time—usually six years or less—from the time when the cause of action accrues, and not after, while for land the "general if not universal limitation of the right to bring action or to make entry is to twenty years after the right to enter or to bring the action accrues" (Bouvier's *Law Dictionary*, art. "Limitations"). The constitutional provision prohibiting States from passing laws impairing the obligation of contracts is not infringed by a law of limitations, unless it bars a right of action already accrued without giving a reasonable term within which to bring the action. (E. R.)

LIMOGES, capital of the department of Haute Vienne, France, and the ancient capital of Limousin, lies in the form of an amphitheatre on the right bank of the Vienne, 248 miles by rail south-south-west from Paris, on the Paris and Toulouse Railway, at its junction with the Charente line. It has also direct railway communication by Bellac with Poitiers. The population in 1876 was 59,011. In spite of many modern improvements and clearances, commencing with the administration of Turgot in 1762, the city still contains old quarters, which are dark, wretched, and unhealthy.

The cathedral, the most remarkable building, not only in the town but in the entire province, is in the Parisian Ogival style, and occupies the site of an old heathen basilica, which, according to tradition, was transformed into a Christian church by St Martial. The present edifice was built between 1273 and 1327, and has been quite recently restored, the north front of the transept, distinguished by the richness and perfection of its details, having been finally completed in 1851. The campanile is an elegant slightly leaning tower, 204 feet high. The interior of the church is remarkable for the boldness and elegance of its construction. It has a magnificent rood-loft, attributed to Bishop Jean de Langeac (1533); close by the choir screen is the mausoleum of the same prelate. The glass was repaired in the 16th century, but is still undergoing restoration. Under the choir is the crypt of the old Roman church, containing frescos of the 11th century. Some of the houses still standing in Limoges date from the Middle



Plan of Limoges.

Ages; and commemorative tablets mark the birthplace of the chancellor D'Aguesseau and of Marshals Jourdan and Bugeaud. There is a museum of painting and sculpture, and, in connexion with the local industry, a very valuable ceramic museum. Limoges is the headquarters of the 12th army corps, and is also the seat of several learned societies, and of a court of appeal.

The principal industry is the manufacture of porcelain. The kaolin of St Yrieix is of such superior quality that it is exported even to America; the pegmatite used for enamel is obtained at Chanteloube, about 25 miles from Limoges, on the Paris railway. Thirty-five factories with eighty furnaces and fifty-four painting rooms (800 artists) employ 5800 workers of both sexes, and produce goods to the annual value of 12 millions of francs. There are many others in the immediate neighbourhood of the town. Limoges has also wool and cotton spinning-mills, and cloth factories, paper-works, foundries, &c. Shoemaking gives employment to 600 persons, and the manufacture of clogs to 250. There is an extensive trade in wine and spirits, cattle, cereals, and wood. The Vienne is navigable for rafts above Limoges, and the logs brought down by the current are stopped at the entrance of the town by the inhabitants of the Naveix quarter, who form a special guild for this industry.

Limoges was a place of importance even at the time of the Roman conquest, and sent ten thousand soldiers to the defence of Alesia. In 11 B.C. it took the name of Augustus (*Augustoritum*); but in the 4th century it was anew called by the name of the *Lemovices*, whose capital it was. It then contained palaces and baths, had its own senate and the right of coinage. (Till 1837 it had a mint.) Christianity was introduced by St Martial. In the 5th century Limoges was devastated by the Vandals and the Visigoths. Viscounts were set over it by Clovis. It suffered again in the wars between the Franks and the people of Aquitaine, from Norman invasion, and from a struggle which arose between two parties into which the city was divided, led by the abbot of St Martial and by the bishop respectively. During the Hundred Years' War it was taken again and again by the French and English. Confiscated under John Lackland, it was again ceded by Louis IX. In 1370 the Black Prince took it by assault, and gave it up to fire and sword,—a disaster from which it was slow to recover. The religious wars, pestilence, and famine desolated it in turn, but the ravages of all these were surpassed by the plague of 1630–31, which carried off more than twenty thousand persons. The wise administrations of Henri d'Aguesseau, father of the chancellor, and of Turgot enabled Limoges to recover its former prosperity. There have been several noteworthy conflagrations, destroying whole quarters of the city, built, as it then was, of wood. That of 1790 lasted for two months, and destroyed one hundred and ninety-nine houses; that of 1864 laid under ashes an area of 10,000 square metres. Limoges celebrates every seven years a curious religious festival (Fête d'Ostension), during which the relics of St Martial are exposed for seven weeks, attracting large numbers of visitors. It dates from the 10th century, and commemorates a pestilence (mal des ardents) which, after destroying forty thousand persons, is believed to have been stayed by the intercession of the saint.

LINACRE, or LYNAKER, THOMAS (1460–1524), a distinguished humanist and physician, was born at Canterbury about the year 1460. Of his parentage or descent nothing certain is known. He received his early education at the cathedral school of Canterbury, then under the direction of William of Selling, afterwards prior of Canterbury. Selling was an ardent scholar, and one of the earliest in England who cultivated Greek learning. From him Linacre must have received his first incentive to this study, in which he afterwards became eminent. Linacre entered the university of Oxford about the year 1480, and in 1484 was elected a fellow of All Souls' College. Shortly afterwards he visited Italy in the train of William of Selling, who was sent by Henry VIII. as an envoy to the papal court, and accompanied his patron as far as Bologna. There he became the pupil of Angelo Poliziano, and afterwards shared the instruction which that great scholar imparted at Florence to the youthful sons of Lorenzo de' Medici. The younger of these princes became Pope Leo X., and was in after years mindful of his old companionship with Linacre.

Among his other teachers and friends in Italy should be mentioned Demetrius Chalcondylas, Hermolaus Barbarus, Aldus Romanus the printer of Venice, and Nicolaus Leonicenus of Vicenza. Linacre took the degree of doctor of medicine with great distinction at Padua. On his return to Oxford, full of the learning and imbued with the spirit of the Italian Renaissance, he formed one of the brilliant circle of Oxford scholars, including Colet, Grocyn, and William Latimer, who are mentioned with so much warm eulogy in the letters of Erasmus.

Linacre does not appear to have practised or taught medicine in Oxford. About the year 1501 he was called to court as tutor of the young prince Arthur; and continued to act in this capacity till the prince's death in 1503. On the accession of Henry VIII. he was appointed the king's physician, an office at that time of considerable influence and importance, and practised medicine in London, having among his patients most of the great statesmen and prelates of the time, as Wolsey, Warham, and Fox.

After some years of professional activity, and when in advanced life, Linacre received priest's orders. But, as he had for some years previously held several clerical benefices, it would seem that he must have been already a deacon, and thus nominally at least a cleric, but this status would not in those days have interfered with his practising as a physician. There is no doubt, however, that his ordination as priest was connected with his retirement from active life. Literary labours, and the cares of the foundation which owed its existence chiefly to him, the Royal College of Physicians, occupied Linacre's remaining years till his death in 15_4.

Linacre was more of a scholar than a man of letters, and rather a man of learning than a scientific investigator. It is difficult now to judge of his practical skill in his profession, but it was evidently highly esteemed in his own day; and several instances are recorded of his wise prognosis and judicious treatment. He took no part in political or theological questions, and died too soon to have to declare himself on either side in the formidable controversies which were even in his lifetime beginning to arise.

But his career as a scholar was one eminently characteristic of the critical period in the history of learning through which he lived. He was one of the first Englishmen who studied Greek in Italy, whence he brought back to his native country and his own university the lessons of the "New Learning." His teachers, who have already been named, were some of the greatest scholars of the day. Among his pupils was one—Erasmus—whose name alone would suffice to preserve the memory of his instructor in Greek, and others of note in letters and politics, such as Sir Thomas More, the lamented Prince Arthur, and Queen Mary. Colet, Grocyn, William Lilye, and other eminent scholars were his intimate friends, and he was esteemed by a still wider circle of literary correspondents in all parts of Europe.

Linacre's literary activity was displayed in two directions, in pure scholarship and in translation from the Greek. In the domain of scholarship he was known by the rudiments of (Latin) grammar composed in English for the use of the Princess Mary, and afterwards translated into Latin by George Buchanan, and by a work on Latin composition, *De emendata structura Latini sermonis*, which enjoyed a wide popularity. It was originally composed for the use of St Paul's school, when founded by Dean Colet, but was set aside as unsuited for the purpose. It was, however, printed in London, in 1524, and many times reprinted on the Continent.

Linacre's only medical works were his translations. It was the cherished project of his life to make the works of Galen (and indeed those of Aristotle also) accessible to all readers of Latin. What he effected in the case of the first, though not trifling in itself, is inconsiderable as compared with the whole mass of Galen's writings; and of his translations from Aristotle, some of which are known to have been completed, nothing has survived. The following are the works of Galen translated by Linacre:—(1) *De Sanitate Tuenda*, printed at Paris in 1517; (2) *Methodus Medendi*, Paris, 1519; (3) *De Temperamentis et de Inæquali Intemperie*, Cambridge, 1521; (4) *De Naturalibus Facultatibus*, London, 1523; (5) *De Symptomatum Differentiis et Causis*, London, 1524; (6) *De Pulsuum Usu*, London, without date. He also translated for the use of his pupil Prince Arthur an astronomical treatise of Proclus, *De Sphæra*, which was printed at Venice by Aldus in 1499. The accuracy of these translations and their elegance of style were universally admitted. They have been generally accepted as the standard versions of those parts of Galen's writings, and frequently reprinted, either as a part of the collected works or separately.

But the most important service which Linacre conferred upon his own profession and science was not by his writings. To him was chiefly owing the foundation by royal charter of the College of Physicians in London, which first gave the medical profession in this country a recognized legal status, and which has been the model of all the similar colleges of physicians and surgeons in the three kingdoms. He was the first president of the new college, which he further aided by conveying to it his own house, and by the gift of his library. Shortly before his death Linacre obtained from the king letters patent for the establishment of readerships in medicine at Oxford and Cambridge, and placed some valuable estates in the hands of trustees for their endowment. Two readerships were founded in Merton College, Oxford, and one in St John's College, Cambridge, but owing to neglect and bad management of the funds, they fell into uselessness and obscurity. The Oxford foundation was revived by the university commissioners in 1856 in the form of the Linacre professorship of anatomy. Posterity has done justice to the generosity and public spirit which prompted these foundations; and it is impossible not to recognize a strong constructive genius in the scheme of the College of Physicians, by which Linacre not only first organized the medical profession in England, but impressed upon it for some centuries the stamp of his own individuality. The intellectual fastidiousness of Linacre, and his habits of minute accuracy were, as Erasmus suggests, the chief cause why he accomplished so little and left behind no more permanent literary memorials. It will be found, perhaps, difficult to justify by any extant work the extremely high reputation which he enjoyed among the scholars of his time. His Latin style was so much admired that, according to the flattering eulogium of Erasmus, Galen spoke better Latin in the version of Linacre than he had before spoken Greek; and even Aristotle displayed a grace which he hardly attained to in his native tongue. Erasmus praises also Linacre's critical judgment (vir non exacti tantum sed severi judicii). According to others it was hard to say whether he were more distinguished as a grammarian or a rhetorician. Of Greek he was regarded as a consummate master; and he was equally eminent as a "philosopher," that is, as learned in the works of the ancient philosophers and naturalists. In this there may have been, as the custom of the day was, some exaggeration; but all have acknowledged the elevation of Linacre's character, and the fine moral qualities summed up in the epitaph written by John Caius:—"Fraudes dolosque mire perosus; fidus amicis; omnibus ordinibus juxta carus."

The materials for Linacre's biography are to a large extent contained in the older biographical collections of George Lilly (in Paulus Jovius, *Descriptio Britanniæ*), Bale, Leland, and Pits, in Wood's *Athenæ Oxonienses*, and in the *Biographia Britannica*; but all are completely collected in the *Life of Thomas Linacre*, by Dr Noble Johnson, London, 1835. Reference may also be made to Dr Munk's *Roll of the Royal College of Physicians*, 2d ed., London, 1878; and the Introduction, by Dr Payne, to a facsimile reproduction of Linacre's version of *Galen. de Temperamentis*, published by Messrs Macmillan, Cambridge, 1881. With the exception of this treatise, none of Linacre's works or translations have been reprinted in modern times. (J. F. P.)

LINARES, an important mining town in the province of Jaen, Spain, is situated in an arid plain, near the foot of the Sierra Morena, 24 miles north-north-east from the town of Jaen, 12 north-east from that of Baeza, and half an hour by rail from the Vadollano station of the Madrid and Cordova line. The streets are ill paved, irregular, and ugly, and, apart from a fine fountain of Roman origin, the town presents no architectural features of interest. There is some trade in the oil and wine of the neighbourhood, which are excellent and plentiful; wool is exported to Catalonia and Valencia; and cattle-breeding, especially of animals for the bull-ring, is also carried on. But the population, which in 1877 numbered 36,630, and includes some 120 English, with a consul and a chaplain, is chiefly engaged in the working of the extensive lead-mines to the north-west of the town, and in various concomitant industries, such as the manufacture of gunpowder, dynamite, match for blasting purposes, rope, and the like. The mining plant is entirely imported, principally from England. In respect of the quantity and uniform excellence of their productions the lead-mines of the province of Jaen are unsurpassed. For the year 1876–77 the joint output of those of Linares, Vilches, Bailen, Carboneros, Santa Helena, and (in part) La Carolina was stated at 1,620,000 cwts. of ore, worth upwards of £800,000,—the proportion of silver to lead varying from 20 to 60 grammes of the former to every 50 kilogrammes of the latter. The best class of ore is exported, chiefly to France and Belgium; the inferior classes are smelted for the most part in Spain. About 2 miles to the south of Linares is the village of Cazlona, which still shows some remains of the ancient Castulo; and the ancient mines some 5 miles to the north, which are now known as "Los Pozos de Anibal," may with some probability be assigned to the Carthaginian period.

LINCOLN, one of the four eastern maritime counties of England, lies between 52° 39′ and 53° 43′ N. lat., and 0° 22′ E. and 0° 56′ W. long. It is bounded on the N. by the Humber, E. by the German Ocean and the Wash, S.E. for 3 miles by Norfolk, S. by Cambridge and Northampton, S.W. by Rutland, W. by Leicestershire and Notts, and N.W. by Yorkshire. Its greatest length north and south, from Barton-on-Humber to Market Deeping, is 75 miles, its greatest breadth, from Wroot on the west to Saltfleet on the east, is 50 miles, its circuit about 260 miles. Its area is 1,767,962 acres, or about 2762 square miles, making it the second largest county in England.

Coast-Line.—The coast-line, about 110 miles in length, is low and marshy, and artificial banks for guarding against the inroads of the sea are to be found, in places, all along the coast. From Grimsby to Skegness traces of a submarine forest are visible, but while the sea is encroaching upon some parts of the coast it is receding from others, as shown by Holbeach, which is now 6 miles from the sea. Several thousand acres have been reclaimed from this part of the Wash, and round the mouth of the Nene on the south-east. The deep bay between the coasts of Lincolnshire and Norfolk, called the Wash, is full of dangerous sandbanks and silt; the navigable portion, off the Lincolnshire coast, is known as the Boston deeps. The rapidity of the tides in this inlet, and the lowness of its shores, which are generally indistinct on account of mist from a moderate offing, render this the most difficult portion of the navigation of the east coast of England.

Surface and Geology.—The surface of Lincolnshire is generally a large plain, some portions of which are below the level of the sea. The south-east parts are perfectly flat; and about one-third of the county consists of fens and marshes, intersected in all directions by artificial drains, called locally dykes, delphs, drains, becks, leams, and eaux. This flat surface is, however, broken by two ranges of calcareous hills running north and south through the county, and known as the Cliff and the Wolds. The former range, on the west, runs nearly due north from Grantham to Lincoln, and thence to the Humber, traversing the Heaths of Lincolnshire, which were formerly open moors, rabbit warrens, and sheep walks, but are now enclosed and brought into high cultivation. Parallel with this range on the east side of it runs the old Roman Ermine Street, sometimes called the Cliff Row Road. The Wolds form a ridge of bold hills extending from Spilsby to Barton-on-Humber for about 40 miles, with an average breadth of about 8 miles. Between the Wolds and the sea lie the Marshes, a level tract of rich alluvial soil extending from Barton-on-Humber to Wainfleet, varying in breadth from 5 to 10 miles. Between the Welland and the Nene in the south-east of the county are Gedney Marsh, Holbeach Marsh, Moulton Marsh, and Sutton Marsh.

The Fens, the soil of which has been formed partly by tidal action and partly by the decay of forests, occupy the Isle of Axholme on the north-west, the vale of Ancholme on the north, and most of the country south-east of Lincoln. The chief of these are the Holland, Wildmore, West, and East Fens draining into the Witham; and the Deeping, Bourn, Great Porsand, and Whaplode Fens draining into the Welland. Owing to the dead level of these districts there is perhaps more artificial drainage in Lincolnshire than in any other English county; and this part of the country resembles in many respects, especially in embankments and dykes, the continental Holland.

The drainage of the Fens appears to have early occupied attention. Shortly after the Norman Conquest Richard de Rulos, lord of Brunn, and chamberlain to William I., enclosed and drained a large part of Deeping Fen in so complete a manner that the work would not be disgraced by a comparison with the more scientific efforts of modern times. Excluding the Welland by a bank, he changed "deep lakes and impassable fens into most fruitful fields and pastures, and the most humid and moorish parts thereof into a garden of pleasure."

The drainage of the remaining levels of Lincolnshire was chiefly commenced in the reigns of James I. and Charles I. The East, West, and Wildmore Fens were contracted for in the 7th Charles I. The earl of Lindsey undertook all the fens in Holland and Kesteven, north of the river Glen up to Lincoln, on the completion of which 24,000 acres were awarded to him. In the 13th of the same reign, the king declared himself the "Undertaker" of the Holland Fen, containing 22,000 acres, out of which he was to have 8000 for his share. Sir John Monson with other freeholders drained the Ancholme level in the north, and had 5827 acres assigned to them. In the same reign the Isle of Axholme was undertaken by Cornelis Vermuyden and his Dutch and Flemish followers. These operations were interrupted during the civil wars, and many of the works destroyed by the "stilt-walkers," so curiously described by Camden. Little was done towards restoring the works thus destroyed till the middle of the 18th century, when several townships, having a right of common over particular fens, began to join in procuring Acts of

Parliament for their drainage, enclosure, and division. The Holland Fen was the first to be dealt with, about 1768; in spite of renewed and riotous opposition from the "stilt-walkers," all the fen lands were successfully drained and enclosed, and on the completion of the East, West, and Wildmore Fens (about 60,000 acres) the race of "stilt-walkers" became extinct. The low lands adjoining the tidal reaches of the Trent and Humber, and part of those around the Wash, have been raised above the natural level, and enriched by the process of warping, which consists in letting the tide run over the land, and retaining it there a sufficient time to permit of the deposit of the sand and mud held in solution by the waters.

The general appearance of the county is very pleasing. The level tracts are richly cultivated; the hills and dales are interspersed with wood and lawn; and many spots on the Cliff or Wolds command extensive and charming views. The charms of the Fen districts are described as "a beauty as of the sea, of boundless expanse and freedom" (Kingsley). Not a few passages in the writings of Tennyson (a native of the county) bear the impress of the scenery and colourings of the Fens.

The geological formations, for the most part, extend in parallel belts, nearly in the line of the length of the county, from north to south, and succeed one another, in ascending order, from west to east.

1. The lowest is the *Triassic* or *New Red Sandstone* found in the Isle of Axholme and the valley of the Trent in the form of marls, sandstone, and gypsum. The presence of the peroxide of iron which tinges the beds red seems to have been prejudicial to animal life; therefore few fossils are found. Fish scales and teeth, with bones and footprints of the *Labyrinthodon*, are to be met with in the sandstone. The red clay is frequently dug for brick-making. The beds dip gently towards the east. At the junction between the Trias and Lias are series of beds termed Rhætics, which seem to mark a transition from one to the other. These beds are in part exposed in pits near Newark, and extend north by Gainsborough to where the Trent flows into the Humber, passing thence into Yorkshire. The characteristic shells are found at Lea, 2 miles south of Gainsborough, with a thin stratum of bone bed full of fish teeth and scales.

2. The *Lower Lias* comes next in order, with a valuable bed of ironstone now largely worked. This bed is about 27 feet in thickness, and crops out at Scunthorpe, where the workings are open and shallow. The *Middle Lias*, which enters the county near Woolsthorpe, is about 20 or 30 feet thick, and is very variable both in thickness and mineralogical character. The *Upper Lias* enters the county at Stainby, passing by Grantham and Lincoln. It forms the west slope of the Cliff range, and is thickest upon the highest hills. The Lias thus occupies a band about 8 or 10 miles in width in the south, narrowing until on the Humber it is about a mile wide.

3. To this succeed the three Oolite formations. The *Lower Oolite*, somewhat narrower than the Lias, extends from the boundary with Rutland due north past Lincoln to the vicinity of the Humber. The *Middle Oolite*, very narrow in the south near Wilsthorpe, widening gradually about Sleaford, and then suddenly contracting again south of Lincoln, sends out a narrow band south-east towards Spilsby. It then proceeds north from Lincoln with decreasing width to the vicinity of the Humber. The *Upper Oolite* and Kimmeridge clay start from the vicinity of Stamford, and after attaining their greatest width near Horncastle, run north-north-west to the Humber.

4. In the *Cretaceous* system of the Wolds, the Lower Greensand runs nearly parallel with the Upper Oolite past South Willingham to the Humber. The Upper Greensand and Gault run north-west from Irby, widening out as far as Kelstern on the east, and cross the Humber. The Chalk formation, about equal in breadth to the three preceding, extends from Burgh across the Humber.

5. All the rest of the county, comprising all its south-east portions between the Middle Oolite belt and the sea, all its north-east portion between the Chalk belt and the sea, and a narrow tract up the course of the Ancholme river, consists of alluvial deposits or of reclaimed marsh.

Minerals.—Gypsum is dug in the Isle of Axholme, whiting is made from the chalk near the shores of the Humber, and lime is made on the Wolds. Freestone is quarried around Ancaster, and good oolite building stone is quarried near Lincoln and other places. Ironstone is found and worked at Claxby near Caistor, and carried into Yorkshire to be smelted; it is also worked at Frodingham, 9 miles north-north-west of Brigg.

Rivers.—The Humber separates Lincolnshire from Yorkshire. Its ports on the Lincolnshire side are Barton, New Holland, and Grimsby. The Trent divides the Isle of Axholme from Lindsey, and falls into the Humber about 30 miles below Gainsborough. Like the Severn, it is noted for a tidal phenomenon called the "eager" or bore, which, at spring tides, rises to the height of from 6 to 8 feet. The Witham rises on the south-west border of the county, flows north past Grantham to Lincoln, and thence east and south-east to Boston, after a course of about 80 miles. This river was once noted for its pike. The Welland rises in north-west Northamptonshire, enters the county at Stamford, and, after receiving the Glen, flows through an artificial channel into the Fossdyke Wash. The Nene on the south-east has but a small portion of its course in Lincolnshire; it flows due north through an artificial outfall called the Wisbech Cut.

Canals.—The principal canals are—the Stainforth and Keadby, connecting the Trent with the Yorkshire coal-field; the Louth Navigation, from Louth to Tetney Haven; the Sleaford Navigation, connecting Sleaford with the Witham; and the Grantham Canal, from that town to the Trent at Nottingham. The remainder are chiefly small rivers artificially deepened and embanked.

Climate.—The climate of the higher grounds is now noted for its salubrity, and meteorological observation does not justify the reputation for cold and damp often given to the county as a whole. The mean annual temperature of the Fens as given by ten years' observation (1864–73) is 47°·9, 1°·6 below that of Greenwich. The rainfall of the Fen district is very small as compared with other parts of England. While the average of the whole country was little over 30 inches, at Boston the average fall from 1830 to 1849 was 23·58 inches, and from 1850 to 1869 22·08. At Wisbech south-west winds prevail on an average six months in the year, and north-east winds barely two months.

Soil and Agriculture.—The soils vary considerably, according to the geological formations; ten or twelve different kinds may be found in going across the country from east to west. A good sandy loam is common in the Heath division; a sandy loam with chalk, or a flinty loam on chalk marl, abounds on portions of the Wolds; an argillaceous sand, merging into rich loam, lies on other portions of the Wolds; a black loam and a rich vegetable mould cover most of the Isle of Axholme on the north-west; a well-reclaimed marine marsh, a rich brown loam, and a stiff cold clay variously occupy the low tracts along the Humber, and between the north Wolds and the sea; a peat earth, a deep sandy loam, and a rich soapy blue clay occupy most of the east and south Fens; and an artificial soil, obtained by "warping," occupies considerable low strips of land along the tidal reaches of the rivers. The wide grazing lands of Lincolnshire have long been famous, and the arable lands are specially adapted for the growth of wheat and beans. There is no generally recognized rotation of crops. The cattle raised are the Shorthorns and improved Lincolnshire breeds. The dairy, except in the vicinity of large towns, receives little attention. The sheep are chiefly of the Lincolnshire and large Leicestershire breeds, and go to the markets of Yorkshire and the metropolis. Lincolnshire has long been famous for a fine breed of horses both for the saddle and draught. Horse fairs are held every year at Horncastle and Lincoln. Large flocks of geese were formerly kept in the Fens, but their number has been diminished since the drainage of these parts. Where a large number of them were bred, nests were constructed for them one above another; they were daily taken down by the gooseherd, driven to the water, and then reinstated in their nests, without a single bird being misplaced. Decoys were once numerous in the undrained state of the Fens.

According to the agricultural returns for 1881, the total area under crops comprehended 1,498,676 acres, a percentage of 84·7 instead of 81·7 in 1870; corn crops had an area of 611,977 acres, a percentage of 34·6 instead of 34·9 in 1870; green crops, 238,719 acres, a percentage of 13·5 instead of 13·2 in 1870; rotation grasses, 167,252 acres, a percentage of 9·5 instead of 9·4; permanent pasture, 440,422 acres, a percentage of 24·9 instead of 23·0. The area under crops is thus more than three times the amount under pasturage. The area under woods in 1881 was 39,431 acres, and under orchards 1788, under market gardens 660, under nursery grounds 137. Of the corn crops the most largely grown is wheat, which in 1881 occupied 245,645 acres,—barley or bere, grown mostly on the Wolds and the Heath districts, coming next with 199,900 acres; then oats, 113,564 acres; lastly rye, 1300 acres. Beans occupied 41,073 acres, pease 10,495 acres. Of the green crops the most largely grown in 1881 were turnips and swedes, 142,300 acres, mostly on the Wolds and Lincoln Heath. Potatoes occupied 39,794 acres; mangold, 21,438; vetches and other green crops, except clover or grass, 18,615 acres; cabbage, kohl-rabi, and rape, 15,057 acres; carrots, 1515 acres. Onions are raised to a great extent in the Isle of Axholme, and under good management have been known to return £50 per acre. Flax occupied 353 acres, and hops 3. The bare fallow or uncropped arable land in 1881 was 39,950 acres. In 1870, 81·7 per cent. of the entire area of Lincolnshire was returned as cultivated, in 1879, 84·1 per cent., and in 1880, 84·5. The number of horses used solely for agriculture in 1881 was 49,656; mares and unbroken horses, 15,171—total, 64,827. The number of cows and heifers in milk or in calf in 1881 was 53,499, and of other cattle 156,706. The number of sheep was 1,336,147, or 90·2 for every 100 acres, the average for Great Britain being 76·3, for England 62·4. Pigs in 1881 numbered 82,497.

The agriculture of Lincolnshire is only second to that of East Lothian, by which alone it is excelled in the use of fixed steam-engines upon its farmsteads. In the south part of the county small proprietors abound. According to the landowner's returns for 1872–73, the land in the county of Lincoln was divided among 30,497 owners, and its gross estimated rental was £3,173,825. Of the owners, 13,768, or more than 45 per cent., possessed less than 1 acre; the average value per acre was £1, 19s. 6½d. There were four proprietors possessing over 20,000 acres each:—Earl of Yarborough, 55,272 acres; Lady Willoughby de Eresby, 24,696 acres; Henry Chaplin, M.P., 23,370 acres; and Christopher Turnor, 20,664 acres.

The following table gives a classification of holdings according to size as returned on the 25th June 1875 and the 4th June 1880:—

Class of holding	50 Acres and under.		50 to 100 Acres.		100 to 300 Acres.		300 to 500 Acres.		500 to 1000 Acres.		1000 Acres and upwards.		Total.	
	1875.	1880.	1875.	1880.	1875.	1880.	1875.	1880.	1875.	1880.	1875.	1880.	1875.	1880.
Number	19,706	20,263	2,181	2,196	2,8-8	2,826	817	833	370	388	28	36	25,990	26,542
Area in acres	221,837	224,826	156,085	155,559	511.042	500,575	313,136	318,612	239,468	249,538	33,879	45,516	1,475,447	1,494,626

Manufactures and Trade.—The manufactures are few and comparatively small. There are, however, some large agricultural machine and steam-engine factories in and around Lincoln; and similar works exist at Boston, Gainsborough, Grantham, and Louth. At Frodingham there are extensive iron-works. At Little Bytham a very hard brick, called the adamantine clinker, is made of the silicious clay that the Romans used for their manufactures of pottery. At Louth there is a carpet manufactory, also several tanneries and iron foundries. Bone crushing, leather working, the manufacture of oil-cake for cattle, rope making, and sack weaving are carried on in various places. The chief ports are Grimsby, Boston, Sutton Bridge, and Gainsborough, the first being by far the most important. For the fisheries of GRIMSBY see vol. ix. p. 249.

Railways.—The first line opened in the county was the Midland Railway to Lincoln, in August 1846. The Manchester, Sheffield, and Lincolnshire Railway, first opened in 1848–49, goes from Lincoln north-east to Market Rasen, and thence, by way of Barnetby and Ulceby junctions, to Grimsby and Cleethorpes. A second branch runs north-east from Gainsborough to New Holland and Barton on the Humber, and a third from Barnetby due west to the Yorkshire coal-fields. The Great Northern main line runs through the south-west of the county past Grantham to Newark, and throws off several branches. A loop line connecting Spalding, Boston, and Lincoln with the direct line from London to York was opened in 1848. The East Lincolnshire Railway (leased to the Great Northern) runs from Boston to Grimsby.

Administration.—The primary divisions of Lincolnshire are three trithings or ridings. The north division constitutes the Parts of Lindsey, the south-west the Parts of Kesteven, and the south-east the Parts of Holland. Each of these divisions had before the Norman Conquest its own trithing gerefa or reeve, and to this day each has its separate magistrates, quarter sessions, clerk of the peace and treasurer, but they are all under one lord-lieutenant and one sheriff, and subject to the court of assize held at Lincoln. These "Parts" are again subdivided into wapentakes, sokes, and hundreds. The trithings do not in any way coincide with parliamentary divisions. The Parts of Lindsey comprise more than half the county, and contain seventeen wapentakes. The Parts of Kesteven, exclusive of the soke and borough of Grantham and the borough of Stamford, comprise nine wapentakes. The Parts of Holland comprise three wapentakes only. Before the passing of the Reform Act of 1832 Lincolnshire sent twelve members to parliament—two for the county, two for the city of Lincoln, and two each for the boroughs of Great Grimsby, Boston, Grantham, and Stamford. After the passing of that Act the county returned four members, and Grimsby lost one. In 1867 Stamford also lost a member, and the representation of the county, newly divided into Mid, North, and South Lincolnshire, was increased to six, each new division returning two members. Lincolnshire comprises one city, Lincoln (population 37,312), which is also a municipal and parliamentary borough; four other municipal and parliamentary boroughs—Boston (18,867), Grantham (17,345), Great Grimsby (45,373), Stamford, partly in Northampton (8995); and one municipal borough—Louth (10,690).

The county belongs to the midland circuit. Besides the winter and summer assizes held at Lincoln, there are spring assizes held at the same place for Lincoln and Notts, and autumn assizes at Nottingham for Notts and Lincoln. Quarter sessions for the Parts of Lindsey are held at Lincoln and Spilsby, for the Parts of Kesteven at Bourn and Sleaford, for the Parts of Holland at Boston and Spalding. The county is divided into seventeen county court districts, many of which coincide with the unions. For the convenience of rating there are eighteen poor law unions; five of these, however, include eighty parishes in the adjacent counties. Ecclesiastically the county, with that of Nottingham, forms the diocese of Lincoln, which is divided into the three archdeaconries of Lincoln, Stow, and Nottingham, the latter place giving title to a suffragan bishop without a see.

Education.—The educational resources of the county in 1881 embraced one theological and one training college, both at Lincoln, and fourteen endowed grammar schools at the following places:—Alford (founded 1565), Boston (1554), Bourn (1636), Caistor (1630), Donington (1701), Gainsborough (1589), Grantham (1528), Horncastle (1571), Lincoln (1583), Louth (1551), Moulton (1561), Sleaford (1604), Spalding (1588), Spilsby (1550).

Population.—In 1881 the population of the county was 469,994 (235,014 males and 234,980 females); in 1861 it had been 412,246, and 436,599 in 1871. The figures for nine of the principal towns, in addition to the boroughs already given, are as follows:—Bourn (7121), Caistor (8793), Gainsborough (10,964), Glandford Brigg (3107), Holbeach (5190), Horncastle (4814), Sleaford (4967), Spalding (9260), and Spilsby (7082).

History and Antiquities.—It is highly probable that the territory now forming Lincolnshire was first settled by a tribe of the Belgæ, who, however, at the time of the invasion by Cæsar, had become a mixed race with the real Britons. This territory was unaffected by Cæsar's first invasion, and even after the reduction of Britain by Claudius the Fenland remained intact. The county was conquered about 70 A.D., and formed part of the province of Flavia Cæsariensis. The tribes which occupied Lincolnshire, according to Ptolemy, were the Coritani, who had Lindum and Ratæ (Leicester) for their towns. The date of the introduction of Christianity is uncertain, but we learn from Bede (*Hist. Eccles.*, ii. 16) that Adelphius of Colonia Londinensium, which has been mistaken for London, attended the council of Arles (314). Under the Saxon kingdom of Mercia, Lindsey, which probably extended nearly or quite over the modern county of Lincoln, appears to have been a dependent state. Under Edwin of Northumbria, the conqueror of Mercia, Christianity was reintroduced by Paulinus of

York, and Bede tells us that Blæcca, the governor of Lincoln, was, with his household, among the first converts (628).

Early in 870 the Danes or Northmen landed at Humberstone near Grimsby, and ravaged Lindsey and the famous monastery of Bardney on the Witham. Lincolnshire passed permanently into the hands of the Danes about 877, and was included within the boundary of the "Danelage" of Danish jurisdiction as settled by the treaty of 878. Probably the greatest changes consequent upon the Danish invasion are, first, the supplanting of the Anglo-Saxon names of places by those of the Danish termination ending in *by*, which are numerous, and the substitution of the wapentake for the earlier division of the hundred; the ancient British laws and those of the Danes were otherwise not dissimilar. In time the two populations became amalgamated and came under the dominion of the Anglo-Saxon crown. The subsequent history of the county under the Normans is associated more or less with the city of Lincoln. In the civil war between Stephen and the empress Matilda a battle was fought near Lincoln in 1141. In 1174 the Isle of Axholme was the scene of the struggle between Roger de Mowbray, one of the adherents of Prince Henry, and the forces sent against him by his father Henry II. The issue was decided by the Lincolnshire men in favour of the king. In 1216 occurred King John's march across the county, when he lost all his baggage and jewels in the Fossdyke Wash on his way to Swineshead Abbey. In the reign of Edward IV. Sir Robert Wells, at the head of 30,000 Lincolnshire men, was defeated at Losecoat Field near Stamford, March 1470. At the suppression of the monasteries a rebellion broke out at Louth headed by Makerel, the last prior of the abbey of Barlings Oxney, October 1536. The prior was hanged, and the shire for the trouble it gave to King Henry VIII. was designated in a state paper as "one of the most brute and beestalie of the whole realm." During the civil wars the county was a scene of numerous contests, the most famous of which was the battle at Grantham in 1643, won by Cromwell over the royalists. The advantage that was taken by the Fenmen to destroy the efforts made to drain and enclose the remaining levels of Lincolnshire during this stormy period has been already noticed. Riots broke out at intervals, and were continued down to the middle of the 18th century.

Remains of British camps are found at Barrow, Folkingham, Ingoldsby, Revesby, and Well. Traces of Roman camps are found at Alkborough, Caistor, Gainsborough, Gedney Hill near Holbeach, Honington near Grantham, South Ormsby, and Yarborough. The Roman roads are nearly perfect,—Ermine Street, on the east side of the Cliff hills, and the Fossway running south-west from Lincoln. The crown of these remains is without doubt the famous Roman arch called the Newport Gate at Lincoln. Tesselated pavements have been found at Denton, Horkstow, Lincoln, Scampton, and Winterton. Coins of the emperors Nero, Vespasian, and Julian have been found at Lincoln and Ancaster, and two Roman altars to the west of Stow.

There are remains of feudal castles at Boston, Lincoln, Sleaford, Somerton, Tattershall, and Torksey. The seats worthy of note (chiefly modern) are Appleby Hall, Aswarby Hall, Belton House, Blankney Hall, Brocklesby, Bulby House, Burghley House (near Stamford), Burton Hall, Casewick House, Denton Hall, Easton Hall, Hackthorn Hall, Haverholm Priory, Lea Hall, Leadenham House, Manby Hall, Newton House, Nocton Hall, Normanby Hall, Norton Place, Panton Hall, Riby Grove, Somerby Park, Stourton, Syston Park, Thonock House, Thurlby Hall, Uffington, and Willingham by Stow

At the time of the suppression of the monasteries in the reign of Henry VIII. there were upwards of one hundred religious houses; and among the Fens rose some of the finest abbeys held by the Benedictines. The Gilbertines were a purely English order which took its rise in Lincolnshire, the canons following the Austin rule, the nuns and lay brothers that of the Cistercians. They generally lived in separate houses, but formed a community having a common church in which the sexes were divided by a longitudinal wall. These houses were at Alvingham, Catley, Holland Brigg, Lincoln, before the gate of which was erected the first Eleanor Cross, Newstead in Lindsey, Semperingham, the chief house of the order, founded by St Gilbert of Gaunt in 1139, Stamford (a college for students), and Welles. There were nunneries of the order at Haverholm, Nun Ormsby, and Tunstal.

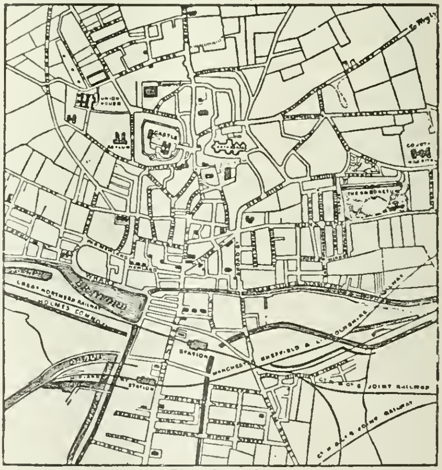
The following are a few of the most famous abbeys. (1) Barlings Oxney (Premonstratensian), founded 1154, for fourteen canons. The tower, Decorated, with arcading pierced with windows, and the east wall of the south wing remain. (2) The Benedictine Mitred Abbey of Crowland, founded 716 refounded in 948. The foundations of the new church in 1114 were laid on massive piles of oak. Part of the west front was repaired in 1255-81, with beautiful Early English sculpture of the legend of St Guthlac and saints; this, with the Perpendicular north-west tower, 1460-70, remain. (3) Swineshead Abbey (Carthusian), colonized from Furness in 1134 by eleven monks. (4) Thornton-upon-Humber Abbey (Black Canons), founded in 1139. There remain a fragment of the south wing of the transept, two sides of the decagonal chapter-house (1282), and the beautiful west gate-house, Early Perpendicular (1332-88), with an oriel window on the east.

The general beauty of the parish churches of Lincolnshire is proverbial, but it is incorrect to suppose that they are equally good in every part of the county. In the Parts of Lindsey, though there are some of considerable beauty and interest, the churches can scarcely be considered above the average; several though small and mean present curious early features, particularly the well-known tower of St Peter, Barton-on-Humber, supposed to be of the Saxon period, and those of Crowle, Heapham, and Stow. Those of Grimsby and Wainfleet are cruciform.

In the Parts of Kesteven the churches are not only elegant but well finished, built of excellent stone which abounds at Ancaster and near Sleaford. The church of St Andrew Heckington is the best example of Middle Pointed architecture in the county; it is famed for its Easter sepulchre and fine sedilia. The largest and finest church in this division is doubtless that of St Wolfran at Grantham, 200 by 87 feet, with three collateral naves, and steeple, 271 feet high, of the 14th century.

It is principally in the Parts of Holland that we are to look for the finest churches in the county; they are not to be equalled by those of any other district in the kingdom, which is the more remarkable as the district is comprised wholly of marsh land, and is without stone of any kind. It is highly probable that the churches of the south part of this district owe their origin to the munificence of the abbeys of Crowland and Spalding. The earliest specimen of Norman architecture is that of Long Sutton, which has been called the counterpart of Christ Church, Oxford. St Mary and Nicholas at Spalding, 157 feet by 95, has the uncommon feature of a double aisle on each side of the nave, as well as a transept. The glory of the division of Holland is beyond question the church of St Botolph, Boston.

Lincoln, the capital of the county of that name, is a city and county in itself, and is also a municipal and parliamentary borough. It is picturesquely situated on the summit and south slope of the limestone ridge of the Cliff range of hills which rises from the north bank of the river Witham, at its confluence with the Foss Dyke, to an altitude of 200 feet above the banks of the river. It is 132 miles north-west from London by road, and 138 miles by rail; 53° 15′ N. lat., 32′ W. long.



Plan of Lincoln.

Lincoln is one of the most ancient and interesting cities in England. The ancient British town occupied the crown of the hill beyond the Newport or North Gate of the subsequent Roman town, the ancient earthworks and ditches of which are nearly conterminous with the present boundaries of the parish of St John. The Roman town consisted of two parallelograms of unequal length, the first of which extended west from the Newport gate to a point

a little west of the castle keep. The second parallelogram extended due south from this point down the hill towards the Witham as far as Newland, and thence in a direction due east as far as Broad Street. Returning thence due north, it joined the south-east corner of the first and oldest parallelogram in what was afterwards known as the Minster yard, and terminated its east side upon its junction with the north wall in a line with the Newport gate. This is the oldest part of the town, and is named "above hill." After the departure of the Romans, the city walls were extended still further in a south direction across the Witham as far as the great bar gate, the south entrance to the High Street of the city; the junction of these walls with the later Roman one was effected immediately behind Broad Street. These three divisions comprise the boundaries of the municipal and parliamentary boroughs, which are conterminous. The "above hill" portion of the city is not well built, but consists of narrow irregular streets, some of which are too steep to admit of being ascended by carriages. The south portion, which is named "below hill," is much more commodious, and contains the principal shops and inns, with many elegant buildings and private residences. Here also are the Great Northern and Midland Railway stations.

The glory of Lincoln is its noble minster. As a study to the architect and antiquary this stands unrivalled, not only as the earliest purely Gothic building in Europe, but as containing within its compass every variety of style from the simple massive Norman of the west front, to the Late Decorated of the east portion. The building material is the oolite and calcareous stone of Lincoln Heath and Haydor, which has the peculiarity of becoming hardened on the surface when tooled. In former days the cathedral had three spires, all of wood or leaded timber. The spire on the central tower was blown down in 1547. Those on the two western towers, 101 feet high, were removed in 1808; good representations of them will be found in the well-known views by Hollar and Buck. The ground plan of the first church, adopted from that of Rouen, was laid by Bishop Remigius in 1086, and the church was consecrated four days after his death, May 6, 1092; the central west front and the font are of this period. The approximate dates of the remaining portions of the fabric may be assigned as follows:—the three west portals and the Norman portion of the west towers above the screen to the top of the third story, about 1148; the nave, its aisles, and the north and south chapels of the west end, completed 1220; the Early English portion of the west front, and the upper parts of the north and south wings, with pinnacle turrets, 1225; the west porch of the main transept, 1220; the crossing, and lower part of the central tower, 1235; the upper part, 1307; the west door of the choir aisles, 1240. The south porch of the presbytery dates 1256. The east window, the finest of its style in England, 57 by 34 feet, dates 1258–88. The choir screens date 1280, the Easter sepulchre 1290. The gables and upper parts of the main transept, the parapets of the south side of the nave, south wing, and west front, and the screen in the south aisle, all date from 1225. The upper parts of the west towers date from 1365; their upper stories, the west windows and parapet of the galilee porch, and the chapel screens in the transept, 1450. The vaulted lantern of the central tower is 127 feet above the floor. The main transept has two fine rose windows; the one on the north called the Dean's Eye is 30 feet in diameter. The Bishop's Eye to the south is very fine Decorated (*c.* 1350). The rood screen is mainly *c.* 1340.[1] The other buildings in the close that call for notice are the chapter-house of ten sides, 60 feet diameter, 42 feet high, with a fine vestibule of the same height built in 1225, and the library, 104 by 17 feet, which contains a little museum. Among the most famous bishops were St Hugh, who died 1200; Grosseteste, died 1253; Flemming, died 1431, founder of Lincoln College, Oxford; Smith, died 1521, founder of Brasenose, Oxford; Wake; and Gibson. Every stall has produced a prelate or cardinal; among those who have been capitular members may be named Walter Mapes, Henry of Huntingdon, Polydore Vergil, W. Grocyn, W. Outram, George Herbert, S. Pegge, W. Paley, Cartwright, inventor of the power-loom, and O. Manning the topographer. Lincoln, the enormous diocese of which in early times extended from the Thames to the Humber, was one of the thirteen cathedrals of the old foundation served by secular canons.

History.—The name of Lincoln is a hybrid of Celtic and Latin. It appears in the Ravenna geographer in the form of Lindum Colonia, and in Bede as Lindocolina. Lindum is purely Celtic, and exactly describes the early British settlement as the "hill fort by the pool." Lindum Colonia was founded on the site of what is now the castle and cathedral, about 100 A.D. It was besieged by Saxons in 518, and became one of the chief cities of Mercia. After being frequently ravaged by the Danes, Lincoln was recovered by Edmund II. in 1016. Lincoln Castle was built by William I. in 1086, which occasioned the removal of one hundred and sixty-six houses. Great and destructive fires occurred in 1110, 1123, and 1141. King Stephen besieged the empress Matilda in the castle in 1140. Henry II. was crowned there in the following year, as was King Stephen at Christmas 1147; David, king of Scots, did homage to King John, 1201. Lincoln was captured by King John in 1216, and invested by the barons in 1217. The battle of Lincoln Fair took place in 1218. The city was sacked in 1266. John of Gaunt, earl of Lincoln, married there in 1396 Lady Swinford, Chaucer's sister-in-law; in virtue of his title he held the castle, but built himself a winter house in the lower part of the city. A parliament of Henry VI. met at Lincoln in 1466. The town was stormed by Earl Menchester on behalf of the Parliament in 1644.

Antiquities.—One of the most perfect specimens of genuine Roman architecture in England is the Newport or North Gate of Lincoln. It is sunk fully 11 feet below the present level of the street, and has two smaller arches on each side, the one to the west being concealed by an adjoining house. The Roman Ermine Street passes through this gate, and runs north from it for 11 or 12 miles as straight as an arrow. Many Roman coins, &c., have been found in the immediate vicinity of the gate. The other gates within the city worthy of notice are the Exchequer Gate, a fine specimen of 13th century work, one of the bosses of the north arch having upon it a carved representation of the crucifixion, Pottergate and Stonebow at the top of High Street, over which is the guildhall. The castle shows traces of Norman work, the foundations of which consisted of massive beams of wood and grouting. The hall of the old episcopal palace is 90 feet by 60 wide, and had two rows of grey marble pillars. The modern palace is at Riseholme, 3 miles north of Lincoln. In the cloister garden are preserved a tesselated pavement and the sepulchral slab of a Roman soldier; the splendidly carved stone coffin lid of Bishop Remigius found there has recently been removed into the cathedral. The ancient conduits of St Mary le Wigford, picturesque Gothic, and "the Greyfriar's goodly conduit" in the High Street, may also be noticed. The St Mary's Guild near St Peters at Gowts is a fine specimen of Norman architecture; another fine relic of the domestic architecture of this period is the Jews' House, the mouldings of which are identical with those of the west portals of the cathedral (*c.* 1148). Near this is Dunestall, where the little Lincoln boy afterwards known as Little St Hugh was crucified by Jews in August 1255. There were formerly three small priories, five friaries, and four hospitals in or near Lincoln. The preponderance of friaries over priories of monks is explained by the fact that the cathedral was served by secular canons. The famous Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries.

There were fifty-two churches in the city before the Reformation, all the names of which are preserved. Fourteen remain or have been rebuilt. There are fifteen benefices in the city, consisting of three rectories and twelve vicarages. There are fourteen Nonconformist places of worship.

[1] The dimensions of the cathedral internally are—nave, 252 × 79·6 × 80 feet; choir, 158 × 82 × 72 feet; angels' choir, which includes presbytery and lady chapel, 166 × 44 × 72 feet; main transept, 220 × 63 × 74 feet; choir transept, 166 × 44 × 72 feet. Externally the west front is 173 feet broad by 130 feet; the west towers are 206 feet high; the central tower, from which booms the new Great Tom of Lincoln (5 tons 8 cwts.), is 262 feet high.

The charities comprise the new county hospital, general dispensary, lunatic asylum, penitent females' home, and institute for nurses. The educational institutions comprise a theological college (formerly old county hospital), grammar school (formerly Greyfriars), blue coat school, training college for mistresses (Newport), St. Martin's parochial schools, British schools (in Newland), Wesleyan school, and a school of art. Of other institutions may be named the Lincolnshire agricultural society, permanent library, mechanics' institute, county newsroom (above hill), city newsroom, and choral society. The remaining public buildings are the new corn exchange and masonic hall, county assembly-room and theater in High Street. The public park is near the cattle market, and the race course beyond Newland. Population in 1811, 7,000; in 1871, 26,766; in 1881, 37,312.

LINCOLN, a city of the United States, capital of Logan county, Illinois, is situated near Salt Creek, at the junction of three railways, 145 miles southwest of Chicago. It has fifteen churches, three banks, a high school, a telephone exchange, a coal-mine, two foundries, three flour-mills, five newspapers, and several grain elevators. It is the seat of Lincoln University (Cumberland Presbyterian) and of the State asylum for feeble-minded youth. A portion of the town dates from 1835, but the newer part was named in honor of Abraham Lincoln, and was incorporated in 1853. Population in 1880, 5,639.

LINCOLN, a city of the United States, county seat of Lancaster county, Nebraska, and capital of the State. It is pleasantly situated about 50 miles west of the Missouri river, at the junction of several railroads, in the midst of a highly fertile and healthful region of undulating prairie, and near rich salt springs. Lincoln is the seat of the following State institutions: university, State prison, insane asylum, and home for the friendless. The prison and the asylum grounds, occupying several hundred acres, are three miles from the center of the city, and two miles from each other. The United States Government has lately completed, at a cost of $200,000, a massive building for collection of revenue, United States courts, and postoffice. With its broad streets, its public park, and the State House and other grounds, the healthful ventilation of Lincoln is amply provided for. It has three daily papers, four banks, one of the largest printing and publishing houses west of the Mississippi, and several prosperous wholesale stores. Although but thirteen years old, it has a population (1890) of 55,154.

ABRAHAM LINCOLN.

ABRAHAM LINCOLN, the sixteenth President of the United States of America, was born February 12, 1809, in Hardin county, Kentucky. His grandfather, Abraham Lincoln, and his father Thomas, were born in Rockingham county, Virginia. His mother, Nancy Hanks, was also a Virginian by birth. His ancestors on his father's side were from Berks county, Pennsylvania.

About 1781, while his father was still a lad, the family of Abraham Lincoln's grandfather moved to Kentucky. When Thomas Lincoln, the father of the future President, was six years old, his father, Abraham Lincoln, was shot and instantly killed by an Indian, while working in a cornfield near his log cabin home. When his son, Abraham was eight years of age, Thomas Lincoln moved with his family to Indiana, in what is now known as Spencer county. Here they made their home in a rude log cabin, and young Lincoln was engaged daily in the hard work incident to a pioneer life. A very limited opportunity was afforded him amid these primitive surroundings of obtaining an education. Our public schools, the pride and glory and safety of our republican institutions, had not then reached so far west. A private school was opened occasionally in these
the far west. A private school was opened occasionally in these
remote settlements by wandering teachers, who were able to instruct in the merest rudiments of learning. Lincoln attended such a school at different times—in all not more than ten or twelve months. His mother, who was a woman of fine physical organization, and of great force of character, and possessed withal of shrewd, practical common sense, combined with deep religious feeling and great gentleness of manner, taught him to read and write.

Although but nine years of age when his mother died (1818), Lincoln had received the lasting impress of her power for good in his deepest life. Three favorite maxims she had thoroughly instilled into his mind—never to swear, never to touch liquor, and never to lie. These three things he never did. He said when President, "All that I am, or hope to be, I owe to my sainted mother."

A year after his mother's death, Lincoln's father married again. At nineteen, Lincoln made a trip to New Orleans as a hired hand on a flat boat, and on his return his father moved to Macon county, Illinois (1830). Lincoln split the timber for a log cabin, and built it, and inclosed ten acres of land with a rail fence of his own making. On account of the unhealthiness of this region at that time the place was abandoned by the family. Soon after, being twenty-one years of age, he hired himself to a Mr. Offut, living in Sangamon county, to build a flat boat and float it down the Sangamon, the Illinois and the Mississippi rivers to New Orleans. He then became clerk in Offut's store at New Salem. He diligently employed his spare time in reading and study. Æsop's Fables, Bunyan's Pilgrim's Progress, a Life of Washington, the poems of Burns and the Bible, had been the books he was able to get hold of in his earlier years. Now he devoted himself especially to the study of English grammar, and other books, among them the Life of Franklin and the Life of Henry Clay, receiving assistance occasionally from the village schoolmaster. Next year (1832), the Black Hawk War broke out, and the hardy boatman volunteered to fight for his country. He was at once elected captain by a company in Sangamon county, and served with honor for a season in military life, although engaged in no battle. He was very popular with the soldiers on account of his great physical strength, and because he could tell more and better stories than any other man in the army. At this time he was also a candidate for the Illinois legislature and made a printed address to "The People of Sangamon County," bearing the date of March 9, 1832.

This address indicates marked ability, and justifies the reputation he had already acquired in the region roundabout as a man of resources and shrewdness. He was defeated for the legislature, but soon afterwards was appointed postmaster at New Salem. The surveyor of Sangamon county, being driven with work, asked Lincoln to take the survey of a tract from off his hands. As Lincoln was somewhat burdened with debt through the failure of his small country store, he eagerly accepted the job. He had never studied surveying, but procuring a treatise on the subject and a chain, he did the work and did it well.

He now borrowed all the law books he was able to obtain, as he was too poor to buy them, and began studying them by the light of his evening fire. He also pored over a volume of Shakspeare which fell in his way. It is mentioned as a curious fact in his life that neither then nor afterwards did he ever read a novel. "The interest he felt in human beings was infinitely stronger with him than the interest in any artistic representation."

In the autumn of 1836 Lincoln obtained a license to practice law, and rose rapidly in his profession. Two years before this, in 1834, he had been elected to the Illinois legislature, and was successively re-elected in 1836, 1838, and 1840. He could have been returned again in succeeding years, but declined to be renominated.

Stephen A. Douglas also became a member of the same legislature in 1836. These two men quickly became party leaders on their respective sides of the house, and thus their political courses and their political rivalries began almost together. Mr. Lincoln was the Whig candidate for speaker, and once lacked one vote only of being elected. The dislike of Mr. Lincoln for slavery was evinced when some strong pro-slavery resolutions were passed by the legislature of Illinois. He, with Mr. Dan Stone, took the most decided stand possible on the subject by putting on the journal of the house a formal protest against the resolutions.

On April 15, Mr. Lincoln removed from New Salem to Springfield, the capital of Illinois, which was afterward his permanent abode. In the presidential campaign of 1844 he made strong and effective speeches for Henry Clay. In this and in other campaigns his reputation as an eloquent and influential public speaker was greatly increased. In 1846 he was elected to Congress as a Whig by a large majority. After his term of service he devoted himself assiduously to the study and practice of law, while still doing duty in the field of politics.

In 1846–50 he was unsuccessful as a candidate for United States senator in the Illinois legislature, but about this time declined several important political positions which were tendered him. With the repeal of the Missouri Compromise of 1820 came on anew and with added force the slavery agitation. The Kansas-Nebraska bill, "with the violence and iniquities connected with it," stirred to its very depths the soul of Mr. Lincoln. Regarding all this action as a most unjustifiable breach of political faith, he sprang to the front to denounce its injustice and wrong. He was at once the acknowledged anti-slavery leader of Illinois. His debates with Stephen A. Douglas, "the little Giant," on the slavery question were of a most masterly character. His fame began to widen far beyond the boundaries of his own State. Mr. Lincoln was justly entitled to an election as United States senator, as his party was in the ascendancy in the legislature of Illinois, but although it was a source of great disappointment and chagrin to him not to be elected, he magnanimously withdrew his candidacy in favor of the Hon. Lyman Trumbull, and by strong personal influence secured his election.

The Republican party of Illinois was formally organized in 1856. Various heterogeneous political elements were found in its composition.

After a long and vain discussion by the committee on platform, Mr. Lincoln was sent for to give advice. It was a critical time, as there was great danger of ultimate discord and disruption. Mr. Lincoln said: "Take the Declaration of Independence and Hostility to Slavery Extension. Let us build our new party on the rock of the Declaration of Independence, and the gates of hell shall not prevail against us." What he advised was done. In 1858, the senatorial term of Mr. Douglas was expiring, and a re-election was sought by him. Mr. Lincoln, as the opposing candidate, challenged Mr. Douglas, on the earnest entreaty of political friends, to a joint public discussion at several important places in the State. The speech that Lincoln made June 17, 1858, at the close of the Republican State Convention at Springfield, which nominated him as United States senator, struck the keynote of his subsequent speeches in this great debate. After stating that the policy which had been adopted, with the avowed object of putting an end to the slavery agitation, had failed, he said:

"A house divided against itself cannot stand. I believe this government cannot endure permanently half slave and half free. I do not expect the Union to be dissolved—I do not expect the house to fall—but I do expect it will cease to be divided. It will become all one thing or the other. Either the opponents of slavery will arrest the further spread of it, and place it where the public mind shall rest in the belief that it is in the course of ultimate extinction, or its advocates will push it forward till it shall become alike lawful in all the States, old as well as new, North as well as South."

At a private dinner at Bloomington, at which some friends, after he was beaten, were criticising these utterances as fatal to his campaign, he replied: "Well, gentlemen, you may think that a mistake, but I have never believed it was, and you will see the day in which you will consider that the wisest thing I ever said."

Besides the seven debates which were held with Mr. Douglas, Lincoln made about fifty other speeches in different parts of Illinois. These debates and speeches won for Lincoln almost a national fame. But his great speech at Cooper Institute in New York city, February 27, 1860, made him a lasting reputation throughout the country and the world. He closed that speech with the ringing words, "Let us have faith that right makes might, and in that faith let us to the end dare to do our duty as we understand it."

Thus he went at once to the heart of the whole question, holding that slavery must be tried not by the standard of political expediency, but by the law of eternal right.

On May 16, 1860, the Republican National Convention met at Chicago. "No Extension of Slavery" was the cardinal feature of its platform. William H. Seward was the principal competitor of Mr. Lincoln for the Presidency, but on the third ballot Lincoln was nominated. Pending the nomination, some of Mr. Lincoln's friends telegraphed him at Springfield that in order to be nominated he must promise cabinet positions to two leaders of prominent delegations. He telegraphed back immediately, "I authorize no bargains, and I will be bound by none."

The Democratic convention was divided, the northern section nominating Stephen A. Douglas, of Illinois; the southern, John C. Breckinridge, of Kentucky. The constitutional Union party nominated John Bell, of Tennessee.

Signs of party lukewarmness and lethargy existed in the East, and friends proposed sending delegations there to induce union and partisan activity, but he alone opposed it. It was not until late in the summer that he consented that Judge Davis should go purely on his own behalf on a tour of inspection, and it is the candid opinion of all who know, that he consented to this reluctantly, and would prefer, in his heart of hearts, that he should not have gone.

He believed the necessities of the party and the great coercive force of a campaign were the real causes of union, and if they failed nothing else could act as a substitute for them. No individual effort could aid or hasten them, and none could defeat them. And so he sat in his Mecca at Springfield, received every one who came, heard what every one said, told a story and said nothing himself, but watched the operation of the great forces as they gradually but slowly brought order out of chaos, and led him on to final triumph. After his election he consented, after persuasion, to have Thurlow Weed invited to Springfield, but this had to be urged upon him.

On November 6, 1860, Lincoln was elected President, and was inaugurated at Washington, March 4, 1861. But as soon as his election had been assured, the extreme partisans of slavery consummated their preparations for an insurrection, and a movement for separation was already begun in South Carolina. The slave States of Georgia, Alabama, Florida, Mississippi, Louisiana and Texas, went with her into secession. A provisional government termed "The Confederate States of America," was immediately organized, with Jefferson Davis as President. Nearly all the arsenal posts and public property of the United States within their limits were seized by strategy or force. Meanwhile the loyal members of both Senate and House were closely organized to concert measures to meet the appalling emergencies that confronted them, and a "Committee of Public Safety" was appointed, consisting of Senator Grimes, of Iowa, and Hon. E. B. Washburne, of Illinois, clothed with full powers to act, who faithfully performed their duty.

President Lincoln, in his inaugural address, declared the acts of secession null and void. He maintained that the Union was perpetual and inviolate. He announced with great firmness, yet with marked moderation, the determination of the government to assert its authority and hold all the forts and places yet under its jurisdiction. He showed very clearly that secession was impossible, but disclaimed any purpose of oppressing, subjugating or invading the seceding States. "In your hands, my dissatisfied fellow-countrymen," he said, "and not in mine, is the momentous issue of civil war. The government will not assail you. You can have no conflict without being yourselves the aggressor."

On April 13, 1861, after a long bombardment by the Confederates of South Carolina, by order of General P. G. T. Beauregard, Fort Sumter surrendered. On April 15, 1861, by proclamation, the President called for an armed force of 70,000 militiamen, and on May 4 following ordered the still further enlistment of over 64,000 soldiers and 18,000 seamen for a service of three years. He declared the Southern ports in a state of blockade, and called a special session of Congress to meet on July 4. All the remaining slave States, except Maryland, Kentucky, Missouri and part of Virginia, joined the secession movement.

On July 21, 1861, at Bull Run, near Manassas Station, Virginia, the first important battle of the war was fought, which resulted in the defeat and panic of the National troops. From the Congress which had convened, President Lincoln asked for and obtained 400,000 men and $4,000,000 for the war. Congress passed an act in August, 1861, confiscating the rights of the slave owners to slaves employed in acts hostile to the Union. General Fremont, on August 31, made the passage of this act the occasion to issue an order to confiscate and emancipate the slaves of Confederates in the State of Missouri. President Lincoln promptly revoked the order, not deeming it a wise action in existing conditions. On General Scott's resignation, October 31, 1861, he placed General George B. McClellan at the head of the Union army. On January 14, 1862, he appointed Edwin M. Stanton Secretary of War. In March, 1862, he sent a special message to Congress, inclosing a resolution offering pecuniary aid from the general government to such States as should gradually abolish slavery, and recommending its passage. The Congress at once passed the resolution. None of the slave States, however, complied with the offer. In April, 1862, Congress passed an act emancipating the slaves in the District of Columbia, with compensation to owners. President Lincoln signed the bill, which embodied the very measure he had fruitlessly proposed when in Congress in 1849. Meanwhile, fugitive slaves were continually streaming into the National camps. General Hunter, an intimate friend of the President, issued a military order on May 9, 1862, without consulting Mr. Lincoln, declaring all persons in Georgia, Florida and South Carolina, heretofore held as slaves, to be forever free. President Lincoln countermanded the order without delay, reserving to himself, as commander in chief, the decision in such important questions. But in his proclamation declaring the order void, he said to the inhabitants of the belligerent slave holding States, regarding State emancipation with compensation: "I do not argue, I beseech you to make the argument for yourselves. You cannot, if you would, be blind to the signs of the times. * * * So much good has not been done, by one effort, in all past time, as in the providence of God it is now your high privilege to do. May the vast future not have cause to lament that you have neglected it." He urged this policy of emancipation with compensation several times upon the members of Congress from the loyal slave holding States, but without success. Meanwhile the anti-slavery sentiment of the North was growing, and the President was subject to severe attacks upon his conservative policy by the anti-slavery supporters of the government. With great moderation and good temper he met them all.

On August 22 he said to Horace Greeley: "My paramount object is to save the Union, and not either to save or destroy slavery. If I could save the Union without freeing any slave, I would do it; if I could save it by freeing all the slaves I would do it, and if I could do it by freeing some and leaving others alone I would also do that. What I do about slavery and the colored race, I do because I believe it helps to save the Union, and what I forbear, I forbear because I do not believe it helps to save the Union." In reply to one religious delegation, who presented a memorial requesting him to issue a proclamation of universal emancipation, he said: "The subject is difficult, and good men do not agree. * * * I can assure you that the subject is on my mind by day and night more than any other. Whatever shall appear to be God's will, I will do." In reply to another delegation, consisting of clergymen headed by Dr. Cheever, who had been making a similar appeal to him, he answered slowly: "Well, gentlemen, it is not very often that one is favored with a *delegation direct from the Almighty*."

After a succession of defeats and victories of the National army, President Lincoln believed the time to be ripe for the proclamation of emancipation which he had been long maturing, if the seceding slaveholding States should refuse the offer of compensation with emancipation. On September 22, 1862, he issued a proclamation, declaring the freedom of all slaves in the States and parts of States then in rebellion, from and after January 1, 1863. He designated the States of Arkansas, Texas, a part of Louisiana, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina and Virginia, excepting certain counties. The measure was taken too soon to please some parties and too late to please others. In England it was received by the aristocratic element, in the face of much military ill-success, with the scoffing epigram that "the President had proclaimed liberty in the States where he had no power, and retained slavery in those where he had." The dissatisfaction, especially manifested at first in the border States, soon disappeared, and the displeasure which the enlistment of negro troops had called out in the same and other quarters soon died away. Mr. Lincoln did not wish to act hurriedly in following up the emancipation proclamation by legislative action, although he saw that it must be secured ere long.

He was urged by some friends to follow it up in his next message to the Congress of 1863, which preceded his second nomination by only about five months, by a recommendation of an amendment to the Constitution abolishing slavery. It was urged upon him that this was an outside position of radicalism, and if he did not take it his rivals would. Turning to the gentlemen present, he said: "Is not the question of emancipation doing well enough now?" "Yes," was the reply. "Well," said he, "I have never yet done an official act because of its bearing upon my renomination, and I don't like to begin now. I can see emancipation coming; whoever can wait for it will also see it; whoever gets in the way of it will be run over by it."

In the winter session of the Congress of 1863–64, he urged that body to propose a constitutional amendment abolishing slavery. It failed, however, to receive the necessary two-thirds vote. In his annual message of December 6, 1864, he pleaded again for the adoption of such an amendment, and this time with success, for by joint resolution, January 31, 1865, the Thirteenth amendment was proposed to the various States that neither slavery nor involuntary servitude, except as a punishment for crime, whereof the party shall have been duly convicted, shall exist within the United States, or any place subject to their jurisdiction. Before the year ended, twenty-seven out of the thirty-six States (the three-fourths required) had ratified the amendment, the President's own State of Illinois leading the van.

With consummate skill and wisdom, President Lincoln carried on the affairs of the government during all its perilous period. Some of the most important State papers framed by Mr. Seward, the Secretary of State, were revised by his hand. The changes made in them indicate the superb diplomatic genius of Mr. Lincoln. His prudence and moderation were signally seen in the surrender of Mason and Slidell, the Confederate envoys, to the British government, after their capture on board a British merchant vessel. The same characteristics of wisdom were evinced in his non-interference with Mexican affairs during the period of the military power of Maximilian. Unbroken friendship was maintained with the republican government of Juarez, and Mr. Lincoln put it on record "that the safety of the people of the United States and the cheerful destiny to which they aspire are intimately dependent upon the maintenance of republican institutions throughout Mexico."

Mr. Lincoln's superior statesmanship was again displayed in averting war with England, which was threatened through the building and fitting out of Confederate cruisers in English ports, and their subsequent escape to prey upon American shipping. As the war continued and created a demand for soldiers greater than volunteer enlistments could meet, a draft of the arms-bearing population of the loyal States was ordered by Congress. This was the occasion of a great riot in New York city, on July 13, 1863. Various orators of the opposition made virulent speeches against the conscription as they termed it. Prominent among them was Clement L. Vallandigham, who was arrested by General Burnside in Ohio, and, by a change of sentence made by President Lincoln, was sent within the lines of the States in secession.

Mr. Vallandigham was nominated that same year by the Democrats of Ohio for governor, to show their determined opposition to the policy of the government. President Lincoln had offered to remit the sentence of Vallandigham, if the committee of prominent Democrats who petitioned for his release would sign a statement that rebellion existed, and that constitutional measures were taken, when the army and navy were used, to suppress it, and that each of the committee would pledge himself to use his personal influence and power to carry on the war. This, however, was not done, and in November, at the Ohio election, Vallandigham was defeated by more than a hundred thousand majority.

On October 16, 1863, President Lincoln called for 300,000 volunteers to replace those whose term of enlistment had expired. On November 19, 1863, he made his celebrated address at the dedication of the battlefield of Gettysburg as a soldiers' cemetery, where at the beginning of the July previous General Lee had suffered such a disastrous defeat. Mr. Lincoln said:

"Four score and seven years ago our fathers brought forth upon this continent a new nation, conceived in liberty and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war, testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battlefield of that war. We have come to dedicate a portion of that field as a final resting place for those who here gave their lives that the nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we cannot dedicate—we cannot consecrate—we cannot hallow—this ground. The brave men, living and dead, who struggled here, have consecrated it far above our power to add or detract. The world will little note, nor long remember, what we say here, but it can never forget what they did here. It is for us, the living, rather, to be dedicated here to the unfinished work that they have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us—that from these honored dead we take increased devotion to the cause for which they here gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain—that this nation, under God, shall have a new birth of freedom—and that government of the people, by the people, and for the people, shall not perish from the earth."

On March 9, 1864, President Lincoln commissioned Ulysses S. Grant as lieutenant-general and general-in-chief of the armies of the Northern States. From this time Mr. Lincoln ceased to exercise any active influence in the movements of the army. He wrote on April 30, 1864, to General Grant: "The particulars of your plans I neither know, nor seek to know. You are vigilant and self-reliant. * * * If there is anything wanting which is in my power to give, do not fail to let me know it. And now, with a brave army and a just cause, may God sustain you."

On June 8, 1864, Mr. Lincoln was unanimously renominated for the presidency by the National Republican Convention at Baltimore, Md. On August 27, 1864, the Democratic National Convention at Chicago nominated General McClellan for the presidency The extreme peace party, in this convention, led by Mr. Vallandigham, who had returned without leave from his banishment, and whom Mr. Lincoln did not deem it wise to rearrest, succeeded in securing a platform, which declared the war a failure and demanded that hostilities should cease.

On the very day the convention adjourned, Atlanta was taken by the Union troops. At the election in November following, Mr. Lincoln received 2,216,000 votes and General McClellan 1,800,000. Mr. Lincoln received 212 electoral votes and General McClellan 21.

On his second inauguration, March 4, 1865, President Lincoln delivered an address which will stand forever as a model of lofty eloquence and august morality.

On April 2, General Lee evacuated Richmond, and the day after its surrender, President Lincoln, being on a visit to the army, entered the former capital of the Confederacy.

On the evening of April 11, 1865, he delivered to the people who had gathered in front of the executive mansion his last public address, in which he discussed tersely but with wondersul dignity and power the burning questions of reconstruction, which were uppermost in the public mind.

On the evening of April 14, 1865, accompanied by Mrs. Lincoln and two friends, he attended a performance of "Our American Cousin," at Ford's theater, on Tenth street, Washington. In the midst of the play, John Wilkes Booth, an actor, the leader of a band of assassins, who had plotted to murder the President and the heads of the governmental departments, stealthily entered the box where Mr. Lincoln was sitting and discharged a pistol at the President's head. Then leaping from the box to the stage, with a knife dripping with the blood of Major Rathbone, whom he had stabbed, he shouted, "*Sic semper tyrannis*, the South is avenged." After escaping from the rear of the building, he fled and hid himself in a barn, where twelve days afterwards he was found by a squadron of troops and shot by Sergeant Corbett. On the 15th of April, 1865, the President died from his wound in the house to which he had been borne.

The character of Mr. Lincoln was that of great directness and extreme simplicity. Clothing to him was made for covering and warmth to the body, and not for ornament. A most intimate friend of his never knew him but once to borrow money or give his note. He never tasted liquor, never chewed tobacco or smoked, but labored diligently in his profession, charging small fees, and was contented with small accumulations. He was, however, very generous in expenditure for his family. In this manner he accumulated less than $10,000 before his election to the presidency, and when he left Springfield had to borrow; and then, so far as is known, gave his note for the first time, for enough to bear his expenses, and tide him over until he could draw from the government the first quarter of his salary. He, in his life, had lived in all circles, moved in every grade of society, and enjoyed it all equally well. To his companions present with him in every station, he was equally entertaining and equally happy.

He never recognized a duty in himself to appoint any man to office simply because he had been a political friend, and would remove no man simply because he had been his political enemy.

A heroic and often valuable characteristic of the man was his self-reliance. An intimate friend has stated that while Lincoln was at the bar of Illinois, he was never known to ask the advice of a friend about anything. During the four years of his administration no one heard of his doing this. He was never known in the preparation of a trial or the perplexity of it in court to turn to his associate and ask his advice. The nearest to his doing this was once in Bloomington in 1858, and about ten days before his joint debate with Douglas at Charleston. He sent for a half-dozen lawyers to meet him at Judge Davis' house, before he was to speak in Bloomington the same day, and when they were assembled he said: "Gentlemen, I am going to put to Douglas the following questions, and the object of the meeting is to have each of you assume you are Douglas and answer from his standpoint."

And yet he was the best listener one could ever have. He would hear any one on any subject, and generally would say nothing in reply. He kept his own counsels or his bottom thought to himself. He weighed thoroughly his own positions and the positions of his adversary. He put himself in his adversary's position or on the opposite side of the question, and argued the question from that standpoint. For instance, when a committee of Chicago clergy went to Washington to urge upon him to issue an emancipation proclamation, he said: "If you call a sheep's tail a leg, how many legs will the sheep have?" The general answer was "Five." "No," said he, "because calling the tail a leg will not make it a leg."

He was taking in that argument the opposite side of the question. A friend was in Washington the next week after these clergymen had held their interview. He met Mr. Lincoln early in the morning, and arising to go, the President said: "What have you got to do? How long have you been in the city?" and being told that he had come there the day before, Mr. Lincoln said, "Sit down, I want to consult you. If you had been here a week I would not give a cent for your opinion," and then the President himself occupied all the morning until 12 o'clock, when the cabinet came in, in talking about the emancipation proclamation, considering every objection to it, asking in the whole interview his friend's opinion of nothing, going over the whole question—simply making of him a friendly audience. And yet at the very time he was there, and at the time the Chicago clergy were there, the proclamation in its rough draft, as was since learned, was then written out and lying in his table drawer in the room where they were talking.

And this was indeed his general way of arriving at a conclusion; but with him, when a conclusion was reached, he was at rest.

Another very remarkable and useful trait of Mr. Lincoln's character was that mental equipoise which was disturbed at nothing, and was rarely diverted from the pathway it had marked out. Although prosecuting the war simply from a sense of duty and not from a belief in its success, yet he kept right on, and was neither depressed by disasters nor elated by success. He seemed to measure the magnitude of the contest in which he was engaged more thoroughly than any other man. The war, like all others, was prosecuted by alternate success and defeat. The first two years it was generally defeat; and yet Mr. Lincoln, in moments of disaster was not disheartened, but was cool, collected and determined. He was a monument of strength upon which even the great men of the nation, and members of his own cabinet could lean. In moments of victory, when everybody else was carried away by the joyousness of the occasion, Mr. Lincoln was as self-restrained and determined as before. In short, he was the strong man in the great contest, and the great men at Washington all learned to gain renewed courage from his calmness and to rely upon his own great arm for support.

The first two years of the war were years of doubt with Mr. Lincoln. He did not see any way to effect the conquest of a people so numerous, so brave, and who occupied more than half of the territorial extent of the whole country. It is not believed that during this time any man ever heard him say that he knew the country would be successful in the war. About the second year, after he had issued the emancipation proclamation and began to see that it worked according to his expectations, it is not believed that any man ever heard him express a doubt of success.

The religious views of Mr. Lincoln were simply a reflex of his own character. He believed in God, as the Supreme Ruler of the world, the guider of men, and the controller of the great events and destinies of mankind. He believed himself to be an instrument and leader of the forces of freedom. He knew the toils of the slave and of the poor whites in the South. Their sufferings and privations were his personal experiences, and he felt their burdens to be his own. He believed that the Declaration of Independence, "that all men are created equal," was not, as said by Rufus Choate, "a glittering generality," but was a standard political truth. Our Savior said in the closing sentences of his Sermon on the Mount: "Be ye perfect, as your Father in heaven is perfect;" not that He expected perfection in the persons to whom He addressed these words; not that He expected perfection of us in our day and generation, but He laid down a religious standard which no one can surpass, and to which all nations might aspire. Mr. Lincoln, thanking the negroes of Baltimore, who in 1864 presented him with a Bible, said: "This great book is the best gift God has given to man. All the good from the Savior of the world is communicated through this book." Mr. Lincoln married Mary Todd, of Kentucky, in 1842, by whom he had four children. One son only survives, namely, Robert Todd Lincoln, who was United States minister to England from 1889 to 1893.

Mr. Lincoln was about six feet four inches high, and was thin, wiry, sinewy and raw-boned. He was narrow across the shoulders and thin through the breast to the back. When standing he leaned forward, and thus became somewhat stoop-shouldered. He was a man of great physical strength, lifting, in his prime, with ease, four hundred, or even six hundred pounds. His head was long and tall from the base of the brain and the eyebrows. His head ran backward, but his forehead was high. He had luxuriant hair, which, in his last years, became tinged with gray. He had high, sharp and prominent cheek bones, a large, long and blunt nose, a long, sharp, and upturned chin, deep set gray eyes, dark eye-brows, and a neat and trim neck. Although homely in his countenance, he was yet prepossessing in his features. He was a man of the working classes, a child of the West, a true typical American, self-reliant, self-made, and honest to the core. He was a charming conversationalist, ever full of enlightening and inspiriting humor.

He was the liberator of the slave and the successful ruler of a mighty people. Dignified, magnanimous, patient, considerate, manly, true, "with malice toward none, with charity for all," his fame, in the language of the immortal Grant, "will ever grow brighter as time passes and his great work is better understood." (S. F.) (L. S.)

LINCOLN, Benjamin, an American general, born at Hingham, Mass., in 1733, died there in 1810. At the outbreak of the Revolution he was very active in organizing the Massachusetts troops. In 1776 he was appointed major general of the State militia. He commanded the expedition that in 1776 cleared Boston harbor of British vessels. Having reinforced Washington after the defeat on Long Island, and in 1777 brought a new levy of militia to Morristown, he was recommended by Washington for an appointment as major general in the Continental army. Lincoln served as such with Schuyler against Burgoyne during the next summer, and afterwards was wounded at Bemis Heights, while reconnoitering. In August, 1778, Lincoln was placed in command of the army in the South. He protected the city of Charleston from Gen. Prevost. In 1780 he was besieged at Charleston by Sir Henry Clinton. After a brave defense against a superior force he had to capitulate, and soon returned to Hingham on parole. But after being exchanged in 1781 he joined Washington again on the Hudson, was with him at the siege of Yorktown, and was deputed by Washington to receive the sword of Lord Cornwallis on his surrender of the British forces. From 1781 to 1784 Lincoln was Secretary of War. After quelling Shay's rebellion in Massachusetts in 1787 he was elected lieutenant governor, and in 1789 Washington appointed him collector of the port of Boston, which office he held till 1808, when he retired from public life.

LINCOLN, Levi, an American statesman, born at Hingham, Mass., in 1749, died at Worcester, Mass., in 1820. He studied law at Harvard College, and became judge of probate in 1776. He was a member of the State constitutional convention in 1780, of the State Legislature in 1796, and of the State Senate in 1797, and was elected to Congress in 1799. From 1801 to 1805 he was attorney general of the United States. In 1807–8 he was lieutenant governor of Massachusetts, and became acting governor in 1809. Lincoln was an original member of the American Academy of Sciences, and was long at the head of the Massachusetts bar.

LINCOLN, Levi, an American statesman, born at Worcester, in 1782, died there in 1868. After graduating at Harvard, he was admitted to the bar at Worcester in 1805. Between 1812 and 1822 he was elected several times to the Legislature, was Speaker of the House in 1822, lieutenant governor in 1823, and judge of the Supreme Court in 1824. In 1825 Lincoln was elected governor of Massachusetts, for which office he had been nominated by both political parties. He held this office till 1834. In 1835 he was elected to Congress and in 1841 he was made collector of the port of Boston. Upon the reorganization of his native town he was made its first mayor. Lincoln was a member of many historical and scientific societies.

LINCOLN, Robert Todd, son of Abraham Lincoln, was born at Springfield, Ill., August 1, 1843, and was educated at Phillips Exeter College and at Harvard. During the latter years of the Civil war he served as a captain on the staff of General Grant. After the war he practiced law in Chicago until 1881, when he became secretary of war in Garfield's cabinet. This office he retained until the close of President Arthur's administration, when he returned to his law practice in Chicago. In 1889 President Harrison appointed him minister to England. which position (1893) he still holds.

LINCRUSTA WALTON, embossed oil-cloth, a material similar to linoleum (see Vol. XIV, p. 676), and invented by the same man, Mr. Frederick Walton. This new material is described as a "compressed mass of cellulose, paper, cork, etc., thoroughly impregnated with oxidized linseed oil and resin." It has ground cork and oxidized linseed oil for its basis, the same as linoleum; but is distinguished from the latter by deeper, sharper and more lasting impressions, that means by higher and more lasting relief patterns used as tapestry, with decorations in imitations of ivory, gold, silver, bronze, etc., it is claimed that it can be furnished much cheaper than any other material used for embossed wall decoration. It produces the same general effect as carved work, and can be colored to any desired shade, so as to imitate costly woods, and to give any desired effect to the pattern.

Lincrusta Walton is known in the trade as "gervita," and has very beautiful and attractive patterns *in relievo*. It is applied to walls with glue and paste, similar to wall paper. The valuable properties claimed for it are: It may be roughly scrubbed without injury; it can even be struck with a hammer, as the elastic material will swell out again; it has no glaze to annoy the eye; yet it does not absorb moisture; it is so flexible that it can be carried around corners without injury; it can be removed from a wall and used again in other places. Lincrusta Walton has even been applied to exterior walls with very satisfactory effect. It was found to resist the weather well. But it is mainly used for interior decoration; and for this purpose it has no equal among the cheap materials.

LIND, Jenny, *Madame Goldschmidt*, a celebrated Swedish singer, was born of humble parentage at Stockholm, October 6, 1820. Her musical gifts were apparent from her third year, and at nine she was admitted to the school of singing attached to the court theater, where she received lessons of Berg and others. She sang before the court with success, and at eighteen appeared in the rôle of Agatha in *Der Freischütz*, Alice in *Robert le Diable*, etc., and soon became the principal support of the royal theater. In June, 1841, she went to Paris to receive lessons from Garcia. Meyerbeer, who heard her at this time, prophesied a brilliant future for Jenny Lind. Her voice was now thought wanting in volume, and when she appeared at the Grand Opera two years later her failure was so mortifying that she is said to have resolved never again to sing in France. In 1844 she went to Berlin, and for a time studied German; returning to Stockholm, she was heard with enthusiasm in *Robert le Diable*, and at the instance of Meyerbeer was engaged at Berlin in October, appearing in *Norma* and Meyerbeer's operas. In 1846 she visited Vienna, in 1847 London. Prices at Her Majesty's rose to a fabulous height, and 'the town,' says Chorley, 'sacred and profane, went mad about the Swedish Nightingale.' Her voice at this time has been described as a soprano of bright, thrilling and remarkable sympathetic quality, with wonderfully developed length of breath, and perfection of execution. She could sing up to high D in rich, full tones, and even touch higher notes; she literally warbled like a bird; and especially striking was her rendering of the weired Swedish melodies. Her return visit to London in 1848 was an immense triumph; and in London, on May 18, 1849, she sang on the stage for the last time in *Roberto;* henceforth her appearances were confined to the concert room. Her share of the profits of a brilliant concert tour in America under Barnum's management (1849–52), amounting to £35,000, was more than spent afterwards in founding and endowing musical scholarships and charities in her native country. In 1851 she was married at Boston to Otto Goldschmidt, a native of Hamburg, her pianist. Returning to Europe, she continued to sing at concerts and in oratorios, as in London (1856), and for the last time at Düsseldorf (1870). Her English charities included the gift of a hospital to Liverpool and of the wing of another to London. She founded the Mendelssohn scholarship, and her interest in the Bach Choir, of which her husband was conductor, was shown by her careful training of the female chorus. Her voice retained its sweetness to the last, although she did not care to sing much even in the semi-privacy of a crowded drawing-room. But from 1883 till 1886 she was professor of singing at the Royal College of Music. She died near Malvern, November 2, 1887. Her moral character was elevated and deeply religious; and 'her smile,' said Bishop Stanley of Norwich, 'is, with the exception of Dr. Pusey's, the most heavenly I ever beheld.'

LINDAU, a town in the government district of Swabia and Neuburg, Bavaria, and the central point of the transit trade between that country and Switzerland, is situated on two islands off the north-eastern shore of Lake Constance, in 47° 34′ N. lat., 9° 43′ E. long. The town is a terminus of the Vorarlberg Railway, and of the Munich-Lindau line of the Bavarian State Railway, and is connected with the mainland both by a wooden bridge and by a railway embankment of stone erected in 1853. There are Roman Catholic and Lutheran churches, a royal château, an old town-hall, classical, commercial, and industrial schools, and also manufactories for surgical and musical instruments, a fishery, and a fine harbour provided with a lighthouse and much visited by steamers from Constance and other places on the lake. Opposite the custom-house is a bronze statue of king Maximilian II., erected in 1856. The trade is chiefly in grain, fruit, wine, cherry-brandy, fish, cheese, and lard. In January 1882 the population was about 5350.

On the site which the town now occupies there is believed to have been formerly an ancient Roman camp, *Castrum Tiberii*. Authentic records of Lindau date back to the end of the 9th century. In 1531 it joined the Smalkald league, and in 1647 was ineffectually besieged by the Swedes. From 1275 to 1803 it was a free imperial town. In 1804 it passed to Austria, and in 1805 to Bavaria.

LINDLEY, JOHN (1799–1865), botanist, was born on February 5, 1799, at Catton near Norwich, where his father, George Lindley, author of *A Guide to the Orchard and Kitchen Garden*, owned a nursery garden. He was educated at Norwich grammar school, and early manifested a taste for the studies in which he afterwards gained distinction. His first publication, in 1819, a translation of the *Analyse du Fruit* of Richard, was followed in 1820 by an original *Monographia Rosarum*, with descriptions of new species, and drawings executed by himself, and in 1821 by *Monographia Digitalium*, and by "Observations on Pomaceæ" contributed to the *Transactions of the Linnean Society*. Shortly afterwards he went to London, where he was engaged by Loudon to write the descriptive portion of the *Encyclopædia of Plants*. In the course of his labours on this undertaking, which was completed in 1829, and of which the "botanical merits" are in the preface assigned by the editor to Lindley, he became thoroughly convinced of the superiority of the "natural" system of Jussieu, as distinguished from the "artificial" system of Linnæus followed in the *Encyclopædia*; the conviction found expression in *A Synopsis of British Flora, arranged according to the Natural Order* (1829), and in *An Introduction to the Natural System of Botany* (1830). In 1829 Lindley, who since 1822 had been assistant secretary to the Horticultural Society, was appointed to the chair of botany in University College, London; he lectured also on botany from 1831 at the Royal Institution, and from 1835 at the Botanic Gardens, Chelsea. During his professoriate of more than thirty years he wrote many scientific and popular works, besides contributing largely to the *Botanical Register*, of which he was editor for many years, and to the *Gardener's Chronicle*, in which he had charge of the horticultural department from 1841. He became a fellow of the Royal, Linnean, and Geological Societies, and had the honour of being admitted to a large number of foreign scientific bodies. He resigned his chair in 1860, and died of apoplexy at Turnham Green on November 1, 1865.

Besides those already mentioned, the works of Lindley include *An Outline of the First Principles of Horticulture* (1832), *An Outline of the Structure and Physiology of Plants* (1832), *A Natural System of Botany* (1836), *The Fossil Flora of Great Britain* (the joint work of Lindley and Hutton, 1831–37), *Flora Medica* (1838), *The Vegetable Kingdom* (1846), *Theory of Horticulture* (2d ed., 1855), *Folia Orchidacea* (1852), *Descriptive Botany* (1858), a *Ladies' Botany*, a *School Botany*, the volume *Botany* in the Library of Useful Knowledge, and most of the botanical articles in the *Penny Cyclopædia*. See BOTANY, vol. iv. p. 81.

LINDSEY, THEOPHILUS (1723–1808), an English theological writer, was born in Middlewich, Cheshire, on June 20, 1723, was educated at the Leeds Free School, and in 1741 entered St John's College, Cambridge, of which, after graduating with distinction, he became a fellow in 1747. For some time he held a curacy in Spitalfields, London, and from 1754 to 1756 he travelled on the Continent in the capacity of tutor to the young duke of Northumberland On his return he was presented to the living of Kirkby-Wiske in Yorkshire, and after exchanging it for that of Piddletown in Dorsetshire he in 1763 removed to Catterick in Yorkshire. Meanwhile he had begun to entertain anti-Trinitarian views, and to be troubled in conscience about their inconsistency with the creed he had repeatedly subscribed; since 1769 the intimate friendship of Priestley had served to foster his scruples, and in 1771 he united with Archdeacon Blackburne (his father-in-law), Jebb, Wyvell, and Law in preparing a petition to parliament with the prayer that clergymen of the church, and graduates of the universities, might be relieved from the burden of subscribing to the thirty-nine articles, and "restored to their undoubted rights as Protestants of interpreting Scripture for themselves." After two hundred and fifty signatures to the document had, with six months of vast effort on Lindsey's part, been obtained, it was, in February 1772, rejected in the House of Commons by a majority of two hundred and seventeen to seventy-one; the adverse vote was repeated in the following year, and in the end of 1773, seeing no prospect of obtaining within the church the relief which his conscience demanded, Lindsey resigned his vicarage and took leave of a warmly attached congregation. In April 1774 he began to conduct a Unitarian service in a room in Essex Street, Strand, London; four years later he removed to a chapel built for him in the same street. Here he continued to labour till 1793, when he resigned his charge in favour of Disney, who like himself had left the established church, and had become his colleague. His active interest in the Unitarian movement continued, however, until his death, which took place on November 3, 1808.

Lindsey's chief work is *An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times*, 1783; in it he claims, amongst others, Burnet, Tillotson, S. Clarke, Hoadly, and Sir I. Newton for the Unitarian view. His other publications, mostly occasional, include *Apology on Resigning the Vicarage of Catterick* (1774), and *Sequel to the Apology* (1776); *The Book of Common Prayer reformed according to the plan of the late Dr Samuel Clarke*, 1774; *Dissertations on the Preface to St John's Gospel and on praying to Jesus Christ*, 1779; *Vindiciæ Priestleianæ*, 1788; *Conversations upon Christian Idolatry*, 1792; and *Conversations on the Divine Government, showing that everything is from God, and for good to all*, 1802. Two volumes of *Sermons, with appropriate prayers annexed*, were published posthumously in 1810; and a volume of *Memoirs*, by Thomas Belsham, appeared in 1812.

LINEN MANUFACTURES. Under this term are comprehended all yarns spun and fabrics woven from flax fibre. The cultivation and preparation of the fibre, and its treatment till it reaches the market as a commercial product, are dealt with under FLAX, vol. ix. p. 293.

From the earliest periods of human history till almost the close of the 18th century the linen manufacture was one of the most extensive and widely disseminated of the domestic industries of European countries. The preparation and spinning of yarn gave occupation to women of all classes; and the operations of weaving employed large numbers of both sexes. The industry was most largely developed in Russia, Austria, Germany, Holland, Belgium, the northern provinces of France, and certain parts of England, in the north of Ireland, and throughout Scotland; and in these countries its importance was generally recognized by the enactment of special laws, having for their object the protection and extension of the trade. The inventions of Arkwright, Hargreaves, and Crompton in the later part of the 18th century, benefiting as they did, almost exclusively, the art of cotton spinning, and the unparalleled development of that branch of textile manufactures, largely due to the ingenuity of these inventors, gave the linen trade as it then existed a fatal blow. Domestic spinning, and with it hand-loom weaving, immediately began to shrink; a large and most respectable section of the operative classes in western Europe found their employment dwindling away, and the wages they earned from their diminished labour insufficient to ward off starvation. The trade which had supported whole villages and provinces entirely disappeared, and the linen manufacture, in attenuated dimensions and changed conditions, took refuge in special localities, where it resisted, not unsuccessfully, the further assaults of cotton, and, with varying fortunes, rearranged its relations in the community of textile industries. The linen industries of the United Kingdom were the first to suffer from the aggression of cotton; more slowly the influence of the rival textile travelled across Continental countries; and even to the present day, in Russia, and in other regions remote from great commercial highways, the domestic manufacture of linens holds its place almost as it has done from the earliest period. In 1810 Napoleon I., with a view partly to promote Continental linen industries, and partly to strike a blow at the great British manufacture of cotton, issued a proclamation offering a reward of one million francs to any inventor who should devise the best machinery for the spinning of flax yarn. Within a few weeks thereafter Philippe de Girard patented in France important inventions for flax spinning by both dry and wet methods. His inventions, however, did not receive the promised reward, and were indeed neglected in his native country. In 1815 he was invited by the Austrian Government to establish a spinning mill at Hirtenberg near Vienna, which was run with his machinery for a number of years, but ultimately it failed to prove a commercial success. In the meantime, however, English inventors, stimulated rather than daunted by the success of cotton machinery, had applied themselves to the task of adapting machines to the preparation and spinning of flax. The foundation of machine spinning of flax was laid by John Kendrew and Thomas Porthouse of Darlington, who, in 1787, secured a patent for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax, or wool." These machines, imperfect as they were, attracted much notice, and were introduced in various localities both in England and Scotland into mills fitted specially for flax spinning. By innumerable successive improvements and modifications, the invention of Kendrew and Porthouse developed into the perfect system of machinery with which, at the present day, spinning-mills are furnished; but progress in adapting flax fibres for mechanical spinning, and linen yarn for weaving cloth by power-loom, was much slower than in the corresponding case of cotton.

The implements used in the preparation of linen yarn in ancient and modern times, down to the end of the 18th century, were of the most primitive and inexpensive description. Till comparatively recent times, the sole spinning implements were the spindle and distaff. The spindle, which is the fundamental apparatus in all spinning machinery, was nothing more nor less than a round stick or rod of wood about 12 inches in length, tapering towards each extremity, and having at its upper end a notch or slit into which the yarn might be caught or fixed. In general, a ring or "whorl" of stone or clay was passed round the upper part of the spindle to give it momentum and steadiness when in rotation. The distaff, or rock, was a rather longer and stronger bar or stick, around one end of which, in a loose coil or ball, the fibrous material to be spun was wound. The other extremity of the distaff was carried under the left arm, or fixed in the girdle at the left side, so as to have the coil of flax in a convenient position for drawing out to yarn. A prepared end of yarn being fixed into the notch, the spinster, by a smart rolling motion of the spindle with the right hand against the right leg, threw it out from her, spinning in the air, while, with the left hand, she drew from the rock an additional supply of fibre which was formed into a uniform and equal strand with the right. The yarn being sufficiently twisted was released from the notch, wound around the lower part of the spindle, and again fixed in the notch at the point insufficiently twisted; and so the rotating, twisting, and drawing out operations went on till the spindle was full. So persistent is an ancient and primitive art of this description that to the present day, in remote districts of Scotland,—the country where machine spinning has attained its highest development,—spinning with rock and spindle is yet practised;[1] and, rude as these implements are, yarn of extraordinary delicacy, beauty, and tenacity has been spun by their agency. The first improvement on the primitive spindle was found in the construction of the hand-wheel, in which the spindle, mounted in a frame, was fixed horizontally, and rotated by a band passing round it and a large wheel, set in the same framework. Such a wheel became known in Europe about the middle of the 16th century, but it appears to have been in use for cotton spinning in the East from time immemorial. At a later date, which cannot be fixed, the treadle motion was attached to the spinning wheel, enabling the spinster to sit at work with both hands free; and the introduction of the two-handed or double-spindle wheel, with flyers or twisting arms on the spindles, completed the series of mechanical improvements effected on flax spinning till the end of the 18th century. The common use of the two-handed wheel throughout the rural districts of Ireland and Scotland is a matter still within the recollection of middle-aged people; but spinning wheels are now seldom seen.

The modern manufacture of linen divides itself into two branches, spinning and weaving, to which may be added the bleaching and various finishing processes, which, in the case of many linen textures, are laborious undertakings and important branches of industry.

Flax, when received into the mills, has to undergo a train of preparatory operations before it arrives at the stage of being twisted into yarn. The whole operations in yarn manufacture comprise (1) heckling, (2) preparing, and (3) spinning.

Heckling.—This first preparatory process consists not only in combing out, disentangling, and laying smooth and parallel the separate fibres, but also serves to split up and separate into their ultimate filaments the strands of fibre which, up to this point, have been agglutinated together. The heckling process was, until recent times, done by the hand; and it was one of fundamental importance, requiring the exercise of much dexterity and judgment. The

[1] See Dr Arthur Mitchell's *The Past in the Present*, Edinburgh, 1880

broken, ravelled, and short fibres, which separate out in the heckling process, form tow, an article of much inferior value to the spinner; and the proportion of tow made in the process of hand-heckling varies according to the skill and knowledge of the heckler. A good deal of hand-heckling is still practised, especially in Irish and Continental factories; and it has not been found practicable, in any case, to entirely dispense with a rough preparation of the fibre by hand labour. In heckling by hand, the heckler takes a handful or "strick" of rough flax, winds the top end around his hands, and then, spreading out the root end as broad and flat as possible, by a swinging motion dashes the fibre into the teeth or needles of the rougher or "ruffer" heckle. The rougher is a board plated with tin, and studded with spikes or teeth of steel about 7 inches in length, which taper to a fine sharp point. The heckler draws his strick several times through this tool, working gradually up from the roots to near his hand, till in his judgment the fibres at the root end are sufficiently combed out and smoothed. He then seizes the root end and similarly treats the top end of the strick. The stricks, as finished, are carefully piled up in a regular manner, keeping each handful separate for convenience of future treatment. The same process is again repeated on a similar tool, the teeth of which are 5 inches long, and much more closely studded together; and for the finer counts of yarn a third and a fourth heckle may be used, of still increasing fineness and closeness of teeth. In dealing with certain varieties of the fibre, for fine spinning especially, the flax is, after roughing, broken or cut into three lengths—the top, middle, and root ends. Of these the middle cut is most valuable, being uniform in length, strength, and quality. The root end is more woody and harsh, while the top, though fine in quality, is uneven and variable in strength. From some flax of extra length it is possible to take two short middle cuts; and, again, the fibre is occasionally only broken into two cuts according to the judgment and requirement of the manufacturer. Flax so prepared is known as "cut line" in contradistinction to "long line" flax, which is the fibre unbroken. The subsequent treatment of line, whether long or cut, does not present sufficient variation to require further reference to these distinctions.

In the case of heckling by machinery, the flax is first roughed and arranged in stricks, as above described under hand heckling. Considerable variations are presented in the construction of heckling machines, but the general principles of those now most commonly adopted, such as the machines of Combe, of Horner, or of Cotton, &c., are identical. These are known as vertical sheet heckling machines (fig. 1), their essential features being a set of endless leather bands or sheets *f*, *g* revolving over a pair of rollers *c*, *h* in a vertical direction. These sheets are crossed by iron bars, to which heckle stocks, furnished with teeth, are screwed. The heckle stocks on each separate sheet are of one size and gauge, but each successive sheet in the length of the machine is furnished with stocks of increasing fineness, so that the heckling tool at the end where the flax is entered is the coarsest, while that to which the fibre is last submitted has the smallest and most closely set teeth. Thus the whole of the endless vertical revolving sheet presents a continuous series of heckle teeth, and the machines are furnished with a double set of such sheets revolving face to face, so close together that the pins of one set of sheets intersect those on the opposite stocks. Overhead, and exactly centred between these revolving sheets, is the head or holder channel *a*, from which the flax hangs down while it is undergoing the heckling process on both sides. The flax is fastened in a holder *b*, consisting of two heavy flat plates of iron, between which it is spread and tightly screwed up. The holder is 11 inches in length, and the holder channel is fitted to contain a line of six, eight, or twelve such holders, according to the number of separate bands of heckling stocks in the machine. The head or holder channel has a falling and rising motion, by which it first presents the ends and gradually more and more of the length of the fibre to the heckle teeth, and, after dipping down the full length of the fibre exposed, it slowly rises and lifts the flax clear of the heckle stocks. By a reciprocal motion the whole of the holders are then moved forward one length; that at the last and finest set of stocks is thrown out, and place is made for filling in an additional holder at the beginning of the series. Thus with a six-tool heckle, or set of stocks, each holder full of flax from beginning to end descends

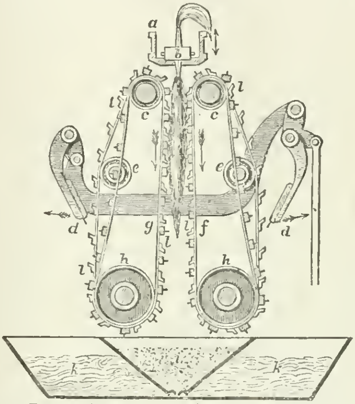

Fig. 1.—Section of Combe's Heckling Machine.

into and rises from the heckle teeth six times in travelling from end to end of the machine. The root ends being thus first heckled, the holders are shot back along an inclined plane, the iron plates unclamped, the flax reversed, and the top ends are then submitted to the same heckling operation. The tow made in the heckling process is cleared from the heckle teeth, as they revolve, by doffers *l*, *l*, which in travelling upwards are, by passing over special guide rollers *e*, *e*, projected out from the line of the heckle teeth. The doffers themselves are cleared by fixed combs *d*, *d*, and the tow falling down is collected in troughs *k*, *k* on each side of the machine. Tow, which is a much less valuable substance than dressed line, undergoes a somewhat different preparing process, and is used only for the lower numbers of yarn.

Preparing.—The various operations in this stage have for their object the proper assortment of dressed line into qualities fit for spinning the different counts or sizes of yarn for which it may be suitable, and the drawing out of the fibres to a perfectly level and uniform continuous ribbon or sliver, containing throughout an equal quantity of fibre in any given length. From the heckling the now smooth, glossy, and clean stricks are taken to the sorting room, where they are assorted into different qualities by the "line sorter," who judges by both eye and touch the quality and capabilities of the fibre. So sorted, the material is passed to the spreading and drawing frames, a series or system of machines all similar in construction and effect. The essential features of the spreading frame are—(1) the feeding cloth or creeping sheet, which delivers the flax to (2) a pair of "feed and jockey" rollers, which pass it on (3) to the gill frame or fallers. The gill frame consists of a series of narrow heckle bars, with short closely studded teeth, which travel between the feed rollers and the drawing or "boss and pressing" rollers to be immediately attended to. They are, by an endless screw arrangement, carried forward at the rate at which the flax is delivered to them, and when they reach the end of their course they fall under, and by a similar screw arrangement are brought back to the starting point; and thus they form an endless moving level toothed platform for carrying away the flax from the feed rollers. The drawing rollers grip the fibre as it leaves the gill, and, as they revolve much more rapidly than the feeding rollers, the fibre is drawn out through the gill teeth say to twenty or thirty times the length it had on the feeding board, and is consequently reduced to a sliver or loose ribbon of correspondingly greater tenuity. The sliver from the drawing frame is delivered into a tin can which holds 1000 yards, and the machine automatically rings a bell when that length is delivered. From the spreading frame the cans of sliver pass to the drawing frames, where from four to twelve slivers combined are passed through feed rollers over gills, and drawn out by drawing rollers to the thickness of one. A third and fourth similar doubling and drawing may be embraced in a preparing system, so that the number of doublings the flax undergoes, before it arrives at the roving frame, may amount to from one thousand to one hundred thousand, according to the quality of yarn in progress. Thus, for example, the doublings on one preparing system may be $6 \times 12 \times 12 \times 12 \times 8 = 82,944$. The slivers delivered by the last drawing frame are taken to the roving frame, where they are singly passed through feed rollers and over gills, and, after drawing to sufficient tenuity, slightly twisted by flyers and wound on bobbins, in which condition the material—termed "rove" or "rovings"—is ready for the spinning frame.

The preparation of tow for spinning differs in essential features from the processes above described. Tow from different sources, such as scutching tow, heckle tow, &c., differs considerably in quality and value, some being very impure, filled with woody shives, &c., while other kinds are comparatively open and clean. A preliminary opening and cleaning is necessary for the dirty much-matted tows, and in general thereafter they are passed through two carding engines called respectively the breaker and the finisher cards till the slivers from their processes are ready for the drawing and roving frames. In the case of fine clean tows, on the other hand, passing through a single carding engine may be sufficient. The processes which follow the carding do not differ materially from those followed in the preparation of rove from line flax.

Spinning.—The spinning operation, which follows the roving, is done in two principal ways, called respectively dry spinning and wet spinning, the first being used for the lower counts or heavier yarns, while the second is exclusively adopted in the preparation of fine yarns up to the highest counts manufactured. The spinning frame does not differ in principle from the throstle spinning machine used in the cotton manufacture (see COTTON, vol. vi. p. 495). The bobbins of flax rove are arranged in rows on each side of the frame (the spinning frames being all double) on pins in an inclined plane A (fig. 2). The rove passes downwards through an eyelet or guide l to a pair of nipping rollers p, p, between which and the final drawing rollers c, c, placed in the case of dry spinning from 18 to 22 inches lower down, the fibre receives its final draft while passing over and under cylinders d and guide-plate g, and attains that degree of tenuity which the finished yarn must possess. From the last rollers the now attenuated material, in passing to the flyers f, receives the degree of twist which compacts the fibres into the round hard cord which constitutes spun yarn; and from the flyers it is wound on the more slowly rotating spool s within the flyer arms, centred on the spindle S. In wet spinning the general sequence of operations is the same, but the rove, as unwound from its bobbin, first passes through a trough of water heated to about 120° Fahr.; and, moreover, the interval between the two pairs of rollers in which the drawing out of the rove is accomplished is very much shorter. The influence of the hot water on the flax fibre appears to be that it softens the gummy principle which binds the separate cells together, and thereby allows the elementary cells to a certain extent to be drawn out without breaking the continuity of the fibre; and further it makes a finer, smoother, and more uniform strand than can be obtained by dry spinning. The extent to which the original strick of flax as laid on the feeding roller for (say) the production of a 50 lea yarn is, by doublings and drawings, extended, when it reaches the spinning spindle, may be stated thus:—35 times on spreading frame, 15 times on first drawing frame, 15 times on second drawing frame, 14 times on third drawing frame, 15 times on roving frame, and 10 times on spinning frame, in all 16,537,500 times its original length, with $8 \times 12 \times 16 = 1536$ doublings on the three drawing frames. That is to say, 1 yard of heckled line fed into the spreading frame is spread out, mixed with other fibres, to a length of about 9400 miles of yarn. In the case of fine yarns, by the additional drawings given, the doublings and elongations are very much greater.

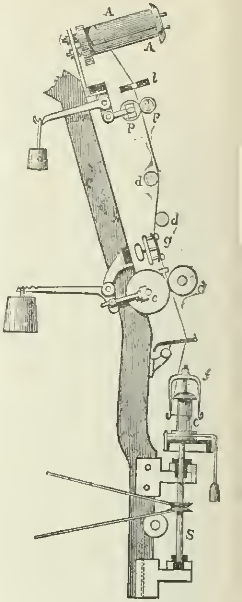

FIG. 2.—Section of Dry Spinning Frame.

The next operation is reeling from the bobbins into hanks. By Act of Parliament, throughout the United Kingdom the standard measure of flax yarn is the "lea," called also in Scotland the "cut" of 300 yards. The flax is wound or reeled on a reel having a circumference of 90 inches ($2\frac{1}{2}$ yards) making "a thread," and one hundred and twenty such threads form a lea. The grist or quality of all fine yarns is estimated by the number of leas in a pound; thus "50 lea" indicates that there are 50 leas or cuts of 300 yards each in a pound of the yarn so denominated. With the heavier yarns in Scotland the quality is indicated by their weight per "spindle" of 48 cuts or leas; thus "3 ℔ tow yarn" is such as weighs 3 ℔ per spindle, equivalent to "16 lea."

The hanks of yarn from wet spinning are either dried in a loft with artificial heat, or, in rural localities, exposed over ropes in the open air. When dry they are twisted back and forward to take the wiry feeling out of the yarn, and made up in bundles for the market as "grey yarn." English and Irish spinners make up their yarns into "bundles" of 20 hanks, each hank containing 10 leas; Scotch manufacturers, on the other hand, adhere to the spindle containing 4 hanks of 12 cuts or leas.

Commercial qualities of yarn range from about 6 ℔ tow yarns (8 lea) up to 160 lea line yarn. Very much finer yarn up even to 400 lea may be spun from the system of machines found in many factories; but these higher counts are only used fo. fine thread for sewing and for the making of lace. The highest counts of cut line flax are spun in Irish factories for the manufacture of fine cambrics and lawns which are characteristic features of the Ulster trade. Exceedingly high counts have sometimes been spun by hand, and for the preparation of the finest lace threads it is said the Belgian hand spinners must work in damp cellars, where the spinner is guided by the sense of touch alone, the filament being too fine to be seen by the eye. Such lace yarn is said to have been sold for as much as £240 per lb. In the Great Exhibition of 1851 yarn of 760 lea, equal to about 130 miles per lb, was shown which had been spun by an Irish woman eighty-four years of age. In the same exhibition there was shown by a Cambray manufacturing firm hand-spun yarn equal to 1200 warp and 1600 weft or to more than 208 and 278 miles per lb respectively

A large proportion of the linen yarn of commerce undergoes a more or less thorough bleaching before it is handed over to the weaver. Linen yarns in the green condition contain such a large proportion of gummy and resinous matter, removable by bleaching, that cloths which might present a firm close texture in their natural unbleached state would become thin and impoverished in a perfectly bleached condition. Manufacturers allow about 20 per cent. of loss in weight of yarn in bleaching from the green to the fully bleached stage; and the intermediate stages of "creamed," "half-creamed," "milled," and "improved," all indicating a certain degree of bleaching, have corresponding degrees of loss in weight. The differences in colour resulting from different degrees of bleaching are taken advantage of for producing patterns in certain classes of linen fabrics.

Linen thread is prepared from the various counts of fine bleached line yarn by winding the hanks on large spools, and twisting the various strands, two, three, four, or six cord as the case may be, on a doubling spindle similar in principle to the yarn spinning frame, excepting, of course, the drawing rollers. A large trade in linen thread has been created by its use in the machine manufacture of boots and shoes, saddlery, and other leather goods, and in heavy sewing-machine work generally. The thread industry is largely developed at Lisburn near Belfast, at Johnstone near Glasgow, and at Paterson, New Jersey, United States. Fine cords, net twine, and ropes are also twisted from flax.

Weaving.—The application of the power-loom to the weaving of linen was hindered by many obstacles which were not met with in dealing with the weaving of cotton and woollen fabrics. The principal difficulty arose through the hardness and inelasticity of the linen wefts, owing to which the yarn frequently broke under the sharp sudden jerk with which the picker throws the shuttle in power-loom weaving. The difficulties in the way of power-loom linen weaving, combined with the obstinate competition of distressed hand-loom weavers, delayed the introduction of factory weaving of linen fabrics for many years after the system was fully applied to other textiles. Competition with the hand-loom against the power-loom is conceivable, although it is absolutely impossible for the work of the spinning wheel to stand against the rivalry of drawing, roving, and spinning frames. To the present day, in Ireland especially, a great deal of fine weaving is done by hand-loom; and the persons who first applied machinery to the weaving of linen damasks in Scotland are yet (1882) alive. Power was applied on a small scale to the weaving of canvas in London about 1812; in 1821 power-looms were started for weaving linen at Kirkcaldy, Scotland; and in 1824 Maberly & Co. of Aberdeen had two hundred power-looms erected for linen manufacture. The power-loom has been in uninterrupted use in the Broadford factory, Aberdeen, which then belonged to Maberly & Co., down to the present day, and to that firm may be awarded the credit of being the effective introducers of power-loom weaving in the linen trade.

The various operations connected with linen weaving, such as winding, warping, dressing, beaming, and drawing-in, do not differ in essential features from the like processes in the case of cotton weaving, &c., neither is there any significant modification in the looms employed. Dressing is a matter of importance in the preparation of linen warps for beaming. It consists in treating the spread yarn with flour paste, applied to it by cylinders, the lowermost of which revolves in a trough of paste. The paste is equalized on the yarn by brushes, and dried by passing the web over steam-heated cans before it is finally wound on the beam for weaving. See WEAVING.

For the bleaching and calendering of such linen fabrics as undergo these processes see BLEACHING vol. iii. p. 821; CALENDER, vol. iv. p. 682.

Linen fabrics are numerous in variety and widely different in their qualities, appearance, and applications, ranging from heavy sailcloth and rough sacking to the most delicate cambrics and lawns. The heavier manufactures include as a principal item sailcloth, with canvas, tarpaulin, sacking, and carpeting. The principal seats of the manufacture of these linens are Dundee, Arbroath, and Forfar. The medium weight linens, which are used for a great variety of purposes, such as tent-making, towelling, covers, outer garments for men, linings, upholstery work, &c., include duck, huckaback, crash, tick, dowlas, osnaburg, low sheetings, and low brown linens. Plain bleached linens form a class by themselves, and include principally the materials for shirts and collars and for bed sheets. Under the head of twilled linens are included drills, diapers, and dimity for household use; and damasks for table linen, of which two kinds are distinguished—single or five-leaf damask, and double or eight-leaf damask, the pattern being formed by the intersection of warp and weft yarns at intervals of five and eight strands of yarn respectively. The fine linens are cambrics, lawns, and handkerchiefs; and lastly, printed and dyed linen fabrics may be assigned to a special though not important class. Numerous local, fancy, and temporary names are frequently attached to linen fabrics; but in the above list are only included such articles as occupy a standing position in the great markets. In a general way it may be said regarding the British industry that the heavy linen trade centres in Dundee; medium goods are made in most linen manufacturing districts; damasks are chiefly produced in Dunfermline and Perth; and the fine linen manufactures have their seat in Belfast and the north of Ireland. Leeds is the centre of the linen trade of England.

Linen fabrics have several advantages over cotton, resulting principally from the microscopic structure and length of the flax fibre. The cloth is much smoother and more lustrous than cotton cloth; and, presenting a less "woolly" surface, it does not soil so readily, nor absorb and retain moisture so freely, as the more spongy cotton; and it is at once a cool, clean, and healthful material for bed-sheeting and clothing. Bleached linen, starched and dressed, possesses that unequalled purity, gloss, and smoothness which make it alone the material suitable for shirt-fronts, collars, and wristbands; and the gossamer delicacy, yet strength, of the thread it may be spun into fits it for the fine lace-making to which it is devoted. Flax is a heavier material than cotton, but weight for weight it is much stronger, single yarn having proportionate strength in the ratio of 3 to 1·83, doubled yarn 3 to 2·26, and cloth 3 to 2·13. Of course cotton, on the other hand, has many advantages peculiarly its own.

Trade and Commerce.—The application of machine power to the entire range of linen manufactures has greatly improved the position and developed the resources of the industry, so that linen now occupies a well-defined and important position among the principal textiles. Had it not been for the sudden and unprecedented growth of the jute trade, no doubt the coarser and heavier branches of the trade would have attained much greater dimensions; and the development of the jute industry of Scotland fully accounts for the comparatively inelastic condition of the Scottish linen trade.

The following table indicates the extent of the linen industries in the United Kingdom at the various dates specified:—

	1856.	1861.	1870.	1880.
Number of factories	417	399	500	...
" spindles	1,288,000	1,217,000	1,553,000	1,367,000
" power-looms	8,689	14,792	35,301	41 990
Horse-power—Steam	14,387	31.727	52.017	
" Water	3,935	4,354	4,978	...
Persons employed—Ireland	28,753	33,525	55,039	...
" " Scotland	31,722	33,599	49,917	...
" " England	19,787	20,305	19,816	...
Total	80,262	87,429	124,772	...

It is only in Ireland that the linen industries during the above period have exhibited a healthy expansion. To that country alone the following figures apply:—

	1856.	1861.	1870.	1880.
Number of factories	113	217	312	...
„ spindles	568,000 (1859)	593,000	867,000 (1871)	911,000
„ power-looms	3,633	4,933	14,509	21,153

The number of flax spindles and power-looms in the European factories in 1881 is given in the *Annual Report of the Irish Flax Supply Association* as follows:—

	Spindles.	Power-Looms.		Spindles.	Power-Looms.
Ireland	879,835	21,177	Russia	160,000	3,000
Scotland	265,263	16,756	Italy	59,223	722
England	190,808	4,081	Switzerland	9,000	...
France	470,000	22,000	Holland	7,700	1,200
Austria-Hungary	380,440	500	Sweden	3,810	98
Germany	318,467	8,000	Spain	...	1,000
Belgium	295,140	4,755			

In all these returns no account is taken of the hand-looms in use, although in most of the Continental districts hand-loom weaving is more common than weaving by power.

The amount and declared value of the exports of linens, linen yarn, &c., from the United Kingdom at intervals extending over fifty years is thus stated from official sources:—

Year.	Linen Manufactures.		Thread, &c.	Yarns.	
	Yards.	Value in £	Value in £	lb	Value in £
1831	69,283,892	2,400,043	61,661	...	..
1841	90,321,761	3,194,827	111,261	17,733,575	822,876
1851	129,106,753	3,822,935	284,461	18,841,326	951,426
1861	116,322,469	3,571,131	269,778	27,981,042	1,622,216
1871	220,467,476	6,911,223	592,593	36,235,625	2,218,129
1881	173,853,300	5,163,669	680,260	18,285,500	1,057,172

The principal consumers of British linen manufactures are indicated in the following table, showing the exports for the year 1881:—

Country.	Piece Goods.		Yarns.	
	Yards.	Value in £	lb	Value in £
United States	82,050,900	2,344,910	...	...
Spanish West Indies	19,038,500	447,653	...	...
Australia	13,526,200	404,917	...	...
Germany	4,980,900	209,223	2,476,500	209,165
British North America	6,281,600	155,237	...	...
France	3,318,060	173,924	1,527,200	182,164
Holland	298,800	11,241	2,438,100	102,364
Belgium	...	...	1,629,500	125,619

(J. PA.)

LING (*Molva vulgaris*), a fish of the cod-fish family (*Gadidæ*), readily recognized by its long body, two dorsal fins (of which the anterior is much shorter than the posterior), single long anal fin, separate caudal fin, a barbel on the chin, and large teeth in the lower jaw and on the palate. Its usual length is from 3 to 4 feet, but larger individuals of 5 or 6 feet in length, and some seventy pounds in weight, have been taken. The ling is found in the North Atlantic, from Spitzbergen and Iceland southwards to the coast of Portugal. Its proper home is the German Ocean; especially on the coasts of Norway, Denmark, Great Britain, and Ireland it occurs in great abundance, generally at some distance from the land, in depths varying between 50 and 100 fathoms. During the winter months it approaches the shores, when great numbers are caught by means of long lines. On the American side of the ocean it is less common, although generally distributed along the south coast of Greenland, and on the banks of Newfoundland. This fish is one of the most valuable species of the cod-fish family; a certain number are consumed fresh, but by far the greater portion are prepared for exportation to various countries on the Continent (Germany, Spain, Italy). They are either salted and sold as "salt-fish," or split from head to tail and dried, forming, with similarly prepared cod and coal-fish, the article of which during Lent immense quantities are consumed in Germany and elsewhere under the name of "stock-fish." Also the oil is frequently extracted from the liver and used by the poorer classes of the coast population for the lamp or as medicine.

LING. See HEATH.

LINGARD, JOHN (1771–1851), the Roman Catholic historian of England, was born of humble parentage at Winchester on February 5, 1771. His intellectual abilities began to manifest themselves at a very early age, and in 1782 he was sent to the English college at Douay, where he continued until shortly after the declaration of war by England (1793). For some time after his return to England he lived as tutor in the family of Lord Stourton, but in October 1794 he settled along with seven other former members of the old Douay college at Crook Hall near Durham, where on the completion of his theological course he became vice-president of the reorganized seminary. In 1795 he was ordained priest, and soon afterwards undertook the charge of the chairs of natural and moral philosophy. In 1808 he accompanied the community of Crook Hall to the new and more commodious buildings at Ushaw, Durham, but in 1811, after declining the presidency of the college at Maynooth, he withdrew to the secluded mission at Hornby in Lancashire, where for the rest of his life he found the leisure which his literary pursuits demanded. In 1817 he visited Rome, where he made some researches in the Vatican Library, and also negotiated some business connected with the English college. In 1821 Pope Pius VII. created him doctor of divinity and of canon and civil law; and in 1825 Leo XII. is said to have made him cardinal *in petto*. He died at Hornby on July 17, 1851.

Lingard was the author of a considerable number of occasional and ephemeral writings of an avowedly controversial character. He also wrote *The Antiquities of the Anglo-Saxon Church* (1806), of which a third and greatly enlarged addition appeared in 1845 under the title *The History and Antiquities of the Anglo-Saxon Church; containing an account of its origin, government, doctrines, worship, revenues, and clerical and monastic institutions*; but the work with which his name is chiefly associated is *A History of England, from the first invasion by the Romans to the commencement of the reign of William III.*, which appeared originally in 8 vols. at intervals between 1819 and 1830. Three successive subsequent editions had the benefit of extensive revision by the author; a fifth edition in 10 vols. 8vo appeared in 1849, and a sixth, with life of the author by Tierney prefixed to vol. x., in 1854-55. Soon after its appearance it was translated into French, German, and Italian. It is a work of ability and research; and, though Cardinal Wiseman certainly claimed too much for its author when he called him "the only impartial historian of our country," yet the candid and dispassionate student will always find it profitable to learn from the pages of Lingard the aspects which the events of English history presented to the mind of an able and intense Roman Catholic in the earlier decades of the 19th century.

LINKÖPING, a city of Sweden, the see of a bishop, and the chief town of the province of East Gothland, is situated in a fertile plain 21 miles by rail south-west of Stockholm, and communicates with Lake Roxen ($\frac{1}{2}$ mile to the north) and the Gata and Kinda canals by means of the now navigable Stångå. Most of the houses are of wood. The cathedral (1150–1499), a Romanesque building with a Gothic choir, is, next to the cathedral of Upsala, the largest church in Sweden, and, since the cathedral of Trondhjem has lost so many of its treasures, presents the richest variety of objects of interest to the student of mediæval art in the country. In the church of St Lawrence, also called the Church of the Estates, are some paintings by Hörberg, the Swedish peasant artist. Other buildings of note are the massive old episcopal palace (1470–1500), afterwards a royal palace, and the old gymnasium founded by Gustavus Adolphus in 1627, which contains a valuable library (30,000 volumes) of old books and manuscripts, formerly kept in the cathedral. The population, 3285 in 1810, was 8706 in 1878.

Linköping early became a place of mark, and was already a bishop's see in 1082. It was at a council held in the town in 1153 that the payment of Peter's pence was agreed to at the instigation of Nicholas Breakspeare, afterwards Adrian IV. The coronation of Birger Jarlsson Waldemar took place in the cathedral in 1251; and in the reign of Gustavus Vasa several important diets were held in the town. A large portion of it was burned down in 1700.

LINLITHGOW, or West Lothian, a county of Scotland, stretching for 17 miles along the south coast of the Firth of Forth, and bounded E. and S.E. by Edinburghshire or Midlothian, S.W. by Lanarkshire, and W. by Stirlingshire. It lies between 55° 49′ and 56° 1′ N. lat., and 3° 18′ and 3° 51′ W. long. According to the ordnance survey the area is 127 square miles, or 81,114 acres, a considerable increase on previous estimates. The longest straight line that can be drawn within the county is one of about 22 miles from north-east to south-west, but the average length does not exceed 16 miles, and the average breadth is about 7. To the east and west the boundaries are in the main natural, following in the one case the Almond and the Breich Water (except in the neighbourhood of Mid Calder, where Edinburgh encroaches on Linlithgow), and in the other the Avon and Drumtassie Burn. To the south they are more conventional, the line of the watershed between the Clyde and the Forth being disregarded, and a good deal assigned to Lanarkshire which physically belongs to the Lothians. The whole county lies in the basin of the Forth, and there is a general slope upwards from the shore of the firth to the hilly district in the south-west. The surface is diversified by hill and dale, and, with the exception of the upland moors on the borders of Lanarkshire, there is no extensive tract of level ground. A kind of irregular valley stretches across the county from east to west, affording the most convenient route for road, canal, and railway. Between this valley and the firth runs a line of crags and hills often beginning to rise immediately behind the shore; the more prominent are Dalmeny, Dundas, the Binns, and Glowerow'rem or Bonnytounhill, the last a rounded eminence 559 feet above the sea, crowned by a conspicuous monument to General A. Hope, who fell in the Indian mutiny of 1858. To the south of the valley the ground rises pretty rapidly towards the west, more gradually towards the east. Between Bathgate and Linlithgow a general height is obtained of from 600 to 700 feet,—the principal eminences being Knock (1017 feet), Cairnpaple or Cairnnaple (upwards of 1000), the Torphichen Hills, Bowden (749), and Cockleroy (942). Farther east come the Riccarton Hills; and the range may be said to terminate with Binny Craig, a striking crag-and-tail similar to those of Stirling and Edinburgh. To the south-east stands the isolated Dechmont Law (686 feet).

There is no stream of any considerable size belonging exclusively to the county. The Almond rises in Lanarkshire, enters Linlithgowshire near Polkemmet, receives the White Burn and the Black Burn, and joining the Breich Water (also from Lanarkshire) passes Livingston, Mid Calder (Midlothian), and Kirkliston, and reaches the firth across the Drum Sands at Cramond. The Avon, which is already nearly as large as it ever becomes when it reaches the borders of the county below Muiravonside, passes Linlithgow bridge and Kinneil, and falls into the firth some distance below Inveravon. With the exception of Lochcot, the only lake in the county is Linlithgow Loch, a sheet of water covering 102 acres to the north of the town, well-known as a meeting place for curling and skating clubs. The eastern end is not more than 10 feet deep, but in the western portion there is one place about 50 feet deep. Eels are still caught in great numbers; and the perch and the worthless roach, locally called the braise, are abundant. See Lake, p. 220.

"The eastern portion of the county," says Mr H. M. Cadell, "consists of Lower Carboniferous Sandstones, thin estuarine limestones, and shales. The Carboniferous Limestone series, to which the strata in the western portion belong, is separated from the underlying Calciferous Sandstone series by the Carboniferous or Mountain Limestone, which dips westward and is well exposed along the outcrop in the disused lime-quarries of Hillhouse, Silvermine, and Bathgate. The overlying rocks consist of sandstones, shales, and coal-seams, which are worked at Bathgate and Bo'ness, above which come the three upper marine bands named respectively the Index, the Calmy or Janet Peat, and the Castlecary or Levenseat Limestone, the last of which is taken as the top of the Carboniferous Limestone series and the base of the Millstone Grit. The strata containing most of the workable coals at Bo'ness have a thickness of about 150 fathoms, measuring from the Index Limestone to the lowest seam. The extensive sheets of contemporaneous volcanic rocks (basalts, dolerites, and tuffs) form a remarkable feature in the geology of the county. The high ground between Linlithgow and Bathgate is formed of an almost uninterrupted pile of these rocks about 2000 feet in thickness. They thin out towards the north and south, and on the shore of the firth they occur regularly interbedded with the seams of the Bo'ness coal-field, which are usually in no degree injured by their presence. The tuffs or ash beds are well seen at Preston Burn, Carriden House, and St Magdalen's near Linlithgow, while Binns Hill near Blackness is the remnant of an old volcano of Lower Carboniferous age. Trap dykes rise through the strata and run in an east and west direction, one of which can be traced for 4 miles between Parkly Craigs and the Avon." A few mineral springs, sulphurous and chalybeate, are known to exist in the county, but none of them are now of medical repute. In 1875 a salt spring was discovered in the volcanic rocks to the west of the town of Linlithgow, boring having been prosecuted to the depth of 451 feet in search of drinking water. (See *Proc. Roy. Soc. Edin.*, 1875.) Coal-mining has been prosecuted in the county probably from the time of the Romans; and the earliest document extant in regard to coal-pits in Scotland is a charter granted about the end of the 12th century to William Oldbridge of Carriden. In 1871 it was estimated by the Government commissioners that the Linlithgow coal-fields still contained 127,621,800 tons of coal accessible at depths not exceeding 4000 feet. About 1440 miners were employed in the twenty coal-mines in 1881, and the output for the year was 504,338 tons. At the same date there were six iron-mines in operation, with 926 miners and an output of 180,194 tons. The Kinneil Company, which is the largest in this department, employs about 700 persons. Fire-clay is worked in connexion with the coal; at Kinneil 60,000 bricks can be turned out per week. Since their value was made apparent by Mr Young about 1850, the shales have been the object of an extensive industry at Broxburn, Uphall, Dalmeny, and Hopetoun. The six mines in 1881 employed 691 miners, and the output was 353,826 tons. Limestone, freestone, and whinstone are all quarried within the county, and the Binny freestone has been used for the Royal Institution, the National Gallery, and many of the principal buildings of both Edinburgh and Glasgow. As a manufacturing district Linlithgow does not stand high,—the chief establishments, apart from those mentioned in connexion with the town, being grist-mills, distilleries, chemical works, glass works, spade and shovel works, and a pottery.

The climate of the county hardly differs from that of the western portion of Midlothian. The annual rainfall, however, is somewhat greater, and is a fifth more than that of East Lothian: for the twenty-one years ending 1880 the mean at Linlithgow was 31·76 inches, while at East Linton (east of Haddington) it was 26·52.[1]

Linlithgow is classed as a mixed agricultural and pastoral county; the agricultural element, however, preponderates largely, though the area of permanent pasture has been increasing. It is calculated that of the total area of 81,114 acres about 20,000 acres consist of the best sorts of clay (carse, &c.), 22,700 of clay on a cold bottom, 9500 of loam, as much of light gravel and sand, 14,000 of moorland and high rocky ground, and 1500 of peat. Only a very small part of the arable land remains unreclaimed; the parish of Livingston, which in the beginning of last century was nearly covered with heath and juniper, is now all under rotation. Bathgate and Torphichen contain patches of peat moss and swamp. In Carriden and Dalmeny, and generally along the coast, the soil is light and early, though in some parts it varies so often that no single term is applicable to any considerable area. According to the agricultural returns for 1881, the corn crops occupied 17,347 acres, green crops 7264, clover and grass under rotation 12,980, permanent pasture (exclusive of heath or mountain land) 21,289. Oats are the most important of the cereals, 10,348 acres; and barley comes next with 4874 acres, an increase on the 3787 acres of 1856. Wheat has been steadily losing ground; while 1856 showed 4643 acres, 1881 gives only 1450. Beans, which used to occupy about 1000 acres, are now reduced to 655. An increasing area is devoted to clover and grasses for hay; but on the other hand the turnip area has been considerably reduced—5142 acres in 1856, 3861 in 1881. The extent of land under potatoes has slightly increased,—3052 acres for 1881, 2355 being the average for 1866–75. Cattle breeding is not much attended to, but a considerable number of animals are bought and fattened, and dairy farming is largely prosecuted, the fresh butter and churn milk being sent mainly to Edinburgh, but also to Newcastle, &c. Very little cheese is made. As a sheep-farming county Linlithgow stands very low—the returns giving 17,605 head in 1881, 23,070 in 1866. But few horses are bred, and the number of those in the county has remained wonderfully steady for the last fifteen years. Pigs have grown greatly fewer—3166 in 1866, and only 1442 in 1881.

The average extent of the farms is 108 acres, rather less than in Midlothian; of the total 542 more than 200 do not exceed 50 acres, and only 35 rise above 300. Very little of the land is rented at more than £3 per acre; an average of £2 to £2, 10s. for the best districts, of 30s. to 35s. for medium soils, and 15s. to 25s. for the worst land, will not be wide of the mark. "The leases of the arable lands are almost invariably for nineteen years, and grass lands are usually let annually by public auction, though in some instances they are taken for a period of three or five years."[2]

Though it is only in the neighbourhood of the principal mansions that large stretches of wood exist, the county as a tree-growing district rises considerably above the average for Scotland,—the woodland area being returned as 4899 acres in 1881, or one-sixteenth of the whole (Edinburgh shows one-twentieth). The finest woods are those of Hopetoun (where the beech avenues are especially noteworthy), Newliston, Kinneil, and Dalmeny. Much of the old timber has been recently cut down, but replanting has been vigorously prosecuted.

The valued rent of the county in 1649 was £75,027 Scots, or about £6252 sterling. In 1806 the real rent was £64,518 sterling, and in 1811, £88,745. Exclusive of railways, the valuation was £189,198 in 1876–77, and £216,011 in 1881–82. In the beginning of the century the county was practically in the hands of between thirty and forty landowners (Trotter). According to the Government return for 1872–73, the total number of owners was 1535, of which 287 possessed upwards of 1 acre. The proprietors holding estates above 2000 acres were as follows:—Earl of Hopetoun, 11,870 acres; Earl of Rosebery, 5680; Sir William Baillie of Polkemmet, 4820; Duke of Hamilton's Trustees, 3694; Lord Cardross, 2995; William Cowan of Linburn, 2231; Robert H. J. Stewart of Champfleurie, 2036; Dundas's Trustee, 2082.

Hopetoun House, the seat of the earl of Hopetoun, and the grandest mansion in the county, occupies a fine position between Queensferry and Blackness. Begun about 1696 by Sir William Bruce of Kinross, and completed long afterwards by Mr Adam, it practically occupies the site of the old castle of Abercorn, which was taken from the Douglas family by James II. in 1455. Dalmeny Park (earl of Rosebery) lies about 1½ mile west of Cramond; the neighbouring ruins of Barnbougle Castle, an ancient seat of the Mowbrays, have been incorporated with a modern building. Almondell House (earl of Buchan) is situated on the Almond, not far from Mid Calder. Kinneil, a now deserted residence of the dukes of Hamilton, associated with memories of Colonel Lilburn and Dugald Stewart, is a short distance to the south-west of Bo'ness. On a trap rock jutting out into the firth stands Blackness Castle, now used as a powder magazine, but once one of the "keys of the kingdom," with a busy little port under its protection. Niddry Castle (often called West or Seton Niddry), one of the resting places of Queen Mary, is now a mere ruin. Newliston (now owned by T. A. Hog) was for many years the residence of Lord Stair, who first introduced the field cultivation of cabbage, and is said to have laid out the woods according to the plan of the battle of Dettingen. Dundas Castle was the original seat of the Dundas family. Pardovan recalls the memory of Walter Steuart, author of the *Collections concerning the Worship, &c., of the Church of Scotland*, and Philipstoun that of John Dundas, another Scottish ecclesiastical lawyer. Kincavel was the birthplace and family mansion of Patrick Hamilton.

There are two royal burghs in the county—Linlithgow and Queensferry, and, besides the towns Bathgate, Borrowstounness or Bo'ness, Armadale, a number of thriving villages.

The Union Canal connecting the Forth and Clyde Canal with Edinburgh passes along the central valley, and crosses the Almond and Avon by bridges designed by Thomas Telford. The North British Railway has two lines between Edinburgh and Glasgow, which pass through the county *via* Linlithgow and Bathgate respectively. Queensferry and Bo'ness are both connected with the system by branch-lines, and Bathgate is a junction of some importance.

The population of West Lothian has increased from 17,844 in 1801 to 43,198 (22,436 males and 20,762 females) in 1881. The greatest increase (8601) took place in the decennial period 1851–1861, the least (606) in 1811–21. The females were in excess of the males in every census down to 1841; since then the preponderance has been on the other side. The total population was 23,291 in 1831, 26,872 in 1841, 30,044 in 1851, 38,645 in 1861, and 40,965 in 1871.

Traces of the prehistoric occupation of the county are fairly numerous. On Bowden Hill is an earthwork connected by Mr Glennie and others with the Arthurian contest. On Cairnpaple may be seen a circular building of unknown but early origin, and at Kipps is a cromlech once surrounded by circles of stones. Stone cists have been discovered at Carlowrie, Dalmeny, Newliston, &c. Near Inveravon is a vast accumulation of shells considered by several geologists to be a natural bed, but claimed by antiquaries as an artificial mound, either a kitchen midden or a heap for the manufacture of lime (see David Grieve, *Proc. Sc. Soc. of Ant.*, 1870–71). The Wall of Antoninus lies for a considerable distance within the county, and is believed to give origin to the names Carriden and Walton (see an account of a detailed exploration of the wall in *Builder*, 1877, pp. 1023–25). A fine legionary tablet was discovered at Bridgeness in 1868 (*Proc. Sc. Soc. of Ant.*, vol. viii.). Roman camps can be distinguished in several places.

At Torphichen[3] are the remains of a preceptory of the Knights of St John of Jerusalem, partly used as a parish church. The churches of Dalmeny, Abercorn, Kirkliston, Uphall, and South Queensferry are of early origin,—Romanesque and Norman Gothic.

LINLITHGOW, the county town of the above county, and a royal and parliamentary burgh, situated in the central valley, 18 miles by rail from Edinburgh, consists almost exclusively of a single street running east and west along both sides of the highway; gardens behind the houses stretch down to the lake or climb the lower slopes of the rising grounds, on which a considerable number of suburban residences have been erected. In the early part of the century the general aspect of the street was antique and picturesque, but the greater proportion of the frontage has been rebuilt or modernized. Apart from the palace and the contiguous church of St Michael, the only edifices of any note are an ancient towerlike building near the railway station, which tradition regards as a mansion of the Knights Templars, the town-house (1688), and the county courts (1865). "Linlithgow for wells" is a proverbial expression; and the cross well in the public

[1] For earlier notices of rainfall, &c., see Trotter's *Agriculture of West Lothian*.

[2] See Thomas Farrall, in *Trans. of Highland and Agric. Soc. of Scotland*, 1877.

[3] See *Abstract of the Charters . . . in the Chartulary of Torphichen* (ed. 1830).

square in front of the town-house is a striking piece of grotesque carved work in stone, originally erected, it is believed, in the reign of James V., but rebuilt in 1807. The burgh school goes back to the pre-Reformation times. Shoemaking and tanning are the leading industries; but a large distillery and (in the neighbourhood) two paper mills, glue works, and a soap factory add considerably to the business of the place. Linen bleaching is altogether a thing of the past. A grain market is held every Friday. The riding of the marches of the burgh is still performed annually by the magistrates and trades. The population of the burgh was 2282 in 1792–93, 3843 in 1861, 3690 in 1871, and 3913 in 1881.

Linlithgow Palace is by general consent the finest ruin of its kind in Scotland. Heavy but effective, the sombre walls rise above the green knolls of the promontory which divides the lake into two nearly equal portions. In plan it is almost square (168 by 174 feet), enclosing a court (91 by 88 feet), in the centre of which stands the ruined fountain used as a model for that erected in front of Holyrood Palace. At each corner there is a tower with an internal spiral staircase,—that of the north-west angle being crowned by a little octagonal turret known as "Queen Margaret's Bower," from the tradition that it was there that the consort of James IV. sat and watched for his return from Flodden. The oldest portion of the building is probably the west side, whose massive masonry, hardly broken by a single window, is supposed to date in part from the time of James III.; but the larger part of the south and east sides belong to James V., about 1535; and the north side was rebuilt in 1619–20. Of James V.'s portion, which is architecturally the richest, the main apartments are the Lyon chamber or parliament hall, and the chapel royal. The grand entrance approached by a drawbridge, was on the east side; above the gate way are still some weather-worn remains of rich allegorical designs, once resplendent with colour. A few yards to the south of the palace is the church of St Michael, a Gothic (Scottish Decorated) building (180 feet long internally excluding the apse and the steeple, by 62 in breadth excluding the transepts) probably founded in 1242, but mainly built in the 15th century. The central west front steeple was till 1821 topped by a crown like that of St Giles, Edinburgh.[1]

Linlithgow (wrongly identified with a Roman Lindum) was a royal burgh with a royal castle and an endowed church as far back as the reign of David I. Edward I., who had encamped there the night before the battle of Falkirk (1298), wintered at Linlithgow in 1301, and next year built "a pele (castle) mekill and strong," which in 1313 was captured by the Scots through the assistance of William Bunnock or Binning and his famous hay-cart. Later in the century (1369) the customs of Linlithgow yielded more than those of any other chief town except Edinburgh; and the burgh was taken along with Lanark to supply the place of Berwick and Roxburgh in the court of the Four Burghs (1368). Robert II. granted it a charter of immunities, the oldest still preserved, in 1384. The palace becoming a favourite residence of the kings of Scotland, and often forming part of the marriage settlement of their consorts (Mary of Guelders, 1449; Margaret of Denmark, 1468; Margaret of England, 1503), is frequently mentioned in Scotch history. James V. was born within its walls in 1512, and his daughter Mary, December 7, 1542. In 1570 the Regent Murray was assassinated in the High Street by Hamilton of Bothwellhaugh. In 1600 the title earl of Linlithgow was bestowed on Alexander, Lord Livingston, by James VI., who after his accession to the English throne retained an affection for the palace, and visited it again in 1617. The university of Edinburgh took refuge at Linlithgow from the plague in 1645–46; and in the same year the national parliament, which had often sat in the palace, was held there for the last time. The public burning of the Covenant (1661), the passing of Prince Charles through the town in 1745, and the burning of the palace by Hawley's dragoons in 1746 are the chief remaining facts in the local annals. Most of the privileges which Linlithgow enjoyed have dropped away. The rise of Bo'ness gave the last blow to the prosperity of its port at Blackness; its burgh lands have all been sold; and, after gaining its case three times in the Court of Session, it was deprived (1859) by the House of Lords of any claim to levy bridge toll and custom from the Edinburgh and Glasgow Railway.

LINNÆUS (1707–1778). Carl von Linné, better known under his earlier name of Carolus Linnæus, was born 13th May 1707 O.S., at Råshult, in the parish of Stenbrohult, in the province of Småland, Sweden.[2] His parents were Nils Linnæus, the comminister, afterwards pastor, of the parish, and Christina, the daughter of Brodersonius, the previous incumbent; Carl, the subject of our notice, being their eldest child. When only four years old he was much impressed with his father's conversation with some of his people concerning the properties and names of certain of the local plants of economic value; from that time he constantly asked his father about the quality and nature of every plant he met with, often asking more than his father could answer; at other times, having forgotten the information previously given him, he was threatened with a refusal to answer his queries unless he promised to remember what he was told. To this early discipline Linnæus afterwards ascribed his tenacious memory, which, added to his extreme sharpness of sight, laid the foundations of his eminence as a reforming naturalist.

His formal education began in 1714, when he was put under the private tuition of Telander, and three years later he entered the primary school at Wexiö. In 1719 he was committed to the care of Gabriel Hök, who afterwards married his pupil's sister Anna Maria; this preceptor had greater skill as a teacher than his predecessors, and was less severe; still he was unable to overcome the distaste the youth had acquired for ordinary scholastic studies. During his last years at school Linnæus took advantage of the greater liberty then allowed him to ramble in search of plants.

In 1724 he passed from the school to the gymnasium, carrying with him the same dislike for all those studies which were considered necessary for admission to holy orders, his father's intention being to bring up his son in his own profession. Botany, a science at that time entirely neglected, almost wholly engrossed his attention; he formed a small library of the few Swedish writers who had treated of plants, which he was constantly poring over, although unable to comprehend all he found in their volumes.

In 1726 his father came to Wexiö, hoping to hear a good report of the two years' study of his son; but, whilst there was no complaint as regards his moral deportment, his progress in the prescribed studies had been so unsatisfactory that his father was recommended to apprentice him to a tailor or shoemaker, in preference to giving him a learned education, for which he was evidently unfitted. The old clergyman, deeply grieved at this poor return for his struggles to keep his son at school during the previous twelve years, went to visit Dr Rothman, a medical practitioner and lecturer on physics in the town, to consult him regarding a bodily ailment from which he was suffering. In the course of conversation he mentioned his mortification at his son's dulness, when Rothman expressed his confident belief that he could end the troubles of both father and son, and that Carl, though extremely backward in theological studies, would yet distinguish himself in medicine and natural history. Rothman further offered to board and lodge Carl during the twelvemonth more which must be passed in the gymnasium. A short time after this, Rothman gave his pupil a course of private instruction in physiology with great success, the young man acquitting himself excellently on examination. His tutor also gave

[2] The new style being then in process of gradual adoption in Sweden, the year 1704 was regarded as a common year in that country, consequently the true date of Linnæus's birth, according to our present reckoning, was 23d May 1707, the commonly received date, 24th May, being an error due to supposing the calendar in Sweden and Russia at that time to be identical.

him hints as to the proper manner of studying plants, and directed his attention to Tournefort's system of arrangement, which was founded on the differences in the flowers.

He proceeded to the university of Lund in 1727, bearing a dubiously worded testimonium from Nils Krok, the rector of the gymnasium, to the effect that shrubs in a garden may disappoint the cares of the gardener, but if transplanted into different soil may prosper, therefore the bearer was sent to the university, where, perchance, he might find a more propitious climate. His former preceptor Hök kept back this doubtful recommendation, and presented Linnæus to the rector and dean as his own private pupil, thus procuring his matriculation.

Whilst studying here, Linnæus lodged at the house of Dr Kilian Stobæus, afterwards professor of medicine, and physician to the king, who possessed an excellent museum of minerals, shells, birds, and dried plants; the methods of preservation here adopted were as a revelation to the young student, and taught him how to prepare his own acquisitions. Stobæus suffered greatly from ill-health, he was also lame, and one-eyed; but he was an amiable and extremely able man, having a large practice among the wealthier classes in the province of Skåne. Linnæus was sometimes called upon to assist the physician by writing the prescriptions, but as he wrote a bad hand, he was frequently sent away again. In those days physicians wrote legibly.

A German student named Koulas also lodged with Stobæus, and amongst the indulgences he enjoyed was that of access to the library of his landlord; with his fellow-student Linnæus formed a close friendship, and in return for instruction in the physiology which Linnæus had learned of Dr Rothman, Koulas supplied him with volumes from the book-shelves of Stobæus, which were read by him stealthily at night. The mother of Stobæus, who was old and wakeful, noticed that there was constantly a light in Linnæus's room, and, being afraid of fire, desired her son to reprimand the young man for his carelessness. Two nights afterwards, Stobæus went into Linnæus's chamber at eleven o'clock, expecting to find him asleep, but was astonished to find him poring over books. He was forced to confess whence these were obtained, and was at once ordered to bed; but the next morning, being further questioned, he was granted full liberty to use the library, and perfect familiarity was accorded by the doctor, who, having no children, held out hopes of making the young student his hei.

Whilst botanizing in the spring of 1728, Linnæus was attacked by what he considered to be a venomous animal, afterwards named by him *Furia infernalis*, in allusion to the torment and danger he suffered from it; after his recovery, he passed the summer at his father's house in Smaland. Here he again met Rothman, who strongly advised him to quit Lund and to go to Upsala, where he would find greater facilities for the prosecution of his medical studies, and possibly obtain some scholarship to eke out his scanty means. Linnæus adopted his patron's advice, and started for Upsala with a sum of £8 sterling, that being all he was to expect from his parents. At this seat of learning his slender funds were soon exhausted; being young and unknown, he found no means of earning money by lecturing or teaching; he became dependent on chance generosity for a meal, and had to repair his shoes with folded paper. He could not well return to Lund, for Stobæus had taken offence at his departing without consulting him; and, besides, the journey required money which he did not possess.

In the autumn of this year, 1729, Linnæus was engaged intently examining some plants growing in the academical garden, when a venerable clergyman asked him what he was studying, whether he understood botany, whence he came, and how long he had been busied in the study. After being questioned at length, he was requested to follow his companion home; there he discovered him to be Dr Olaf Celsius, professor of theology, at that time working at his *Hierobotanicon*, which saw the light nearly twenty years later. When the professor saw Linnæus's collections he was still more impressed, and, finding him necessitous, he offered him board and lodging; he afterwards admitted him to close intimacy, and allowed him the free use of his rich library. The temporary adjunctus of the faculty of medicine being incompetent, Linnæus, by the recommendation of Celsius, was able to get some private pupils, and thereby to assume a more creditable appearance.

At this time there was only one medical student who distinguished himself by diligence in study, and that was Peter Arctedius, who afterwards styled himself Artedi. A close friendship sprang up between the two young men; they studied in concert, and vied with each other in their attainments, with perfect good temper, though of very diverse dispositions. Linnæus was sovereign in ornithology, entomology, and botany, Artedi reserving to himself the umbelliferous plants, fishes, and amphibia. A silence, almost total, prevailed in the university at this time on topics of natural history; during his whole curriculum Linnæus did not hear a single public lecture delivered on anatomy, botany, or chemistry.

During this period of intense receptivity, he came upon a critique which ultimately led to the establishment of his artificial system of plant classification. This was a review of Vaillant's *Sermo de Structura Florum*, Leyden, 1718,[1] a thin quarto in French and Latin; it set him upon examining the stamens and pistils of flowers, and, becoming convinced of the paramount importance of these organs, he formed the idea of basing a system of arrangement upon them. Another work by Wallin, Γάμος φύτων, *sive Nuptiæ Arborum Dissertatio*, Upsala, 1729, having fallen into his hands, he drew up a short treatise on the sexes of plants, and showed it to Dr Celsius, who put it into the hands of the younger Olaf Rudbeck, at that time professor of botany in the university. In the following year Rudbeck, whose advanced age compelled him to lecture by deputy, appointed Linnæus his adjunctus; in the spring of 1730, therefore, the latter began his lectures, and was accompanied by many pupils on his botanical excursions. The academic garden was entirely remodelled under his auspices, and furnished with many rare species, he being now in a position to direct the gardener, whereas in the year before he had actually solicited appointment to the vacant post of gardener, which was refused him on the ground of his capacity for better things.

His evenings were now devoted to the preparation of his epoch-making books, which were issued several years afterwards in the Netherlands. His position at the university having become unpleasant, he readily undertook to explore the little known country of Lapland, at the cost of the Academy of Sciences of Upsala. He started thence on May 12, 1732 o.s., carrying all his luggage on his back, journeying at first on horseback along the road skirting the coast to Umeå, thence by boat up the river to Lyksele within the Arctic Circle, penetrating to what he terms Olycksmyran (*i.e.*, the unlucky marsh) in spite of the melting of the ice, which made travelling in that part almost impossible. Unable to penetrate farther into the interior, he returned to Umeå, still skirting the sea-shore by Piteå to Luleå. From this latter place he made a long excursion to the north-west by Jockmock and Qvickjock;

[1] This work has a serious mistake on both title pages; it is corrected in the errata, but the correction seems to have escaped the notice of every bibliographer.

then, crossing the mountain range, he came out upon the coast of Finmark. He retraced his steps to Luleå, and at Calix he learned the art of assaying "in two days and a night," continuing his journey through Torneå, and the eastern coast of the gulf of Bothnia to Åbo; there he rested eight days, and finally reached Upsala by sea. The distance traversed in this tour was upwards of 4600 English statute miles; the cost of his journey is given at 112 silver dollars, or less than £25 sterling. His own account of the journey was published in English by Sir J. E. Smith, under the title *Lachesis Lapponica*, in 1811; the scientific results were published in his *Flora Lapponica*, Amsterdam, 1737. In 1733 Linnæus was engaged in teaching the method of assaying ores, and hoped to be allowed to lecture on botany; but a quarrel broke out between a rival, Rosen, and himself, the former having, by private influence, contrived to get a prohibition put on all private lectures on medicine in the university. Linnæus, enraged at finding his livelihood thus cut off, went so far as to draw his sword upon Rosen, but was prevented from harming his antagonist. At this juncture the governor of Dalecarlia invited Linnæus to travel through his province, as he had done through Lapland. Whilst on this journey he lectured at Fahlun to large audiences; Browallius, the chaplain there, afterwards bishop of Åbo, now strongly urged Linnæus to go abroad and take his degree of M.D. at a foreign university, by which means he could afterwards settle where he pleased. Linnæus, having become attached to the eldest daughter of Dr Moré or Moræus, left Sweden in 1735 to seek his fortune in the manner stated, and to return to claim her hand.

He travelled by Lübeck and Hamburg; detecting a seven-headed hydra to be a fabrication at the latter, he was obliged to quit the town in haste to avoid the wrath of its possessor. From Altona he went by sea to Amsterdam, staying there a week; he then proceeded to Harderwijk, where he went through the requisite examination, and defended his thesis on the cause of intermittent fever. His scanty funds were now nearly spent, but he passed on through Haarlem to Leyden; there he called on Gronovius, who, returning the visit, was shown the *Systema Naturæ* in MS., and was so greatly astonished at it that he sent it to press at his own expense. The first edition was in eight folio sheets; the subsequent editions were in 8vo; and the twelfth immensely enlarged edition appeared during the author's lifetime. This famous system, which, artificial as it was, substituted order for confusion, largely made its way on account of the lucid and admirable laws, and comments on them, which were issued almost at the same time. See BOTANY, vol. iv. p. 80. Boerhaave, whom Linnæus saw after waiting eight days for admission, recommended him to Burman at Amsterdam, where he stayed a twelvemonth, living at the house of the professor. While there he issued his *Fundamenta Botanica*, an unassuming small octavo, which has exercised immense influence. The wealthy banker Cliffort having invited Linnæus to visit his magnificent garden at Hartecamp, he remained there, living like a prince, but working most assiduously in the garden and library, both of which were kept up without regard to cost. His *Flora Lapponica* was now printed, containing a description of the genus *Linnæa*, by his friend Gronovius; he selected this plant to bear his name, from a similarity, as he thought, between it and himself. Whilst living with Cliffort, Linnæus met with his old fellow-student Artedi, who was quite destitute, having spent all his money in London; Linnæus introduced him to Seba, then working at fishes, Artedi's chief object of study; he worked hard at describing them, until only six remained undescribed, when he unfortunately fell into a canal at night, and was drowned. Linnæus persuaded Cliffort to redeem the manuscript, and he published it as a memorial of his deceased friend.

In 1736 Linnæus visited England. He was warmly recommended by Boerhaave to Sir Hans Sloane, but the old collector seems to have received him coldly. A better reception awaited him at Oxford, where Dr Shaw welcomed him cordially; Dillenius, the professor of botany there, was icy at first, but afterwards thawed completely, kept him a month, and even offered to share the emoluments of the chair with him. At Chelsea he saw Philip Miller, and took some plants thence to Cliffort; but certain other stories which are current about Linnæus's visit to England are of very doubtful authenticity.

On his return to the Netherlands he completed the printing of his *Genera Plantarum*, a volume which must be considered the starting point of modern systematic botany; Tournefort formed many genera, but Linnæus was the first to circumscribe them. During the same year, 1737, Linnæus finished arranging Cliffort's collection of plants, living and dried; these were described in the *Hortus Cliffortianus*, a folio illustrated with engravings by Ehret; this book was entirely written in nine months. During the compilation he used to "amuse" himself with drawing up the *Critica Botanica*, also printed in the Netherlands. But this strenuous and unremitting labour told upon him; the atmosphere of the Low Countries seemed to oppress him beyond endurance; he resisted all Cliffort's entreaties to remain with him, and started homewards.

Van Royen managed to detain him a year at Leyden, to help in rearranging the garden, thereby offending Cliffort, whom he had quitted on the plea of hastening back to Sweden. Linnæus now published his *Classes Plantarum*, and almost at the same time appeared Van Royen's *Hortus Leydensis* and Gronovius's *Flora Virginica*, both of these being drawn up on the Linnæan system. In 1738 Boerhaave pressed Linnæus to accept a post at Surinam; he declined this for himself, but passed it on to Johan Bartsch of Königsberg, a member with himself of a select club of naturalists at Leyden. Bartsch ultimately fell a victim to the climate of that colony.

While residing at Leyden Linnæus was warned that one of his acquaintance was endeavouring to supplant him in the affections of Sara Moré; he intended to set out at once, but was attacked by ague before he could start. Cliffort, hearing of this, took Linnæus to his own house again, and would not suffer him to depart until he was sufficiently well. His complete recovery, however, did not take place until he had gained the higher country of Brabant, where in one day he felt himself entirely renovated. He continued his journey to Paris, where he visited Antoine and Bernard de Jussieu, botanizing with the latter. Abandoning all notion of returning through Germany, he went to Rouen, sailed for Sweden, and landed at Helsingborg.

Linnæus established himself in September 1738 as physician in Stockholm, but, being unknown as a medical man, no one at first cared to consult him, a great change from the attention paid to him abroad; he himself declared "that, had he not been in love, he would certainly have left his native country." By degrees he found patients, was then appointed naval physician at Stockholm, with minor appointments, and was married on the 26th June 1739.

Early in 1740 Rudbeck died, and Roberg resigned; the chairs of botany and medicine at Upsala being thus vacant, Rosen and Linnæus were chosen respectively to fill them. The former rivals afterwards agreed to exchange professorships to their mutual benefit; in 1741, previous to this exchange, Linnæus travelled through Öland and Gothland, by command of the state, publishing his results in *Öländska och Gothländska Resa*, 1745. The index to this volume shows the first employment of trivial names in nomenclature.

Henceforward his life was a continuous course of prosperity, his time being taken up by teaching and the preparation of other works. In the year 1745 he issued his *Flora Suecica* and *Fauna Suecica*, the latter having occupied his attention during fifteen years; afterwards, two volumes of observations made during journeys in Sweden, *Wästgöta Resa*, Stockholm, 1747, and *Skånska Resa*, Stockholm, 1751. He examined the collections made many years before in Ceylon by Hermann, the full publication taking place in his *Flora Zeylanica*, Stockholm, 1747. In 1748 he brought out his *Hortus Upsaliensis*, showing that he had added eleven hundred species to those formerly in cultivation in that garden. In 1750 his *Philosophia Botanica* was given to the world; it consists of a commentary on the various axioms he had published in 1735 in his *Fundamenta Botanica*, and was dictated to his pupil Löfling, while the professor was confined to his bed by an attack of gout so violent as to threaten his life; he attributed his recovery to eating plentifully of wood-strawberries, a regimen he afterwards carefully observed. A much slighter attack in the following year was mainly cured by the pleasure caused by Kalm bringing home many new plants from Canada.

He catalogued the Queen's Museum at Drotningholm, and the King's at Ulrichsdal, but the most important work of this period of his life is unquestionably his *Species Plantarum*, Stockholm, 1753,—a second edition being issued in 1762. In this volume the trivial names are fully set forth; although they had been previously shadowed forth by Linnæus and others, yet to him belongs the merit of establishing the use of a single epithet in addition to the generic name. In the same year Linnæus was created knight of the Polar Star, the first time a scientific man had been raised to that honour in Sweden.

In 1755 he was invited by the king of Spain to settle in that country, with a liberal salary, and full liberty of conscience, but he declined on the ground that whatever merits he possessed should be devoted to his country's service; Löfling was sent instead, but died within two years. He was enabled now to purchase the estates of Söfja and Hammarby; at the latter he built his museum of stone, to guard against loss by fire. His lectures at the university drew men from all parts of the world; the normal number of students at Upsala was five hundred, whilst he occupied the chair of botany there it rose to fifteen hundred. In 1761 a patent of nobility was granted, antedated to 1757, from which time Linnæus was styled Carl von Linné; his arms were those now borne by the Linnean Society of London. To his great delight the tea plant was introduced alive into Europe in 1763; this year also his son Carl was allowed to assist his father in his professorial duties, and to be trained as his successor.[1] At the age of sixty Linné's memory began to fail; an apoplectic attack in 1774 greatly weakened him; two years after he lost the use of his right side; and he died 10th January 1778, of an ulceration of the bladder. He was buried in the cathedral of Upsala, with every token of universal regret.

In person Linnæus was described as of medium height, with large limbs, brown piercing eyes, and acute vision, and quick-tempered. He was accustomed to sleep five hours in summer and ten in winter. He lived simply, acted promptly, and noted down his observations at the moment. His handwriting was peculiar, and not very easy to read; copies of his own books were interleaved and copiously annotated, every new discovery being posted into its proper place at once, so that new editions were readily prepared when wanted.

With him arrangement seems to have been a passion; he delighted in devising classifications; not only did he systematise the three kingdoms of nature, but even drew up a treatise on the *Genera Morborum*. He found biology a chaos; he left it a cosmos. When he appeared upon the scene, new plants and animals were in course of daily discovery in increasing numbers, due to the increase of trading facilities; he devised schemes of arrangement by which these acquisitions might be sorted provisionally, until their natural affinities should have become clearer. He made many mistakes; but the honour due to him for having first enunciated the true principles for defining genera and species, and his uniform use of trivial names, will last so long as biology itself endures. His style is terse and laconic; he methodically treated of each organ in its proper turn; he had a special term for each, the meaning of which did not vary, so that the term did not suggest two ideas at once. The reader cannot doubt the author's intention; his sentences are business-like, and to the point. The omission of the verb in his descriptions was an innovation, and gave an abruptness to his language which was foreign to the writing of his time; but it probably by its succinctness added to the popularity of his works.

By his force of character he shifted the scientific centre of gravity during his life to a small town in Sweden; he was constantly receiving presents and praise from crowds of correspondents in every civilized country and in every station of life; hence it is not surprising that this universal homage should have bred the vanity which disfigures the latter part of his diary.

No modern naturalist has impressed his own character with greater force upon his pupils than did Linnæus. He imbued them with his own intense acquisitiveness, reared them in an atmosphere of enthusiasm, trained them to close and accurate observation, and then dispatched them to various parts of the globe. His students being drawn from many quarters, he had an extensive choice; some fell victims to fatigue and unkindly climates, but there was no lack of successors. With these young enthusiasts their master's lore was like a gospel; they were eager to extend the knowledge of it, and to contribute to its richness.

The published works of Linnæus amount to more than one hundred and eighty, including the *Amœnitates Academicæ*, for which he provided the material, revising them also for press; corrections in his handwriting may be seen in the Banksian and Linnean Society's libraries. His correspondence was wide and copious. Some of his letters have been published, but the bulk of them remains inedited. Many works remain in MS.; some have lately been published, such as the *Flora Dalecarlica*, and the *Svenska Arbeten*, both edited by Dr Ewald Ährling; those which were issued during the author's life are enumerated by Dr Pulteney in his *General View of the Writings of Linnæus*. (B. D. J.)

LINNELL, John (1792–1882), a richly gifted English painter, was born in London on the 16th of June 1792. His father being a carver and gilder, Linnell was early brought into contact with artists, and when he was ten years old he was already drawing and selling his portraits in chalk and pencil. His first artistic instruction was received from Benjamin West, and he spent a year in the house of John Varley the water-colour painter, where he had William Hunt and Mulready as fellow pupils, and made the acquaintance of Shelley, Godwin, and other men of mark and individuality. In 1805 he was admitted a student of the Royal Academy, where he obtained medals for drawing, modelling, and sculpture. He was also trained as an engraver, and executed a transcript of the Burial of Saul, one of Varley's most impressive pictures. In after life he frequently occupied himself with the burin, publishing, in 1834, a series of outlines from Michelangelo's frescos in the Sistine chapel, and, in 1840, superintending the issue of a selection of plates from the pictures in Buckingham Palace, one of them, a Titian landscape, being mezzotinted by himself. At first he supported himself mainly by miniature painting, and by the execution of

[1] Carl von Linné the younger, the elder son of the distinguished naturalist, was born at Fahlun, 20th January 1741. Delicate in constitution, he seemed to be oppressed with his father's reputation and his having to support it. He published two decades of new plants, and three dissertations, contributing also some descriptions to the first edition of Aiton's *Hortus Kewensis*, at the time of his visit to England. He died unmarried at Upsala, 1st November 1783; and, his only brother Johan having died in infancy, the succession became extinct in the male line. His mother sold the collections and books of father and son to Dr. J. E. Smith, the first president of the Linnean Society of London. When Smith died in 1828, a subscription was raised to purchase the herbarium and library for the Society, whose property they now remain. Smith sold the collection of minerals in 1796, and added many insects to the Linnean types, but the herbarium is practically in the same state as when the elder Linné himself last used it. The manuscripts of most of his publications, and the letters he received from his contemporaries, are likewise in the possession of the Society.

larger portraits, such as the likenesses of Mulready, Whately, Peel, and Carlyle. Several of his portraits he engraved with his own hand in line and mezzotint. He also painted many subjects like the St John Preaching, the Covenant of Abraham, and the Journey to Emmaus, in which, while the landscape background is usually prominently insisted upon, the figures are yet of sufficient size and importance to supply the title of the work. But it is mainly in connexion with his long series of paintings of pure landscape that his name is known to the public. When he was only seventeen, his Removing Timber carried off the fifty-guinea prize offered by the British Institution for the best landscape, and for many years Linnell was a regular contributor to the exhibitions of that body, and to those of the Royal Academy and the Society of Painters in Oil and Water Colours. His works commonly deal with some scene of typical uneventful English landscape, which is made impressive by a gorgeous effect of sunrise or sunset. They are full of true poetic feeling, and are rich and glowing in colour. His art proved exceptionally remunerative; he was able to command very large prices for his pictures, and about 1850 he purchased a property at Redhill, Surrey, where he resided till his death, on the 20th of January 1882, surrounded by his children—two of them artists like himself—and his children's children, and painting with unabated power till within the last few years of his life. His leisure was greatly occupied with a study of the Scriptures in the original, and he published several pamphlets and larger treatises of Biblical criticism. Among his literary productions are a work on *The Misnaming of the Scripture the Old and New Testament*, 1856; *The Lord's Day the Day of the Lord*, 1859; a pamphlet on *The Ascension Sacrifice of the Old Testament*, 1864; and one on *The Royal Academy a National Institution*, 1869. A word should be said regarding Linnell's connexion with William Blake. He was one of the best friends and kindest patrons of the great visionary artist. He gave him the two largest commissions he ever received for single series of designs—£150 for drawings and engravings of *The Inventions to the Book of Job*, and a like sum for those illustrative of Dante.

LINNET, Anglo-Saxon *Linete* and *Linet-wige*, whence seems to have been corrupted the old Scottish "Lintquhit," and the modern northern English "Lintwhite,"—originally a somewhat generalized bird's name, but latterly specialized for the *Fringilla cannabina* of Linnæus, the *Linota cannabina* of recent ornithologists. This is a common and well-known song-bird, frequenting almost the whole of Europe south of lat. 64°, and in Asia extending to Turkestan. In Africa it is known as a winter visitant to Egypt and Abyssinia, and is abundant at all seasons in Barbary, as well as in the Canaries and Madeira. Though the fondness of this species for the seeds of flax (*Linum*) and hemp (*Cannabis*) has given it its common name in so many European languages,[1] it feeds largely, if not chiefly, in Britain on the seeds of plants of the order *Compositæ*, especially those growing on heaths and commons. As these waste places have been gradually brought under the plough, and improved methods of cultivation have been applied to all arable land, in England and Scotland particularly, the haunts and means of subsistence of the Linnet have been slowly but surely curtailed, and hence of late years its numbers have undergone a very visible diminution throughout Great Britain, and its diminution has also been aided by the detestable practice of netting it in spring—for it is a popular cage-bird—so popular indeed as to require no special description. According to its sex, or the season of the year, it is known as the Red, Grey, or Brown Linnet, and by the earlier English writers on birds, as well as in many localities at the present time, these names have been held to distinguish at least two species; but there is now no question among ornithologists on this point, though the conditions under which the bright crimson-red colouring of the breast and crown of the cock's spring and summer plumage is donned and doffed may still be open to discussion. Its intensity seems due, however, in some degree at least, to the weathering of the brown fringes of the feathers which hide the more brilliant hue, and it is to be remarked that in the Atlantic islands examples are said to retain their gay tints all the year round, while throughout Europe there is scarcely a trace of them visible in autumn and winter; but, beginning to appear in spring, they reach their greatest brilliancy towards midsummer; and it is also to be remarked that they are never assumed by examples in confinement. The Linnet begins to breed in April, the nest being generally placed in a bush at no great distance from the ground. It is nearly always a neat structure composed of fine twigs, roots, or bents, and lined with wool or hair. The eggs, often six in number, are of a very pale blue marked with reddish or purplish brown. Two broods seem to be commonly brought off in the course of the season, and towards the end of summer the birds—the young of course greatly preponderating in number—collect in large flocks and move to the sea-coast, whence a large proportion depart for more southern latitudes. Of these emigrants some return the following spring, and are invariably recognizable by the more advanced state of their plumage, the effect presumably of having wintered in countries enjoying a brighter and hotter sun.

Nearly allied to the foregoing species is the Twite, so named from its ordinary call-note, or Mountain-Linnet, the *Linota flavirostris*, or *L. montium* of ornithologists, which can be at once distinguished by its yellow bill, longer tail, and reddish-tawny throat. This bird never assumes any crimson on the crown or breast, but the male has the rump at all times tinged more or less with that colour. In the breeding-season it seems to affect exclusively hilly and moorland districts from Herefordshire northward, in which it partly or wholly replaces the common Linnet, but is very much more local in its distribution, and, except in the British Islands and some parts of Scandinavia, it only appears as an irregular visitant in winter. At that season it may, however, be found in large flocks in the low-lying countries, and as regards England even on the sea-shore. In Asia it seems to be represented by a kindred form, *L. brevirostris*.

The Redpolls (*q.v.*) form a little group placed by many authorities in the genus *Linota*, to which they are unquestionably closely allied, but in this work they may be considered later; and, as before stated (Finch, vol. xi. p. 192), the Linnets seem on the other hand to be related to the birds of the genus *Leucosticte*, the species of which, in number uncertain, inhabit the northern parts of North-West America and of Asia. The most recent list of the birds of the former country by Mr Ridgway (*Bull. U. S. Nat. Museum*, No. 21, 1881) includes four species and one local race, of which there is need here to mention only *L. tephrocotis*. It is generally of a chocolate colour, tinged on some parts with pale crimson or pink, and has the crown of the head silvery-grey. Another species, *L. arctoa*, was formerly said to have occurred in North America, but its proper home is in the Kurile Islands or Kamchatka. This has no red in its plumage. The birds of the genus *Leucosticte* seem to be more terrestrial in their habit than those of *Linota*, perhaps from their having been chiefly observed where trees are scarce; but it is possible that the mutual relationship of the two groups is more apparent than real. Allied to *Leucosticte* is *Montifringilla*,

[1] *E.g.*, French, *Linotte*; German, *Hänfling*; Swedish, *Hämpling*.

to which belongs the Snow-Finch of the Alps, *M. nivalis*, so often mistaken by travellers for the Snow-Bunting, *Plectrophanes nivalis*. (A. N.)

LINOLEUM is a kind of floor-cloth, invented and introduced by Mr F. Walton, who in 1860 obtained a patent for its manufacture. It consists of a preparation of linseed oil and ground cork intimately mixed and spread in a uniform layer over a sheet of rough jute canvas. Under the name of kamptulicon, a material similar in appearance and properties, but in which prepared india-rubber took the place of oxidized linseed oil, was in use to a limited extent previous to the introduction of linoleum; the latter material, however, was found to possess several advantages; among others it had the merit of comparative cheapness as against kamptulicon, which it entirely supplanted. Linoleum also became a formidable competitor with the old form of oil floor-cloth, and on the expiry of Mr Walton's patent the manufacture of the new material was very generally taken up in Kirkcaldy, the principal seat of the floor-cloth trade. In the hands of Messrs Michael Nairn & Co., who were the first to introduce the floor-cloth industry into Scotland, the machinery used for making linoleum has been improved in important respects, and the ingenuity and resource of Mr Walton, the original patentee, have discovered several new adaptations and modifications of his original invention.

The making of linoleum involves three distinct preliminary operations—(1) the oxidation of the linseed oil, (2) the grinding of the cork, and (3) the weaving of the jute canvas backing. Of these operations the oxidation of the oil is the most peculiar and distinctive. The linseed oil is first boiled with litharge in the way practised for preparing ordinary boiled oil (see LINSEED), and it is next oxidized by exposure, in exceedingly thin films, to the influence of air. To secure the exposure of sufficient surfaces of oil to the atmosphere, a large lofty apartment is hung with sheets or continuous webs of calico cloth, which are allowed to depend from near the roof into troughs or tanks on the floor. These webs of calico are kept sufficiently far apart to allow free circulation of air between them. They are daily drenched with boiled oil by allowing it to trickle down from the top over their entire surface, the distribution being effected by a special arrangement of movable tanks and tubs. It will be seen that an enormous surface of oil can thus be exposed within a comparatively limited space. The influence of oxygen on the oil films is facilitated by the blowing of heated air into the chamber so as to keep up a continual circulation; and the activity of the process is unpleasantly manifested by the extremely acrid odour which is evolved by the oil. Day by day the thickness of the coating of oxidized oil increases, and when a deposit of about half an inch has been accumulated, the drenching is stopped. The product, now ready for being withdrawn, forms firm translucent sheets of a caoutchouc-like substance having a straw yellow colour, possessed of a certain amount of elasticity, and communicating no oily stain to paper. These sheets are now torn into small pieces and reduced to a uniform plastic mass by means of powerful crushing rollers, after which the material is placed in a close boiler with the addition of certain proportions of kawrie gum, rosin, and ochre, umber, or other pigment, according to the ground-colour desired. The boiler is heated by steam, and the entire mass, being thoroughly incorporated by means of stirrers, is run into a shallow trough, from which, after cooling and solidifying, it is taken in large slabs. These are piled up awaiting future use, and when required for manufacturing purposes they are cut into blocks about the size of an ordinary brick.

Ground cork, which is the second essential constituent of linoleum, may be made from cork cuttings and scraps; but, the supply of such material being unequal to the demand, bale cork, of secondary quality as imported, is very largely used. It is first broken to pieces about the size of a nut; the fragments are fed into the hopper of a mill; and the cork passes thence between a pair of ordinary millstones in which it is reduced to a meal-like condition, in exactly the same way as wheat is ground to flour. The product is sifted, and the insufficiently ground portions are returned to be passed again through the mill. In the grinding of the cork great care is necessary to prevent iron, stone, or other hard foreign material from getting into the mill, as such substances, causing sparks between the stones, readily give rise to explosions in air so laden with fine dust as that of the mill necessarily is.

In the making of the jute backing the only notable feature is the great width of the loom, in which webs 12 feet broad are woven by Messrs Nairn. The maximum width of that produced by other makers, however, has hitherto been 6 feet.

The actual preparation of linoleum floor-cloth in the factory of Messrs Nairn is conducted in a continuous series of operations by machinery which has been patented by that firm. The bricks of oxidised oil and the requisite proportion of cork are thrown into a hopper, where they are thoroughly mixed in a kind of pug mill, whence the mixture is shot forward in a tube, at the open end of which it is sliced off in thin crumbling masses by a revolving knife. Spread out in thin sheets, it passes from this between a series of steam-heated rollers, from the last of which it is scratched off by a circular drum covered with sharp steel points, and falls in a fine shower into a feeding box the whole width of the linoleum to be made. From this feeding box the mixture is uniformly delivered on the surface of the canvas, which here meets it, and passing immediately between powerful smooth rollers, the semi-plastic mixture is firmly squeezed on the surface of, and rendered adherent to, the rough open canvas which forms its back. The distance between the upper and lower compressing roller determines the thickness of the linoleum, three standard thicknesses being recognized, viz., $\frac{3}{32}$, $\frac{4}{32}$, and $\frac{5}{32}$ parts of an inch. Linoleum of the thickness of $\frac{1}{4}$ of an inch is also made for public libraries and reading-rooms on account of its perfect noiselessness. It only remains to coat or waterproof the raw canvas back with oil paint, and the floor-cloth is finished as plain linoleum. The printing of patterns in various colours on its surface is done as described under FLOOR-CLOTH, vol. ix. p. 329. Corticine is a form of linoleum, in which the oil is oxidized by chemical agents.

Recently a method of ornamenting linoleum with patterns in the form of tiles or tessaræ, the colour of each tile going right through to the canvas or sufficiently deep for constant wear, has been devised and patented by Mr C. F. Leake. The patentee prefers to use canvas first covered with a thin linoleum coating. This he brings on a table on which are a series of moulds corresponding with the coloured tile pattern required. Into each mould is put the required quantity of properly-coloured granulated linoleum material, which is compressed into solid tiles by the descent of plungers. The part covered by the pattern is carried forward and powerfully squeezed between hydraulic rams, the tiles being thus made smooth, homogeneous, and firmly adherent, while in the meantime the moulds are being filled and a new set of tiles prepared in the first stage of the operation. Mr Walton, the original patentee of linoleum, has adapted a preparation of oxidized oil and cork or other thickening material embossed with patterns for wall decorations under the name of "Lincrusta Walton." (J. PA.)

LINSEED is the seed of the common flax or lint, *Linum usitatissimum*, from which also the well-known fibre flax is obtained. The plant itself is figured and described under FLAX, vol. ix. p. 293. The fruit of the flax plant consists of a globose capsule which splits into five cocci, each containing two seeds. These seeds, the linseed of commerce, are of a lustrous brown colour externally, and a compressed and elongated oval form, with a slight beak or projection at one extremity. The brown testa contains, in the outer of the four coats into which it is microscopically distinguishable, an abundant secretion of mucilaginous matter; and it has within it a thin layer of albumen, enclosing a pair of large oily cotyledons. The seeds when placed in water for some time become coated with glutinous matter from the exudation of the mucilage in the external layer of the epidermis; and by boiling in sixteen parts of water they exude sufficient mucilage to form with the water a thick pasty decoction. The cotyledons contain the valuable linseed oil referred to below. Linseed grown in tropical countries is much larger and more plump than that obtained in temperate climes, but the seed from the colder countries, on the other hand, yields a finer quality of oil. Flückiger and Hanbury found that six seeds of Sicilian linseed, thirteen of Black Sea, and seventeen of Archangel linseed weighed respectively one grain. The average composition of linseed may be fairly represented by the following analysis by Dr Thomas Anderson:—albuminous substances, 24·44; oil, 34·00; gum sugar and cellulose, 30·73; ash, 3·33; water, 7·50. Linseed is cultivated and secured as a crop in all European flax-growing countries, where the seed is probably not less valuable than the fibre. It is also obtained from Egypt and India, being cultivated in the latter country solely on account of the seed.

Apart from its value as a source of oil, and for sowing, linseed is not a product of much economic importance. It formed an article of food among the Greeks and Romans, and it is said that the Abyssinians at the present day eat it roasted. The oil is to some extent used as food in Russia, and in parts of Poland and Hungary. Linseed meal, partly on account of its bland oily constitution, is a valuable material for poultices. At one time the crushed seeds were the officinally recognized cataplasmic material, but the readiness with which that preparation became rancid through the oxidation of its abundant oil frequently rendered it a dangerous application for open sores. The *lini farina* of the pharmacopœia is now the powdered meal of the cake left after expression of the oil, with a proportion of olive oil added when about to be used. An infusion of linseed under the name of "linseed tea" is a popular diluent in bronchial and other inflammatory affections. The abundant mucilage in linseed meal makes it a most useful material for luting stoppers in chemical jars, and other such joints in glass-work. Linseed cake, the marc left after the expression of the oil, is a most valuable feeding substance for cattle. According to a recent analysis by Dr Voelcker (*Journ. Roy. Agric. Soc.*, 2d ser., vol. xvii. p. 659) it contains in 100 parts—oil, 10·90; albuminous compounds, 24·56; mucilage, sugar, and digestible fibre, 31·97; woody fibre, 11·47; ash, 6·20; moisture, 14·90.

Linseed is subject to extensive and detrimental adulterations, resulting not only from careless harvesting and cleaning, whereby seeds of the flax dodder and other weeds and grasses are mixed with it, but also from the direct admixture of cheaper and inferior oil seeds, such as wild rape, mustard, sesame, poppy, &c., the latter adulterations being known in trade under the generic name of "buffum." In 1864, owing to the serious aspect of the prevalent adulteration, a union of traders was formed under the name of the "Linseed Association," the members of which bind themselves to give compensation for all adulterations in excess of 4 per cent. of foreign matter. Highly adulterated linseed is, however, still very common outside the field of operations of the Linseed Association.

The quantity of linseed imported into the United Kingdom during the year 1881 was 1,829,838 quarters, of a value of £4,395,061. About one-half of this amount, 937,059 quarters, valued at £2,299,877, came from the East Indies, and the imports from Russia, amounting to 728,358 quarters, valued at £1,694,720, account for the greater part of the remainder.

Linseed Oil, the most valuable and characteristic of the series of drying oils, is obtained by expression from the seeds, with or without the aid of heat. Preliminary to the operation of pressing, the seeds are crushed between a pair of revolving rollers, and ground to a fine meal under heavy edge stones on a stone bed. For the extraction of the fine quality of oil known as cold-drawn the meal is, without further preparation, filled into woollen or canvas bags and enclosed in horse-hair envelopes for pressure, either in a Dutch mill worked by means of wedges and falling stampers or in a screw press, or, what is now more prevalent, in a special form of hydraulic press. The oil so obtained is of a clear yellow colour, and is comparatively devoid of odour and taste. The cake left by cold pressure is again ground up, heated in a steam kettle to about 212° Fahr., and while hot submitted to further pressure, which results in the exudation of a less pure oil of a brownish-yellow colour. In general practice, cold-drawn oil is little prepared; the linseed after grinding is submitted to a high heat, whereby the mucilage in the epidermis is destroyed, and the oil flows more freely; and in many crushing establishments the oil is obtained by a single operation under the press. The yield of oil from different classes of seed varies, but from 23 to 28 per cent. of the weight of the seed operated on should be obtained. A good average quality of seed weighing about 392 ℔ per quarter has been found in practice to give out 109 ℔ of oil.

Commercial linseed oil has a peculiar rather disagreeable sharp taste and smell; its specific gravity is given as varying from 0·928 to 0·953, and it does not solidify under the influence of very low temperature. It is soluble in 32 parts of alcohol, sp. gr. 0·82, in 6 parts of boiling alcohol, and in 1·6 of ether. By saponification it yields about 95 per cent. of fatty acids, principally linoleic acid ($C_{16}H_{26}O_2$), a body peculiar to the drying oils, and by treatment with oxide of lead about nine-tenths of the resulting lead salt is found to be linoleate of lead. The oil may be perfectly bleached by treatment with a solution of green sulphate of iron, with repeated shaking and exposure to the light for a period of four to six weeks. Exposed to the air in thin films, linseed oil absorbs oxygen and forms a resinous semi-elastic caoutchouc-like mass, oxylinoleic acid, $C_{16}H_{26}O_5$. The oil, when boiled with small proportions of litharge and minium, undergoes the process of resinification in the air with greatly increased rapidity. Sacc found by boiling 2500 grains of raw oil for ten minutes with 30 grains each of litharge and minium, and weighing after twenty-four hours exposure to the atmosphere, that the oil had lost only 60 grains. A second sample he boiled till there was a loss of 5 per cent. in weight, when the product assumed the consistency of molasses; and a third portion boiled to a loss of 12 per cent. became a caoutchouc-like mass. The first of these products he found dried, on exposure, to a fine transparent varnish; the second did not resinify after fifteen days' exposure; and the atmosphere had no effect on the third portion. The weight of the film of the first after complete resinification was increased 50 per cent. through absorption of oxygen, and the rate at which absorption took place was much influenced by heat.

To these physical properties the varied industrial applications of linseed oil are principally due. Its most important use is certainly found in the preparation of oil paints and varnishes. By painters both raw and boiled oil are used, the latter not only forming the principal medium in oil painting, but also serving separately as the basis of all oil varnishes. Boiled oil is prepared in a variety of ways—that most common being by heating the raw oil in an iron or copper boiler, which, to allow for frothing, must only be about three-fourths filled. The boiler is heated by a furnace, and the oil is brought gradually to the point of ebullition, at which it is maintained for two hours, during which time moisture is driven off, and the scum and froth which accumulate on the surface are ladled out. Then by slow degrees a proportion of "dryers" is added—usually equal weights of litharge and minium being used to the extent of 3 per cent. of the charge of oil; and with these a small proportion of umber is generally thrown in. After the addition of the dryers the boiling is continued two or three hours the fire is then suddenly withdrawn, and the oil is left covered up in the boiler for ten hours or more. Before sending out, it is usually stored in settling tanks for a few weeks, during which time the uncombined dryers settle at the bottom as "foots." Besides the dryers already mentioned, acetate of lead, borate of manganese, binoxide of manganese, sulphate of zinc, and other bodies are used. The theory of the influence of boiling and of the addition of these bodies on linseed oil is not well understood. By Liebig it was suggested that they simply removed the mucilaginous and other foreign constituents of the oil which by their presence intercepted the action of oxygen; but by Chevreul and others the opinion was held that the chemicals used, by giving up oxygen to the oil, thereby induce a more rapid and energetic absorption from the air. However this may be, it does not appear at least that boiling is essential for the production of that active condition of the oil, as it may also be induced by treatment of cold raw oil with lead acetate and other agencies. Boiled oil is now very largely used in the manufacture of linoleum floor-cloth. See LINOLEUM.

Linseed oil is also the principal ingredient in printing and lithographic inks. The oil for ink-making is prepared by heating it in an iron pot up to the point where it either takes fire spontaneously or can be ignited with any flaming substance. After the oil has been allowed to burn for some time according to the consistence of the varnish desired, the pot is covered over, and the product when cooled forms a viscid tenacious substance which in its most concentrated form may be drawn into threads. By boiling this varnish with dilute nitric acid vapours of acrolein are given off, and the substance gradually becomes a solid non-adhesive mass the same as the ultimate oxidation product of both raw and boiled oil.

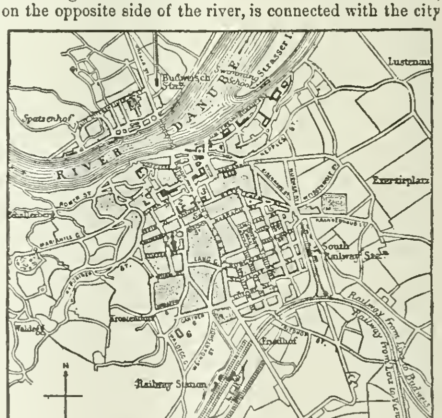
Linseed oil is subject to various falsifications, chiefly through the addition of cotton-seed, niger-seed, and hemp-seed oils; and rosin oil and mineral oils also are not infrequently added. Except by smell, by change of specific gravity, and by deterioration of drying properties, these adulterations are difficult to detect. (J. PA.)

LINUS is one of a numerous class of heroic figures in Greek legend, of which other examples may be found under HYACINTHUS, ADONIS. The connected legend is always of the same character: a beautiful youth, fond of hunting and rural life, the favourite of some god or goddess, suddenly perishes by a terrible death in spite of the heavenly love that would fain protect him. In some cases nothing is known to us with certainty beyond the mythological figure, but in many cases the religious background from which the legend stands out in relief has been preserved to us; in such cases we see that an annual ceremonial, everywhere of the same enthusiastic character, commemorated the legend. At Argos this religious character of the Linus myth was best preserved: the secret child of Psamathe by the god Apollo, Linus is exposed, nursed by sheep, and torn in pieces by the sheep-dogs. Every year in the festival Arnis or Cynophontis, the women of Argos mourned for Linus and propitiated Apollo, who in revenge for his child's death had sent a plague on the Argive children. The grave of Linus, like that of Hyacinthus at Amyclæ, was shown at Argos, at Thebes, at Chalcis, and probably at other places. The enthusiasm and *abandon* which characterized the similar festivals over Greece, Asia Minor, and Syria prove that it was part of the nature worship which spread in various forms by different roads and at different periods from the East into Greece. The songs of lamentation which accompanied the festival strongly impressed the Greeks, and it is most probable that the Phœnician words *ai lenu, ai lenu*, which formed the burden of the Adonis songs, originated the Greek words Linus and Αἴλινος. The Linus song is frequently mentioned in Greek literature, Homer, *Il.*, xviii. 569; Pind., *Fr.* 139 (Bergk), &c.; the tragic poets often use the word Αἴλινος as the refrain in mournful songs, and Euripides calls the custom Phrygian (*Or.* 1380). In Phrygia the mythic correspondent of Linus is called Lityerses. There can be no doubt that Linus, Adonis, Manerus, Narcissus, &c., are personifications of the life and bloom of nature suddenly slain by the hot sun of summer, while with the religious mourning over the catastrophe of nature were intertwined the ideas of life in relation to death, of good and evil, and so on. The religious side of the Linus myth seems hardly to have existed in Greece outside of Argos; in Thebes, which also was a chief home of the legend, Linus was a hero of song and music. In this form he has passed into literature, *e.g.*, Virgil, *Ecl.*, vi. 67. He is conceived as the inventor of musical methods, especially of the Θρῆνος, a kind of lament; this idea was expanded in various ways, particularly by the Alexandrine poets, and finally he was, after the analogy of Musæus, transformed into a composer of prophecies and legends.

See Brugsch, *Die Adonis Klage und das Linos Lied*, &c.

LINUS, one of the saints of the Gregorian canon, was, according to the *Breviarium Romanum*, the immediate successor of Peter in the see of Rome. He was a native of Volterra, who had attained a high degree of sanctity, and by his prevailing faith was able, not only to cast out devils, but to raise the dead. He wrote an account of the *res gestæ* of Peter, especially of his controversy with Simon Magus. He was beheaded by the orders of the ungrateful consul Saturninus, whose daughter he had freed from demoniac possession, after a pontificate of eleven years two months and twenty-three days. The authorities for the statement that Linus was, leaving Peter out of account, the earliest president of the Roman Church, are very early (Irenæus, *Adv. Hær.*, iii. 3, 3, Euseb., *H. E.*, iii. 2, 13); and that there actually was a presbyter of that name may be gathered from 2 Tim. iv. 21. According to Tertullian, however (*De Præscr.*, 32), Peter appointed Clement to be his successor. The genuineness of the alleged epitaph of Linus found in Rome is now no longer maintained; and the two books on the martyrdom of Peter and Paul, which pass under his name, must also be regarded as apocryphal and late.

LINZ, capital of Upper Austria, and see of a bishop, in 48° 19' N. lat., 14° 16' E. long., lies upon the right bank of the Danube, 98 miles west of Vienna, at the junction of the Kaiserin-Elizabeth Western Railway with a line from Prague and Budweis. The market-town of Urfahr, on the opposite side of the river, is connected with the city



Plan of Linz.

3. Post Office.
4. Telegraph Office.
5. Public Library.
6. Military Hospital.
7. Theatre.

by an iron bridge 700 feet in length, constructed in 1872. Linz possesses two cathedrals, one dating from 1670, and another, dedicated to the Immaculate Conception, commenced in 1862, and still unfinished, a Lutheran (1845) and several Roman Catholic churches, the new synagogue opened in 1877, and many religious houses. The old

Landeshaus, or House of the Estates (1562), the Bibliotheca Publica (1788), now (1882) containing 34,000 volumes, the Museum Francisco-Carolinum (1834), and a state theatre (1803) may also be noticed, with the episcopal and archducal palaces, and the castle now used as barracks. There are many educational establishments, including the theological diocesan lyceum, a new gymnasium and normal schools, and several hospitals and asylums. The principal manufactories are of tobacco (in 1880 employing 787 hands, and producing 25,286,050 cigars and 1850 tons of tobacco), and boot-varnish and blacking (2500 cwts.), the last chiefly exported to Hungary and Italy. Two breweries in 1881 produced 1,781,828 gallons of beer, and the other industries include iron-boat-building, and the manufacture of locomotives and agricultural implements. Trade and commerce are facilitated by the river. About forty-six thousand passengers embark or disembark at the steamboat landing stage, and the imports and exports there amount together to about 500,000 cwts. annually. There is a considerable traffic in woollen goods, carpets, linen fabrics, thread, prepared leather, iron wares, and salt. Cattle and meat markets are held twice a week. The Volksfest, a popular fair held generally every second September, is much resorted to by strangers. The surrounding country is highly picturesque. On the 31st December 1880 the population (exclusive of the garrison, 2799) was 36,116, or with the suburbs of Waldegg (1204) and Lustenau (1568) 38,888, chiefly Roman Catholics.

Linz is believed to stand on the site of the Roman station *Lentium* or *Lentia*. The authentic history of Linz cannot be traced farther back than 799. In 1140 it was purchased from Gottschalk, count of Kyrnberg, by Leopold IV., margrave of Austria; in 1324 it first received municipal rights, and in 1490 became the capital of the province above the Enns. Of various attacks which Linz from time to time successfully resisted the most notable was that by the insurgent peasants under Stephen Fadinger, 21st and 22d July 1626, when the suburbs were laid in ashes. At Linz (16th December 1645) peace was concluded between the emperor Ferdinand III. and the Transylvanian prince Rákóczy (see HUNGARY, vol. xii. p. 370). During the siege of Vienna in 1683 the castle at Linz was the residence of Leopold I. The triple deliverance of Linz from war, fire, and pestilence was commemorated by Charles VI., in 1723, by the erection of a marble monument known as Trinity Column. In 1741, during the war of the Austrian succession, Linz was taken by the troops of the elector of Bavaria, but on the 23d January 1742 it was recovered by the Austrians. The bishopric was established by Pope Pius VI. in 1784. On the 15th of August 1800 many of the principal buildings were destroyed by fire. On the 17th May 1809 an Austrian force was defeated near the city in an engagement with Saxon and Wurtemberg troops. The chain of outlying forts, thirty-two in number, now abandoned, and to a great extent demolished, was constructed between 1828 and 1836 under the direction of Archduke Maximilian d'Este. A general assembly of the Catholic Union for Germany was held here 24th to 26th September 1850. Tramways were introduced in 1880, and a new line of railway through the Kremsthal was completed as far as Kremsmünster in 1881.

See the anonymous *Führer auf der Kremsthalbahn, mit Beschreibung von Linz*, Linz, 1881; the *Statisticher Bericht Oberösterreichs* 1876–1880, Linz, 1881, vol. ii. pp. 243–283; the official *Ergebnisse uber die Volkszählung in Linz*, Linz, 1881; F. Krackowizer, *Die Landeshauptstadt Linz*, Linz, 1875; and G. H. Heinse, *Linz und seine Umgebungen*, 2d ed., Linz, 1838.

LION. From the earliest historic times few animals have been better known to man than the lion. Its geographical habitat made it familiar to all the races among whom human civilization took its origin, and its strongly marked physical and moral characteristics have rendered it proverbial, perhaps to an exaggerated degree, and have in all ages afforded favourite types for poetry, art, and heraldry.

The literature of the ancient Hebrews abounds in allusions to the lion; and the almost incredible numbers that are stated to have been provided for exhibition and destruction in the Roman amphitheatres (as many as six hundred on a single occasion by Pompey, for example) show how abundant these animals must have been within accessible distance of the capital of the world.

The geographical range of the lion was once far more extensive than at present, even within the historic period covering the whole of Africa, the south of Asia, including Syria, Arabia, Asia Minor, Persia, and the greater part of northern and central Hindustan, and also the south-eastern portion of Europe, as shown by the well-known story told by Herodotus of the attacks by lions on the camels which carried the baggage of the army of Xerxes on its march through the country of the Pæonians in Macedonia. The very circumstantial account of Herodotus shows that the animal at that time ranged through the country south of the Balkans, through Roumania to the west of the river Carasu, and through Thessaly as far south as the Gulf of Lepanto and the Isthmus of Corinth, having as its western boundary the river Potamo and the Pindus mountains. The whole of the evidence relating to the existence of lions in Europe, and to their retreat from that continent shortly before the commencement of the Christian era, has been collected in the article on "Felis spelæa" in Boyd Dawkins and Sanford's *British Pleistocene Mammalia*, 1868. Fossil remains attest a still wider range, as it is shown in the same work that there is absolutely no osteological or dental character by which the well-known cave lion (*Felis spelæa* of Goldfuss), so abundantly found in cave deposits of the Pleistocene age, can be distinguished from the existing *Felis leo*. There are also remains found in North America of an animal named *Felis atrox* by Leidy, which the palæontologists just quoted attribute to the common lion; but, as they are very fragmentary, and as the specific characters by which most of the *Felidæ* are distinguished are more dependent on external than on anatomical conformation, this determination cannot be so absolutely relied upon.

At the present day the lion is found in localities suitable to its habits, and where not exterminated (as it probably was in Europe) by the encroachments of man, throughout Africa from Algeria to the Cape Colony, and in Mesopotamia, Persia, and some parts of the north-west of India. According to Blanford,[1] lions are still very numerous in the reedy swamps bordering the Tigris and Euphrates, and also occur on the west flanks of the Zagros mountains and the oak-clad ranges near Shiraz, to which they are attracted by the immense herds of swine which feed on the acorns. The lion nowhere exists in the table-land of Persia, nor is it found in Balúchistán. In India it appears now to be confined to the province of Kathiawar in Gujerat, though within the present century its range extended through the north-west parts of Hindustan, from Baháwalpur and Sind to at least the Jumna (about Delhi), southward as far as Khándesh, and in Central India through the Sagur and Nerbudda territories, Bundelkund, and as far east as Palamau. It was extirpated in Hariána about 1824. One was killed at Rhyli, in the Dumaoh district, Sagur and Nerbudda territories, so late as in the cold season of 1847–48; and about the same time a few still remained in the valley of the Sind river in Kotah, Central India (Blyth).

The great variations in external characters which different lions present, especially in the colour and the amount of mane, has given rise to the idea that there are several species, or at all events distinct varieties peculiar to different localities. It was at one time supposed, on the authority of Captain Walter Smee,[2] that the lion of Gujerat differed essentially from that of Africa in the absence of mane, but subsequent evidence has not supported this view, which was probably founded upon young specimens having been mistaken for adults. Lions from that district as well as from Babylonia, which have lived in the gardens of the London Zoological Society, have had as

[1] *Zoology and Geology of Eastern Persia*, 1876.

[2] *Transactions of the Zoological Society*, vol. i. p. 165, 1835.

fully developed manes as any other of the species. Mr F. C. Selous[1] has shown that in South Africa the so-called black-maned lion and others with yellow scanty manes are found, not only in the same locality, but even among individuals of the same parentage.

The lion belongs to the very natural and distinctly defined group constituting the genus *Felis* of Linnæus (for the characters and position of which see article MAMMALIA), a genus held by Pallas and other philosophical naturalists as a model of what a genus ought to be, although recent writers have divided and subdivided it into as many as thirteen sections, on each of which a new generic term has been imposed. Among these sections is one containing the largest members of the group, and differing from the others in the well-marked anatomical character that the anterior cornu of the hyoid arch is but little ossified, and by the less important one that the pupil of the eye when contracted is a circular hole, instead of a vertical slit as in the cat. The lion agrees with the tiger and the leopard in these respects, but differs from them in its uniform style of colouring, and from all the other *Felidæ* in the arrangement of its hairy covering, the hair of the top of the head, chin, and neck, as far back as the shoulder, being not only very much longer, but also differently disposed from the hair elsewhere, being erect or directed forwards and so constituting the characteristic ornament called the mane. There is also a tuft of elongated hairs at the end of the tail, one upon each elbow, and in most lions a copious fringe along the

FIG. 1.—Lion and Lioness, after a Drawing by Wolf in Elliot's Monograph of the *Felidæ*.

middle line of the under surface of the body, wanting, however, in some examples.[2] It must, however, be observed that these characters are peculiar to the adults of the male sex only, and that, even as regards their coloration, young lions show indications of the darker stripes and mottlings so characteristic of the greater number of the members of the genus; just as the young of nearly all the plain-coloured species of deer show for a time the light-coloured spots which are met with in the adults of only some of the species. The usual colour of the adult lion is yellowish-brown, but it may vary from a deep red or chestnut brown to an almost silvery grey. The mane, as well as the long hair of the other parts of the body, sometimes scarcely differs from the general colour, but it is usually darker and not unfrequently nearly black. The mane begins to grow when the animal is about three years old, and is fully developed at five or six.

In size the lion is only equalled or exceeded by the tiger among the existing *Felidæ*; though both species present great variations, the largest specimens of the latter appear to surpass the largest lions. A full-sized South African lion, according to Selous, measures slightly less than 10 feet from nose to tip of tail, following the curves of the body. Harris gives 10 feet 6 inches, of which the tail occupies 3 feet. The lioness is about a foot less.

The internal structure of the lion, except in slight details, resembles that of the other *Felidæ*, the whole organization being that of an animal modified to fulfil, in the most perfect degree yet attained, an active, predaceous mode of existence. The teeth especially exemplify the carnivorous

FIG. 2.—Front View of Skull of Lion.

type in its highest condition of development. The most important function they have to perform, that of seizing and holding firmly animals of considerable size and strength, violently struggling for life, is provided for by the great, sharp-pointed, and sharp-edged canines, placed wide apart at the angles of the mouth, the incisors between them being greatly reduced in size and kept back nearly to the same level, so as not to interfere with their action. The jaws are short and strong, and the width of the zygomatic arches, and great development of the bony ridges on the skull, give ample space for the attachment of the powerful muscles by which they are closed. In the molar series of teeth the sectorial or scissor-like cutting function is developed at the expense of the tubercular or grinding, there being only one rudimentary tooth of the latter form in the upper jaw, and none in the lower. They are, however, sufficiently strong to break bones of large size. The dental formula is expressed as follows:—incisors $\frac{3}{3}$, canines $\frac{1}{1}$, premolars $\frac{3}{2}$, molars $\frac{1}{1} = \frac{8}{7}$; total, 30. The tongue is long and flat, and remarkable for the development of the papillæ of the anterior part of the dorsal surface, which (except near the edge) are modified so as to resemble long, compressed, recurved, horny spines or claws, which, near the middle line, attain the length of one-fifth of an inch. They give the part of the tongue on which they occur the appearance and feel of a coarse rasp, and serve the purpose of such an instrument in cleaning the flesh from the bones of the animals on which the lion feeds. The vertebral

[1] *A Hunter's Wanderings in Africa*, 1881, p. 258.

[2] Mr Selous, whose opportunities for obtaining evidence upon this subject were very large, says that in the region of South Africa, between the Zambesi and the Limpopo rivers, he never saw a lion with any long hair under the body, and that the manes of the wild lions of that district are far inferior in development to those commonly seen in menageries in Europe.

column is composed of seven cervical, thirteen dorsal, seven lumbar, three sacral, and about twenty-six caudal vertebræ. The clavicles are about 3 inches in length, embedded loosely in the muscles, and not directly connected either with the sternum or the scapula. The limbs are digitigrade, the animal resting upon round soft pads or cushions covered with thick, naked skin, one on the under surface of each of the principal toes, and one larger one of trilobed form, behind these, under the lower ends of the metacarpal and metatarsal bones, which are placed nearly vertically in ordinary progression. The fore feet have five toes, of which the third and fourth are nearly equal and longest, the second being slightly and the fifth considerably shorter. The first or pollex (corresponding to the human thumb) is much shorter than the others, and does not reach to the ground in walking. The hind feet have only four toes, the third and fourth being the longest, the second and fifth somewhat shorter and nearly equal. The first or hallux (or great toe) is represented only by a rudimentary metatarsal bone. The claws are all very large, strongly compressed, very sharp, and exhibit the retractile condition in the highest degree, being drawn backwards and upwards into a cutaneous sheath by the action of an elastic ligament so long as the foot is in a state of repose, but exserted by muscular action when the animal strikes its prey. By this remarkable piece of animal mechanism their edges and points are always kept sharp and unworn.

The habits of the lion in a state of nature are fairly well known from the united observations of numerous travellers and sportsmen who have explored those districts of the African continent in which it is still common. It lives chiefly in sandy plains and rocky places interspersed with dense thorn-thickets, or frequents the low bushes and tall rank grass and reeds that grow along the sides of streams and near the springs where it lies in wait for the larger herbivorous animals on which it feeds. Although it is occasionally seen abroad during the day, especially in wild and desolate regions, where it is subject to but little molestation, the night is, as in the case of so many other predaceous animals, the period of its greatest activity. It is then that its characteristic roar is chiefly heard, as thus graphically described by Gordon Cumming:—

"One of the most striking things connected with the lion is his voice, which is extremely grand and peculiarly striking. It consists at times of a low deep moaning, repeated five or six times, ending in faintly audible sighs; at other times he startles the forest with loud, deep-toned, solemn roars, repeated in quick succession, each increasing in loudness to the third or fourth, when his voice dies away in five or six low muffled sounds very much resembling distant thunder. At times, and not unfrequently, a troop may be heard, roaring in concert, one assuming the lead, and two, three, or four more regularly taking up their parts, like persons singing a catch. Like our Scottish stags at the rutting season, they roar loudest in cold frosty nights; but on no occasions are their voices to be heard in such perfection, or so intensely powerful, as when two or three troops of strange lions approach a fountain to drink at the same time. When this occurs, every member of each troop sounds a bold roar of defiance at the opposite parties; and when one roars, all roar together, and each seems to vie with his comrades in the intensity and power of his voice. The power and grandeur of these nocturnal concerts is inconceivably striking and pleasing to the hunter's ear."

"The usual pace of a lion," C. J. Andersson[1] says, "is a walk, and, though apparently rather slow, yet, from the great length of his body, he is able to get over a good deal of ground in a short time. Occasionally he trots, when his speed is not inconsiderable. His gallop—or rather succession of bounds—is, for a short distance, very fast,—nearly or quite equal to that of a horse. Indeed, unless the steed has somewhat the start when the beast charges, it will be puzzled to escape. Many instances are on record of horsemen who have incautiously approached too near to the lion, prior to firing, who have been pulled down by him before they could get out of harm's way. Happily, however, the beast soon tires of the exertion of galloping, and unless his first rush succeeds he, for the most part, soon halts and beats a retreat." "The lion, as with other members of the feline family," the same writer tells us, "seldom attacks his prey openly, unless compelled by extreme hunger. For the most part he steals upon it in the manner of a cat, or ambushes himself near to the water, or a pathway frequented by game. At such times he lies crouched upon his belly in a thicket until the animal approaches sufficiently near, when, with one prodigious bound, he pounces upon it. In most cases he is successful, but should his intended victim escape, as at times happens, from his having miscalculated the distance, he may make a second or even a third bound, which, however, usually prove fruitless, or he returns disconcerted to his hiding-place, there to wait for another opportunity." His food consists of all the larger herbivorous animals of the country in which he resides,—buffaloes, various kinds of antelopes, zebras, giraffes, or even young elephants or rhinoceroses, though the adults of these latter he dare not attack. In cultivated districts the cattle, sheep, and even human inhabitants are never safe from his nocturnal ravages. He appears, however, as a general rule, only to kill when hungry or attacked, and not for the mere pleasure of killing, as with some other carnivorous animals. He, moreover, by no means limits himself to animals of his own killing, but, according to Selous, often prefers eating game that has been killed by man, even when not very fresh, to taking the trouble to catch an animal himself. All books of African travel and sport abound with stories, many of which are apparently well authenticated, of the lion's prodigious strength, as exemplified by his being able to drag off a whole ox in his mouth to a long distance, even leaping fences and dykes with it.

The lion appears to be monogamous, a single male and female continuing attached to each other irrespectively of the pairing season. At all events the lion remains with the lioness while the cubs are young and helpless, and assists in providing her and them with food, and in educating them in the art of providing for themselves. The number of cubs at a birth is from two to four, usually three. They are said to remain with their parents till they are about three years old. The following account by an eyewitness gives a good idea of lion family life[2]:—

"I once had the pleasure of, unobserved myself, watching a lion family feeding. I was encamped on the Black Umfolosi in Zululand, and towards evening, walking out, about half a mile from camp, I saw a herd of zebra galloping across me, and when they were nearly 200 yards off, I saw a yellow body flash towards the leader, and saw him fall beneath the lion's weight. There was a tall tree about 60 yards from the place, and anxious to see what went on, I stalked up to it, while the lion was still too much occupied to look about him, and climbed up. He had by this time quite killed the beautifully striped animal, but instead of proceeding to eat it, he got up and roared vigorously, until there was an answer, and in a few minutes a lioness, accompanied by four whelps, came trotting up from the same direction as the zebra, which no doubt she had been to drive towards her husband. They formed a fine picture, as they all stood round the carcase, the whelps tearing it and biting it, but unable to get through the tough skin. Then the lion lay down, and the lioness driving her offspring before her did the same 4 or 5 yards off, upon which he got up, and commencing to eat, had soon finished a hind-leg, retiring a few yards on one side as soon as he had done so. The lioness came up next and tore the carcase to shreds, bolting huge mouthfuls, but not objecting to the whelps eating as much as they could find. There was a good deal of snarling and quarrelling among these young lions, and occasionally a stand-up fight for a minute, but their mother did not take any notice of them, except to give them a smart blow with her paw if they got in her way. . . . There was now little left of the zebra but a few bones, which hun-

[1] *The Lion and the Elephant*, 1873, p. 19.

[2] Hon. W. H. Drummond, *The Large Game and Natural History of South and South-East Africa*, 1875, p. 278.

dreds of vultures were circling round waiting to pick, while almost an equal number hopped awkwardly about on the ground within 50 or 60 yards of it, and the whole lion family walked quietly away, the lioness leading, and the lion, often turning his head to see that they were not followed, bringing up the rear."

Though not strictly gregarious, lions appear to be sociable towards their own species, and often are found in small troops, sometimes consisting of a pair of old lions, with their nearly full-grown cubs, but occasionally of adults of the same sex; and there seems to be good evidence that several lions will associate together for the purpose of hunting upon a preconcerted plan. As might be supposed, their natural ferocity and powerful armature are sometimes turned upon one another; combats, often mortal, occur among male lions under the influence of jealousy; and Andersson relates an instance of a quarrel between a hungry lion and lioness over the carcase of an antelope which they had just killed, and which did not seem sufficient for the appetite of both, ending in the lion not only killing, but even devouring his mate. Old lions, whose teeth have become injured with constant wear, often become "man-eaters," finding their easiest means of obtaining a subsistence in lurking in the neighbourhood of villages, and dashing into the tents at night and carrying off one of the sleeping inmates. Lions differ from most of the smaller *Felidæ* in never climbing trees; indeed, as mentioned before, they are rarely found in forests.

With regard to the character of the lion, those who have had opportunities of observing it in its native haunts differ greatly. The exaggerated accounts of early writers as to its courage, nobility, and magnanimity have led to a reaction, which causes some modern authors to speak of it in language quite the reverse, and to accuse it of positive cowardice and all kinds of meanness. Livingstone goes so far as to say, "nothing that I ever learned of the lion could lead me to attribute to it either the ferocious or noble character ascribed to it elsewhere," and he adds that its roar is not distinguishable from that of the ostrich. Of course these different estimates depend to a great extent upon the particular standard of the writer, and also upon the circumstance that lions, like other animals, undoubtedly show considerable individual differences in character, and behave differently under varying circumstances. They are certainly not so reckless as to be entirely devoid of the instinct of self-preservation, and if one, perhaps satiated with a good meal the night before, unexpectedly disturbed in the day time, will occasionally retreat when confronted, even by an unarmed man, that is scarcely a reason for assigning cowardice as one of the characteristics of the species. The latest authority, Selous, while never denying the daring courage of the lion when hungry or provoked, and vindicating the awe-inspiring character of the roar of several lions in unison, when heard at close quarters, as the grandest sound in nature, says with regard to its outward aspect:—

"It has always appeared to me that the word 'majestic' is singularly inapplicable to the lion in its wild state, as when seen by daylight he always has a stealthy furtive look that entirely does away with the idea of majesty. To look majestic a lion should hold his head high. This he seldom does. When walking he holds it low, lower than the line of his back, and it is only when he first becomes aware of the presence of man that he sometimes raises his head and takes a look at the intruder, usually lowering it immediately, and trotting away with a growl. When at bay, standing with open mouth and glaring eyes, holding his head low between his shoulders, and keeping up a continuous low growling, twitching his tail the while from side to side, no animal can look more unpleasant than a lion; but there is then nothing majestic or noble in his appearance."

Notwithstanding this evidently truthful description of the animal when seen under what may be called unfavourable circumstances, no one with an eye for beauty can contemplate the form of a fine specimen of a lion, at all events in a state of repose, even though in the confinement of a menagerie, without being impressed with the feeling that it is a grand and noble-looking animal. (W. H. F.)

LIPARI ISLANDS. These islands, which take their name from the largest and most populous member of the group, are situated to the north of the eastern half of Sicily, between 38° 20′ and 38° 55′ N. lat., and 14° 15′ and 15° 15′ E. long. The seven principal islands are Lipari, Salina, Vulcano, Stromboli, Panaria, Filicudi, and Alicudi; besides which there are ten islets, some of them mere rocks, the remains of a great central volcano now submerged. The total population of the islands in 1871 was 18,400, and the area is less than 50 square miles. They were known to the ancients as the *Hephæstiades* or *Vulcaniæ insulæ*, from their supposed connexion with Vulcan; the *Liparenses*, from their mythical king Lipara; and the *Æoliæ insulæ*, from Æolus, who was said to have married the daughter of Lipara, and to have succeeded to the kingdom. Lipara, the chief island, was colonized in the 6th century B.C. by Cnidians and Rhodians, who rapidly spread to the adjacent islands of Hiera and Didyme. The new settlers maintained their independence in spite of the attacks of the Tyrrhenian pirates, but they later became subject successively to the Athenians, Carthaginians, and Romans. In the Middle Ages the Saracens took possession of the islands, but they were expelled by the Normans in the 11th century. Finally Ferdinand the Catholic annexed them to Sicily.

Lipari has an area of about 11 square miles, with a population of 12,000. It is mountainous in character, and consists of tuffs and lavas, and of highly siliceous volcanic products such as quartz-trachyte, pumice, and obsidian. The great central cone, Monte Sant' Angelo (1952 feet), is the ruin of an extinct volcano, as is also Monte Chirica (1978 feet); while Campo Bianco or Monte Pelato (1500 feet) is a mountain of white pumice, breached by an outflow of vitreous lava. Hot springs exist in various parts of the island, the most important being those of San Calogero, mentioned by Diodorus Siculus, and situated about 6 miles from the town. The water, which possesses a temperature of 198° Fahr., contains free carbonic acid and sulphuretted hydrogen, together with carbonates of calcium and magnesium, and chlorides of calcium and sodium. The chief town, which stands on the eastern point of the island, is quite modern, and contains no objects of interest. The cathedral and several other churches are within the precincts of the castle, and they are presided over by a bishop and thirty-two canons. The castle is used as a prison for some four hundred malefactors, sent from various parts of Italy. The island is governed by a delegate, subject to the prefect of Messina. The soil is fertile; and a considerable trade is carried on by a number of merchants who export currants, figs, pumice stone, and malmsey wine. Water is scarce owing to the great porosity of the soil.

Six miles to the south of Lipari is the island of Vulcano, anciently known as *Hiera*, *Vulcania*, and *Therusia*. In early times it was a very active volcano; and it is described by Thucydides, Aristotle, and Callias as being frequently in a state of violent eruption. In the 2d century B.C. the smaller island of Vulcanello was upheaved from the sea. The present crater was probably formed during the eruption of 1786, from which time the volcano remained in a quiescent state till the autumn of 1873, when it commenced to discharge clouds of vapour, showers of sand, and large stones. Blue and green flames were also seen to issue from rifts in the floor of the crater. When visited by the writer in 1879, the volcano had again relapsed into the solfatara stage, and it had recently been purchased by a Scotch firm for £8000, for the purpose of extracting alum, boracic acid, and sulphur from the numerous products which line the sides and cover the floor of the crater. A number of volcanic minerals have been obtained from Vulcano; the most remarkable perhaps was that lately analysed by Professor Cossa of Turin, which was found to contain seven non-metallic elements and eight metals, among them the rare bodies thallium, cæsium, and rubidium. The highest point of Vulcano—a portion of the old crater ring—has an altitude of 1601 feet.

A little more than 20 miles to the north-north-east of Lipari, the cone of Stromboli rises from the sea to a height of 3022 feet. It is of special interest to the vulcanologist from the fact that it is the only example in Europe of a volcano in a state of constant activity, and also because, from an elevated point above the crater (which is at the side of the cone below the summit), it is possible, when the wind blows away from the observer, to sit for hours and watch the operations going on within the crater. Such observations, carried out in 1788 by Spallanzani, made him the father of modern vulcanology, and furnished some of the most important data upon which the science is founded. The mountain is mentioned as early as the 4th century B.C.

Between Stromboli and Lipari there is a group of islets representing portions of the crater ring of a great volcano, the largest of which, Panaria (*Hicesia*), is 7 miles in circuit, and contains about 200 inhabitants. It produces wheat, oil, and wine. Salina (*Didyme*), 3 miles to the north-west of Lipari, has an area of 10 square miles, and consists of two volcanic cones rising respectively to the height of 3156 and 2821 feet. The island contains nearly 5000 inhabitants, who are mainly employed in cultivating the vines, which produce a fine malmsey wine. The cone of Filicudi rises to a height of 2598 feet, some 10 miles to the west of Salina, while at an equal distance further west is Alicudi, the most westerly member of the Lipari group. It is partly cultivated, and is inhabited by about 500 fishermen and shepherds.

Good maps of the Lipari Islands have been published by the Italian Government. The best general account of the islands is still that of Admiral Smyth (*Sicily and its Islands*, 1824), while Professor J. W. Judd has exhaustively discussed their geology in the pages of the *Geological Magazine* for 1875. (G. F. R.)

LIPETSK, a district town of Russia, in the government of Tamboff, 95 miles west of the chief town of the government, and 23 miles north-west of Gryazi railway junction, at the confluence of Lyesnoy Voronesh and Lipovka rivers. The town is built of wood, and the streets are unpaved, but it is a commercial centre of some importance. There are several beetroot-sugar and leather works, tallow-melting houses, and distilleries. There is a brisk business at the weekly fairs, and the merchants carry on active trade in horses, cattle, tallow, skins, and honey, sent by rail to the northern provinces, and in timber, shipped down to the province of the Don Cossacks. The Lipetsk mineral springs came into repute in the time of Peter I., who caused them to be surrounded by galleries, and laid down three gardens; they continue to attract visitors during the summer. Lipetsk received municipal institutions in 1779. Population 14,500.

LIPPE is the name of a territory in north-western Germany, now divided into two small sovereign principalities, but formerly united under the same ruler. The name is derived from the river Lippe, which rises in the Teutoburgian Forest, and flows into the Rhine at Wesel.

I. LIPPE proper, also called LIPPE-DETMOLD, is bounded on three sides by the Prussian province of Westphalia, and on the E. and N.E. by Hanover, Pyrmont, and Hesse-Cassel. It also possesses three small enclaves in Westphalia. Its area is about 450 square miles. The greater part of the surface is mountainous, especially towards the south, where it is intersected by the Teutoburgian Forest. The chief rivers are the Weser, which crosses the north extremity of the principality, and its affluents the Werre, Exter, Kalle, and Emmer. The forests of Lippe are among the finest in Germany, and produce abundance of excellent timber. The valleys contain a considerable amount of good arable land, the tillage of which occupies the greater part of the inhabitants. The principal crops are corn, flax, and rape. Cattle, sheep, and swine are also reared, and the "Senner" breed of horses is celebrated. The industries of Lippe are almost confined to a little yarn-spinning and linen-weaving. Its trade is also inconsiderable; but, besides agricultural products, timber, meerschaum pipes, and starch are exported. The brine springs of Salzuflen produce about 1500 tons of salt annually. In 1880 the population amounted to 120,216 souls, upwards of 95 per cent. of whom were Calvinists (Reformed Church), the remainder being Lutherans, Roman Catholics, and Jews. Education is provided for by two gymnasia and numerous other efficient schools. The principality contains seven small towns, the chief of which are Detmold, the seat of government, and Lemgo. The present constitution was granted in 1836, and is modified by a new election law of 1876. It provides for a representative chamber of twenty-one members, whose functions are mainly consultative. For electoral purposes the population is divided into three classes, rated according to taxation, each of which returns seven members. The estimated revenue in 1881 was £49,200, and the expenditure £50,850. The public debt amounts to nearly £60,000. Lippe has one vote in the German Reichstag, and also one vote in the Federal Council. Its military forces form a battalion of the 6th Westphalian infantry.

II. SCHAUMBURG-LIPPE, or LIPPE-BÜCKEBURG, to the north of Lippe-Detmold, consists of the western half of the old countship of Schaumburg, and is surrounded by Westphalia, Hanover, and the Prussian part of Schaumburg. The northern extremity of the principality, which is 175 square miles in extent, is occupied by a lake named the Steinhuder Meer. The southern part is mountainous, but the remainder consists of a fertile plain, producing abundant crops of cereals and flax. Besides husbandry, the inhabitants practise yarn-spinning and linen-weaving, and the coal-mines of the Bückeburg, on the south-eastern border, are very productive. The great bulk of the population, which in 1880 amounted to 35,374, are Lutherans. The capital is Bückeburg, and Stadthagen is the only other town. Under the constitution of 1868 there is a legislative diet of fifteen members, ten of whom are elected by the towns and rural districts and three by the nobility, clergy, and educated classes, while the remaining two are nominated by the prince. Schaumburg-Lippe sends one deputy to the Federal Council, and has one vote in the Reichstag. It contributes a battalion of riflemen to the imperial army. The budget of 1881–82 showed an estimated revenue of £25,750, which was balanced by the expenditure. The public debt is about £18,000.

History.—The district now named Lippe was inhabited in the earliest times of which we have any record by the Cherusci, whose leader Arminius annihilated the legions of Varus in the Teutoburgian Forest (9 A.D.). It was afterwards occupied by the Saxons, and was subdued by Charlemagne. The founder of the present reigning family, one of the most ancient in Germany, was Bernard I. (1128–58), who received a grant of the territory, till then called the countship of Haholt, from the emperor Lothair, and assumed the title of lord of Lippe. Bernard VIII., who with his people embraced the tenets of the Reformation in 1556, was the first to style himself count of Lippe. In 1613 Lippe was divided among the three sons of Simon VI., the lines founded by two of whom still exist, while the third (Brake) became extinct in 1709.

Lippe-Detmold was the patrimony of the eldest son, whose descendants became princes of the empire in 1789. In 1809 it joined the Confederation of the Rhine, and in 1813 the German Confederation. Under the prudent government of the Princess Pauline (1807–20) the little country enjoyed great prosperity. Her son, Paul Alexander Leopold, ruled in the same spirit, and in 1836 granted the charter of rights on which the government is now based. In 1842 Lippe entered the German Customs Union

(Zollverein), and in 1866 it threw in its lot with Prussia and joined the North German Confederation.

Philip, the youngest son of Simon VI. (see above), received but a scanty share of his father's possessions, but in 1640 he inherited a large part of the countship of Schaumburg, including Bückeburg, and adopted the title of count of Schaumburg-Lippe. The ruler of this territory became a sovereign prince in 1807. In 1866 the prince at first sided with Austria, but afterwards entered the German Confederation.

For further information consult Falkmann, *Beiträge zur Geschichte des Fürstenthums Lippe*, 1869; Schikedanz, *Das Fürstenthum Lippe-Detmold in geographischer, statistischer, und geschichtlicher Beziehung*, 1830; "Erinnerungen aus dem Leben der Fürstin Pauline," in Sybel's *Historische Zeitschrift*, 1861.

LIPPI, the name of three celebrated Italian painters.

I. Fra Filippo Lippi (1412–1469), commonly called Lippo Lippi, one of the most celebrated painters of the Italian quatrocento, was born in Florence,—his father, Tommaso, being a butcher. His mother died in his earliest infancy, and his father two years later. His aunt, a poor woman named Monna Lapaccia, then took charge of him; and in 1420, when only eight years of age, he was registered in the community of the Carmelite friars of the Carmine in Florence. Here he remained till 1432, and his early faculty for fine art was probably developed by studying from the works of Masaccio in the neighbouring chapel of the Brancacci. Between 1430 and 1432 he executed some works in the monastery, which were destroyed by a fire in 1771; they are specified by Vasari, and one of them was particularly marked by its resemblance to Masaccio's style. Eventually Fra Filippo quitted his convent, but it appears that he was not relieved from some sort of religious vow; there is a letter of his, dated in 1439, in which he speaks of himself as the poorest friar of Florence, and says he is charged with the maintenance of six marriageable nieces. In 1452 he was appointed chaplain to the convent of S. Giovannino in Florence, and in 1457 rector (*Rettore Commendatario*) of S. Quirico at Legnaia, and his gains were considerable, and even uncommonly large from time to time; but his poverty seems to have been chronic none the less, the money being spent, according to one account, in frequently recurring amours.

Vasari relates some curious and romantic adventures of Fra Filippo, which modern biographers are not inclined to believe. Except through Vasari, nothing whatever is known of his visits to Ancona and Naples, and his intermediate capture by Barbary pirates and enslavement in Barbary, whence his skill in portrait-sketching availed to release him. The doubts thrown upon his semi-marital relations with a Florentine lady appear, however, to be somewhat arbitrary; Vasari's account is circumstantial, and in itself not greatly improbable, and to say that he is the sole authority for the facts goes but a small way towards invalidating them. Towards June 1456 Fra Filippo was settled in Prato (near Florence) for the purpose of fulfilling an important commission which had been given him to paint frescos in the choir of the cathedral. Before actually undertaking this work he set about painting, in 1458, a picture for the convent chapel of St Margaret of Prato, and there saw Lucrezia Buti, the beautiful daughter of a Florentine, Francesco Buti; she was either a novice or a young lady placed under the nuns' guardianship. Lippi asked that she might be permitted to sit to him for the figure of the Madonna; he made passionate love to her, abducted her to his own house, and kept her there spite of the utmost efforts the nuns could make to reclaim her. The fruit of their loves was a boy, who became the painter, not less celebrated than his father, Filippino Lippi (noticed below). Such is substantially Vasari's narrative, published less than a century after the alleged events; it is not refuted by saying, more than three centuries later, that perhaps Lippo had nothing to do with any such Lucrezia, and perhaps Lippino was his adopted son, or only an ordinary relative and scholar. The argument that two reputed portraits of Lucrezia in paintings by Lippo, one as a Madonna in a very fine picture in the Pitti gallery, and the other in the same character in a Nativity in the Louvre, are not alike comes to very little; and it is reduced to nothing when the disputant adds that the Louvre painting is probably not done by Lippi at all. This painting comes, however, from St Margaret's at Prato, and is generally considered to be the very one on which Vasari's story hinges.

The frescos in the choir of Prato cathedral, being the stories of the Baptist and of St Stephen, represented on the two opposite wall spaces, are the most important and monumental works which Fra Filippo has left, more especially the last of the series, showing the ceremonial mourning over Stephen's corpse. This contains a portrait of the painter, but which is the proper figure is a question that has raised some diversity of opinion. Some of the subjects are legendary, as, for instance, the attempt of the devil to substitute a changeling for the infant protomartyr. At the end wall of the choir are S. Giovanni Gualberto and S. Albert, and on the ceiling the four evangelists.

The close of Lippi's life was spent at Spoleto, where he had been commissioned to paint, for the apse of the cathedral, some scenes from the life of the Virgin. In the semidome of the apse is Christ crowning the Madonna, with angels, sibyls, and prophets. This series, which is not wholly equal to the one at Prato, was completed by Fra Diamante after Lippi's death.

That Lippi died in Spoleto, on or about 8th October 1469, is an undoubted fact; the mode of his death is again a matter of dispute. It has been said that the pope granted Lippi a dispensation for marrying Lucrezia, but that, before the permission arrived, he had been poisoned by the indignant relatives either of Lucrezia herself, or of some lady who had replaced her in the inconstant painter's affections. This is now generally regarded as a fable; and it may very well be such, although the incident does not present any intrinsic improbability in relation to the Italy of the 15th century. Fra Filippo lies buried in Spoleto, with a monument erected to him by Lorenzo the Magnificent; he had always been zealously patronized by the Medici family, beginning with Cosmo Pater Patriæ. Francesco di Pesello (called Pesellino) and Sandro Botticelli were among his most distinguished pupils.

Some leading pictures by Lippi not already mentioned are the following. In 1441 he painted an altarpiece for the nuns of S. Ambrogio which is now a prominent attraction in the Accademia of Florence, and has been celebrated in Browning's well-known poem. It represents the Coronation of the Virgin among angels and saints, of whom many are Bernardine monks. One of these, placed to the right, is a half-length portrait of Lippo, pointed out by an inscription upon an angel's scroll "Is perfecit opus." The price paid for this work in 1447 was 1200 Florentine lire, which seems surprisingly or even unaccountably large. For Geminiano Inghirami of Prato he painted the death of St Bernard, a fine specimen still extant. His principal altarpiece in this city is a Nativity in the refectory of S. Domenico,—the Infant on the ground adored by the Virgin and Joseph, between Sts George and Dominic, in a rocky landscape, with the shepherds playing and six angels in the sky. In the Uffizi is a fine Virgin adoring the infant Christ, who is held by two angels; in the London National Gallery, a Vision of St Bernard. The picture of the Virgin and Infant with an Angel, in this same gallery, also ascribed to Lippi, is disputable.

Few pictures are so thoroughly enjoyable as those of Lippo Lippi; they show the naiveté of a strong rich nature, redundant in lively and somewhat whimsical observation. He approaches religious art from its human side, and is not pietistic though true to a phase of Catholic devotion. He was perhaps the greatest colourist and technical adept of his time, with good draughtsmanship,—a naturalist, with less vulgar realism than some of his contemporaries, and with much genuine episodical animation, including semi-humorous incidents and low characters. He made little effort after perspective and none for foreshortenings, was fond of ornamenting pilasters and other architectural features. Vasari says that Lippi was wont to hide the extremities in drapery, to evade difficulties. His career was one of continual development, without fundamental variation in style or in colouring. In his great works the proportions are larger than life,

II. Filippino or Lippino Lippi (1460-1505) was the natural son of Fra Lippo Lippi and Lucrezia Buti, born in Florence and educated at Prato. Losing his father before he had completed his tenth year, the boy took up his avocation as a painter, studying under Sandro Botticelli, and probably under Fra Diamante. The style which he formed was to a great extent original, but it bears clear traces of the manner both of Lippo and of Botticelli,—more ornamental than the first, more realistic and less poetical than the second. His powers developed early; for we find him an accomplished artist by 1480, when he painted an altarpiece, the Vision of St Bernard, now in the Badia of Florence; it is in tempera, with almost the same force as oil painting. Soon afterwards, probably from 1482 to 1490, he began to work upon the frescos which completed the decoration of the famous Brancacci chapel in the Carmine, commenced by Masolino and Masaccio many years before. He finished Masaccio's subject of the Resurrection of the King's Son, and was the sole author of Paul's Interview with Peter in Prison, the Liberation of Peter, the Two Saints before the Proconsul, and the Crucifixion of Peter. These works, were none others extant from his hand, are sufficient to prove that Lippino stood in the front rank of the artists of his time. The dignified and expressive figure of St Paul in the second-named subject has always been particularly admired, and appears to have furnished a suggestion to Raphael for his Paul at Athens. Portraits of Luigi Pulci, Antonio Pollaiuolo, Lippino himself, and various others are to be found in this series. In 1485 he executed the great altarpiece of the Virgin and Saints, with several other figures, now in the Uffizi Gallery. Another of his leading works is the altarpiece for the Nerli Chapel in S. Spirito—the Virgin Enthroned, with splendidly living portraits of Nerli and his wife, and a thronged distance. In 1489 Lippino was in Rome, painting in the church of the Minerva, having first passed through Spoleto to design the monument for his father in the cathedral of that city. Some of his principal frescos in the Minerva are still extant the subjects being in celebration of St Thomas Aquinas. In one picture the saint is miraculously commended by a crucifix; in another, triumphing over heretics. In 1496 Lippino painted the Adoration of the Magi now in the Uffizi, a very striking picture, with numerous figures. This was succeeded by his last important undertaking, the frescos in the Strozzi Chapel, in the church of S. Maria Novella in Florence—Drusiana Restored to Life by St John the Evangelist, St John in the Cauldron of Boiling Oil, and two subjects from the legend of St Philip. These are conspicuous and attractive works, yet somewhat grotesque and exaggerated,—full of ornate architecture, showy colour, and the distinctive peculiarities of the master. Filippino, who had married in 1497, died in 1505 of an attack of throat disease and fever, aged only forty-five. His character for amiability and courtesy is described in very laudatory terms by Vasari. The best-reputed of his scholars was Raffaellino del Garbo.

Like his father, Filippino had a most marked original genius for painting, and he was hardly less a chief among the artists of his time than Fra Filippo had been in his; it may be said that in all the annals of the art a rival instance is not to be found of a father and son each of whom had such pre-eminent natural gifts and leadership. The father displayed more of sentiment, and candid sweetness of motive; the son more of richness, variety, and lively pictorial combination. He was admirable in all matters of decorative adjunct and presentment, such as draperies, landscape backgrounds, and accessories; and he was the first Florentine to introduce a taste for antique details of costume, &c. He formed a large collection of objects of this kind, and left his designs of them to his son. In his later works there is a tendency to a mannered development of the extremities, and generally to facile overdoing. The London National Gallery possesses a good and characteristic though not exactly a first-rate specimen of Lippino, the Virgin and Child between Sts Jerome and Dominic.

III. Lorenzo Lippi (1606-1664), a painter and poet, was born in Florence. He studied painting under Matteo Rosselli, the influence of whose style, and more especially of that of Santi di Tito, is to be traced in Lippi's works, which are marked by taste, delicacy, and a strong turn for portrait-like naturalism. His maxim was "to poetize as he spoke, and to paint as he saw." After exercising his art for some time in Florence, and having married at the age of forty the daughter of a rich sculptor named Susini, Lippi went as court painter to Innsbruck, where he has left many excellent portraits. There he wrote his humorous poem named *Malmantile Racquistato*, which was published under the anagrammatic pseudonym of "Perlone Zipoli." Lippi was a friend of Salvator Rosa, and was a man of pleasant and generous temper, and very polite. He was, however, somewhat self-sufficient, and, when visiting Parma, would not look at the famous Correggios there, saying that they could teach him nothing. He died of pleurisy in 1664.

The most esteemed works of Lippi as a painter are a Crucifixion in the gallery at Florence, and a Triumph of David which he executed for the saloon of Angiolo Galli, introducing into it portraits of the seventeen children of the owner. His poem the *Malmantile Racquistato* is a burlesque romance, mostly compounded out of a variety of popular tales; its principal subject-matter is an expedition for the recovery of a fortress and territory whose queen had been expelled by a female usurper. It is full of graceful or racy Florentine idioms, and is counted by Italians as a "testo di lingua." Lippi is more generally or more advantageously remembered by this poem than by anything which he has left in the art of painting. It was not published until 1688, several years after his death. (W. M. R.)

LIPSIUS, Justus (1547-1606), the Latinized form of Joest Lips, an eminent humanist of the 16th century, born 18th October 1547, at Overyssche, a small village in Brabant, about half way between Brussels and Ottignies. Sent early to the Jesuit college in Cologne, he was removed at seventeen to the university of Louvain by his parents, who had some reason for fearing that he might be induced to become a professed member of the Society of Jesus. But he had received at Cologne two mental tendencies from which he never emancipated himself. One of these, which was suppressed or suspended in middle life, asserted itself later in his return to the bosom of the Catholic Church before his death. The other, derived from his Jesuit training, showed itself in his merely rhetorical or verbal view of classical literature, of which the one interest lay in its style.

Lipsius rushed into print at twenty with one of those volumes of miscellaneous remarks then in vogue (*Variarum Lectionum Libri Tres*, 1567), the dedication of which to Cardinal Granvella procured him an appointment as Latin secretary, and a visit to Rome in the retinue of the cardinal. Here Lipsius remained two years, using his spare time in study of the Latin classics, in viewing the monuments, collecting inscriptions, and handling MSS. in the Vatican. A comparison of a second volume of miscellaneous criticism (*Antiquarum Lectionum Libri Quinque*, 1575), published after his return from Rome, with the *Variæ Lectiones* of eight years earlier shows that he had advanced from the notion of purely conjectural emendation to that of emending by collation, and that he had learnt to distinguish between a "good" and a "bad" MS. In Rome he also made the acquaintance of Muretus, Paullus Manutius, and the other humanists of the catholic reaction who were then in credit there. He was also noticed by Cardinal Sirleto and Fulvio Orsini; but he can hardly have even seen in the street Sigonio and Vettorio, and the introduction of these celebrated names is perhaps only a stylistic flourish of the biographer Le Mire, to whom we owe the only original account of Lipsius's life. In 1570 he wandered over Burgundy, Germany, Austria, Bohemia, in search of learning and learned acquaintance, and was engaged for more than a year as teacher in the university of Jena, a position which implied an outward conformity to the Lutheran Church. On his way back to Louvain, he stopped some time at Cologne, where he must again have comported himself as a Catholic. Here he married, but the union was without issue, and in other respects did not conduce to happiness, as we gather from various allusions scattered through Lipsius's letters. He returned to Louvain, but was soon driven by the civil war to take refuge in Antwerp, where he received, in 1579, a call to the newly founded university of Leyden, as professor of history.

At Leyden, where he must have outwardly conformed to the Calvinistic creed and worship, Lipsius remained eleven years,—years about which his Catholic biographer Le Mire has nothing to tell, but speaks of the period as an enforced temporary sojourn among the infidels,—till the restoration of peace allowed him to return to his home in Brabant. In truth, this period of Lipsius's life was the period of his greatest productivity. It was now that he prepared his *Seneca*, and that he perfected, in successive editions, his *Tacitus*. To edit and comment on two authors of the first class, such as Tacitus and Seneca, in addition to the daily drudgery of teaching, might seem work enough for eleven years. But Lipsius's industry enabled him, over and above, to bring out, from the press of Plantin at Antwerp, a series of works of varied character and contents, some of pure scholarship, others collections from classical authors, and others again of more general interest. Of this latter class was a treatise on politics (*Politicorum Libri Sex*, 1589), in which he let it be seen that, though a public teacher in a country which professed toleration, he had not departed from the state maxims of Alva and Philip II. He lays it down that a Government should only suffer one religion to exist in its territory, and that dissent should be extirpated by fire and sword. This frank avowal of what were known to be his real sentiments might have easily had disagreeable consequences for the author, if he had not been sheltered from the attacks to which it exposed him by the prudence of the authorities of Leyden. Lipsius was prevailed upon to publish a declaration that his expression "*Ure, seca*," was not intended of material fire and sword, but was only a metaphor for "vigorous treatment."

The time at last arrived when Lipsius, who had always been somewhat ill at ease in his Calvinistic disguise, was to throw it off and return into the bosom of the church. In the spring of 1591 he left Leyden under pretext of taking the waters at Spa for the relief of a liver complaint. He went to Mainz, where he was reconciled to the church by the instrumentality of the Jesuit fathers. The event was one which deeply interested the Catholic world, and invitations poured in on Lipsius from the courts and universities of Italy, Austria, and Spain. But he preferred to remain in his own country, and after two years of unsettled residence at Liége, Spa, &c., settled at Louvain, as professor of Latin in the Collegium Buslidianum. He was not expected to teach, and his trifling stipend was eked out by the appointments of privy councillor and historiographer to the king of Spain.

From this time till his death Lipsius continued to publish antiquarian collections and dissertations as before. But he was, in fact, lost to learning. His name and fame, and his sententious and amusing style, were placed at the disposal of the Jesuits, and used by them to restore the credit of two local images of the Virgin, whose authentic miracles were retailed by Lipsius in two tracts, *Diva Virgo Hallensis*, and *Diva Virgo Sichemensis*. Joseph Hall, afterwards bishop of Norwich, was at Spa in the suite of Sir E. Bacon at the time of the appearance of Lipsius's brochures, and was like to have got into trouble by disputing against them (Hall's *Epistles*, cent. i. ep. 5). Lipsius died at Louvain on the 23d of March 1606, at the age of fifty-eight. His Greek books and MSS. he left to the Jesuit college at Louvain; the rest of his library, choice rather than extensive, to a nephew. His furred doctor's robe he ordered to be offered at the shrine of the Virgin at Hall.

If, according to the fancy of some biographers, Scaliger, Casaubon, and Lipsius be erected into a literary triumvirate, Lipsius represents Lepidus. His knowledge of classical antiquity was extremely limited. He had but slight acquaintance with Greek; "pour sa provision" only, said Scaliger. He is fond of adorning his letters with Greek phrases, his quotations betraying that he is a stranger in that country. In Latin literature the poets and Cicero lay outside his range; he had no ear for metre, and no taste for poetical expression. Where he was strong was in the Latin historians and in Roman antiquities. His greatest work was his edition of Tacitus. This author he had so completely made his own that he could repeat the whole, and offered to be tested in any part of the text, with a poniard held to his breast, to be used against him if he should fail. His *Tacitus* first appeared in 1575, and was five times revised and corrected by the editor—the last time in 1606, shortly before his death. His *Seneca* is dated Antwerp, 1605. His *Opera Omnia* were collected in 4 vols., Antwerp, 1637, of which the Wesel edition, 1675, is a verbal reprint in the same number of volumes, but in a smaller form. The first volume contains also Le Mire's *Life of Lipsius*, which had appeared separately in 1607. Both editions contain ten centuries of his epistles, to which additions have been made in *Epistolarum quæ in Centuriis non ex ant Decades XII.*, &c., Harderwijk, 1621; Burmann's *Sylloge*, tom. i.; *Lettres inédites*, ed. Delprat, Amst., 1858. On Lipsius's relations with Scaliger see Bernay's *J. J. Scaliger*, note 40. A bibliographical list of his separate publications, forty-eight in number, may be found in Niceron, *Mémoires*, xxiv. p. 118. (M. P.)

LIQUEURS are perfumed and sweetened spirits prepared for drinking, and for use as a flavouring material in confectionery and cookery. The term liqueur is also applied to certain wines and spirits remarkable for their amount of bouquet, such as tokay and liqueur brandy, &c. Ordinary liqueurs consist of certain mixtures of pure spirit with essential oils and vegetable extracts, and with syrup of refined sugar. A certain number of such preparations have an established reputation; but the methods by which these are compounded, and the precise proportions of the various ingredients they contain, are valuable trade secrets, scrupulously kept from public knowledge.

The raw materials employed in the preparation of liqueurs are—(1) a pure flavourless spirit, which must be free from fusel oil; (2) various essential oils, on the purity and constant quality of which much of the success of the manufacture depends, or, in place of the oils, the aromatic substances from which they may be distilled; (3) bitter aromatic vegetable substances, fruits, rinds, &c., or their alcoholic extracts called tinctures; (4) fresh juicy fruits possessed of special flavour; (5) refined sugar prepared in the form of a perfectly smooth colourless syrup; (6) soft or distilled water; and (7) tinctorial substances for these liqueurs in which a particular colour is demanded by fashion. The French, who excel in the preparation of liqueurs, grade their products according to their sweetness and alcoholic strength into *crêmes*, *huiles*, or *baumes*, which have a thick oily consistency, and *eaux*, *extraits*, or *elixirs*, which, being less sweetened, are perfectly limpid. Liqueurs of British fabrication, generally of inferior quality, are frequently dealt in under the name of *cordials*. *Bitters* form a class of liqueurs by themselves, claiming to possess certain tonic properties and a medicinal value. Certain liqueurs, containing only a single flavouring ingredient, or having a prevailing flavour of a particular substance, are named after that body, as for example—crême de rose, vanille, thé, cacao, anisette, and kümmel, &c. On the other hand, the liqueurs which in general are most highly prized are compounded of very numerous aromatic principles, and they are not considered fit for use till they have matured and mellowed for several years.

The simplest method of preparing liqueurs is by adding the requisite proportion of essential oil to spirit of known strength, and then mixing this with the necessary amount of clear syrup. In this way, indeed, the greater number of the commoner and cheaper kinds are manufactured. Thus for making (say) 20 gallons inferior quality of kümmel, there are added to 7 gallons of spirit of wine ¼ lb of essential oil of caraway seed, 7½ drachms of fennel-seed oil, and 15 drops of bitter almond oil. With this preparation is mixed a syrup containing 40 lb of refined sugar dissolved in about 12 gallons of water, and when fined with gelatine or with alum and soda solution the liqueur is ready for use. To prepare, on the other hand, 20 gallons of fine kümmel liqueur, there would be placed in a simple still, with 10 gallons of spirit and 8 of water, 4 lb of caraway seeds, ½ lb of fennel, and 2 oz. of Florentine iris root. This mixture after maceration is distilled, the first portion of the distillate being put aside on account of its rough aroma, after which about 8 gallons of fine kümmel spirit is obtainable. There still may be procured, by forcing the heat, from 3 to 4 gallons of inferior spirit. To the 8 gallons of fine spirit is added a syrup consisting of 60 lb of refined sugar dissolved in 10 gallons of water, the two compounds being thoroughly incorporated with heat in an open vessel. On cooling, the amount of water necessary to make up 20 gallons is added; the liqueur is fined with isinglass, and stored to mature and mellow. All varieties of liqueurs may be made or imitated by both these methods; but as a rule it is only the simple-flavoured and commoner varieties which are compounded by the addition of essential oils and alcoholic tinctures. Fine liqueurs are made by macerating aromatic bodies and subsequent distillation; bitters by maceration and straining.

Of trade liqueurs the most highly esteemed in the United Kingdom are Chartreuse, Curaçoa, Maraschino, and Doppel-Kümmel or Allasch. Of all kinds the most famous is *Chartreuse*, so called from being made at the famous Carthusian monastery near Grenoble. Three qualities are made—green, yellow, and white, the green being the richest and most delicate in flavour. Chartreuse is said to be a most complex product, resulting from the maceration and distillation of balm leaves and tops as a principal ingredient, with orange peel, dried hyssop tops, peppermint, wormwood, angelica seed and root, cinnamon, mace, cloves, Tonquin beans, *Calamus aromaticus*, and cardamoms. *Curaçoa*, which is a simple liqueur, is chiefly made in Amsterdam from the dried peel of the Curaçoa orange. The peel is first softened by maceration in water; then three-fourths of the quantity in preparation is distilled with mixed spirit and water, and the remaining fourth is macerated in a proportion of this distillate for two or three days; the tincture is strained off and expressed and added to the original distilled Curaçoa spirit. The flavour of Curaçoa is improved by the addition of about one per cent. of Jamaica rum. The centre of the *Maraschino* trade is at Zara in Dalmatia. Genuine Maraschino is prepared from a variety of cherry—the Marasca—peculiar to the Dalmatian mountain regions. The juice of the cherry fermented and distilled yields the spirit, which is flavoured with the broken cherry kernels themselves. Imitations of Maraschino are easily prepared,—a praiseworthy liqueur resulting from raspberry juice, bitter almonds, and orange-flower water. In the preparation of *Allasch*—which is a rich *Kümmel*—bitter almonds, star-anise, angelica root, Florentine iris root, and orange peel are used in addition to caraway seeds. Gold-water and silver-water are liqueurs to which small quantities of powdered gold-leaf and silver-leaf have been added, on account of their lustre. They are now little used.

Gentian root is the fundamental "bitter" in most of the preparations known as *Bitters*. These compounds, prepared by maceration, are very various in their constitution, but the following is a fair typical sample of the composition of a kind largely used. To prepare 20 gallons of bitters there are taken 6 lb of gentian, 5 lb each of cinnamon and caraway seeds, 1 lb of juniper berries, and ½ lb of cloves. These are macerated in 7 gallons of spirit, 60° over proof, strained and filtered, and to the product is added 10 lb of sugar dissolved in 13 gallons of water, and the resulting liquor is coloured with cochineal.

The following list includes the names of the principal commercial liqueurs not already named :—Noyeau (white and pink), trappistine (yellow and green) (from the Abbey de la Grâce Dieu), bénédictine (from Fécamp), peppermint liqueur, French cherry brandy or kirsebaer (from Copenhagen), mandarine, parfait amour, crême de vanille, crême de rose, thé, café, menthe, cacao, vanille, pomeranzen, ratafia (from Dantzie), anisette (from Amsterdam and Bordeaux), kirschenwasser (from Switzerland and the Black Forest), absinthe, and vermouth. (J. PA.)

LIQUIDAMBAR, LIQUID AMBER, or SWEET GUM, is a product of *Liquidambar styraciflua*, L., order *Hamamelideæ*, a deciduous tree of from 30 to 50 feet high and attaining 15 feet in circumference in Mexico, of which country it is a native, as well as of the greater portion of the United States. It bears palmately-lobed leaves, somewhat resembling those of the maple, but larger. The male and female inflorescences are on different branches of the same tree, the globular heads of fruit resembling those of the plane. This species is nearly allied to *L. orientalis*, Miller, a native of a very restricted portion of the south-west coast of Asia Minor, where it forms forests. It is from the bark of this latter tree that the storax of the ancients (Herod., iii. 107; Diosc., i. 79), the medicinal styrax of to-day, is prepared (Bentley and Trimen, *Med. Plants*, No. 107). The earliest record of the tree appears to be in a Spanish work by F. Hernandez, published in 1651, in which he describes it as a large tree producing a fragrant gum resembling liquid amber, whence the name (*Nov. Plant.*, &c., p. 56). In Ray's *Historia Plantarum* (1686) it is called *Styrax liquida*. It was introduced into Europe in 1681 by Banister, the missionary collector sent out by Bishop Compton, who planted it in the palace gardens at Fulham.

The wood is very compact and fine-grained,—the heart-wood being reddish, and, when cut into planks, marked transversely with blackish belts. It is employed for veneering in New York. Being readily dyed black, it is sometimes used instead of ebony for picture frames, balusters, &c.; but it is too liable to decay for out-door work. The principal product of the tree, however, is the resinous gum which issues from between the bark and wood. It is sometimes called white balsam of Peru, or liquid storax, though it is said by Michaux (*Les Végétaux résineux*, ii. p. 337) to differ materially from the latter. It is considered to be styptic and to possess healing and balsamic properties, being stimulant and aromatic. It possesses nearly the same properties as the balsam of Peru and of Tolu, for which it is often substituted, as well as for storax. Mixed with tobacco, the gum was used for smoking at the court of the Mexican emperors (Humb., iv. 10). It has been long used in France as a perfume for gloves, &c. It is mainly produced in Mexico, little being obtained from trees growing in higher latitudes of North America, or in England For localities where it has been observed, see Pickering's *Chron. Hist. of Plants*, p. 741.

LIQUORICE. The hard and semi-vitreous sticks of paste, black in colour and possessed of a sweet somewhat astringent taste, known as liquorice paste or black sugar, are the inspissated juice of the roots of a leguminous plant, *Glycyrrhiza glabra*, the *radix glycyrrhizæ* of the pharmacopœia. The plant is cultivated throughout the warmer parts of Europe, especially on the Mediterranean shores, and its geographical limits travel eastward throughout Central Asia to China, where its cultivation is also prosecuted. In the United Kingdom it is grown in Surrey and in Yorkshire. The roots for use are obtained in lengths of 3 or 4 feet, and varying in diameter from ¼ to 1 inch, soft, flexible, and fibrous, and internally of a bright yellow colour with a characteristic sweet pleasant taste. To this sweet taste of its root the plant owes its generic name *Glycyrrhiza* (the sweet root), of which liquorice is a corruption. According to the analysis of Sestini (*Gaz. Chim. Ital.*, vol. viii. p. 131), the root dried at 110° C. has the following composition :—resin, fat, and colouring matters, 3·220; glycyrrhizin, 6·378; starch, 57·720; cellulose, 19·790; albuminoid substances, 6·373; ammonia (combined), 0·043; asparagine, 2·416; ash, 4·060. It is to the sugar-like body glycyrrhizin in combination with ammonia that the peculiar taste and properties of liquorice root are due. Glycyrrhizin in itself is a tasteless nearly insoluble substance having the composition of $C_{16}H_{24}O_6$; but in combination with ammonia, potash, or soda it develops its sweet taste. It is easily precipitated from its combination by the influence of mineral acids. Liquorice has been known and its virtues appreciated from the most remote periods, and the root is an article of some commercial importance on the Continent.

Stick liquorice is made by crushing and grinding the roots to a pulp, which is boiled in water over an open fire, and the decoction separated from the solid residue of the root is evaporated in copper pans till a sufficient degree of concentration is attained, after which, on cooling, it is rolled into the form of sticks or other shapes for the market. The preparation of the juice is a widely extended industry along the Mediterranean coasts; but the quality best appreciated in the United Kingdom is made in Calabria, and sold under the names of Solazzi and Corigliano juice. The liquorice grown in Yorkshire is made into a confection called Pontefract cakes. Liquorice in various forms is a popular remedy for coughs; and it is largely used by children as a sweetmeat. It enters into the composition of many cough lozenges and other demulcent preparations; and in the form of aromatic syrups and elixirs it has a remarkable effect in masking the taste of nauseous medicines, a property peculiar to glycyrrhizin. A considerable quantity of liquorice is used in the preparation of tobacco for chewing. Commercial liquorice paste is frequently much adulterated, and often contains distinct traces of copper, apparently derived from the vessels in which the juice is inspissated.

LIQUOR LAWS may be divided into the three great systems of free trade, restriction, and prohibition. The system of free trade may mean either that no special licence is required by law for carrying on a traffic in intoxicating liquors, or that such a licence is required, but that the licensing authority is bound to grant it in every case in which certain conditions are complied with. Wherever the determination of these conditions involves an appeal to the discretion of the licensing authority, the system of free trade tends to pass into the system of restriction. For practical purposes it does not matter much whether the law says, "every man of good character is entitled to a licence for a properly constructed house in a suitable locality," or "the magistrate must consider the character of the applicant and of the premises, but is not bound to give reasons for his decision." But wherever the applicant can submit to a court capable of dealing with evidence the question of fact whether he has fulfilled certain conditions defined by law, the system of free trade may be said in theory to exist. Wherever, on the other hand, the law distinctly affirms an absolute discretion in the magistrate, or lays down a positive principle, such as the "normal number" or the fixed proportion between public-houses and population, the system is properly described as restriction, or monopoly. This system, again, in its extreme form, tends to pass into one of prohibition. Under one of the alternative plans permitted by the Swedish licensing law of 1855, generally known as the Gothenburg plan, the municipality begins by the partial, and advances to the total, prohibition of liquor traffic, except by servants of the municipality; and this plan is sometimes advocated merely as a step towards the suppression of all trade in liquor. In nearly all countries the nature of the trade carried on in public-houses has subjected them to a much more rigorous police supervision than ordinary trades. All trades, however, must be carried on under the conditions required by the public comfort and safety; and to give unlimited licence in such matters to publicans would be to violate social rights not inferior to freedom of industry and trade.

Of recent years there has been a considerable increase in the amount of drunkenness in Europe generally. There are no means of determining the law of the increase by reliable statistics, but it seems probable that the increase is confined to the large towns and to the lowest classes. There has also been of late, both in the United Kingdom and on the Continent, a very earnest and animated discussion on the policy and results of the various systems of liquor law. It cannot be said that so far any decisive experience has been adduced on the subject. In fact the legislation of Europe is in a very uneasy and changeful state. Thus, prior to the federal constitution of 1874, the cantons of Switzerland were in the habit of directing the municipal authorities to observe a certain proportion between the number of licences and the population. The new constitution, however, laid down the general principle of free trade, and the federal council intimated to the various cantons that it was no longer lawful to refuse a licence on the ground that there was no public need of it. In the previous year precisely the opposite change took place in Denmark. The licence system rested on the law of 29th December 1857, but this was modified by the law of 23d May 1873, which increased the conditions to be fulfilled by those applying for a licence, and conferred upon the communal authorities the power of fixing the maximum number of licences to be granted. Similarly, in France, the liquor law rests upon the decree of 1851, but public opinion is turning against the absolute discretion reposed in the administrative authority, and the law proposed by M. de Gasté and approved of by the chamber of deputies on 22d March 1878 will probably lead to a system of greater freedom. In the German empire the various states are still permitted by a law of the confederation, dated 21st June 1869, to restrict the issue of licences to what the public seem to require, but except in Würtemberg this permission seems not to have been used. In Austria the rapid growth of drunkenness in Galicia made necessary the severe police law of 19th July 1877, but in other parts of the empire the exceptionally lenient law of 20th December 1859 seems to be considered sufficient. In the midst of so many fluctuations of opinion, the practical questions of legislation must be decided on general principles and not by experimental evidence. Those who speak and write on the reform of the liquor laws are divided into two great classes—(1) the nephalists, who consider alcohol, in every form, whether in distilled or in fermented liquors, to be poison, and therefore wish the sale of it to be entirely suppressed; (2) those who see no objection to moderate drinking, especially of the less alcoholic beverages, or at least regard the idea of suppression as an impracticable chimæra. In the United Kingdom the nephalists are at present agitating for Sir Wilfrid Lawson's Permissive Bill, which has latterly taken the form of a local option resolution. This means that in each burgh or parish two-thirds of the ratepayers may decide that no licences shall be given, a vote to be taken on the subject every three years. On 17th March 1879 the select committee of the House of Lords on intemperance reported emphatically against the scheme of the Permissive Bill. The committee did not examine witnesses from the United States with respect to the experiments in prohibition which have been made there on a large scale; but it is generally admitted that the Maine Liquor Law has succeeded only in villages and rural districts; in towns it has failed. So also the Michigan Law, prohibiting the sale of liquor except for medicinal or mechanical purposes, was condemned after twenty years' experience; and in 1875 a licence tax was imposed on dealers in liquor.

The result is the same under those celebrated "local option laws which are in force in some of the United States. These laws proceed from the legislatures of the various States. They sometimes take the form of a general prohibition of the sale of intoxicants, subject to a vote of the inhabitants in each township or county, but more frequently they merely provide in general terms for the issue of licences in the usual way, unless the local constituency shall otherwise determine. Such laws are in force in Massachusetts, New Jersey (which had the Chatham Local Option Law of 1871), New Hampshire, Connecticut, and Vermont. But whether they are constitutional or not is a matter of serious controversy in the courts of the United States. On the one hand, it is said that such a law amounts to a delegation by the State of its legislative power,—that it leaves the hands of the senate and general assembly in an unfinished state, commanding nothing, prohibiting nothing. On the other hand, it is said this is a police regulation, which is properly entrusted to county commissioners, or boards of select men for the protection of the health and morals of the localities over which they preside; and it is quite competent for a State to make a law delegating the power to determine some fact or state of things, upon which the law makes, or intends to make, its own action depend. In the case of the States already mentioned the constitutional character of the local option law has been upheld by decision, but in the cases of Delaware, Texas, Indiana, California (Wall's Case), Iowa, and Pennsylvania, it has been denied. The question has also been raised in the American courts whether in the case of intoxicants being imported from one State to another a local option law, which prohibits the sale of the imported goods, does not violate the freedom of commerce which is guaranteed to all the States by the American Constitution.[1]

Among those who are not nephalists a variety of schemes has been suggested. A small minority are in favour of free trade subject to certain conditions. An experiment of this kind was tried by the Liverpool magistrates in 1853. "The premises were to be of high rateable value; the excise duty was to be greatly increased; the licencee was invariably to reside on the premises; and a special police for the inspection of licensing houses was to be provided." These conditions being complied with, no licence was refused. This experiment was made the subject of inquiry by Mr Villier's select committee of 1854. That committee, which included Sir George Grey and Lord Sherbrooke (Mr Lowe), reported unanimously in its favour. A similar experiment was made in Liverpool during the years 1862–66 without evil results, and also since 1862 in the Prescot division of the county of Lancashire. On the Continent the only countries where free trade prevails are Belgium, Holland, Greece, Spain, and Roumania. In certain parts of Bavaria communes possess breweries, the produce of which they are by custom entitled to sell without any licence; and the Rhenish Palatinate has never been subject to the restrictions mentioned below which apply to the rest of the empire. In Belgium licences are unknown. The only tax which the publican pays is the "patent" which is paid by every trade. So strong is the general law in Belgium that in 1866, when the municipal authorities of Antwerp issued a regulation prohibiting the sale of alcoholic drinks in the streets, this was held to be illegal by the court of cassation. The Dutch law is the same as in Belgium. It must not be supposed, however, that the Dutch are satisfied with the present law. The Dutch "society for total abstinence from strong drink" is very active; and in 1880 the Government presented to the lower chamber a bill, introducing a licence and also the principle of the normal number, the proportion of licences to population varying according to the total population of towns. In Belgium the *Association contre l'abus des boissons alcooliques* is endeavouring to secure amendments of the law, chiefly of a fiscal and police character, but the introduction of the licence is not suggested. In Germany, with the exception of Würtemberg and those places where the licence is unknown, the liquor trade is practically free. The law of 1869 declares that a licence can be refused for two reasons only—if the police condemn the structure or situation of the premises, or if the applicant is likely to encourage drunkenness, gaming, reset of theft, or improper meetings. This system may be contrasted with those of Italy and Russia. In Italy, under the law of 20th March 1865, a licence is obtained from the sub-prefect or *autorita politica del circondario* on the demand of the syndic (*sindaco*) of the commune and after consulting with the municipal *giunta*. In Russia, under the decree of 1861 and the communal law of 28th June 1870, the licence is got from the municipal or communal council, or, in certain cases, from the owners of land, especially church land. In both countries the licensing authorities have unlimited discretion, which they have exercised so as to multiply public-houses enormously. Assuming that sufficient guarantees can be got for the respectability of the applicant and the good sanitary condition of his premises, the system of free trade, or of unrestricted licensing on defined conditions, is the only one which can be defended on principle. It is impossible for the magistrates to exercise a just discretion in deciding what public-houses are required for a locality. The fact that an applicant has invested capital in the business and is ready to begin is the best evidence that there is a demand to be supplied. There is, however, no prospect of free trade being established in the United Kingdom. The select committee of 1879 reported against it.

A larger number of licensing reformers support the scheme for introducing the "normal number" to the United Kingdom. This was embodied in the bills of Sir Robert Anstruther and Sir Harcourt Johnstone (1876). No new licences were to be granted till the number had been reduced to 1 in 500 of the population in towns, and 1 in 300 in country districts. At present the proportion is 1 to 173 of the population in towns in England and Wales. It seems impossible to determine any such proportion *ab ante*. Even were it possible, the rough classification of towns by population, and the failure to discriminate between various rural districts, would result in great injustice. In Mr Cowen's bill of 1877 and Lord Colin Campbell's bill of 1882 it was proposed to have in each locality a separate licensing board elected annually by the ratepayers. This proposal sins against the recognized principle in the reform of local government that authorities must be consolidated, not multiplied. The select committee of 1879 suggested that the function of licensing might be entrusted to the proposed representative county boards.

Another scheme, which has the advantage of appealing to modern experience in Europe, was contained in Sir Robert Anstruther's bills of 1872 and 1874 and Mr Chamberlain's bill of 1877. These were all modifications of the Gothenburg system, which Mr Carnegie, a Scotch brewer in Gothenburg, has done much to make known in the United Kingdom. In Sweden, prior to 1855, there was absolute free trade in liquor. The General Licensing Act, passed in that year, gave power to local authorities, subject to confirmation by the provincial governor, to fix annually the number of licences, and to sell them for three years on certain conditions. If a company, or "bolag," were formed for the purpose of taking all the licences, the local authority might contract with the company for three years. The Act did not apply to beer. The result of this Act has been twofold. In rural districts almost no licences have been issued. In towns, on the other hand, drinking has increased of late, and has led to the severe police laws of 18th September 1874 and 15th October 1875. In 1866 Gothenburg set the example of transferring the whole public-house traffic to a bolag, which undertakes to appropriate no profit

[1] See Cooley, *On Constitutional Limitations*, and *On Taxation*, p. 403; Dillon, *On Municipal Corporations*, i. p. 392; and the recent case of Boyd *v.* Bryant, 37 Amer. Rep. 6. In some States it has been attempted to prohibit indirectly by raising enormously the licence fee. The subject is frequently before the courts, and it is decided that where the licensing power is given for revenue purposes there is no limit to the discretion of the licensing authority, but where it is given for purposes of regulation the fee should not exceed the expense of issuing the licence and inspecting and regulating the licensed trade.

from the business, but to conduct its establishments in the interest of temperance and morality, and to pay over to the municipality the profits made beyond a fair interest on capital. This experiment has been a great financial success, and if developed will relieve the town from the greater part of its local taxation. The example has been followed by every town in Sweden having a population above 5000; and in 1877, after long discussion, it was adopted in Stockholm, the capital, where the number of life licences presented unusual difficulties. Mr Chamberlain proposed that the work done by the Swedish bolag should be attempted by town councils in the United Kingdom. For this purpose he asked power to acquire the freehold of all licensed premises and the interests of the licence holders. The business would then be carried on by the town council, the profits being carried to the credit of the education and poor rates. The powers of the licensing justices would cease on the adoption of the scheme by the town council. The select committee of 1879 recommended that legislative facilities should be given for the adoption of this scheme. It is doubtful, however, if the burden would be generally submitted to, except on the understanding that the local rates would be *pro tanto* diminished; and, were this realized, the tendency would be to support the municipality on the liquor trade by extending its operations.

The great mass of opinion in the United Kingdom, however, seeks some modification of the present licensing system. That system is extremely complicated. The wholesale licences are granted by the excise without a magistrate's certificate, but for nearly all retail licences such a certificate is required. Generally, the magistrates have absolute discretion as regards licences to sell *on* the premises, but in England a licence to sell *off* the premises can be refused only for one or more of the following reasons—no satisfactory evidence of good character, disorderly house, previous forfeiture of licence by misconduct, want of legal qualification. The English law is contained in the Wine and Beerhouse Act 1869, and the Licensing Act 1872 and 1874.[1] The great features of the legislation of 1872 were (1) the introduction of a confirming authority (viz., the licensing committee in counties and the whole magistrates in burghs) for the purpose of restricting the issue of new licences; (2) the qualification of annual value in public-house premises for the purpose of raising the character of those engaged in the trade; (3) the new regulations for closing; (4) the new regulations of police penalties, especially with reference to the endorsement of convictions on the licence and the forfeiture of the licence. The Act of 1874 abolished the necessity of confirmation in the case of "off" licences, gave the magistrates absolute discretion as regards the endorsement of convictions, and removed from magistrates all discretion as regards closing hours. There are not many peculiarities in the licensing law of Ireland. Public-house licences are generally held by shopkeepers, and no qualification of value is required except in the case of beerhouses. Mr Meldon's Act of 1877 (37 & 38 Vict. c. 69) closed public-houses on Sunday. In Scotland prior to 1853 licences were regulated by the Home-Drummond Act (9 Geo. IV. c. 58), which authorized only one form of certificate for "common inns."[2] In 1846 a select committee reported that the combination of the grocer trade with the sale of spirits to be consumed on the premises was productive of evil to the working classes. This led to the Forbes Mackenzie Act of 1853, which was amended in 1862, upon the report of a royal commission in 1860 (16 & 17 Vict. c. 67; 25 & 26 Vict. c. 35). It created three licences—(1) for hotels, (2) for public-houses, (3) grocers' licences. Under the hotel licence intoxicating liquors may be sold to lodgers and travellers. On Sundays the public-houses are closed, and on week days the sale is practically limited to the period between 8 A.M. and 11 P.M. Cameron's Act of 1876 (39 & 40 Vict. c. 26) makes the refusal of a certificate by the magistrate final, and in the case of a new licence requires the confirmation of a county licensing committee or in burghs of a joint committee of magistrates and justices.

Information on this subject is to be found chiefly in the *Reports* of royal commissions and select committees. It has been much discussed at the meetings of the Social Science Association, and there is a large literature of pamphlets and magazine articles, to which, among many others, Lord Sherbrooke, Mr Chamberlain, and Mr Arthur Arnold have contributed. The reports of the various international congresses "pour l'étude des questions relatives à l'alcoolisme," may be studied with advantage. See also Metman's *Études sur les Legislations Européennes relatives aux débits de boissons alcooliques*, Paris, 1879. (W. C. S.)

[1] 32 & 33 Vict. c. 27; 35 & 36 Vict. c. 94; 37 & 38 Vict. c. 49.

[2] So also the first English Act, 5 & 6 Edw. VI., provided one form of licence for "alehouses."

LISBON (Portuguese, *Lisboa*), the capital of the kingdom of Portugal, is situated in 38° 42′ N. lat. and 9° 5′ W. long., on the northern bank of the Tagus (*Tejo*), at the spot where the river broadens to a width of 9 miles, some 8 or 9 miles from the point where it enters the Atlantic. Standing on a range of low hills, backed by the lofty granite range of Cintra, and extending along the margin of the wide Tagus, Lisbon wears a very noble aspect to those who approach it from the sea. In regard to beauty of position it may rightly claim to be the third of European cities, Constantinople and Naples alone ranking before it. The river affords secure anchorage for a very large number of vessels, and the bar at the mouth is easily crossed even in rough weather. Like London, Paris, and Vienna, Lisbon stands in a geological basin of Tertiary formation. The upper portion consists of loose sand and gravel destitute of organic remains, below which is a series of beds termed by Mr Daniel Sharpe the Almada beds, composed of yellow sand, calcareous sandstone, and blue clay, rich in marine remains. The greater part of Lisbon stands on those beds which belong to the older Miocene epoch, and are nearly of the same age as those of Bordeaux. Next comes a conglomerate without fossils. These Tertiary deposits, which cover altogether an area of more than 2000 square miles, are separated, near Lisbon, from rocks of the secondary epoch by a great sheet of basalt which covered the Secondary rocks before any of the Tertiary strata were in existence. The uppermost of the Secondary deposits is the Hippurite Limestone, which corresponds to a part of the Upper Chalk of northern Europe. The narrow valley of Alcantara, in the immediate neighbourhood of Lisbon, has been excavated in this deposit; and here there are extensive quarries, where abundance of its peculiar shells may be collected.[3]

Lisbon stretches along the margin of the river for 4 or 5 miles, and extends northward over the hills for nearly 3 miles, but much of it is scattered amongst gardens and fields. In the older parts the streets are very irregular, but that portion which was rebuilt after the great earthquake of 1755 consists of lofty houses arranged in long straight streets. Here are the four principal squares, the handsomest of which, the Praça do Commercio, is open on one side to the river, and on the other three is surrounded by the custom-house and Government offices, with a spacious arcade beneath. In the middle is a bronze equestrian statue of Joseph I., in whose reign the earthquake and restoration of the city took place. At the middle of the north side is a grand triumphal arch, under which is a street leading to another handsome square, the Rocio or Praça do Dom Pedro (built on the site of the Inquisition palace and prisons), where stands the theatre of D. Maria II. The houses are for the most part well built, and are divided into flats for the accommodation of several families. The streets had formerly a bad reputation in regard to cleanliness, but of late years great improvement has taken place in this respect, although no general system of drainage has yet been adopted. They are lighted with gas made from British coal. The public gardens, five in number, are small, but are much frequented in the evenings. The city contains seven theatres and a bull ring. The hotels of Lisbon offer but indifferent accommodation to

[3] After careful investigation, Mr Sharpe discovered that the greatest force of the earthquake of 1755 was expended upon the area of the above-mentioned Almada blue clay, and that not one of the buildings standing upon it escaped destruction. Those upon the slopes of the hills immediately above the clay suffered very severely, and all on the Tertiary strata were more or less injured, whilst none of the buildings on the hippurite limestone or the basalt suffered any damage whatever,—the line at which the earthquake ceased to be destructive corresponding exactly with the boundary of the Tertiary beds.

strangers; the shops present little display, and are ill furnished with wares. The markets are tolerably well supplied with meat, fish, and country produce. A large quantity of excellent fruit is brought in for sale during the season.

The king usually resides at the palace of Ajuda, situate on a hill above the suburb of Belem. It is in the Italian style, and was intended to be one of the largest palaces in Europe, but it has been left incomplete. It contains a large library, a collection of pictures, and a numismatic cabinet. There is another royal palace at Lisbon (that of the Necessidades), where former monarchs were wont to reside; and in the neighbourhood of the city are numerous others. Several of the nobility have good and spacious houses in the city, which are dignified with the name of palaces. The houses of the British residents are mostly to be found in the elevated district called Buenos Ayres.

Two or three small forts, one on a rock at the mouth of the Tagus, afford a very inadequate defence against the attacks of a hostile fleet. In ascending the river the picturesque Tower of Belem, built about the end of the 15th century, is seen on the north bank close to the water's edge. On a rocky hill stands the citadel of St George, surrounded by the most ancient part of Lisbon, composed of narrow tortuous streets, still retaining its old Moorish name, Alfama. The chief naval and military arsenals of the kingdom are at Lisbon. Attached to the former are a naval school and a hydrographical office. Here also is a museum of colonial products. In various parts of the city are barracks for the accommodation of the

FIG. 1.—Plan of Lisbon.

troops and for the municipal guard. The churches are numerous, but are nearly all in the same tasteless Italian style; the interiors, overlaid by heavy ornament, contain pictures utterly devoid of merit. The cathedral is gloomy without being grand, but the oldest part behind the high altar may deserve inspection. The largest church in the city is St Vincent's, 222 feet by 82. The large adjacent convent is now the residence of the cardinal patriarch. In a modern chapel attached to the church the coffined corpses of the monarchs of the house of Braganza are deposited, and the public are admitted to see them on certain days in the year. Perhaps the most striking church in Lisbon itself is that of the Estrella, with a dome commanding an extensive view, and two towers, the whole design reminding the visitor of St Paul's, London. At St Roque is the famous chapel of St John the Baptist, designed by Vanvitelli, and made at Rome for King John V., who had been enriched by the discovery of the gold and diamond mines in Brazil. Before being sent to Portugal it was set up in St Peter's, and Benedict XIV. celebrated the first mass in it. It is composed of precious marbles with mosaics and ornaments in silver and bronze, and is said to have cost upwards of £120,000. By far the most interesting architectural object at Lisbon is, however, the unfinished Hieronymite church and monastery at Belem. The church was begun in 1500 near the spot where Vasco da Gama had embarked three years before on his famous voyage to India. The style is a curious mixture of Moorish Gothic and Renaissance, with beautiful details. The English college was founded in 1628 for the education of British Roman Catholics; and the Irish Dominicans have a church and convent originally established for the education of youths intended for the priesthood. Ecclesiastically Lisbon is a patriarchate, the holder of the dignity being at the head of the clergy of the kingdom, and president of the chamber of peers. He is usually made a cardinal.

The two chambers of parliament hold their sittings in a huge building, formerly the monastery of St Bento, to which a handsome façade has been added. New and ornamental buildings have been erected for the courts of justice and the municipal chamber. The mint is fitted up with steam machinery on a small scale for coining gold, silver, and copper. Postage stamps and inland revenue stamps are printed at this establishment. The national astronomical observatory is near the Ajuda palace, and the meteorological observatory is at the Polytechnic school, which also contains the national museum of natural history. Here is a good collection of the birds of Portugal, with collections in other branches of the zoology of Portugal and the Portuguese possessions in Africa—minerals, fossils, &c. The fossils collected by the Geological Commission to illustrate the geology of the kingdom are preserved in the sequestrated Convento do Jesus.

Lisbon is singularly destitute of works of high art. The gallery of the Academy of Fine Arts contains only a few pictures worth notice. In the custody of the academy is an interesting assemblage of gold and silver plate taken from suppressed monasteries. There is also a collection of pictures at the Ajuda palace. At the Carmo church is an archæological museum. The great national library consists for the most part of old theological works and ecclesiastical histories swept out of various suppressed monasteries, and has a collection of 24,000 coins with some Roman bronzes. The Portuguese take little interest in literature, art, or science, and almost everything connected with them is in a neglected state. Literary and scientific societies are few in number and badly supported, the principal one being the Royal Academy of Sciences, founded in 1779. The national printing office, a Government establishment, turns out creditable work, but the booksellers' shops are few and ill-stocked. Eight or ten daily journals are published in Lisbon, and there are a few weekly newspapers, besides periodicals appearing at longer intervals, and chiefly devoted to special interests.

Several cemeteries have been constructed of late years near Lisbon, the practice of interring in churches having been abandoned. In the English cemetery lies the English novelist Fielding, who died here in 1754; a marble sarcophagus with a long Latin inscription covers his remains. The British residents maintain a chaplain who performs service regularly in an adjacent chapel, and the Scottish Presbyterians have also a place of meeting. The great hospital of S. José contains beds for nine hundred patients, and the large lunatic asylum has accommodation for four hundred patients. The Foundling Hospital takes in more than two thousand children annually. At Belem is an excellent establishment where a large number of male orphans and foundlings are fed, clothed, educated, and taught various trades. The Lazaretto is a vast building on the south side of the Tagus, where one thousand inmates can be received at one time.

Lisbon is connected by railway with Madrid, and there is also a line northward to Coimbra and Oporto, as well as lines southward to Setubal, Evora, and Beja. Submarine cables connect it with England and with Brazil. There is communication by regular lines of steamers with the Portuguese islands in the Atlantic and the colonies in Africa, and with a great number of ports in Britain, continental Europe, and other parts of the world. Lisbon is the largest port in the kingdom, and its custom-house is a spacious and very substantial fire-proof building worthy of any capital in Europe, in which merchants are allowed to deposit their goods free of duty for a year, or for two years in the case of Brazilian produce. The duties annually collected here exceed £1,150,000, tobacco alone producing £400,000. Upwards of 1400 foreign vessels, and about 1100 Portuguese ships, including coasters, enter the port annually. The annual imports amount to about £5,600,000, and the exports to £4,500,000. A considerable number of foreign merchants reside in Lisbon, and there are about fifty British firms. The most active commerce is carried on with Brazil and Great Britain, tropical produce being

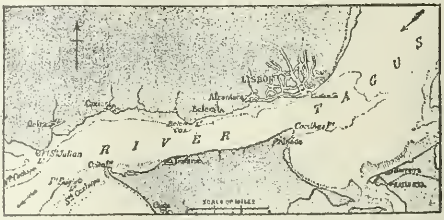

Fig. 2.—Port of Lisbon.

imported from the one, and manufactured goods from the other, while wine and oil are sent to both in return. The wine for exportation is all made and stored outside the city bounds, so as not to be subject to the octroi duty. There are several joint-stock banks, one of them being British (the New London and Brazilian Bank), as well as private bankers. Manufactures are carried on only to a limited extent. The largest establishment by far is the tobacco manufactory, where 1600 persons are employed, and three millions of pounds are annually manufactured.

The chief supply of water for the use of the city is brought by an aqueduct 9 miles in length, from springs situated on the north-west. This work, one of the boasts of Lisbon, was completed in 1738, and was so well executed that the great earthquake did it no injury. It crosses the Alcantara valley on thirty-five arches, the principal one being 263 feet above its base, with a span of 110 feet. On reaching the city the water is conducted into a covered massive stone reservoir, which an inscription styles "urbis ornamentum orbis miraculum," and thence it flows to the fountains, thirty-one in number, distributed throughout the city. From these fountains it is removed in barrels to the houses by "Gallegos," men from Galicia, who do the principal part of the hard work in Lisbon. Although there are two other reservoirs near the city, the supply of water is insufficient for the requirements of the place during the warm season.

For municipal purposes the city is divided into four districts (*barros*), the whole under one municipal chamber, and two suburban districts under separate chambers. The city chamber consists of twelve members elected by the burgesses every two years. Its revenue is about £75,000. The octroi duties, levied on provisions and fuel entering the city, are collected on account of the Government, and exceed £270,000 a year. The police force is paid by the Government, and consists of the municipal guard, a military force of cavalry and infantry under the orders of the home secretary, and a body of ordinary policemen at the orders of the civil governor, an official appointed by Government. According to the census of 1878 the population in the thirty-nine parishes of the city and suburbs was 253,000.

Climate.—Notwithstanding the mildness of the climate, Lisbon is not considered a healthy place of residence, owing chiefly to the defective sanitary arrangements. The annual death-rate is 36 per thousand. The deaths are said to exceed the births, and the population would therefore decrease were the city not continually recruited from the country. To chest invalids it is not by any means to be recommended as a winter resort, on account of the frequent and rapid changes of temperature to which it is subject. These changes, and the great difference between the temperature of sun and shade during the winter and spring, are dangerous to the delicate. In summer the heat is great, and all who have the means betake themselves during that season to Cintra or to the seaside. The following data, deduced from twenty years' observations (1856 to 1875) taken at the Meteorological Observatory, a well-managed institutio which stands 335 feet above the level of the sea, will afford the means of judging the climate in its principal features. Mean annual temperature of shade, 60°·37 Fahr.; mean annual range, 61°·2; mean daily range, 12°·6; highest and lowest registered during the whole period, 98°·8 and 30°·3. Mean annual quantity of rain, 28·84 inches; greatest and least annual quantity during the period, 38·8 inches (1865) and 17·22 inches (1874). The rainfall of 1876, however, amounted to 45 inches, more than one-third of which fell in the mouth of December. The mean annual number of days on which rain fell was one hundred and twelve, whilst snow fell only three times during the twenty years. The mean atmospheric moisture (100 = saturation) was 70·89. The mean annual height of the barometer was 29·8 inches, and its mean annual range 1·3 inches. The prevailing winds of the winter and autumn are from the north, of the spring and summer from the north-north-west.

History.—The name Lisbon (Portuguese, *Lisboa*) is a modification of the ancient name Olisipo, also written Ulyssippo under the influence of a mythical story of a city founded by Ulysses in Iberia, which, however, according to Strabo, was placed by ancient tradition rather in the mountains of Turdetania. Under the Romans Olisipo became a municipium with the epithet of Felicitas Julia, but was inferior in importance to the less ancient Emerita Augusta (Merida). After the Romans the Goths and the Moslems successively became masters of the town and district. Under the latter the town bore in Arabic the name of Lashbûna or Oshbûna. It was the first point of Moslem Spain attacked by the Normans in the invasion of 844. When Alphonso I. of Portugal took advantage of the decline and fall of the Almoravid dynasty to incorporate the provinces of Estremadura and Alemtejo in his new kingdom, Lisbon was the last city of Portugal to fall into his hands, and yielded only after a siege of several months (21st October 1147), with the aid of English and Flemish crusaders who were on their way to Syria. In 1184 the city was again attacked by the Moslems under the powerful caliph Abu Ya'kub, but the enterprise failed. In the reign of Ferdinand I., the greater part of the town was burned by the Castilian army under Henry II. (1373), and in 1384 the Castilians again beseiged Lisbon, but without success. Lisbon became the seat of an archbishop in 1390, the seat of government in 1422. It gained much in wealth and splendour from the maritime enterprises that began with the voyage of Vasco da Gama (1497). The patriarchate dates from 1716. From 1586 to 1640 Lisbon was a provincial town under Spain, and it was from this port that the Spanish Armada sailed in 1588. In 1640 the town was captured by the duke of Braganza, and the independence of the kingdom restored. For many centuries the city had suffered from earthquakes, of more or less violence, but these had been almost forgotten when, on the 1st of November 1755, it was reduced almost in an instant to a heap of ruins. A fire broke out to complete the work of destruction, and between 30,000 and 40,000 persons lost their lives. Pombal, an unscrupulous minister, but a man of great talent, applied himself with unremitting energy both to the protection of the rights of property (for the place was infested by bands of robbers) and to the reconstruction of the buildings. The handsomest part of the present city was erected under his direction, but even to this day there are edifices which speak forcibly of the great earthquake. In 1807 Napoleon proclaimed that the house of Braganza had ceased to reign in Europe, whereupon the regent Don John (his mother the reigning queen Maria I. having become insane) thought it prudent to quit the country for Brazil, and next day a French army under Junot entered the city, possession of which he retained for ten months. He then quietly embarked his army under the protection of the inexplicable convention of Cintra so disgraceful to the English generals. In 1859 Lisbon was stricken by yellow fever, and many thousands were carried off before the plague was stayed. Lisbon boasts of having been the birthplace of St Anthony, surnamed of Padua, of Camoens, the national epic poet (to whose honour a bronze statue has been placed in one of the squares), and of Pope John XXI. (J. Y. J.)

LISBURN, a market-town, cathedral city, and municipal and parliamentary borough of Ulster, Ireland, partly in Antrim and partly in Down, is situated in a beautiful and fertile district on the Lagan, and on the Ulster Railway, 8 miles south-south-west of Belfast. It is substantially built, and consists principally of one long and irregular street, in the centre of which there is a large open space for the market. The parish church, which possesses a fine octagonal tower, is the cathedral church of the united dioceses of Down, Connor, and Dromore, and contains a monument to Jeremy Taylor, who was bishop of the see. Among other buildings are the court-house, the market-house, the linen-hall, and the county infirmary. There are a number of charitable foundations. The staple manufacture of the town is linen, specially damasks and muslins. There are also bleaching and dyeing works. The population in 1871 was 9326, and in 1881 it was 10,834.

In the reign of James I. Lisburn, which was then known as Lisnegarvy, was only an inconsiderable village, but in 1627 it was granted by Charles I. to Viscount Conway, who erected the castle for his residence, and laid the foundation of the prosperity of the town by the introduction of English and Welsh settlers. In November 1641 the town was taken by the insurgents, who on the approach of superior numbers set fire to it. The troops of Cromwell gained a victory near the town in 1648, and the castle surrendered to them in 1650. The church was constituted a cathedral by Charles II., from whom the town received the privilege of returning two members to parliament, but since the Union it has returned only one.

LISIEUX, capital of an arrondissement in the department of Calvados, France, 113 miles by rail west-north-west from Paris, and 24 miles as the crow flies east from Caen, is prettily situated on the Touques, at the point where it is joined by the Orbiquet, 24 miles above Trouville. The Paris and Caen Railway has a branch from Lisieux to Honfleur and Trouville, and another to Orbec. The cathedral church, dedicated to St Peter, founded about 1045, and finished in 1233, which has recently been restored, is the most interesting specimen to be found in Normandy of the transition from the Roman to the Ogival style. It is 360 feet in length, 90 in breadth, and 65 in height; the south tower rises to 230 feet. The nave is remarkable for harmony of proportion, purity of design, and unity of style. The church of St Jacques, built at the end of the 15th century, contains some beautiful glass of the Renaissance, some remarkable woodwork and old frescos, and a curious picture on wood, restored in 1681. The old episcopal palace (Lisieux ceased to be a bishopric in 1801) near the cathedral is now used as a court-house and prison. In the court-house is a beautiful hall called the Salle Dorée. The town still retains quaint examples of the wooden houses of the 14th, 15th, and 16th centuries; and there are some elegant modern villas. It also possesses a charming public garden and a small museum. The confluence of the two rivers renders it subject to disastrous inundations; but its commerce and industry cause it, notwithstanding, to rank among the richest towns of Normandy. There is a large cattle trade, and the arrondissement has nearly three hundred factories, employing about ten thousand workmen in the manufacture of cloth and cretonnes. Connected with this industry are numerous spinning-mills, bleach-fields, and dye-works; and there are besides wool-mills, chemical works, tanneries, saw-mills, and the like, which bring up the trade of Lisieux to an annual aggregate of upwards of 50 million francs. The population in 1876 was 18,400.

In the time of Cæsar, Lisieux, by the name of *Noviomagus*, was the capital of the Lexovii. Though destroyed by the barbarians, by the 6th century it had become one of the most important towns of Neustria. Its bishopric is said to date from the 3d or 4th century. In 877 it was pillaged by the Normans; and in 911 we find it included in the duchy by the treaty of St Clair-sur-Epte. Civil authority was exercised by the bishop as count of the town. In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois. The war lasted five years, and reduced Lisieux and its neighbourhood to the direst extremities of famine. In 1152 the marriage of Henry II. of England to Eleanor of Guienne, which added so largely to his dominions, was celebrated in the cathedral. Thomas à Becket took refuge here, and some vestments used by him are still shown in the hospital chapel. Taken by Philip Augustus and reunited to France in 1203, the town was a frequent subject of dispute between the contending parties during the Hundred Years' War, the religious wars, and those of the League, Among the bishops of Lisieux may be mentioned Nicholas Oresme, who died in 1382, and Pierre Cauchon, the judge of Joan of Arc, who occupied this see after he had been driven from that of Beauvais.

LISKEARD, anciently LISCARRET, a market-town and municipal and parliamentary borough in the county of Cornwall, England, is picturesquely situated, partly in a hollow and partly on a rocky eminence, 12 miles east of Bodmin, and 265 west-south-west of London by rail. The church of St Martin, in the Perpendicular style, with a tower of earlier date which possesses a Norman arch, is the largest ecclesiastical building in the county, except the church of Bodmin. A town-hall in the Italian style was erected in 1859. A grammar school was founded at a very early period, and there are several other schools and charities. There are manufactures of leather, but the prosperity of the town is dependent chiefly on agriculture, and the neighbouring tin, lead, and copper mines. Liskeard returns one member to parliament. It received its first charter in 1240, from Richard, earl of Cornwall, brother of Henry III., but its principal charter in 1586, from Queen Elizabeth. The population of the municipal borough (area 810 acres) in 1871 was 4700, and in 1881 it was 4479, that of the parliamentary borough (area 8387 acres) in the same years being 6576 and 5591.

LISLE, JOSEPH NICOLAS DE (1688–1768), astronomer, was born at Paris on April 4, 1688, and was educated at the Collége Mazarin. His devotion to astronomy dates from 1706, in which year he carefully observed an eclipse of the sun. In 1714 he was admitted to the Academy of Sciences, and in 1720 he made the proposals for determining the figure of the earth, which were carried out under the auspices of that body some years afterwards. In 1724 De Lisle visited England, where, through Newton and Halley, he was received into the Royal Society, and in 1726 he accepted an invitation from Catherine I. to the chair of astronomy in the Imperial Academy of Sciences at St Petersburg. In 1747 he returned to Paris, and was allowed a very imperfect observatory in the Hôtel Cluny, where Messier and Lalande were among his pupils. In 1753, previous to the transit of Mercury, he published a map of the world representing the effect of that planet's parallaxes in different countries, and in 1754 he was made geographical astronomer to the naval department. In 1762 he resigned in favour of Lalande, and withdrew to the abbey of Sainte Geneviève, where he died of apoplexy on September 11, 1768.

Besides numerous papers contributed to the *Transactions* of the Academies of Paris, Berlin, and St Petersburg, he wrote *Mémoires pour servir à l'histoire et aux progrès de l'Astronomie, de la Géographie, et de la Physique* (St Petersburg, 1738), *Eclipses circumjovialium, ad annos* 1734, 1738, *et menses priores* 1739 (Berlin, 1734), and *Mémoire sur les nouvelles découvertes au nord de la mer du Sud* (Paris, 1752–53). See ASTRONOMY, vol. ii. p. 757.

LISMORE, an island of 9600 acres, about 10 miles long and averaging 1½ miles broad, with a population in 1881 of 630, lying south-west and north-east at the entrance of the Linnhe Loch in Argyllshire, Scotland. The name means the great enclosure (whether "garden," as the Scotch, or "fort," as the Irish authorities suppose, is uncertain), and occurs in Ireland in the Waterford Lismore and ten other places. "Lis" is one of the most frequent words in compound Irish names, there being one thousand four hundred townlands or villages which begin with it. A Columban monastery was founded there by St Moluag about 592 (Reeves, *Adamnan*, p. 34), whose bell is perhaps that found in 1814 at Kilmichael Glassary,[1] and whose crozier or staff is in the possession of the duke of Argyll.[2] About 1200 the see of Argyll was separated from Dunkeld by Bishop John "the Englishman," and Lismore soon after became the seat of the bishop of Argyll, sometimes called "Episcopus Lismoriensis" (Skene, *Celtic Scotland*, ii. p. 408 *sq.*), quite distinct from the bishop of the Isles (Sudreys and Isle of Man), called "Episcopus Sodoriensis" or "Insularum," whose see was divided into the English bishopric of Sodor and Man and the Scottish bishopric of the Isles in the 14th century (Keith's *Catalogue*, p. 173). The monastic establishment of Lismore, at one time consisting of Culdees (Reeves, *Culdees*, p. 49), was converted into a chapter of canons regular and a dean, whose right to elect the bishop was recognized as early as 1249 (Baluze, *Miscel.*, vii. p. 442; *Orig. Paroch. Scot.*, ii. pt. 1, p. 161).

Lismore has an accidental celebrity from the *Book of the Dean of Lismore*, a MS. collection of poems, Gaelic and English, made by James M'Gregor, vicar of Fortingall and dean of Lismore (1514–51). A selection of the Gaelic poems, with translations by Rev. T. M'Lauchlan, and introduction by Mr W. F. Skene, published 1862, is of value both for the language and the contents. The language is the Gaelic of the West Highlands, spelt phonetically, as spoken in the beginning of the 16th century, and its variations from ancient Irish on the one hand and modern Gaelic on the other are of much interest to Celtic scholars. Its contents are Ossianic fragments, some of Irish, others of Scotch origin, and a few more recent Gaelic verses. The publication of this work, and J. F. Campbell of Islay's collection from oral sources of the existing traditional Gaelic poetry, have for the first time given a genuine historical solution of the Ossianic problem (see OSSIAN). There are remains of three castles on Lismore:—at Tireforr a fort of two concentric circles of dry stones, supposed to be Norse or Danish; at Achindown a square keep with walls 40 feet high, believed to be the palace of the bishop; and on the west side of the island Castle Coffin, mentioned in a grant to Campbell of Glenurqhay in 1470 (*Orig. Par. Sc.*, ii. p. 109).

LISMORE, a market-town and seat of a diocese, partly in Cork but chiefly in Waterford, Ireland, is beautifully situated on a steep eminence rising abruptly from the Blackwater, 40 miles west-south-west of Waterford. At the verge of the rock on the western side is the old baronial castle, erected by King John in 1185, which was the residence of the bishops till the 16th century. It was besieged in 1641 and 1643, and in 1645 it was partly destroyed by fire. To the east, on the summit of the height, is the cathedral of St Carthagh, erected in 1663 by the earl of Cork, in the Later English style, with a square tower surmounted by a tapering spire. There are a grammar school, a free school, and a number of charities. Some trade is carried on by means of the river, and there is a salmon fishery. The population of the town in 1871 was 1946.

The original name of Lismore was Maghsciath. Its present name was derived from a monastery, founded by St Carthagh in 633, which became so celebrated as a seat of learning that it is said no less than twenty churches were erected in its vicinity. In the 9th and beginning of the 10th centuries the town was repeatedly plundered by the Danes, and in 978 the town and abbey were burned by the Ossorians. Henry II., after landing at Waterford, received in Lismore castle the allegiance of the archbishops and bishops of Ireland. In 1518 the manor was granted to Sir Walter Raleigh, from whom it passed to Sir Richard Boyle, afterwards earl of Cork. From the earls of Cork it descended by marriage to the dukes of Devonshire. It was incorporated as a municipal borough in the time of Charles I., when it also received the privilege of returning members to parliament, but at the Union it was disfranchised, and also ceased to exercise its municipal functions. Lismore is the birthplace of Robert Boyle, but its claim to be the birthplace of Congreve does not rest on a sufficient foundation.

LISSA (in Polish, *Leszna*), a manufacturing town in the circle of Fraustadt, district of Posen, Prussia, is situated on the Breslau and Posen Railway, near the frontier of Silesia. The most prominent buildings are the handsome château, the mediæval town-house, the three churches, and the synagogue. Its manufactures consist chiefly of cloth, liqueurs, tobacco, and wax; it also

[1] Anderson, *Scotland in Early Christian Times*, 1st ser., p. 206, where it is figured.

[2] See *Orig. Paroch. Scot.*, where it is figured.

possesses several tanneries and a large steam flour-mill, and carries on a brisk trade in grain, cattle, spirits, wine, and furs. The population in 1880 was 11,758, including 3810 Roman Catholics and 1833 Jews.

Lissa owes its origin to a number of Moravian Brothers from Bohemia, who were banished by the emperor Ferdinand I. in the 16th century, and found a refuge on the estate of the Polish family of Leczynski. Their settlement received municipal rights in 1548. During the Thirty Years' War the population was reinforced by other refugees, and Lissa became an important commercial town, and the chief seat of the Moravian Brothers in Poland. COMENIUS (*q.v.*) was long rector of the celebrated Moravian school there. Lissa was twice burned down (in 1656 and 1707) during the Swedish and Polish wars.

LISSA (Lat., *Issa*; Slav., *Vis*), an Austrian island in the Adriatic, 9 miles long, with a greatest breadth of 4 miles, is situated 41 miles from the coast of southern Dalmatia, almost due west of the mouth of the Narenta, in 43° 1′ N. lat. and 16° 6′ E. long. "The shape is a long parallelogram with two breaks, the Porto di S. Giorgio (one of the finest harbours of refuge in the Adriatic) on the eastern short side, and the Vallone di Comisa contained between two long prongs stretching due west and south-west. The outer walls are stony ridges rising from 470 to 610 feet above sea-level, and declining quaquaversally to the fertile plateau which, averaging 400 feet high, forms the body of the island. The apex is Monte Hum, a bald and flattened cone (1868 feet) on the south-west" (Burton). Wine-growing (for which Issa was famous of old) still forms the principal means of subsistence, an average season yielding from 70,000 to 80,000 barrels; but the sardine fishery (15,000 to 25,000 barrels per annum) is of growing importance, and the peasants distil about 24,000 ℔ of rosemary oil annually. The island is divided into two communes, Lissa and Comisa. In the former is the chief town, Lissa, with the palace of the old Venetian counts Gariboldi, the former residence of the English governor, the monastery of the Minorites, and at a little distance to the west the ruins of the ancient city of Issa. The population, 6485 in 1869, was 7871 in 1880.

Issa is said to have been settled by people from Lesbos, the Issa of the Ægean. The Parians, assisted by Dionysius the Elder of Syracuse, introduced a colony in the 4th century B.C. During the First Punic War the Issæans with their beaked ships helped the Roman Duilius; and the great republic, having defended their island against the attacks of Agron of Illyria and his queen Teuta, again found them faithful and serviceable allies in the war with Philip of Macedon. As early as 996 we find the Venetians in possession of the island, and, though they retired for a time before the Ragusans, their power was effectually established in 1278. Velo Seto, which by that time had become the chief settlement, was destroyed by Ferdinand of Naples in 1483, and by the Turks in 1571. The present city arose shortly afterwards. During the Napoleonic wars Lissa was occupied by the French, but the English defeated their squadron in 1810, and kept possession of the island till July 1815, erecting fortifications (dismantled in 1870) and making it a centre of operations. In 1866 the Italians under Persano made an attack on Lissa, but were defeated by the Austrians under Tegetthoff—the battle being fought about 10 miles north of the harbour.

See Wilkinson (1848); Neale (1861); Brackenbury, in the *Times*, August 14, 1866; *Revue marit. et col.*, 1867; and Burton in *Journ. Roy. Geog. Soc.*, 1879.

LISTON, JOHN (1776–1846), comedian, was the son of a watchmaker in Soho, London, where he was born in 1776. While the teacher of a day school near Leicester Square, he began to take part in private theatricals, and soon conceived a passion for the stage. He made his début at a small theatre in the Strand, and shortly afterwards obtained an engagement at Dublin theatre, where, although he adopted tragedy as his role, his natural talent for acting attracted the attention of Stephen Kemble, who engaged him for his theatre at Newcastle-on-Tyne. Discovering accidentally that his forte was not tragedy but comedy, Liston displayed in his personation of old men and country boys a fund of drollery and humour which proved irresistible. An introduction to Charles Kemble led to his appearance at the Haymarket in 1805 as Zekiel Homespun, and from this time he occupied an unrivalled position in his own line of performance. His broad humour being tempered by true artistic finish, while he possessed an original power of creation which, with his boundless faculty in the elaboration of absurdities, filled up meagre and commonplace outlines with the characteristics of vivid individuality. Paul Pry, first represented in 1825, and always his most popular part, soon became to many a real personage. Liston played successively at Covent Garden, Drury Lane, and the Olympic, and remained on the stage till almost the close of his life. He died March 22, 1846.

LISTON, ROBERT (1794–1847), an eminent Scottish surgeon, was born on the 28th of October 1794, at Ecclefechan, where his father was parish minister. He commenced the study of anatomy under Dr Barclay in Edinburgh University in 1810, and soon became a skilful anatomist. After eight years' study, he began his career as a lecturer on anatomy and surgery in the Edinburgh School of Medicine; and in 1827 he was elected one of the surgeons to the Royal Infirmary. In 1835 he was invited to fill the chair of clinical surgery in University College, London. He held the appointment until his death, on the 7th of December 1847. Liston was a teacher more by what he did than by what he said. He taught simplicity in all operative procedures; fertile in expedients, of great nerve, and of powerful frame, his name is remembered at the present day as a bold and rapid operator. He inspired all around with confidence, and every one present at his operations felt that the knife in his hands, however rapidly he worked, was guided with skill founded upon knowledge. He was the author of *The Elements of Surgery* and *Practical Surgery*, and made several improvements in methods of amputation, and in the dressing of wounds.

LITANY. This word (λιτανεία), like λιτή (both from λίτομαι), is used by Eusebius and Chrysostom, most commonly in the plural, in a quite general sense, to denote a prayer, or prayers, of any sort whatever, whether public or private; it is similarly employed in the law of Arcadius (*Cod. Theod.*, xvi. tit. 5, leg. 30), which forbids heretics to hold assemblies in the city "ad litaniam faciendam." But some trace of a more technical meaning is found in the epistle (*Ep.* 63) of Basil to the church of Neocæsarea, in which he argues, against those who were objecting to certain innovations, that neither were "litanies" used in the time of Gregory Thaumaturgus. The nature of the recently introduced litanies, which must be assumed to have been practised at Neocæsarea in Basil's day, can only be vaguely conjectured; probably they had many points in common with the "rogationes," which, according to Sidonius Apollinaris, had been gradually coming into occasional use in France about the beginning of the 5th century, especially when rain or fine weather was desired, and which, so far as the three fast days before Ascension were concerned, were first definitely fixed, for one particular district at least, by Mamertus or Mamercus of Vienne (*c.* 450 A.D.) We gather that they were penitential and intercessory prayers offered by the community while going about in procession, fasting, and clothed in sackcloth. Sidonius alludes to the incongruity of men going "castorinati ad litanias." In the following century the manner of making litanies (litanias facere) was to some extent regulated for the entire Eastern empire by one of the *Novels* of Justinian, which forbade their celebration without the presence of the bishops and clergy, and ordered that the crosses (which were carried about in procession) should not be deposited elsewhere than in churches, nor be carried by any but such persons as were duly appointed to do so. The first synod of Orleans (511 A.D.) in its twenty-seventh canon enjoins for all Gaul that the "litanies" before Ascension be celebrated for three days; on these days all menials are to be exempt from work, so that every one may be free to attend divine service. The diet is to be the same as in Quadragesima; clerks not observing these rogations are to be punished by the bishop. In 517 A.D. the synod of Gerunda provided for two sets of "litanies"; the first were to be observed for three days (from Thursday to Saturday) in the week after Pentecost with fasting, the second for three days from November 1. A synod of Paris (573) in its tenth canon ordered litanies to be held for three days at the beginning of Lent, and the fifth synod of Toledo (636) appointed litanies to be observed throughout the kingdom for three whole days from December 14. The first mention of the word litany in connexion with the Roman Church goes back to the pontificate of Pelagius I. (555), but implies that the thing was at that time already old. In 590 Gregory I., moved by the pestilence which had followed an inundation, ordered a "litania septiformis," that is to say, a sevenfold procession of clergy, laity, monks, virgins, matrons, widows, poor, and children. He is said also to have appointed the processions or litanies of April 25 (St Mark's day), which seem to have come in the place of the ceremonies of the old Robigalia. In 747 the synod of Cloveshoe (can. 16 and 17) ordered the litanies or rogations to be gone about by all the clergy and people with great reverence,—on April 25 "after the manner of the Roman Church," and on the three days before Ascension "after the manner of our ancestors." The latter are still known in the English Church as Rogation Days. Games, horse racing, junkettings were forbidden; and in the litanies the name of Augustine was to be inserted after that of Gregory. The reforming synod of Mainz in 813 ordered the major litany to be observed by all for three days, not with horses or in magnificent attire, but in sackcloth and ashes, and barefoot. The sick only were exempted from this command.

As regards the form of words prescribed for use in these "litanies" or "supplications," documentary evidence is somewhat defective. Sometimes it would appear that the "procession" or "litany" did nothing else but chant "Kyrie eleison" without variation. There is no reason to doubt that from an early period the special written litanies of the various churches all showed the common features which are now regarded as essential to a litany, in as far as they consisted of (1) invocations, (2) deprecations, (3) intercessions, (4) supplications. But in details they must have varied immensely. The offices of the Roman Catholic Church at present recognize two litanies, the "Litaniæ majores" and the "Litaniæ breves," which differ from one another chiefly in respect of the fulness with which details are entered upon under each of the four heads mentioned above. It is said that in the time of Charlemagne the angels Orihel, Raguhel, Tobihel were invoked, but the names were removed by Pope Zacharias as really belonging to demons. In some mediæval litanies there were special invocations of S. Sapientia, S. Fides, S. Spes, S. Charitas. The major litanies, as given in the Breviary, are at present appointed to be recited on bended knee, along with the penitential psalms, in all the six week days of Lent when ordinary service is held. Without the psalms they are said on the feast of Saint Mark and on the three rogation days. They are also chanted in procession before mass on Holy Saturday. The "litany" or "general supplication" of the Church of England, which is appointed "to be sung or said after morning prayer upon Sundays, Wednesdays, and Fridays, and at other times when it shall be commanded by the ordinary," closely follows the "Litaniæ majores" of the Breviary, the invocations of saints being of course omitted. A very similar German litany will be found in the works of Luther. In the Roman Church there are a number of special litanies peculiar to particular localities or orders, such as the "Litanies of Mary" or the "Litanies of the Sacred Name of Jesus."

LITHGOW, WILLIAM (*c.* 1583–*c.* 1660), a noted Scottish traveller, was born in Lanark, where his father was a burgess, possessed of considerable heritable property. The date generally assigned to his birth is 1583; and he was educated at the grammar school of his native town, then celebrated as a seminary of learning. His natural disposition was probably active and restless, as even in his boyhood he tells us that he made voyages to both the Orkneys and the Shetlands, and somewhat later travelled through the Low Countries, Germany, Bohemia, and Switzerland. The final impelling cause of his leaving Scotland, however, appears to have been some savage outrage committed either upon himself or on one nearly connected with him, arising, it is thought, from some love affair, which gave him an intolerable disgust to home. He left his native country about 1608 or 1609, and proceeded to Paris, where he remained ten months, and then crossed the Alps to Rome and Naples; after which he wandered through Istria, Dalmatia, Albania, Greece, Asia Minor, Syria, Mesopotamia, Palestine, and Egypt, most of his journey having been performed on foot. In the course of his travels he escaped innumerable dangers from robbers, and hardships from exposure to inclement weather. He returned to England by Sicily and Paris. Another tour which he made lay through Morocco, Algiers, Tunis, Tripoli, Hungary, Germany, and Poland. On his arrival in London he became an object of interest to King James, who, on the spirit of travel again returning upon him, furnished him with commendatory letters to all kings, princes, dukes, &c., whose territories he might desire to visit. In 1619, accordingly, he went over to France, and thence passed through Portugal and Spain as far as Malaga. There he was apprehended as a spy, and after suffering the most excruciating tortures, first in prison and afterwards in the Inquisition, he was at length released on the interference of the English consul, and allowed to return to England in 1621. The minute description which he gives of the terrible torture to which he was subjected is almost unequalled for horror, and, when he arrived in London, he had the appearance of a man more dead than alive. He was carried on a feather bed to Theobald's in order that King James might be an eyewitness of what he called his "martyred anatomy." The whole court crowded to see him. The king commanded that the greatest care should be taken of him, and he was twice sent to Bath at his Majesty's expense. On recovering his health, he was desired by James to apply to Gondomar, the Spanish ambassador, for recovery of the money and other valuables of which he had been plundered by the governor of Malaga, and for a thousand pounds in reparation of his injuries. Gondomar gave fair promises that all his demands should be granted, but nothing was done. Whereupon, having met the ambassador at the royal levee, and reproached him with his perfidy, after high words on both sides, Lithgow furiously assailed him with his fists, in the presence of the king, the imperial ambassador, and the knights and gentlemen of the court. This, of course, was an offence which could not be passed over, and, though his boldness was generally commended, he had to suffer an imprisonment of nine weeks in the Marshalsea. His latter years are understood to have been spent in his native town, and he is said to have died somewhere about 1660.

A portion of his travels appeared in a small volume in London in 1614, but the complete work was not published till 1632. It has been repeatedly reprinted. It was also translated into Dutch and published at Amsterdam in his lifetime. His other works are —*An Account of the Siege of Breda* (1637) at which he had been present; *A Survey of London and England's State*, 1643; *Relation of the Siege of Newcastle*, 1645. His poetical remains, collected by James Maidment, were published at Edinburgh in 1863.

LITHIUM, one of the rarer metallic elements, intermediate in its character between sodium and barium. It was discovered in 1817 by Arfvedson in the course of an analysis of petalite in Berzelius's laboratory. He recognized the presence in this mineral of a new kind of alkali, which his master subsequently named "lithia," to denote its mineral origin. Lithia, though widely disseminated throughout the mineral world—traces of it being found in almost all alkaliferous silicates, in the soils derived from these, and in many mineral waters—nowhere occurs in any abundance, except in the immense masses of lithia-mica (lepidolite) known to exist in Bohemia. Of other lithia-minerals (all rare) we may name petalite and spodumene (both silicates of alumina and alkalies) and triphylline, a mixed phosphate of ferrous, manganous, and lithium oxides. Only lepidolite comes into consideration as a raw material for the preparation of lithia and its salts. But the extraction from it of pure lithia in any form is difficult. The first step is the disintegration of the finely powdered mineral, which may be effected by means of vitriol and hydrofluoric acid (or vitriol and fluorspar); the silicon goes off as gaseous fluoride, the bases remain as sulphates. Or else we may mix the mineral intimately with quicklime, and by very intense heating of the mixture produce a more highly basic silicate, which is readily disintegrable by acids. In either case it is easy to unite all the bases (Al_2O_3, Fe_2O_3, CaO, MgO, Li_2O, K_2O, Na_2O) into a solution of chlorides or sulphates. From it we precipitate successively and remove by filtration (1) the bases not alkalies or Li_2O by means of excess of milk of lime, and (2) the lime introduced by operation (1) by means of carbonate of ammonia. There results a mixed solution of potash, soda, lithia, and ammonia salt, from which the last-named component is easily removed by evaporation to dryness and ignition. For these very tedious operations Troost has substituted an elegant process which, though admittedly imperfect in the analytic sense, lends itself admirably to manufacturing purposes. He mixes ten parts of the finely powdered mineral with ten parts of carbonate of baryta, five parts of sulphate of baryta, and three parts of sulphate of potash, and melts down the mixture in a powerful wind-furnace. There results a mass which separates spontaneously into a lower layer forming a transparent glass, and an upper one consisting of the sulphates of barium, potassium (sodium), and lithium, the latter representing about three-fourths of the lithia contained in the mineral. By treatment with water the sulphate of baryta is easily removed as an insoluble residue; the mixed alkaline sulphates are converted into chlorides by decomposition with chloride of barium, and from the dry mixed chlorides approximately pure chloride of lithium is obtained by lixiviation with ether-alcohol, which solvent dissolves only very small proportions of the other chlorides. To purify the crude chloride it is dissolved in water and, by double decomposition with carbonate of soda, converted into a precipitate of carbonate of lithia, Li_2CO_3, which must be washed with small instalments of water, as it is very appreciably soluble in water. This carbonate of lithia is still contaminated with soda. To purify it fully dissolve it in water with the help of carbonic acid, filter, and evaporate slowly on a water-bath; the added carbonic acid goes off, and pure carbonate of lithia separates out in crystalline crusts (Troost). One litre of pure water dissolves 12 grammes; 1 litre of water kept saturated with carbonic acid dissolves 52·5 grammes of the carbonate. The dry salt fuses at a red heat, but before doing so loses part of its carbonic acid, which, after cooling, it shows no tendency to take up again from the atmosphere. Perfectly acid-free lithia, Li_2O, can be obtained by heating a mixture of the carbonate and pure charcoal in a platinum crucible, or by heating the nitrate for a long time in a silver one. If the preparation, ultimately, of the hydrate $Li_2OH_2O = 2LiOH$ is contemplated, the latter operation may be very materially shortened by addition of metallic copper, which reduces the nitric acid. The anhydrous oxide, when treated with water, dissolves without much evolution of heat as hydrate, LiOH, which, by evaporation (in silver) is easily obtained in the solid form. It melts at a dull red heat, but at even higher temperatures loses no water. It dissolves in water (far less abundantly than soda), with formation of a strongly alkaline solution, which neutralizes all acids, with formation of salts. Like baryta, it refuses to form acid sulphates or carbonates (the bodies $HLiSO_4$ and $HLiCO_3$ exist only in solution), and forms insoluble or almost insoluble salts with carbonic and phosphoric acids (formulæ Li_2CO_3 and Li_3PO_4); and, last not least, it is not reducible to metal by charcoal at any temperature. Add to this that the highly deliquescent chloride LiCl, when dehydrated by heating, always loses part of its chlorine as HCl, and we feel tempted to conclude that in the case of lithium, as in that of barium or magnesium, two equivalents are united into one atom $\text{Li} = Li_2 = 14$. But the specific heat of the metal demands the lesser number.[1]

Metallic Lithium, although long before known to exist, was successfully prepared for the first time in 1855, by Bunsen. He obtained it by fusing the pure chloride in a porcelain crucible, and decomposing the fused salt by a battery of four or six "Bunsens," using a rod of retort charcoal as a positive and a knitting wire as a negative pole. The metal separates out in about pea-sized globules, which stick to the wire, and, thanks to the protecting action of the fused chloride, can be lifted out and collected without reoxidation, under rock-oil. Lithium is a silver-white metal, of only ·58 specific gravity (it floats on rock-oil), somewhat softer than lead, and like it susceptible of being pressed into wire. It tarnishes in air, though far less readily than sodium. When thrown upon water it gradually dissolves as hydrate, with evolution of hydrogen, but without fusing. The metal melts at 180° C., and at a somewhat higher temperature takes fire and burns into oxide with a brilliant white flame. Hence the characteristic intensely red colour which a colourless gas flame assumes when a lithium salt is volatilized in it must be a property of something else than the metal itself; perhaps it is the hydroxide LiOH that emits it. The red lithium flame forms a spectrum consisting chiefly of one brilliant red and a somewhat faint orange line.

Lithia-salt solutions behave to general reagents pretty much like those of potash or soda, from which, however, they differ in the following points:—(1) concentrated solutions are precipitated by carbonate of potash or soda; (2) even dilute solutions when mixed with phosphate of soda and caustic soda, in the heat more readily, give precipitates of the phosphate PO_4Li_3, soluble in 2530 parts of plain, and in 3900 parts of ammonia water, more largely in solutions of ammonia salts; (3) unlike potassium salts, they give no precipitate with chloride of platinum. (W. D.)

LITHOGRAPHY. The principle upon which the art of lithography is based is very simple—the antagonistic qualities of grease and water. An unctuous composition is made to adhere to a peculiar kind of limestone; the parts thus covered acquire the power of receiving printing ink; the other parts are prevented from receiving it by the interposition of a film of water; and then by pressing paper strongly upon the stone impressions are obtained. There are two distinct branches in lithography—drawing and printing. Those practising the first are known as lithographic *draughtsmen* or *writers*, the second as lithographic *printers*.

The art of lithography was discovered by Alois Senefelder, a native of Prague, born 6th November 1771. His father, Peter Senefelder, was one of the performers of

[1] Lithia oxide and carbonate were long supposed to exert a characteristically powerful corrosive action on platinum vessels used for their fusion. This, according to Troost, holds only for such preparations as are contaminated with rubidia- or cæsia. The pure lithia compounds, even the oxide (and hydrate ?), do not attack platinum

the Theatre Royal at Munich. The son Alois wished to follow the same profession, but, his father being opposed to this, he went to the university of Ingolstadt, and devoted himself to the study of jurisprudence. Owing to the death of his father shortly afterwards, he was unable to continue his studies at the university, and, yielding to his old inclination, he tried to support himself as a performer and author, but without success. In order to accelerate the publication of one of his works, he frequently spent whole days in the printing office, and thus became acquainted with all the particulars of the process of printing. It appeared so simple that he conceived the idea of purchasing a small printing press, thus enabling himself to print and publish his own compositions; but his means were inadequate, and to this circumstance we probably owe the invention of lithography. Unable to pay for the engraving of his compositions, he attempted to engrave them himself. He tried numerous experiments with little success; tools and skill were alike wanting. Copper-plates were expensive, and the want of a sufficient number entailed the tedious process of grinding and polishing afresh those he had used. About this period his attention was accidentally directed to a fine piece of Kellheim stone which he had purchased for the purpose of grinding his ink. His first idea was to use it merely for practice in his exercises in writing backwards, the ease with which the stone could be ground and polished afresh being the chief inducement. The idea of being able to take impressions from the stone had not yet occurred to him. While he was engaged one day in polishing a stone slab on which to continue his exercises, his mother entered the room and desired him to write her a bill for the washerwoman, who was waiting for the linen. Neither paper nor ink being at hand, the bill was written on the stone he had just polished. The ink used was composed of wax, soap, and lamp-black. Some time afterwards, when about to wipe the writing from the stone, the idea all at once struck him to try the effect of biting the stone with aqua fortis. If the parts written on resisted its action, impressions might then be taken in the same way as from wood engravings. Surrounding the stone with a border of wax, he covered its surface with a mixture of one part of aqua fortis and ten parts of water. The result of the experiment was that at the end of five minutes he found the writing elevated about the tenth part of a line ($\frac{1}{120}$ inch). He then proceeded to apply the printing ink to the stone, using at first a common printer's ball, but soon found that a thin piece of board covered with fine cloth answered better, communicating the ink more equally. He was able to take satisfactory impressions, and, the method of printing being new, he hoped to obtain a patent for it, or even some assistance from the Government. For years Senefelder continued his experiments, until the art not only became simplified, but reached a high degree of excellence in his hands. In later years the king of Bavaria settled a handsome pension on Senefelder. He died at Munich in 1834, having lived to see his invention brought to comparative perfection.

Materials Employed by the Lithographic Artist.—Lithographic stones are very compact homogeneous limestones, imported chiefly from Germany. The traffic has its centre in the village of Solenhofen, in the district of Monheim. The Solenhofen stone, in its chemical decomposition, consists of lime and carbonic acid. It is generally cut in slabs from 2 to 3 inches in thickness, and is sold by weight. Stones yielding impressions in the lithographic press have been found in England, France, Italy, Canada, and the West Indies; but all are much inferior to the best German stones. Lithographic stones vary in colour from a dull grey or yellow to a light creamy shade, the dark grey stones being the hardest. They are sometimes uneven in colour, having light and dark patches. These are suitable for ordinary transfer work; but, in cases where the artist requires to see the effect he is producing during progress (as in chalk drawing), stones of an even grey or drab colour should be selected.

Lithographic ink is composed of tallow (4 oz.), wax (5 oz.), soap (4 oz.), shellac (3 oz.), and *quant. suff.* of fine Paris black. The inks of Lemercier and Vanhymbeeck are generally considered as among the best. Lithographic chalk is made in the same manner as the ink, but requires to be burnt sufficiently hard for use in drawing. Excellent lithographic crayons are manufactured by Lemercier of Paris. They are made of several degrees of hardness. copal chalk, used for outlining, being the hardest.

Transfer paper for writing and drawing is prepared by coating the surface of the paper with a composition of size, made from parchment cuttings and flake white. Sometimes the coating is composed of starch and glue. Colouring matter, generally gamboge, is added, the object being to show more readily which is the coated side of the paper. The coating is applied with a full brush. For writing, the paper used is thin, for drawing it is thicker; for large subjects ordinary drawing paper is used. It is afterwards glazed by being pulled through the lithographic press, face down, on a smooth stone, or hot pressed. There are several other varieties of transfer papers—a transparent or tracing paper, and a transfer paper for chalk drawing, having a finely granulated surface. Mr Nelson of Edinburgh patented a method of graining transfer paper by means of stippled plates. The older method was to press the coated surface of the paper on an ordinary sand-grained stone or plate.

Instruments and Appliances used in Lithographic Drawing and Writing.—For the finer purposes of lithography ordinary steel pens are useless; "Perry's lithographic pen" may be found serviceable when the work is not very delicate. Transfer writers prefer pens of their own making. These are either made from quills scraped down, before cutting, with a piece of broken glass, until the barrel yields to pressure of the nail, or cut with a pair of sharp scissors from thin sheets of steel prepared for the purpose. This operation is difficult, and requires much skill and practice. Pens are also made of watch springs, reduced to the necessary tenuity by nitric acid and water.

Lithographic brushes are made from red sable crowquill pencils; a portion of the hair is cut away all round, and only the central part of the brush is used.

Scrapers are employed in correcting the work upon stone, but a penknife or ordinary erasing knife answers the purpose equally well.

Crayon holders of the ordinary kind may be used for lithographic chalk. When cut in two and fitted with a wooden handle. they will be found lighter and pleasanter to work with.

The hand-board is a piece of wood about 6 inches wide, three-eighths of an inch thick, and somewhat longer than the stone on which the draughtsman works. It rests upon thick strips of millboard fixed round the edges of the stone, to keep it from touching the part to be drawn on.

Ruling and circle pens, parallel rulers, tracing paper, a tracing point, and red tracing paper, for transferring tracings to paper or stone, are also requisites.

Drawing on Stone.—The Chalk Method.—For artistic purposes this is perhaps the most important and interesting department of lithography. In preparing the stone for chalk drawing, the surface, instead of being polished, is broken up into minute points or "grained." The coarseness or fineness of the grain is varied according to the work to be done. A hard stone, free from veins, marks, and chalk spots, and of a clear grey colour, is selected. It is first ground and pumiced to free it from scratches. A small quantity of the finest gravel sand, or "graining-sand," is sprinkled over the surface, and a few drops of water added; a smaller stone of the same size and hardness is placed above, face downwards, and moved about with a circular motion; water is added from time to time, and fresh sand when needed. Care must be taken that no scratches are caused by grains of coarser sand finding their way to the stone; the stone is afterwards washed in clean water and dried, and the grain tested with a crayon. If it prove too coarse or too fine, or if scratches are discovered, the graining is done over again.

The drawing is then traced upon the stone. As it has to be reversed, the tracing is fastened face downwards; red tracing paper is introduced between, and the outline carefully gone over with a steel tracing point or a hard pencil. The tracing papers are then removed, and the surface of the stone protected with a sheet of plain paper. The hand-board is placed across to keep the warmth of the hand from causing the condensation of moisture resulting from its coming in contact with the paper covering the stone. The paper covering the part of the drawing to be first commenced is then removed. The crayons are pointed with the knife, cutting from the point upwards.

Great care and cleanliness are necessary to prevent injury to the work. If the artist wishes to talk he ought first to cover up the surface of the stone, as a drop of saliva falling upon it prevents the penetration of the chemical chalk, and a white spot will be the result when the drawing is "brought up" by the printer. If the stone is touched by greasy hands, the form of the fingers and of the skin will appear in black.

The drawing is commenced by outlining. For this purpose the hardest chalk (copal) may be used, but No. 1, when it will answer the purpose, is better. The "tinting" or shading follows; lights may be picked out with the scraper or penknife, and ink used when sharp, dark touches are desirable. It is difficult to rectify mistakes;—prevention is better than cure. In reversing the drawing a small hand looking-glass will be found useful.

When completed the drawing is "etched." There are two different ways of applying the acid—one by flooding the stone with nitric acid diluted with water, the other with acid diluted with gum-water, applied with a flat, soft brush about 4 or 5 inches in width. Although this operation appears simple, it is not without risks; much of the success of the impressions depends upon it. If the stone is too strongly etched, the delicate tints and lines disappear; if not etched strong enough, the drawing is apt to lose clearness, and run smutty in printing. When the etching is completed, the water is drained off and the stone gummed and allowed to dry. It may then be put into the hands of the printer for proving.

Pen and Brush Method.—The surface of the stone is ground and afterwards polished with Water-of-Ayr stone or snake-stone. The drawing or writing is traced upon the surface in the manner already described. The principal drawback in this method is the necessity of reversing writing and lettering, which cannot be done without considerable practice. Its advantages over the transfer method scarcely compensate for the additional difficulties. The stone is etched as in chalk drawing before passing into the printer's hands.

Engraving on stone is chiefly useful in the reproduction of drawings by architects, civil engineers, &c. Its advantages are accuracy and sharpness in drawing and printing. A thin film of gum is spread on the surface of the stone, and when dry washed off; a dark ground is then laid on by rubbing in Paris black. Red grounds also are sometimes used. The tracing, if on a black ground, is made with paper prepared with chrome yellow, if on a red ground with Paris black. The method of engraving is simple. The tools are strong needles, firmly fixed in cane handles, and good spring dividers; the incised lines show white upon the black or red ground. When the work is finished they are filled up with fatty ink, and the stone cleared with water and a piece of coarse flannel.

In printing, the stone is damped in the usual way, but the ink is applied with a dabber instead of a roller.

Lithography on Paper, or Transfer Lithography.—By this method the work is done on paper, and afterwards transferred to the stone. The paper has been already described, as also the instruments used in writing and drawing. The ink is prepared by rubbing a small quantity into a saucer of white delft or china, the saucer being first heated to make the ink adhere; water is then added, and the ink rubbed with the finger till it dissolves. Care has to be taken to make it of the proper consistency. If pale and thin, it will not transfer properly; if too thick, it will not flow freely from the pen or brush, and will spread in transferring.

The paper should not be handled or touched, except at the edges. Finger marks from a moist or greasy hand will roll-up black. A piece of clean white paper is kept under the hand when working. The same line must not be gone over twice while wet, as the composition on the surface of the paper is apt to get mixed with the ink and destroy its qualities. In drawing on chalk transfer paper the crayon is used instead of the brush or pen. Dark touches may be put in with ink, and the lights picked out with the knife.

The stone for the reception of transfers is polished free from perceptible scratches, and is generally warmed to make it more susceptible of receiving the ink. The transfer is placed face downwards on the stone, pulled repeatedly through the press, and afterwards removed to the trough, where hot water is poured over it. It is then peeled off, leaving the ink and the composition on the stone; the latter is washed off, and the stone gummed and allowed to dry. The work is afterwards "proved" by rolling-up, cleaning, etching, and taking the first impressions.

The transfer method is also applied successfully to the reproduction by lithography of engraved plates, wood engravings, and type.

Photo-Lithography.—By this method copies of prints or drawings executed in clear lines or dots can be produced. They may be either of the same or of altered dimensions. The copying is done by photography upon glass; but, as it is necessary that the negatives should have straight marginal lines, ordinary photographic lenses are not adapted for the purpose—"rectilinear," "aplanatic," "symmetrical," and other varieties being used instead. The negative is put into a photographic printing frame, and a piece of sensitive transfer paper placed face downwards upon it, the glass side being exposed to the light. The time of exposure varies according to the intensity of the light and the quality of the negative. When sufficiently exposed it is carried into a dark room, the photographic print taken out of the frame, laid face downwards on a stone coated over with transfer ink, and pulled through the press. It is then soaked for a few minutes in water warmed to the temperature of 100°, and the inked side of the paper carefully sponged with gum-water to remove the transferring ink from the parts upon which the light could not act. After being washed in warm water it is allowed to dry, and is then transferred to the stone and printed from in the usual manner.

Zincography so nearly resembles lithography in its principles that a very few words of explanation will be sufficient. Zinc plates possess the advantage of costing less and being much more portable than lithographic stones, and are easily cut into convenient sizes. They are grained in the same manner as lithographic stones, a muller of zinc being used instead of one of stone. Drawings on zinc, whether in chalk or ink, are executed on a grained surface. Zinc plates are subject to oxidation, and care must be taken to dry them off quickly after graining. The drawing is done precisely in the same way as on stone; the etching solution is applied with a flat camel-hair brush. It consists of a decoction of nut-galls; a solution of gum and phosphoric acid is sometimes added. During printing the plate is screwed for support to a block of beech or other hard wood. As neither crayon nor ink penetrates the zinc as they do the stone, the adhesion of the ink forming the drawing is less thorough than in lithography, and greater precautions have to be taken to prevent accidents in printing.

Chromo-Lithography.—Great advances have been made in recent years in this branch of the art, notably in the reproduction of works of an artistic character. Its simplest form is the tint, in several gradations of one colour, printed over drawings in chalk or line; in its more elaborate forms it includes imitations of water-colour drawings, decorative and ornamental designs, &c. The term "chromo-lithography" is usually applied only to the more elaborate kinds of colour printing.

All lithographs in two or more colours are printed from two or more stones. It is therefore necessary to employ some method to get a correct repetition of the subject on the first stone made upon the others, and to be able in printing to place the sheet so correctly in position that the second and each succeeding printing shall fall exactly into its place upon the first. Much of the success of the work depends upon this, and various modes of "registering," by "lay," by needles, by fixed points, &c., are employed. The first drawing is generally in outline. It is called the keystone, and provision is made in it for "registering," according to the particular method adopted by the artist. It is used only to take as many impressions on other stones as are required for the several colours, and as a means of getting each colour in its exact place. In work of an artistic character it is omitted in printing.

For ordinary colour printing the stone is polished; when gradation of colour is required the stone is grained, but in a somewhat coarser way than for chalk drawing. It will be sufficient here to describe the production of drawings with two tints. The principal drawing is done upon a grained stone in chalk, and should be very bold, more like a sketch on tinted paper, the middle and finer tints being left out. The stone is then etched, and two impressions are taken, so that when each of these is put upon a roughly-grained stone, and passed through the press, counter impressions will be found upon the stones, revealing the drawing quite distinctly. After having cut in the outlines with a sharp-pointed graver, or steel needle, the artist covers those parts on the two stones which are not to appear in the one or the other colour, as well as the margin of the two stones, with a brush containing acid and gum. The stones are then warmed, and a composition containing the same ingredients, as soft chalk, with double the quantity of soap, and three times the quantity of tallow, is rubbed over it with a bit of coarse flannel, until it is of a dark greyish-brown colour. From having been previously cut in, the outline comes out very distinctly. The artist can now produce an effect similar to crayon sketches which have been washed in with two separate colours. Those portions which have been rubbed in, and which appear dark greyish-brown, form the middle tint, and the scraper may be used to reduce the colour of the tint where the gradation of colour is desired,—the darkest portions being laid in with lithographic ink, and the blending together done with chalk, brush, pen, and scraper, so as to produce in many places the effect of shadings of one colour over another. When the work is of a very elaborate or complicated nature, the order in which the colours should succeed each other in printing is of much importance, and requires to be very carefully considered. In highly finished chromo-lithographs, fifteen or more printings are frequently necessary. Difficulties sometimes arise from the paper stretching, either from the moisture on the surface of the stone or from the action of the press.

Oleography differs from chromo-lithography only in name, and is a mere vulgar attempt to imitate oil painting. The finished print is mounted on canvas, sized, and varnished. The loaded colours and rough textures, if there happen to be such in the original, are suggested by embossing, with what result it is hardly needful to say.

Instruments, Tools, and Apparatus used in Printing.—Lithographic presses are of a great variety of construction, and we can only glance at the chief points in their mechanism. The scraper is a wedge-formed plate of boxwood, fixed to the bottom of the platten; its edge is covered with a piece of leather, and properly adjusted. The table on which the stone with the paper for receiving the impression is placed, and on which the tympan is brought down, is, by means of a handle or wheel, brought upon the metallic moving roller and under the scraper; the pressure is applied with a lever, and continued from one end of the stone to the other; when it has passed through the press, the lever is lifted, the moving table brought to its original place, and the printed sheet removed. The lithographic steam-press began to be generally used about 1867, and has quite revolutionized the lithographic trade.

The rollers for printing may be made of different lengths, from 6 to 24 inches long, and 3½ to 5 inches in diameter. They are made of wood of the alder and lime tree, with wooden handles to project and hold by; the roller is then covered with several complete turns of flannel, well stretched and fastened by sewing at the extremities near the handles; the whole is then covered with calf-skin, sewed with great care, so as to fit tightly, and laced near the handles. For printing chalk, tints, and colours, skins of different preparations are required. Hollow metallic rollers, covered with flannel and calf-skin, are in use on some parts of the Continent, where they are preferred to rollers made of wood.

The best varnishes for making the printing-ink are boiled from old linseed oil, of different degrees of strength—thin, middle, strong, and very strong varnish; for printing with gold-leaf, bronze, and dusting colours, the very strong varnish is required. For writings, maps, and music, common calcined lamp-black is ground with the varnish; some hard blue is added to improve the colour, and to make the ink dry in a short time; for chalk ink, Paris black is used instead of the common lamp-black. For tinting and colour-printing, colourless or bleached varnish must be used, as otherwise the purity of the colours will suffer.

Printing.—After the stones containing the writings or drawings in chalk and those used for tinting or colour-printing are etched, and the preparation has become dry, the stones may be put into the press and properly fixed. To prevent a stone containing drawings of any value from breaking, it should, if thin, be backed to another stone, or, what is better, to a slab of Aberdeen granite. This is done by a mixture of plaster of Paris and cold water, of the consistency of syrup, a pretty thick coating of which should be spread evenly and quickly on the slab; the stone containing the drawing is placed into this layer, and moved in all directions until the plaster of Paris becomes quite hard, which will take place in a very short time. After the printing is accomplished, the stone can be quite easily removed from the slab, by using a chisel, and by giving some side strokes with a wooden hammer. The old dry plaster of Paris is now removed, and the slab is again fit for use.

Everything being ready, the gum is entirely washed away with a soft Turkey sponge and water; the writing or drawing is then obliterated by taking a clean sponge and oil of turpentine, to which may be added, at pleasure, a few drops of sweet oil, after which the stone must be cleaned with water. An entirely clean sponge (or for writings, a bit of soft canvas manufactured for the purpose) is now required for the printing. The stone is slightly wetted with this sponge; the printing roller, charged already with the proper ink, is passed repeatedly over the whole stone, and the writing or drawing will begin to reappear; the roller is again worked on the ink-slab, the stone wetted anew with the sponge, and again rolled over, until the writing or drawing appears in full strength. A sheet of damped paper (dry paper may be used for writings and drawings in line) is put on the stone, the tympan is let down, the scraper brought to its proper place, the pressure effected, and, by means of the handle, cross, or wheel, according to the style of press, the table with the stone is slowly and equally drawn through to nearly the end of the stone, for which purpose the press requires to be set properly beforehand. The printer now relaxes the pressure, the table with the stone runs to its original place, the tympan is put back, and the impression is carefully taken up from the stone. The stone is then again wetted as before, inked in anew, the paper placed upon the stone, and further impressions are effected. When the stone is to be kept after the required number of impressions has been struck off, it should always be inked up with preserving ink, which is made by melting lard, tallow, and wax, in equal proportions, with a quantity of printing-ink. When about to be used, this preserving-ink may be thinned with some oil of turpentine, thinly spread on a roller kept for this purpose; it must then be properly turned on the slab; the writing or drawing is washed out with oil of turpentine, the whole removed with a clean sponge, and the stone wetted and inked in with this preserving-ink. A few minutes afterwards, when the turpentine has evaporated, a thin solution of gum-arabic is spread over the stone, containing a little sugar-candy to prevent the cracking of the gum by change of atmosphere. The stone will keep any length of time; but the preserving-ink should be renewed at least every twelve months.

The printing of tint and colour stones is treated in the same way, only the rollers, varnishes, and colours are different from those used for ordinary black and chalk printing. The printing of this class of work requires great skill and taste. Many of the lithographic printers of London, Paris, Brussels, Munich, Berlin, Vienna, and Dresden are justly famed for their beautiful productions.

An engraved stone is printed by using a small wooden tapper or tampon, either round at the sides, flat below, with handle at top, or square, with the corners rounded off. This tampon is covered several times with a very coarse blanket, or coarse thick firm cloth, fastened at the sides; the ink is then spread very thinly on the slab, the tapper is properly tapped into it, the gum is removed from the stone, and the drawing is removed with oil of turpentine; the stone is wetted, the tampon is tapped over the whole drawing, the stone cleaned with a bit of wet canvas, and finally a printing roller is passed once or twice over the stone, which removes all impurities; a damped sheet of paper is then placed on the stone, and the impression made as formerly explained.

Some printers print engraved outlines or drawings done with thin lines entirely with the roller, which is a great saving of time; other printers again ink an engraving with a large shoe brush with long, stiff bristles—which is rubbed on the ink-slab to give it the ink required—by brushing over the drawing in all directions.

Paper.—The proper selection of paper for lithographic printing when beauty of impression is a chief consideration, is of great importance. Hand-made and hand-sized papers are objectionable, the materials used in sizing being frequently inimical to perfect lithographic printing. Absorbent papers, such as India paper, plate-paper, half-sized plate-paper, and fine printing paper yield the best impressions; common writing paper, hand-made writing, loan, or other hand-made English-sized papers should be used only when the work is for business or similar purposes.

Since the invention of photography, and its wide application to processes connected with art, artistic lithography, except in the way of colour printing, has been perhaps rather less in demand than formerly. Many of the finest British examples of lithographic art date from more than twenty to thirty years back, when artists such as J. D. Harding, Samuel Prout, Louis Haghe, Ghemar, William Simpson, and others were largely—some of them almost exclusively—engaged in its practice. Harding, although practising as a water-colour painter, devoted much of his time to lithography. The dexterity and brilliancy of his execution give to his works in this style a peculiar charm, altogether wanting in the more laboured productions of the professional lithographic artist. Of this quality in Harding's drawings on stone, Mr Ruskin writes—"His execution, *in its way*, no one can at all equal. The best chalk drawing of Calame and other foreign masters is quite childish and feeble in comparison." Samuel Prout, also a water-colour painter, produced many admirable works in lithography. Mr Ruskin's testimony may again be quoted:—"All his published lithographic sketches are of the greatest value, wholly unrivalled in power of composition, and in love and feeling of architectural subject." "His lithographic work (*Sketches in Flanders and Germany*), which was, I believe, the first of the kind, still remains the most valuable of all, numerous and elaborate as its various successors have been. Their value is much increased by the circumstance of their being drawn by the artist's own hand upon the stone." Louis Haghe's work on the *Architecture of the Middle Ages in Germany and the Netherlands*, Roberts's *Holy Land and Egypt* (drawn on stone by Haghe), and Simpson's drawings of the Crimean war may also be cited as excellent examples of artistic lithography. Lithographic studies of heads and figures by Julien of Paris, and other foreign artists, were at one time largely employed as copies by drawing masters; the new system of teaching introduced of late years has almost put an end to their use for this purpose, and they are now less frequently met with. Although lithography is increasingly employed for commercial and other purposes, artists of first-rate ability now seem, on the whole, to prefer other processes for the reproduction of their works. (G. RE.)

LITHUANIANS, a people (about 3,000,000 in number) of Indo-European origin, which inhabits several western provinces of Russia and the north-eastern parts of Poland and Prussia, on the shores of the Baltic Sea, and in the basins of the Niemen and of the Duna. Very little is known about their origin, and nothing about the time of their appearance in the country they now inhabit. Ptolemy mentions (lib. iii. chap. 5) two clans, the Galindæ and Sudeni, most probably Lithuanians of the western branch of this nationality, the Borussians. In the 10th century they were already known under the name of Litva, and, together with two other branches of the same stem,—the Borussians and the Letts,—they occupied the south-eastern coast of the Baltic Sea from the Vistula to the Duna, extending north-east towards the Lakes Wierzi-yärvi and Peipus, south-east to the watershed between the affluents of the Baltic and those of the Black Sea, and south to the middle course of the Vistula (Brest Litovsky),—a tract bounded by Finnish tribes in the north, and by Slavonians elsewhere.

The country which since that time they have continued to inhabit is flat, undulating, and covered by numberless small lakes, ponds, and wide marshes, which, though to a great extent drained during the last ten centuries, nevertheless still cover immense tracts of land. The costly work of artificial draining has been actively carried on during late years, but in the south the marshes are disappearing slowly. The soil, being sandy in the north, and a hard boulder-clay elsewhere, is unproductive. Thick forests cover it, and—though considerable tracts have been destroyed by fires and by the hatchets of the *budniki* who during many centuries have cleared the most remote thickets, founding there their villages, while, later, wide forest regions, given by Catherine II. as gifts to her officials, have quite disappeared—there still remain immense tracts of land covered with nearly virgin forests; thus, the Byelovyesh Pushcha covers no less than 550,000 acres of land on the level plateau 650 feet high, where tributaries of the Nareff and Bug have a common origin in marshes. These forests have played an important part in the history of the Lithuanians, giving many original features to their history, as well as to their mythology, poetry, and music. They protected them from foreign invasions, and have contributed to the maintenance of their national character, notwithstanding the vicissitudes of their history, and of their primitive religion until the 14th century. Their chief priest, the Krive-Kriveyto (the judge of the judges), under whom were no less than seventeen different classes of priests and elders, worshipped in the forests; the Waidelots brought their offerings to the divinities at the foot of mighty oaks, and even during the 14th century an unextinguishable fire, the "zincz," was maintained in the midst of the "pushta," or "pushcha"; even now, the worship of great oaks is a widely spread custom in the villages of the Lithuanians, and even of the Letts. In the absence of great forests they worship isolated trees.

Even at that time the Lithuanian stem was divided into three main branches:—the *Borussians* or *Prussians*; the *Letts* (who call themselves *Latvis*, whilst the name under which they are known in Russian chronicles, *Letygola*, is an abbreviation of *Latvin-galas*, "the confines of Lithuania"); and the *Lithuanians*, or rather *Lituanians*, *Litva*, or *Letuvininkai*,—these last being subdivided into Lithuanians proper, and *Jmud'* (*Zmudz*, *Samoghitians*, or *Zemailey*), the "Lowlanders." To these three main branches, which have maintained their national distinctions uninterrupted until the present time, must be added also the *Yatvyags*, or *Yadzvings*, a warlike, black-haired people who inhabited the thick forests at the upper tributaries of the Niemen and Bug, and the survivors of whom are easily distinguishable now as a mixture with White-Russians and Mazurs in some parts of the governments Grodno and Plotsk, and in several north-eastern parts of those of Lomza and Warsaw. Nestor's chronicle distinguishes also the *Jemgala*, who later became known under the name of *Semigallia*, and inhabited in the 10th century the left bank of the Duna. Several authors consider also as Lithuanians the *Kors* of Russian chronicles, or *Courons* of Western authors, who inhabited the peninsula of Courland, and the *Golad'*, a clan settled on the banks of the Porotva, tributary of the Moskva river, which seems to have been thrown far from the main stem during its migration to the north.[1] The *Krivitchi*, who inhabited what is now the government of Smolensk, whose name recalls the Krive-Kriveyto, and whose ethnological features recall the Lithuanians, seem to belong to the same stem; but now these are rather a mixture of Lithuanians and Slavonians.

All these peoples are only ethnographical subdivisions, and each of them was subdivided in its turn into numerous independent clans and villages, separated from one another by forests and marshes; they had no towns or fortified places, a feature which has struck many earlier Occidental writers. The Lithuanian territory thus lay open to foreign invasions, and the warlike Russian *Kniazes*, as well as the German crusaders, availed themselves of the opportunity. The Borussians soon fell under the dominion of Germans, and ceased to constitute a separate nationality, leaving only their name to the state which later became Prussia. The Letts were driven farther to the north, mixing there with Livs and Ehsts, and fell under the dominion of the Livonian order. Only the Lithuanians proper, together with Samoghitians, succeeded in forming an independent state. The early history of this state is but imperfectly known, all the more that the old Lithuanian chronicles have suffered from subsequent alterations (Antonovitch, *loc. cit.*). During the continuous petty war carried on against Slavonic invasions, the military chief of one of the clans, Ryngold, acquired, in the first half of the 13th century, a certain preponderance over other clans of Lithuania and Black Russia (Yatvyags), as well as over the republics of Red Russia. At this time, the invasions of the Livonian order becoming more frequent, and always extending southward, there was a general feeling of the necessity of some organization to resist them, and Ryngold's son, Mendowg, availed himself of this opportunity to pursue the policy of his father. He made different concessions to the order, ceded to it several parts of Lithuania, and even agreed to be baptized, in 1250, at Novograd Litovsky, receiving in exchange a crown from Innocent IV., with which he was crowned king of Lithuanians. He ceded also the whole of Lithuania to the order in case he should die without leaving offspring. But he had accepted Christianity only to increase his influence among other clans; and, as soon as he had consolidated a union between Lithuanians, Samoghitians, and Cours, he relapsed, proclaiming, in 1260, a general uprising of the Lithuanian people against the Livonian order. The yoke was shaken off, but internal wars followed, and three years later Mendowg was killed. About the end of the 13th century a new dynasty of rulers of Lithuania was founded by Lutouver, whose second son, Gedymin (1316–1341), with the aid of fresh forces he organized from his relations with Red Russia, established something like regular government; he extended at the same time his dominions over Russian countries—over Black Russia (Novogrodok, Zditoff, Grodno, Slonim, and Volkovysk) and the principalities of Polotsk, Tourovsk, Pinsk, Vitebsk, and Volhynia. He named himself *Rex Lethowinorum et multorum Ruthenorum.* In 1325 he concluded a treaty with Poland against the Livonian order, which treaty was the first step towards the union of both countries realized two centuries later. The seven sons of Gedymin considered themselves as quite independent; but two of them, Olgerd and Keistut, soon became the more powerful. They represented two different tendencies which existed at that time in Lithuania. Olgerd, whose family relations attracted him towards the south, was the advocate of union with Russia; rather politician than warrior, he increased his influence by diplomacy and by organization. His wife and sons being Christians, he also soon agreed to be baptized in the Greek Church. Keistut represented the revival of the Lithuanian nationality. Continually engaged in wars with Livonia, and remaining true to the national religion, he became the national legendary hero. In 1345 both brothers agreed to re-establish the great principality of Lithuania, and, after having taken Vilna, the old sanctuary of the country, all the brothers recognized the supremacy of Olgerd. His son Yagello, who married the queen of Poland, Yadviga, after having been baptized in the Latin Church, was crowned, on February 14, 1386, king of Poland. At the beginning of the 15th century Lithuania was a mighty state, extending her dominions as far east as Vyazma on the banks of the Moskva river, the present government of Kaluga, and Poutivl, and south-east as far as Poltava, the shores of the Sea of Azoff, and Hadji-bey (Odessa), thus including Kieff and Loutsk. The union with Poland remained, however, but nominal until 1569, when Sigismund Augustus was king of Poland. In the 16th century Lithuania did not extend its power so far east and south-east as two centuries before, but it constituted a compact state, including Polotsk, Moghileff, Minsk, Grodno, Kovno, Vilna, Brest, and reaching as far south-east as Tchernigoff. From the union with Poland, the history of Lithuania becomes a part of Poland's history, Lithuanians and White-Russians partaking of the fate of the Polish kingdom. After its three partitions, they fell under the dominion of the Russian empire. In 1792 Russia took the provinces of Moghileff and Polotsk, and in 1793 those of Vilna, Troki, Novgorod-Syeversk, Brest, and Vitebsk. In 1797 all these provinces were united together, constituting the "Lithuanian government" (Litovskaya Gubernia). But the name of Lithuanian provinces was usually given only to the governments of Vilna and Kovno, and, though Nicholas I. prohibited the use of this name, it is still used, even in official documents. In Russia, all the White-Russian population of the former Polish Lithuania are mostly considered as Lithuanians, the name of Jmud being restricted to Lithuanians proper.

The ethnographical limits of the Lithuanians are quite undefined, and their number is estimated very differently by different authors. The Letts occupy a part of the Courland peninsula (according to M. Rittich, they numbered there 305,300 in 1870, to which several authors add 185,800 Cours), of Livonia (416,400 at same date), and of Vitebsk (185,600), a few other settlements being spread also in the governments of Kovno (18,500), St Petersburg (2700), and

[1] W. B. Antonovitch, *A Sketch of History of the Great Principality of Lithuania*, and Professor Barsoff, *Russian Historical Geography*, both in Russian.

Moghileff (1000). The Lithuanians proper inhabit the governments of Kovno (435,810), Vilna (350,700), Suvalki (54,300), and Grodno (2500); whilst the Samoghitians, or Jmud, inhabit the governments of Kovno (498,900) and Suvalki (165,200). To these must be added about 200,000 Borussians, the whole number of Lithuanians being 2,687,000 in 1870 (2,873,000 with the Cours), or, taking into account the rate of increase of population for different governments, about 3,014,700 in 1882 (3,231,000 with Cours). Other authors estimate the number of Lithuanians in the Polish provinces at 277,050 in 1869, probably including Yatvyags, mixed to some extent with Mazurs. In this case the number of Lithuanians would be in 1882 about 3,082,000 (3,298,000 with Cours). They are now slowly extending towards the south, especially the Letts, who leave their country in consequence of want of land and of the difficulty they experienced in getting means of subsistence; numerous emigrants have already penetrated into Slavonic lands as far as the government of Voronesh.

The Lithuanians are well built; the face is mostly elongated, the features fine; the very fair hair, blue eyes, and delicate skin distinguish them from Poles and Russians. Their dress is usually plain in comparison with that of Poles, and the predominance in it of greyish colours has been frequently noticed. Their language has great similarities to the Sanskrit. It is affirmed that whole Sanskrit phrases are well understood by the peasants of the banks of the Niemen. But it contains also a considerable amount of Slavonic words. The vocabulary is very copious, especially in words referring to natural phenomena, and which express certain pathological states of the mind. Diminutives are exceedingly numerous, and various diminutive forms are applied even to adjectives and verbs. But, as a whole, the Lithuanian language is at a very low stage of development, and the written literature is very poor; only religious books, a few translations, and a single newspaper are published in it. On the other hand, the unwritten popular literature is very rich, and contains true treasures of poetry. It was long doubted if Lithuanians have any epic poetry; it now appears, however, that there are, scattered in songs, fragments of a great Lithuanian epic poem. But the popular poetry is especially rich in idyllic and lyric songs, imbued with tenderest love and melancholy, and a most poetical feeling of nature, and remarkable by their absolute chastity; the irony which sometimes appears in them is usually refined and gentle. The elegies (*raudas*) are very melancholy, and of a rare beauty. The national character is fully expressed in these songs,—not warlike at all, melancholy, very lovely, and not very sociable.

The language of the Letts is, according to Schleicher, as similar to the Lithuanian as the Italian to the Latin, but contains a greater mixture of German and Slavonic words. The literary language is more developed. A scientific Lettish grammar was published by Stender at the end of the last century, and the Letts possess translations of Shakespeare, Schiller, and other great poets. Five political papers were published in Lettish in 1876. A revival of national feeling having begun in this century, rich collections of Lettish songs were published by Germans, Russians, and Letts, M. Briwsemniaks's collection, published by the Moscow Anthropological Society, being the most recent. The Lettish songs have the same characters as those of the Lithuanians, to which a special feature, the hatred of the people to the German landholders, must be added.

The Letts of Courland, with the exception of about 50,000 who belong to the Greek Church, are Lutherans. Nearly all can read. Those of the government of Vitebsk, who were under Polish dominion, are Catholics, as well as the Lithuanians proper, a part of whom, however, have returned to the Greek Church, in which they were before the union with Poland. The Samoghitians are Catholics; they more than other Lithuanians have conserved their national features. But all Lithuanians have maintained much of their heathen practices and creed; the names of pagan divinities, very numerous in the former mythology, are continually mentioned in songs, and also in common speech.

The chief occupation of Lithuanians is agriculture. The trades in towns are generally carried on by men of other races—mostly by Germans, Jews, or Poles. The only exception is afforded to some extent by the Letts. The Samoghitians are good hunters, and all Lithuanians are given to apiculture and cattle breeding. But the Lithuanians, as well in the Baltic provinces as in the central ones, were not until the most recent time proprietors of the soil they tilled. They have given a few families to the Russian nobility, but the great mass of the people became serfs of foreign landowners, German and Polish, who reduced them to the greatest misery. Since the Polish insurrection of 1863, the Russian Government has given to the Lithuanians the land of the Polish proprietors on much easier terms than in central Russia; but the allotments of soil and the redemption taxes are very unequally distributed; and a not insignificant number of peasants (the *tchinshevik-i*) were even deprived of the land they had for centuries considered their own. The Letts remain in the same state as before, and are restrained from emigrating *en masse* only by coercive measures. (P. A. K.)

LITMUS (German, *Lackmus*; French, *Tournesol*), a colouring matter which occurs in commerce in the form of small blue tablets, which, however, consist mostly, not of the pigment proper, but of carbonate and sulphate of lime and other matter devoid of tinctorial value. Litmus is never used as a dye, but is extensively employed by chemists as a reagent for the detection of free acids and free alkalies. An aqueous infusion of litmus, when exactly neutralized by an acid, exhibits a violet colour, which by the least trace of free acid is changed to red, while free alkali turns it to blue. The reagent is generally used in the form of test paper,—bibulous paper dyed red, purple, or blue by the respective kind of infusion. Litmus is manufactured in Holland from the same kinds of lichens (species of *Roccella* and *Lecanora*) as are used for the preparation of ARCHIL (*q.v.*).

What orcein is to archil, a substance "azolitmin," which Kane extracted from it, seems to be to litmus. At any rate, Kane's analysis supports the idea of its being formed from orcin, thus:—

$$\underset{\text{Orcin.}}{C_7H_8O_2} + NH_3 + O_3 = H_2O + \underset{\text{Azolitmin.}}{C_7H_9NO_4}.$$

A solution of this substance when treated with nascent hydrogen loses its colour. So does litmus solution when left to itself in closely stoppered bottles. When preserved in contact with air it retains its colour.

LITTLE FALLS, a village and township in Herkimer county, New York, on the Erie canal, 73½ miles west-north-west of Albany by the New York Central and Hudson River Railroad, at a point where the Mohawk river passes by a series of rapids through a picturesque defile. The water-power is turned to account in the manufacture of paper, woollen and cotton goods, starch, &c. The village, which lies partly in the township of Manheim, had a population of 6910 in 1880. Little Falls has the largest cheese market in the United States.

LITTLE ROCK, capital of the State of Arkansas, United States, as well as of Pulaski county, is situated on the south bank of the Arkansas river, about 250 miles from its mouth, and near the centre of the State. It derives it name from occupying the top of a rocky cliff about 50 feet in height, which is much less conspicuous than the precipitous cliffs that line the river just above the city. The river, which is navigable by large steamers to this point during two-thirds of the year, is crossed here by an iron drawbridge on the St Louis, Iron Mountain, and Southern Railway. Little Rock, founded in 1820, contains the State house, the State asylums for the blind and for deaf mutes, the State prison, the State library, St John's Military College, and other schools. It is also the seat of the United States court of the eastern district of Arkansas, and a United States arsenal and land office. Flour-mills, carriage-works, and foundries are among the chief industrial establishments. Population in 1880, 13,138.

LITTLETON, THOMAS DE, of Frankley in Worcestershire, judge of the court of common pleas in the reign of Edward IV., and author of the well-known work on *Tenures*. Littleton's surname was that of his mother, who was the sole daughter and heiress of Thomas de Littleton, lord of Frankley. She married one Thomas Westcote. Thomas was the eldest of four sons of the marriage, and took the name of Littleton, or, as it seems to have been more commonly spelt, Luttelton. The date of his birth appears to be uncertain. He is said by Sir E. Coke to have been a member of the Inner Temple, and to have lectured there on the Statute of Westminster II., *De Donis Conditionalibus*. His name occurs in the Paston letters about 1445 as that of a well-known counsel. He appears to have been recorder of Coventry in 1450, to have been made king's sergeant in 1455, and afterwards to have been a justice of assize on the northern circuit. In 1466 he was made a judge of the common pleas, and in 1475 a knight of the Bath. He died, according to the inscription on his tomb in Worcester cathedral, on August 23, 1481. He married Joan, widow of Sir Philip Chetwind of Ingestre in Staffordshire, and by her had three sons, through whom he became ancestor of the families in which are the existing peerages of Lyttelton and Hatherton.

The work on tenures was probably written late in his life. It is addressed to his second son Richard, who went to the bar, and whose name occurs in the year books of the reign of Henry VII. The book, both historically and from its intrinsic merit, may be characterized as the first text-book upon the English law of property. The law of property in Littleton's time was mainly concerned with rights over land, and it was the law relating to this class of rights which Littleton set himself to digest and classify. The time was ripe for the task. Ever since the Conquest regular courts of justice had been at work administering a law which had grown out of an admixture of Teutonic custom and of Norman feudalism. Under Henry II. the courts had been organized, and the practice of keeping regular records of the proceedings had been carefully observed. The centralizing influence of the royal courts and of the justices of assize, working steadily through three centuries, had made the rules governing the law of property uniform throughout the land; local customs were confined within certain prescribed limits, and were only recognized as giving rise to certain well-defined classes of rights, such, for instance, as the security of tenure acquired by villeins by virtue of the custom of the manor, and the rights of freeholders, in some towns, to dispose of their land by will. Thus, by the time of Littleton (Henry VI. and Edward IV.), an immense mass of material had been acquired and preserved in the rolls of the various courts. Reports of important cases were published in the "year books." A glance at Statham's *Abridgment*, the earliest digest of decided cases, published nearly at the same time as Littleton's *Tenures*, is sufficient to show the enormous bulk which reported cases had already attained as materials for the knowledge of English law.

Littleton's treatise was written in French, or rather in that peculiar dialect compounded of Norman-French and English phrases called law French. Although it had been provided by a statute of 36 Edward III. that *viva voce* proceedings in court should no longer be conducted in the French tongue, "which was much unknown in the realm," the practice of reporting proceedings in that language, and of using it in legal treatises, lingered till a much later period, and was at length prohibited by a statute passed in the time of the Commonwealth in 1650. Unlike the preceding writers on English law, Glanville, Bracton, and the authors of the treatises known by the names of Britton and Fleta, Littleton borrows nothing from the sources of Roman law or the commentators. He deals purely and exclusively with English law.

The book is written on a definite system, and is the first attempt at something like a scientific classification of rights over land. Littleton's method is to begin with a definition, usually clearly and briefly expressed, of the class of rights with which he is dealing. He then proceeds to illustrate the various characteristics and incidents of the class by stating particular instances, some of which refer to decisions which had actually occurred, but more commonly they are hypothetical cases put by way of illustration of his principles. He occasionally but rarely refers to reported cases. His book is thus much more than a mere digest of judicial decisions; to some extent he pursues the method which gave to Roman law its breadth and consistency of principle. In Roman law this result was attained through the practice of putting to jurisconsults hypothetical cases to be solved by them. Littleton, in like manner, is constantly stating and solving by reference to principles of law cases which may or may not have occurred in actual practice.

In dealing with freehold estates Littleton adopts a classification which has been followed by all writers who have attempted to systematize the English law of land, especially Sir M. Hale and Sir William Blackstone. It is indeed the only possible approach to a scientific arrangement of the intricate "estates in land" known to English law. He classifies estates in land by reference to their duration, or in other words by reference to the differences between the persons who are entitled to succeed upon the death of the person in possession or "tenant." First of all, he describes the characteristics of tenancy in fee simple,—an interest in lands which devolves on the death of the tenant to his heir, whether such heir be of the same line or collateral. This is still as it was in Littleton's time the largest interest in land known to the law. Next in order comes tenancy in fee tail, the outcome, as Littleton informs us, of the Statute of Westminster II., 13 Edw. I. c. 1, "De Donis Conditionalibus," which enacted in the interest of the great lords that a gift to a man and "the heirs of his body" should no longer bear the construction which the courts had put upon the words, holding the donee to be thereby invested with full power over the land so soon as he had issue born, but should descend according to the form of the gift to lineal descendants so long as lineal descendants should exist. The various classes of estates tail are sketched by Littleton with brevity and accuracy, but he is silent as to the important practice, which first received judicial recognition shortly before his death, of "suffering a recovery," whereby through a series of judicial fictions a tenant in tail was enabled to convert his estate tail into a fee simple, thus acquiring full power of alienation. After discussing in their logical order other freehold interests in land, he passes to interests in land called by later writers interests less than freehold, namely, tenancies for terms of years and tenancies at will. With the exception of tenancy from year to year, now so familiar to us, but which was a judicial creation of a date later than the time of Littleton, the first book is a complete statement of the principles of the common law, as they for the most part still exist, governing and regulating interests in lands. The first book concludes with a very interesting chapter on copyhold tenures, which marks the exact point at which the tenant by copy of court roll, the successor of the villein, who in his turn represented the freeman reduced to villenage by the growth of the manorial system, acquired security of tenure by the judicial recognition of the fact that the "will of the lord" was controlled by and could only be exercised in accordance with the "custom of the manor."

The second book relates to the reciprocal rights and duties of lord and tenant, and is mainly of historical interest to the modern lawyer. It contains a complete statement of the law as it stood in Littleton's time relating to homage, fealty, and escuage, the money compensation to be paid to the lord in lieu of military service to be rendered to the king, a peculiar characteristic of English as distinguished from Continental feudalism.

Littleton then proceeds to notice the important features of tenure by knight's service with its distinguishing incidents of the right of wardship of the lands and person of the infant heir or heiress, and the right of disposing of the ward in marriage. The non-military freehold tenures are next dealt with; we have an account of "socage tenure," into which all military tenures were subsequently commuted by a now unrecognized Act of the Long Parliament in 1650, afterwards re-enacted by the well-known statute of 12 Charles II. c. 24, and of "frankalmoign," or the spiritual tenure by which churchmen held, their duty being "to make orisons, prayers, masses, and other divine services for the souls of their grantor or feoffor, and being bound to no fealty to the lord because that this divine service is better for them before God than any doing of fealty." In the description of burgage tenure and tenure in villenage, the life of which consists in the validity of ancient customs recognized by law, we recognize survivals of a time before the iron rule of feudalism had moulded the law of land in the interests of the king and the great lords. Finally he deals with the law of rents, discussing the various kinds of rents which may be reserved to the grantor upon a grant of lands and the remedies for recovery of rent, especially the remedy by distress.[1]

The third and concluding book of Littleton's treatise deals mainly with the various ways in which rights over land can be acquired and terminated in the case of a single possessor or several possessors. This leads him to discuss the various modes in which several persons may simultaneously have rights over the same land, as parceners:—daughters who are co-heiresses, or sons in gavelkind;

[1] These two books are stated, in a note to the table at the conclusion of the work, to have been made for the better understanding of certain chapters of the *Antient Book of Tenures*. This refers to a tract called *The Old Tenures*, said to have been written in the reign of Edward III. By way of distinguishing it from this work, Littleton's book is called in all the early editions "Tenores Novelli."

joint tenants, where the interest does not pass to the heir of the deceased joint tenant, but devolves upon the surviving joint tenant; and tenants in common, where the interest is separate and descends to the heir of each of the co-tenants, though the land over which the right exists is undivided and held in common with one or more other persons." Next follows an elaborate discussion upon what are called estates upon condition,—a class of interests which occupied a large space in the early common law, giving rise on one side to estates tail, on another to mortgages. In Littleton's time a mortgage, which he carefully describes, was merely a conveyance of land by the tenant to the mortgagee, with a condition that, if the tenant paid to the mortgagee a certain sum on a certain day, he might re-enter and have the land again. If the condition was not fulfilled, the interest of the mortgagee became absolute, and Littleton gives no indication of any modification of this strict rule, such as was introduced by courts of equity, permitting the debtor to redeem his land by payment of all that was due to the mortgagee although the day of payment had passed, and his interest had become at law indefeasible. The remainder of the work is occupied with an exposition of a miscellaneous class of modes of acquiring rights of property, the analysis of which would occupy too large a space.

The work is thus a complete summary of the common law as it stood at the time. It is nearly silent as to the remarkable class of rights which had already assumed vast practical importance—equitable interests in lands. These are only noticed incidentally in the chapter on "Releases." But it was already clear in Littleton's time that this class of rights would become the most important of all. Littleton's own will, which has been preserved, may be adduced in proof of this assertion. Although nothing was more opposed to the spirit of Norman feudalism than that a tenant of lands should dispose of them by will, we find Littleton directing by his will the feoffees of certain manors to make estates to the persons named in his will. In other words, in order to acquire over lands powers unknown to the common law, the lands had been conveyed to "feoffees" who had full right over them according to the common law, but who were under a conscientious obligation to exercise those rights at the direction and for the exclusive benefit of the person to whose "use" the lands were held. This conscientious obligation was recognized and enforced by the chancellor, and thus arose the class of equitable interests in lands. Littleton is the first writer on English law after these rights had risen into a prominent position, and it is curious to find to what extent they are ignored by him. Unlike their treatment of copyhold interests, the common lawyers wholly refused to recognize the right of the real or beneficial owner, when the legal interest was vested in another, though the latter had then but the semblance without the reality of ownership. Hence it was that the most important class of rights developed outside the common law. After an unhappy attempt to reunite the classes of legal and equitable interests by the Statute of Uses (27 Henry VIII. c. 10), the effect of which was to introduce still greater technicality and complication into the law of real property, the two classes have continued to exist side by side, until in our own time the Judicature Act of 1873, by uniting in one court the tribunals the difference between which originally gave rise to the distinction between legal and equitable interests, has perhaps paved the way for a simpler and more rational classification of rights over land.

The work of Littleton occupies a place in the history of typography as well as of law. The earliest printed edition seems to be that by John Lettou and William de Machlinia, two printers who probably came from the Continent, and carried on their business in partnership, as their note to the edition of Littleton states, "in civitate Londoniarum, juxta ecclesiam omnium sanctorum." The date of this edition is uncertain, but the most probable conjecture, based on typographical grounds, places it about the latter part of 1481. The next edition is one by Machlinia alone, probably about two or three years later than the former. Machlinia was then in business alone "juxta pontem quæ vulgo dicitur Fleta brigge." Next came the Rohan or Rouen edition, erroneously stated by Sir E. Coke to be the earliest, and to have been printed about 1533. It was, however, of a much earlier date. Tomlins, the latest editor of Littleton, gives reasons for thinking that it cannot have been later than 1490. It is stated in a note to have been printed at Rouen by William le Tailleur "ad instantiam Richardi Pynson." Copies of all these editions are in the British Museum. In all these editions the work is styled *Tenores Novelli*, probably to distinguish it from the "Old Tenures."

There are three early MSS. of Littleton in the University Library at Cambridge. One of these formerly contained a note on its first page to the effect that it was bought in St Paul's Churchyard on July 20, 1480. It was therefore in circulation in Littleton's lifetime. The other two MSS. are of a somewhat later date; but one of them contains what seems to be the earliest English translation of the *Tenures*, and is probably not later than 1500.

In the 16th century editions of Littleton followed in rapid succession from the presses of Pynson, Redmayne, Berthelet, Tottyl, and others. The practice of annotating the text caused several additions to be introduced, which, however, are easily detected by comparison of the earlier copies. In 1581 West divided the text into seven hundred and forty-six sections, which have ever since been preserved. Many of these editions were printed with large margins for purposes of annotation, specimens of which may be seen in Lincoln's Inn Library.

The practice of annotating Littleton was very general, and was adopted by many eminent lawyers besides Sir E. Coke, amongst others by Sir M. Hale. One commentary of this kind, by an unknown hand of earlier date than Sir E. Coke's, was edited by Cary in 1829. Following the general practice of dealing with Littleton as the great authority on the law of England, "the most perfect and absolute work that ever was written in any human language," Sir E. Coke makes it the text of that portion of his work which he calls the first part of the institutes of the law of England, in other words, the law of property.

The first printed English translation of Littleton was by Rastell, who seems to have combined the professions of author, printer, and sergeant-at-law, between 1514 and 1533. Many English editions by various editors followed, the best of which is Tottyl's in 1556. Sir E. Coke adopted some translation earlier than this, which has since gone by the name of Sir E. Coke's translation. He, however, throughout comments not on the translation but on the French text; and the reputation of the commentary has to some extent overlaid and obscured the intrinsic merit of the original. (K. E. D.)

LITTRÉ, Paul Maximilien Emile (1801-1881), the compiler of the best dictionary of any living language, and the Frenchman of most encyclopædic knowledge since Diderot, was born at Paris on February 1, 1801. His father had been a gunner, and afterwards sergeant-major of marine artillery, in the French navy, and was deeply imbued with the revolutionary ideas of the day. Settling down as a collector of taxes, he married Sophie Johannot, a free-thinker like himself, and devoted himself to the education of his son Émile. The boy was sent to the Lycée Louis-le-Grand, where he had for friends Hachette and Eugène Burnouf, and he distinguished himself alike in his work and in all athletic exercises. After he had completed his course at school, he hesitated for a time as to what profession he should adopt, and meanwhile made himself master, not only of the English and German languages, but of the classical and Sanskrit literature and philology. At last he determined to study medicine, and in 1822 entered his name as a student of medicine. He passed all his examinations in due course, and had only his thesis to prepare in order to obtain his degree as doctor when in 1827 his father died, leaving his mother absolutely without resources. He at once renounced his degree, and, while attending the lectures of Rayer and taking a keen interest in medicine, began teaching Latin and Greek for a livelihood. He carried a musket on the popular side in the revolution of February 1830, and was one of the national guards who followed Charles X. to Rambouillet. At last, in 1831, when quite thirty years of age, he obtained an introduction to Armand Carrel, the editor of the *National*, who gave him the task of reading the English and German papers for excerpts. Carrel by the merest chance, in 1835, discovered the ability of his reader, who from that time became a constant contributor, and eventually director of the paper. In 1836 he began to contribute articles on all sorts of subjects to the *Revue des Deux Mondes*; in 1837 he married; and in 1839 appeared the first volume of his edition of the works of Hippocrates. This volume at once placed Littré in the forefront of the literary and scientific world; its ability was recognized by his election the same year into the Académie des Inscriptions et Belles-Lettres. At the age of thirty-eight then he had won for himself a high reputation as a learned man of letters and of science, but was still tormented by the unsettled ideas and thoughts which generally beset younger men, and were only increased by the study of his favourite authors Byron and Obermann. At this epoch he came across the works of Auguste Comte, the reading of which formed, as he himself said, "the cardinal point of his life," and from this time onward appears the influence of positivism on his own life, and, what is of even more importance, his influence on positivism, for he gave at least as much to positivism as he received from it. He brought to it a wide knowledge of science and literature, a great and growing reputation, and a clear head. He soon became an intimate friend of Comte's, and set to work to popularize his ideas in numerous works on the positivist philosophy, while at the same time continuing his edition of Hippocrates, which was not completed till 1862, publishing a similar edition of Pliny's *Natural History*, assisting after 1844 in the place of Fauriel at the committee engaged on the *Histoire littéraire de la France*, where his knowledge of the early French language and literature was invaluable, and contributing largely to the *National* and *Revue des Deux Mondes*. In the revolution of July 1848 he took a keen interest, and himself took part in the repression of the extreme republican party in June 1849, under the banner of order. His essays, contributed during this period to the *National*, were collected together and published under the title of *Conservation, Révolution, et Positivisme* in 1852, and show, not only a lively faith in a good time coming, but a thorough acceptance of all the doctrines propounded by Comte. However, during the later years of his master's life, he began to perceive that he could not wholly accept all the dogmas or the more mystic ideas of his friend and master, but he studiously concealed his differences of opinion almost from himself, and Comte failed to perceive that his pupil had outgrown him, as he himself had outgrown his master Saint-Simon. Comte's death in 1858 freed Littré from any fear of embittering his master's later years, and he published his own ideas in his *Paroles de la Philosophie Positive* in 1859, and at still greater length in his work in *Auguste Comte et la Philosophie positive* in 1863. In this book he traces the origin of Comte's ideas through Turgot, Kant, and Saint-Simon, then eulogizes Comte's own life, his method of philosophy, his great services to the cause, and the effect of his works, and finally proceeds to show where he himself differs from him. He approved wholly of Comte's philosophy, his great laws of society, and his philosophical method, which indeed he defended warmly against J. S. Mill, but declared that, while he believed in a positivist philosophy, he did not believe in a religion of humanity. In the year 1863, after completing his Hippocrates and his Pliny, he set to work on his great French dictionary, bringing to the task an unexampled knowledge of old French, of modern and classical languages, and of modern philology, which were to make his dictionary unique in its interest and accuracy. In the same year he was proposed for the Académie Française, but rejected, owing to the opposition of the fiery bishop of Orleans, who denounced him as the chief of the French materialists. He also at this time started with M. Wyrouboff the *Philosophie Positive*, a review which was to embody the views of modern positivists, and to which he largely contributed. His life was thus absorbed in literary work, and flowed quietly on, till the overthrow of the empire called on him to take a part in politics. He felt himself too old to undergo the privations of the siege of Paris, and retired with his family to Britanny, whence he was summoned by M. Gambetta to Bordeaux, to lecture on history, and thence to Versailles to take his seat in the senate to which he had been chosen by the department of the Seine. In December 1871 he was elected a member of the Académie Française in spite of the renewed opposition of the Mgr. Dupanloup, bishop of Orleans, who resigned his seat rather than receive him. His dictionary was completed in 1873, and he lived on full of years and honours, for in 1874 he was elected a life senator. The most notable of his productions in these latter years were his political papers attacking and unveiling the confederacy of the Orleanists and legitimists, and in favour of the republic, his republication of many of his old articles and books, among others the *Conservation, Revolution, et Positivisme* of 1852 (which he reprinted word for word, appending a formal, categorical renunciation of many of the Comtist doctrines therein contained), and a little tract *Pour la dernière fois*, in which he maintained his unalterable belief in materialism. When it became obvious that the old man could not live much longer, his wife and daughter, who had always been fervent Catholics, strove to convert him to their religion. He had long interviews with Père Milleriot, a celebrated controversialist, and was much grieved at his death; but it is hardly probable he would have ever been really converted. Nevertheless, when on the point of death, his wife had him baptized, and his funeral was conducted with the rites of the Catholic Church. He died June 2, 1881.

It is almost impossible to characterize the varied learning and immense intellectual activity of Littré. As a philosopher he had popularized and sifted the ideas of Comte, and had succeeded Comte as Comte succeeded Turgot, Kant, and Saint-Simon; as a lexicographer he has been compared to Johnson, though his work is as far ahead of Johnson's as the philological knowledge of the 19th century is in advance of that of the 18th; and as a man of almost universal knowledge, and a writer on every sort of subject, from barbarian learning and modern science to epic poetry and the military genius of Napoleon, he remains unrivalled, even in a country which can boast of Diderot and Comte.

It would take too much space to give a complete list of all Littré's voluminous works, but the following are those of greatest importance:—his editions of Hippocrates, 1839–61, and of Pliny's *Natural History*, 1848–50; his translation of Strauss's *Vie de Jésus*, 1839–40, and Muller's *Manuel de Physiologie*, 1851; his edition of the works of Armand Carrel, with notes, 1854–58; the *Histoire de la langue française*, a collection of magazine articles, 1862; and his *Dictionnaire de la langue française*, 1863–72. In the domain of science must be noted his edition, with Charles Robin, of Nysten's *Dictionnaire de médecine, de chirurgie*, &c., 1855; in that of philosophy, his *Analyse raisonnée du cours de philosophie positive de M. A. Comte*, 1845; *Application de la Philosophie positive au Gouvernement*, 1849; *Conservation, Révolution, et Positivisme*, 1852 (2d edition with supplement, 1879); *Paroles de la Philosophie positive*, 1859; *Auguste Comte et la Philosophie positive*, 1863; *La Science au point de vue philosophique*, 1873; *Fragments de philosophie et de sociologie contemporaine*, 1876; and his most interesting miscellaneous works, his *Études et Glanures*, 1880; *La Verité sur la mort d'Alexandre le Grand*, 1865; *Études sur les barbares et le moyen âge*, 1867; *Médecine et Médecins*, 1871; *Littérature et Histoire*, 1875; and *Discours de Reception à l'Académie française*, 1873.

For his life consult Sainte-Beuve's notice, 1862, and the numerous articles published after his death in the newspapers and reviews, of which the best are the notices of M. Durand-Gréville in the *Nouvelle Revue* of August 1881, of M. Caso in the *Revue des Deux Mondes*, and of M. Frédéric Godefroy in the *Lettres chrétiennes*. (H. M. S.)

LITURGY. The word "Liturgy" technically denotes the "Order for the Celebration and Administration of the Eucharist." It has come to be used in a more popular sense to denote any or all of the various services of the Christian church, whether contained in separate volumes or bound up together in the form of a Book of Common Prayer. We propose to treat of "the liturgy" chiefly, but not exclusively, in the former and stricter sense, and, without further discussion of the use of the word in Biblical or patristic literature, and without entering into various questions with reference to their origin, growth, first committal to writing, &c., to give our readers some account of the principal liturgies which exist, or have existed, in the Christian church.

There are five main families or groups of liturgies, three of them Eastern in origin and use, one Eastern in origin but Western in use, one Western both in origin and use. They are known either by the names of the apostles with whom they are traditionally connected, or by the names of the countries or cities in which they are known or believed to have been once or always in use.

GROUP I. *St James, West Syrian, Jerusalem.*—The principal liturgies to be enumerated under this group are the Clementine, so called from being found in the eighth book of the *Apostolic Constitutions*, which have been erroneously referred to St Clement, first bishop of Rome (lib. viii. 10–15); the Greek and Syriac liturgies of St James; the Greek liturgies of St Basil and St Chrysostom; the Armenian liturgy of St Gregory the Illuminator, first patriarch of Armenia; a large number of later Syriac liturgies springing from the Syriac liturgy of St James. Of these liturgies, that of St Chrysostom is used now by the Orthodox Eastern Church, except on the first five Sundays in Lent, Thursday and Saturday in Holy Week, the vigils of Christmas and Epiphany, and St Basil's Day, when the liturgy of St Basil is used; and in Lent (except Sundays and Saturdays and Lady Day), when the liturgy of the pre-sanctified is used.

This group, like all the purely Eastern liturgies, is marked by an absence of flexibility as to number and shape of prefaces, collects, &c. Its special feature, if we may adopt a recently employed canon of differentiation, is the position of the great intercession for quick and dead, for rulers in church and state, for the sick, for travellers, for the fruits of the earth, &c., after the consecration of the elements has been completed by the invocation of the Holy Spirit (C. E. Hammond, *Lit. Eastern and Western*, pp. 26-29).

GROUP II. *St Mark, Egyptian, Alexandria.*—This group includes the Greek liturgies of St Mark, St Basil, and St Gregory; the Coptic liturgies of St Cyril, St Basil, and St Gregory; the Ethiopic liturgy known as the "Canon Universalis" or "Liturgy of all the Apostles," together with sixteen other subordinate Ethiopic liturgies. They are distinguished by the position of the great intercession in the middle of the preface, as well as by the prominent part assigned throughout to the deacon.

GROUP III. *St Adæus, East Syrian, Edessa.*—There are three extant liturgies belonging to this group, now exclusively used by Nestorian Christians,—those of SS. Adæus and Maris, Theodore of Mopsuestia, and Nestorius; the titles of three lost liturgies have been preserved,—those of Narses, Barsumas, and Diodorus of Tarsus. The liturgy of the Christians of St Thomas, on the Malabar coast of India, formerly belonged to this group, but it was almost completely assimilated to the Roman liturgy by Portuguese Jesuits at the synod of Diamper in 1599. The characteristic of this group is the position of the great intercession in the middle of the consecration, between the words of institution (or, to speak more accurately, the place where the words of institution must have occurred) and the invocation.

GROUP IV. *St John, Hispano-Gallican, Ephesus.*—This group of Latin liturgies, which once prevailed very widely in western Europe, has been almost universally superseded by the liturgy of the Church of Rome. Where it survives it has been either partially or almost completely assimilated to the Roman pattern. It prevailed once throughout Spain, France, part of northern Italy, and Great Britain and Ireland, in forms of which a detailed account is appended. The term "Ephesine" has been applied to this family of liturgies, chiefly by modern English liturgiologists, to denote a theory as to their origin which, although upheld by other than English writers, must be regarded rather as a possible hypothesis than a proved fact (Leslie, *Pref. to Mozar. Missal*, sect. 25; Bickell, *Messe und Pascha*, p. 10). The many traces of Eastern influence in their composition, and the close connexion which is known to have existed at a very early period between the churches of Lyons and of western Asia Minor, have suggested the theory that the latter country must have been the birth-place of this class of liturgies. The names of the apostle St John and of Ephesus his place of residence have been pressed into service as further particularizations of the same theory. The special feature of these liturgies is the position of the great intercession after the offertory, before the commencement of the preface and canon.

The chief traces of Oriental affinity lie in the following points:—(1) the various proclamations made by the deacon, including that of "Silentium facite" before the epistle (Migne, tom. lxxxv. p. 534); (2) the presence of a third lesson, preceding the epistle, taken from the Old Testament; (3) the occasional presence of "preces," a series of short intercessions resembling the Greek "Ektene," or deacon's litany; (4) the position of the kiss of peace at an early point in the service, before the canon, instead of the Roman position after consecration; (5) the exclamation "sancta sanctis" occurring in the Mozarabic rite, the counterpart of the Eastern τὰ ἅγια τοῖς ἁγίοις; (6) traces of the presence of the "Epiklesis," that is to say, the invocation of the Holy Spirit, in its Eastern position, after the words of institution, as in the collect styled the Post-pridie in the Mozarabic service for the second Sunday after Epiphany:—"We beseech thee that thou wouldest sanctify this oblation with the permixture of Thy Spirit, and conform it with full transformation into the Body and Blood of our Lord Jesus Christ." On the other hand, the great variableness of its parts, and its immense number of proper prefaces, ally it to the Western family of liturgies.

We now proceed to give a more detailed account of the chief liturgies of the Hispano-Gallican group.

1. *The Mozarabic Liturgy.*—This was the national liturgy of the Spanish Church till the close of the 11th century, when the Roman liturgy was forced upon it. Its use, however, lingered on, till in the 16th century Cardinal Ximenes, anxious to prevent its becoming quite obsolete, had its books restored and printed, and founded a college of priests at Toledo to perpetuate its use. It survives now only in that and one other church in Spain, and even there not without certain Roman modifications of its original text and ritual.

Its date and origin, like the date and origin of all existing liturgies, are uncertain, and enveloped in the mists of antiquity. It is evidently not derived from the Roman liturgy. Its whole structure, and every separate detail, disprove such a parentage, and therefore it is strange to find St Isidore of Seville (*Lib. de Eccles. Offic.*, i. 15) attributing it to St Peter. No proof is adduced, and the only value which can be placed upon such an unsupported assertion is that it shows that a very high and even apostolic antiquity was claimed for it. A theory, originating with Pinius, that it may have been brought by the Goths from Constantinople when they invaded Spain, is as improbable as it is unproven. It may have been derived from Gaul. The Gallican liturgy stood to it in the relation of twin-sister, if it could not claim that of mother. The resemblance was so great that, when Charles the Bald (843–877) wished to gain some idea of the character of the already obsolete Gallican rite, he sent to Toledo for some Spanish priests to perform mass according to the Mozarabic rite in his presence. But there is no record of the conversion of Spain by Gallican missionaries. Christianity existed in Spain from the earliest times. Probably St Paul travelled there (Rom. xv. 24–28). It may be at least conjectured that its liturgy was Pauline rather than Petrine or Johannine.

2. *Gallican Liturgy.*—This was the ancient and national liturgy of France till the commencement of the 9th century, when it was suppressed by order of Charlemagne, who directed the Roman missal to be everywhere substituted in its place. All traces of it seemed for some time to have been lost, until three Gallican sacramentaries were discovered and published by Thomasius in 1680, under the titles of *Missale Gothicum*, *Missale Gallicum*, and *Missale Francorum*, and a fourth was discovered and published by Mabillon in 1687, under the title of *Sacramentarium Bobbiense*. Fragmentary discoveries have been made since then. Mone discovered fragments of eleven Gallican masses, and published them at Carlsruhe in 1850. Other fragments from the library of St Gall have been published by Bunsen (*Anal. Ante-Nic.*, iii. 263–66), and from the Ambrosian library at Milan by Cardinal Mai (*Scrip. Vet. Vat. Coll.*, iii. 2, 247). More of this MS. is being prepared for publication by Dr Ceriani. A single page was

discovered in the library of Gonville and Caius College, Cambridge, in 1867, which has not yet been published. These documents, illustrated by early Gallican canons, and by allusions in the writings of Sulpicius Severus, Cæsarius of Arles, Gregory of Tours, Germanus of Paris, and other authors, enable scholars to reconstruct the greater part of this liturgy. The previously enumerated signs of Eastern origin and influence are found here as well as in the Mozarabic liturgy, together with certain other more or less minute peculiarities, which would be of interest to professed liturgiologists, but which we must not pause to specify here. They point to the possibility of the theory that the Gallican liturgy was introduced into use by Irenæus, bishop of Lyons (*c.* 130–200), who had learned it in the East from St Polycarp, the disciple of the apostle St John.

3. *Ambrosian Liturgy.*—Considerable variety of opinion has existed among liturgical writers as to the proper classification of the "Ambrosian" or "Milanese" liturgy. If we are to accept it in its present form, and to make the present position of the great intercession the test of its *genus*, then we must place it under Group V., the "Petrine," and consider it as a branch of the Roman family. If, on the other hand, we consider the important variations from the Roman liturgy which yet exist, and the still more marked and numerous traces of variation which confront us in the older printed and MS. copies of the Ambrosian rite, we shall detect in it an original member of the Ephesine group of liturgies, which for centuries past has been undergoing a gradual but ever increasing assimilation to Rome. We know this as a matter of history, as well as a matter of inference from changes in the text itself. Charlemagne adopted the same policy towards the Milanese as towards the Gallican Church. He carried off all the Milanese Church books which he could obtain, with the view of substituting Roman books in their place, but the completeness of his intentions failed, partly through the attachment of the Lombards to their own rites, partly through the intercession of a Gallican bishop named Eugenius (Mabillon, *Mus. Ital.*, i., ii. p. 106). It has been asserted by Joseph Vicecomes that this is an originally independent liturgy drawn up by St Barnabas, who first preached the gospel at Milan (*De Missæ Rit.*, i. chap. xi., xii.), and this tradition is preserved in the title and proper preface for St Barnabas Day in the Ambrosian missal (Pamelius, i. 385, 386).

We can trace the following points in which the Milanese differs from the Roman liturgy, many of them exhibiting distinct lines of Ephesine or Eastern influence. Some of them are no longer found in recent Ambrosian missals, and only survive in the earlier MSS. published by Pamelius (*Liturgicon*, tom. i. p. 293), Muratori (*Lit. Rom. Vet.*, i. 132), and Ceriani (in his edition, 1881, of an ancient MS. at Milan).

(*a*) The collect entitled "oratio super sindonem," corresponding to the *εὐχὴ μετὰ τὸ ἁπλωθῆναι τὸ εἰλητόν*; (*b*) the proclamation of silence by the deacon before the epistle; (*c*) the litanies said after the Ingressa (introit) on Sundays in Lent, closely resembling the Greek Ektene; (*d*) varying forms of introduction to the Lord's Prayer, in Cœna Domini (Ceriani, p. 116), in Pascha (*ib.*, p. 129); (*e*) the presence of passages in the Prayer of Consecration which are not part of the Roman canon, and one of which at least corresponds in import and position though not in words to the Greek Ἐπίκλησις: *Tuum vero est, omnipotens Pater, mittere*, &c. (*ib.*, p. 116); (*f*) the survival of a distinctly Gallican form of consecration in the Post-Sanctus "in Sabbato Sancto": *Vere Sanctus, vere benedictus Dominus noster*, &c. (*ib.*, p. 125); (*g*) the varying nomenclature of the Sundays after Pentecost; (*h*) the position of the fraction before the Lord's Prayer; (*i*) the omission of the second oblation after the words of institution (Muratori, *Lit. Rom. Vet.*, i. 133); (*k*) a third lection or *Prophetia* from the Old Testament preceding the epistle and gospel; (*l*) the lay offering of the oblations and the formulæ accompanying their reception (Pam., i. 297); (*m*) the position of the ablution of the hands in the middle of the canon just before the words of institution; (*n*) the position of the "oratio super populum" which corresponds in matter but not in name to the collect for the day before the Gloria in Excelsis.

4. *Celtic Liturgy.*—We postpone the consideration of this subject to a position under the heading of the liturgies of Great Britain and Ireland.

GROUP V. *St Peter, Italian, Rome.*—There is only one liturgy to be enumerated under this group, viz., the present liturgy of the Church of Rome, which, though originally local in character and circumscribed in use, has come to be nearly coextensive with the Roman Church, sometimes cuckoo-like ejecting earlier national liturgies, as in France and Spain, sometimes incorporating more or less of the ancient ritual of a country into itself, and producing from such incorporation a subclass of distinct uses, as in England, France, and North Italy. Even these subordinate uses have for the most part become, or are rapidly becoming, obsolete. The genius and policy of Rome are in favour of uniformity; and it requires no keen powers of vision to foretell that, liturgically speaking, she will be, before long, within all her dominions supreme.

The date, origin, and early history of the Roman liturgy are obscure. The first Christians at Rome were a Greek-speaking community, and their liturgy must have been Greek, and is possibly represented in the so-called Clementine liturgy. But the date when such a state of things ceased, when and by whom the present Latin liturgy was composed, whether it is an original composition, or, as its structure seems to imply, a survival of some intermediate form of liturgy,—all these are questions which are waiting for their solution, and to which no certain answer can be given, unless and until some further discovery shall be given of earlier liturgical remains.

One MS. exists which claims to represent the Roman liturgy as it existed in the time of Leo I., 440–61. It was discovered at Verona by Blanchini in 1735, assigned by him to the 8th century, and published under the title of *Sacramentarium Leonianum*; but this title was from the first purely conjectural, and is in the teeth of the internal evidence which the MS. itself affords, and is now being gradually abandoned. It is impossible here to enter into the minutiæ of the evidence for this and other conclusions. The question is discussed at some length by Muratori, *Lit. Rom. Vet.*, i. chap. 3.

A MS. of the 9th or 10th century was found at Rome by Thomasius, and published by him in 1680 under the title of *Sacramentarium Gelasianum.* But it was written in France, and is certainly not a pure Gelasian codex; and, although there is historical evidence of that pope (492–96) having made some changes in the Roman liturgy, and although other MSS. have been published by Gerbertus and others, claiming the title of Gelasian, we neither have nor are likely to have genuine and contemporary MS. evidence of the real state of the liturgy in that pope's time.

The larger number of MSS. of this group are copies of the Gregorian sacramentary, that is to say, MSS. representing, or purporting to represent, the state of the Roman liturgy in the days of Gregory the Great (590–604). But they cannot be accepted as certain evidence, for the following reasons:—not one of them was written earlier than the 9th century; not one of them was written in Italy, but every one north of the Alps; every one contains internal evidence of a post-Gregorian date in the shape of masses for the repose or for the intercession of St Gregory, and in various other ways.

The Roman liturgy was introduced into England in the 7th, into France in the 9th, and into Spain in the 11th century. In France certain features of the service and certain points in the ritual of the ancient national liturgy became interwoven with its text, and formed those many varying mediæval Gallican uses, which are associated with the names of the different French sees.

The distinguishing characteristics of the Petrine liturgy are these:—(*a*) the position of the great intercession within the canon.

the commemoration of the living being placed just before, and the commemoration of the departed just after, the words of institution; (b) the absence of the Epiklesis or Invocation of the Holy Spirit; (c) the position of the Pax or "Kiss of Peace" after the consecration and just before the communion, whereas in other liturgies it occurs at a much earlier point in the service.

Liturgies of the British Islands.

PERIOD I. *The Celtic Church.*—Until recently almost nothing was known of the character of the liturgical service of the vast Celtic Church which existed in these islands before the Anglo-Saxon conquest, and which continued to exist in Ireland, Scotland, Wales, and Cornwall for very considerable though varying periods of time after that event. But recently a good deal of light has been thrown on the subject, partly by the publication of the few genuine works of SS. Patrick, Columba, Columbanus, and other Celtic saints; partly by the discovery of liturgical remains in the Scottish *Book of Deer*, and in the Irish *Books of Dimma and Mulling* and the *Stowe Missal*; partly by the publication of mediæval Irish compilations such as the *Leabhar Breac*, *Liber Hymnorum*, &c., which contain ecclesiastical calendars, legends, treatises, &c., of considerable but very varying antiquity. The evidence collected from these sources is sufficient to prove that the liturgy of the Celtic Church was of the Ephesine type. In central England the churches, together with their books and everything else belonging to them, were destroyed by heathen invaders from Jutland, Schleswig, and Holstein at the close of the 5th century; but the Celtic Church in the remoter parts of England, as well as in the neighbouring kingdoms of Scotland and Ireland, retained its liturgical independence for many centuries afterward.

An examination of its few extant service books and fragments of service books yields the following evidence of the Ephesine origin and character of the Celtic liturgy:—(a) The presence of whole collects and anthems which occur in the Gallican and Mozarabic but not in the Roman liturgy; (b) various formulæ of thanksgiving after communion; (c) frequent addresses to the people in the form of Gallican *Præfationes*; (d) the Gallican form of consecration prayer, being a variable Post-Sanctus leading up to the words of institution; (e) the complicated rite of fraction as described in an Irish tract at the end of the Stowe missal finds its only counterpart in the elaborate ceremonial of the Mozarabic Church; (f) the presence of the Gallican ceremonial of *Pediluvium* or "Washing of Feet" in the earliest Irish baptismal office. For a further description of these and of other features which seem to be peculiar to the Celtic liturgy the reader is referred to Warren's *Liturgy and Ritual of the Celtic Church*, 1881.

PERIOD II. *The Anglo-Saxon Church.*—We find ourselves here on firmer ground, and can speak with certainty as to the nature of the liturgy of the English Church after the beginning of the 7th century. Information is drawn from the liturgical allusions in the extant canons of numerous councils, from the voluminous writings of Bede, Alcuin, and many other ecclesiastical authors of the Anglo-Saxon period, and above all from a very considerable number of service books written in England before the Norman Conquest. Three of these books are manuscript missals of more or less completeness, and, as none of them have yet been published, their names are appended:—(1) the Leofric missal, a composite 10th to 11th century MS., presented to the cathedral of Exeter by Leofric, the first bishop of that see (1046–1072), now in the Bodleian Library at Oxford; (2) the missal of Robert of Jumièges, archbishop of Canterbury (1051–52), executed probably at Winchester, and presented by Archbishop Robert to his old monastery of Jumièges in the neighbourhood of Rouen, in the public library of which town it now lies; (3) the Red Book of Derby, an incomplete missal of the second half of the 11th century, now in the library of Corpus Christi College, Cambridge.

A perusal of these volumes proves, what we should have expected *a priori*, that the Roman liturgy was in use in the Anglo-Saxon Church. This was, no doubt, the case from the very first. That church owed its foundation to the forethought of a Roman pontiff, and the energy of a band of missionaries, headed by St Augustine, who came directly from Rome, and who brought, as we are expressly assured by Bede, their liturgical codices with them from their native country (*Hist. Ec.*, ii. 28). Accordingly, when we speak of an Anglo-Saxon missal, we mean a Roman missal only exhibiting one or more of the following features which differentiate it from an Italian missal of the same century.

(a) Rubrics, and other entries of a miscellaneous character, written in the vernacular language of the country; (b) the commemoration of national or local saints in the calendar, in the canon of the mass, and in the litanies which occur on Easter eve, and in the baptismal offices; (c) the presence of a few special masses in honour of these national saints, together with a certain number of collects of a necessarily local character, for the rulers of the country, for its natural produce, &c.; (d) the addition of certain peculiarities of liturgical structure and arrangement interpolated into the purely Roman service from an extraneous source. There are two noteworthy examples of this in Anglo-Saxon service books. Every Sunday and festival, and almost every votive mass, has its proper preface, although the number of such prefaces in the Gregorian sacramentary of the same period had been reduced to eight. There were a large but not quite an equal number of triple episcopal benedictions to be pronounced by the bishop after the Lord's Prayer and before the communion. This custom must either have been perpetuated from the old Celtic liturgy, or directly derived from a Gallican source.

PERIOD III. *Anglo-Norman Church.*—The influx of numerous foreigners, especially from Normandy and Lorraine, which preceded, accompanied, and followed the Conquest, and the occupation by them of the highest posts in church as well as state, had a distinct effect on the liturgy of the English Church. These foreign ecclesiastics brought over with them a preference for and a habit of using certain features of the Gallican liturgy and ritual, which they succeeded in incorporating into the service books of the Church of England. One of these prelates named Osmund, a Norman count, earl of Dorset, chancellor of England, and bishop of Salisbury, 1078–99, undertook the revision of the English service books, and the missal which he produced in 1085, which we know as the *Sarum Missal*, or the *Missal according to the Use of Sarum*, practically became the liturgy of the English Church. It was not only received in the province of Canterbury, but was largely adopted beyond those limits—in Ireland in the 12th, and in various Scottish dioceses in the 12th and 13th centuries.

It would be outside the scope of a general article like the present to tabulate the numerous and frequently minute differences between a mediæval Sarum and the earlier Anglo-Saxon or contemporaneous Roman liturgy. They lie mainly in differences of collects and lections, variations of ritual on Candlemas, Ash Wednesday, and throughout Holy Week, the introduction into the canon of the mass of certain clauses and usages of Ephesine character or origin, the wording of rubrics in the subjunctive or imperative tense, the peculiar "Preces in Prostratione," the procession of Corpus Christi on Palm Sunday, the forms of ejection and reconciliation of penitents, &c. The varying episcopal benedictions as used in the Anglo-Saxon Church were retained, but the numerous proper prefaces were discarded, the number being reduced to ten.

Besides the famous and far-spreading use of Sarum, other uses, more local and less known, grew up in various English dioceses. In virtue of a recognized diocesan independence, bishops were able to regulate or alter their ritual, and to add special masses or commemorations for use within the limits of their jurisdiction. The better known and the more distinctive of these uses were those of York and Hereford, but we also find traces of, or allusions to, the uses of Bangor, Lichfield, Lincoln, Ripon, St Asaph, St Paul's, Wells, and Winchester.

Other Service Books.—The Eucharistic service was contained in the volume called the MISSAL (*q.v.*), as the ordinary choir offices were contained in the volume known as the BREVIARY (*q.v.*). But besides these two volumes there were a large number of other service books. Mr Maskell has enumerated and described ninety-one such volumes in the use of the Western Church only. It must be understood, however, that many of these ninety-one names are synonyms (*Mon. Rit. Eccles. Anglic.*, 1846, vol. i. p. cxciv.). The list might be increased, but it will be possible here only to name and describe a few of the more important of them. (1) *Agenda* = *Rituale*. (2) The *Antiphonary* contained the antiphons sung at the canonical hours, and certain other minor portions of the service. (3) The *Benedictional* contained those triple episcopal benedictions previously described as used on Sundays and the chief festivals throughout the year. (4) The *Collectarium* contained the collects for the season, together with a few other parts of the day offices. It was an inchoate Breviary. (5) The *Epistolarium* contained the epistles, and (6) the *Evangelistarium* the gospels for the year. (7) The *Gradual* contained the introit, gradual, sequences, and the other portions of the communion service which at high mass were sung by the choir. (8) The *Legenda* contained the lections read at matins and at other times, and may be taken as a generic term to include the *Homiliarium*, *Martyrology*, *Passional*, and other volumes. (9) The *Manual* was the term usually employed in England to denote the *Rituale*. (10) The *Pontifical* contained the order of ordination, consecration, and such other rites as could, ordinarily, only be performed by the bishop. (11) The *Rituale* or *Ritual* comprised the occasional offices for baptism, marriage, burial, and those other offices which it ordinarily fell to the lot of the parish priest to execute. To these we must add a book which was not strictly a church office book, but a handy book for the use of the laity, and which was in very popular use, and often very highly embellished in the 14th to 16th century, the *Book of the Hours*, or *Horæ Beatæ Mariæ Virginis*. It contained portions of the canonical hours, litanies, the penitential psalms, and other devotions of a miscellaneous and private character.

The Eastern Church, too, possessed and still possesses numerous and voluminous office books, of which the chief are the following:—The *Euchologion*, containing the liturgy itself with the remaining sacramental offices bound up in the same volume; the *Horologion*, containing the unvarying portion of the Breviary, the *Menæa* being equivalent to a complete Breviary; the *Menologion*, or martyrology; the *Octoechus* and *Paracletice*, containing Troparia, and answering to the Western Antiphonary; the *Pentecostarion*, containing the services from Easter Day to All Saints' Sunday, as the *Triodion* contained those from Septuagesima Sunday to Easter eve. The *Typicum* was a general book of rubrics corresponding to the Ordinale or the Pie of Western Christendom.

PERIOD IV. *The Reformed Church.*—The liturgy of the English Church passed through a more marked phase of change in the 16th century than during any of those periods which we have briefly described. The desire for some reform, and the sense of its necessity, which had been manifesting itself in various ways for more than a century and a half, culminated in the reign of Edward VI., and caused the appearance, with the full sanction of church and state, of the First Prayer Book of Edward VI. which was published on March 7, 1549, and came into general use on the feast of Whitsunday, June 9, 1549. Without attempting to enumerate particular points, we will summarize the general features which marked this change, and will exhibit the gains of such a reform, which, from an Anglican point of view, constitute its complete justification.

(*a*) Simplification in the number and character of books required for divine service. The Prayer Book is a compendium of most of the volumes which have been recently named and described. Its matins and evensong are a compilation from the Breviary; the office of Holy Communion, with the collects, epistles, and gospels, is a translation and adaptation of the missal; the occasional offices represent the ritual or manual, and the offices of confirmation and of ordination are taken, with modifications, from the pontifical.

(*b*) The removal from the service of a vast quantity of legendary matter which was read in the form of lections, and which was objectionable partly because it was unhistorical, partly because it was ludicrous and almost profane. As an instance of unhistorical matter, we quote a passage from the fourth lection for the festival of St Silvester, December 31, bishop of Rome, 314–335:—

"In which office of the priesthood he (Silvester) distinguished himself above the rest of the clergy, and afterwards succeeded Melchisdes on the papal throne in the reign of Constantine. That emperor suffered from leprosy, and, in order to cure himself, by the advice of his physicians he ordered a bath to be prepared of infants' blood. But the holy apostles Peter and Paul appeared to him in private, and told him that, if he wished to be free from his leprosy, he should abandon the mad plan of an impious bath, and send for Silvester dwelling in seclusion at Mount Soracte, that by him the emperor should be refreshed in the bath of salvation, and should order temples to be built in every province of the Roman empire after the fashion of the Christians, and that he should do away with the images of vain deities, and institute the worship of the true God. Constantine, therefore, in obedience to the divine warnings, made diligent search for and summoned Silvester, by whom, recognizing the description of the apostles, he was baptized; and incited to defend and extend the Christian religion."

This lection retains its position in the present Roman Breviary, although its unhistorical character can be abundantly proved and is generally acknowledged. The Breviary in fact is still, and was even more so then, full of legends which once passed for but have long since been abandoned as history.

As examples of the ludicrous we quote the first lection for the festival of St Fœlanus from the Aberdeen Breviary of 1509, fol. xxvi., and the eighth lection for the festival of St Serf from the same Breviary (July 2, fol. xvi.):—

"He (Fœlanus) was born, as it was foretold of him, with a stone in his mouth, on account of which he was so despised by his father that he was ordered immediately after his birth to be thrown into a neighbouring pond and drowned. In this pond he was miraculously nourished by angels for a whole year. But after the lapse of a year he was found by Bishop Ibarus, to whom a divine revelation of the fact had been given, playing among the angels. He was taken out of the pond safe and sound, was baptized, and afterwards became distinguished in sacred literature."

"A certain robber carried off one day a sheep which used to live and feed in the house of St Serf, and killed it and ate it. Diligent inquiry was made for the thief but without success. At length suspicion fell on the robber, and he hastened into St Serf's presence, prepared to deny the accusation with an oath. He swore a big oath that he was innocent of the charge laid against him, when, wonderful to relate (a fact which would not be believed on merely human testimony), the sheep which had lately been eaten began to baa in the stomach of the robber. Whereupon in confusion the man fell prostrate to the ground, and humbly asked for pardon, and the saint prayed for him."

There was also a quantity of objectionable matter introduced by a process of adaptation, or sometimes, as it was technically termed, by a process of farsing, into the older prayers. The Gloria in Excelsis in the Sarum Missal is printed thus (Burntisland edit., 1861, p. 586)—the farsed words are represented by italics:—

"Qui tollis peccata mundi, suscipe deprecationem nostram, *ad Mariæ gloriam*. Qui sedes ad dexteram Patris, miserere nobis. Quoniam tu solus sanctus, *Mariam sanctificans*. Tu solus Dominus, *Mariam gubernans*. Tu solus altissimus, *Mariam coronans*, Jesu Christe, cum Sancto Spiritu in gloria Dei Patris. Amen."

(*c*) For the first time, so far as can be ascertained, in the history of the English Church, the vernacular tongue was employed.

(*d*) The numerous litanies to and invocations of the saints, especially of the Virgin Mary, were expunged.

(*e*) There was a very great extension of the portion of Holy Scripture read in divine service, partly by the excision of non-Scriptural matter, partly by the lengthening of lessons which sometimes consisted only of one or two verses, so "that many times there was more business to find out what should be read than to read it when it was found out."

(*f*) There was a general simplification of the services, by the reduction of the number of saints' days, by the cutting away of anthems, invitatories, and responds, by the compression of the seven canonical hours into the two daily services of matins and evensong, &c.

(*g*) The various offices for the dead were abolished, and numerous prayers which involved a belief in the mediæval idea of the penal flames of purgatory made way for the present burial office and the commemoration of the departed in the Eucharistic service.

The first reformed Prayer Book of 1549 remained in use till 1552, when by Act of Uniformity passed on April 6 it was ordered that a further reformed Prayer Book should come into general use on the feast of All Saints (November 1) following. This second Prayer Book, commonly spoken of as the Second Prayer Book of King Edward the VI., marks the furthest point in the Puritan direction which was ever reached by the liturgy of the Church of England. An idea of its character may be gained by mentioning some of the features retained in the first and discarded in the Second Prayer Book, and some of the features added in the Second but absent from the First Prayer Book.

In the former class are—(*a*) the sign of the cross used in consecration, confirmation, marriage, and visitation of the sick; (*b*) the use of exorcism, chrisom, and chrism in baptism; (*c*) unction of the sick; (*d*) certain prayers for the dead, and a special Eucharist for funerals; (*e*) the mention of vestments with albs and tunics for Eucharistic use, and of the pastoral staff and cope for bishops; (*f*) the ceremonies of crossing and knocking on the breast left optional; (*g*) the invocation of the Holy Ghost before consecration; (*h*) the mixed chalice; (*i*) directions to communicants to receive the consecrated bread in their mouths, and for reservation for the sick. In the latter class are—(*a*) the addition of the Scriptural sentences, exhortation, confession, and absolution before morning and evening prayer; (*b*) the addition of the Jubilate, Cantate, and Deus Misereatur as alternative canticles; (*c*) the words "commonly called the mass" omitted from the title of Holy Communion; (*d*) the words "militant here on earth" added to the title of the prayer for the whole state of Christ's Church; (*e*) the decalogue introduced at the commencement of the communion service; (*f*) the second clause in the formula of sacramental distribution was substituted for the first, the two being subsequently combined in 1559. These are merely samples out of many more points which might be named.

It has not been ascertained that this Prayer Book ever received the sanction of Convocation, and it probably never came into complete use. Such use was in any case short-lived, for Edward VI. died on July 6, 1553, and the English Prayer Book was abolished and the Latin missal restored to use by one of the first Acts of Queen Mary, in October 1553. Queen Mary died on November 17, 1558, and another complete change of policy took place. The reformed Prayer Book was brought into use again on June 24, 1559, not in the exact shape which it bore in 1552, but with various modifications, which we forbear to enumerate in detail. It may be said of them, as of the various alterations introduced subsequently into the Prayer Book, that their general tendency was conservative rather than destructive, and in a Catholic rather than in a Protestant direction. The next important revisions of the Prayer Book took place in 1604, under James I., after the Hampton Court Conference, and in 1661-62, after the restoration of Charles II. The Book of Common Prayer had been abolished under the Commonwealth, and it could only be used under the risk of heavy penalties from 1645 to 1661. It was now restored with a considerable number of additions and alterations, after having been discussed without any satisfactory result between churchmen and Puritans at the Savoy conference in 1661. When these had received the sanction of the Convocations of Canterbury and York, it was attached to an Act of Uniformity which received the royal assent on May 19, 1662, by the provisions of which Act it came into general use on St Bartholomew's Day, August 24, 1662. Since that date, although various slight changes have been made in recent years, nothing has been done amounting to a revision or new edition of the Prayer Book, or demanding notice in these columns.

A few words are added about other national versions of the reformed liturgy.

The Liturgy of the Scottish Episcopal Church.—This liturgy in nearly its present form was compiled by Scottish bishops in 1636, and imposed, or, to speak more accurately, attempted to be imposed upon the Scottish people by the royal authority of Charles I. in 1637. The prelates chiefly concerned in it were Spottiswood, bishop of Glasgow; Maxwell, bishop of Ross; Wedderburn, bishop of Dunblane; and Forbes, bishop of Edinburgh. Their work was approved and revised by certain members of the English episcopate, especially Laud, archbishop of Canterbury; Juxon, bishop of London; and Wren, bishop of Norwich. This liturgy has met with varied fortune, and passed through several editions. It is now used as an alternative form with the English communion office in the Scottish Episcopal Church.

Among its more noteworthy features are—(*a*) the retention in its integrity and in its primitive position after the words of institution, of the invocation of the Holy Spirit;[1] (*b*) the reservation of the sacrament is permitted for the purpose of communicating the absent or the sick; (*c*) the mixed chalice is explicitly ordered; (*d*) the minimum number of communicants is fixed at one or two, instead of three or four. The general arrangement of the parts approximates more closely to the First Prayer Book of Edward VI. than to the present Anglican Book of Common Prayer.

The American Liturgy.—The Prayer Book of the "Protestant Episcopal Church" in America was adopted by the General Convention of the American Church held in 1789. It is substantially the same as the English Book of Common Prayer, but among the more important variations we may name the following:—(*a*) the arrangement and wording of the communion office rather resembles that of the Scottish than of the Anglican liturgy, especially in the position of the oblation and invocation immediately after the words of institution; (*b*) the Magnificat, Nunc Dimittis, and Athanasian creed are disused; (*c*) ten selections of psalms are appointed to be used as alternatives for the psalms of the day. In addition to these there are various verbal and other unimportant alterations.

The Irish Prayer Book.—The Prayer Book in use in the Irish portion of the United Church of England and Ireland was the Anglican Book of Common Prayer, but after the disestablishment of the Irish Church several changes were introduced into it by a synod held in Dublin in 1870. These changes included (*a*) the excision of all lessons from the Apocrypha, (*b*) of the rubric ordering the recitation of the Athanasian creed, (*c*) of the rubric ordering the vestments of the second year of Edward VI., (*d*) of the form of absolution in the office for the visitation of the sick, (*e*) the addition of one question and answer in the Church Catechism, bringing out more clearly the spiritual character of the real presence.

The Presbyterian Church.—The Presbyterian churches of Scotland at present possess no liturgy properly so called. Certain general rules for the conduct of divine service are contained in the "Directory for the Public Worship of God," agreed upon by the Assembly of Divines at Westminster, with the assistance of commissioners from the Church of Scotland, approved and established by an Act of the General Assembly, and by an Act of Parliament, both in 1645. In 1554 John Knox had drawn up an order of liturgy, closely modelled on the Genevan pattern, for the use of the English congregation to which he was then ministering at Frankfort. On his return to Scotland this form of liturgy was adopted by an Act of the General Assembly in 1560, and became the established form of worship in the Presbyterian Church, until the year 1645, when the Directory of Public Worship took its place. Herein regulations are laid down for the conduct of public worship, for the reading of Scripture, and for extempore prayer before and after the sermon and in the administration of the sacraments of baptism and the Lord's supper, for the solemnization of marriage, visitation of the sick, and burial of the dead, for the observance of days of public fasting and public thanksgiving, together with a form of ordination, and a directory for family worship. In all these cases, although the general tenor of the prayer is frequently indicated, the wording of it is left to the discretion of the minister, with these exceptions:—at the act of baptism this formula must be used—"I baptize thee in the name of the Father, and of the Son, and of the Holy Ghost;" and for the Lord's Supper these forms are suggested, but with liberty to the minister to use "other the like, used by Christ or his apostle upon this occasion:"—

"According to the holy institution, command, and example of our blessed Saviour Jesus Christ, I take this bread, and, having given thanks, break it, and give it unto you. Take ye, eat ye; this is the body of Christ which is broken for you; do this in remembrance of him." And again; "According to the institution, command, and example of our Lord Jesus Christ, I take this cup and give it unto you; this cup is the New Testament in the blood of Christ, which is shed for the remission of the sins of many; drink ye all of it."

There is also an unvarying form of words directed to be used before the minister by the man to the woman and by the woman to the man in the case of the solemnization of matrimony. The form of words on all other occasions, including ordination, is left to the discretion of the officiating minister, or of the presbytery.

Continental Protestant Churches. The Calvinistic Churches.—Rather more of the liturgical element, in the shape of a set form of

[1] The present clause runs thus:—"And we most humbly beseech thee O merciful Father to hear us, and of Thy almighty goodness vouchsafe to bless and sanctify with Thy word and Holy Spirit these and Thy gifts and creatures of Bread and Wine, that they may become the Body and Blood of Thy most dearly-beloved Son." This petition is found in the Eastern but not in the Roman or Anglican liturgies.

words, enters into the service of the French and German Calvinistic Protestants. The Sunday morning service, as drawn up by Calvin, was to open with a portion of Holy Scripture and the recitation of the Ten Commandments. Afterwards the minister, inviting the people to accompany him, proceeded to a confession of sins and supplication for grace. Then one of the Psalms of David was sung. Then came the sermon, prefaced by an extempore prayer and concluding with the Lord's Prayer, creed, and benediction. The communion service began with an exhortation leading up to the apostles' creed; then followed a long exhortation, after which the bread and cup were distributed to the people, who advanced in reverence and order, while a Psalm was being sung or a suitable passage of Scripture was being read. After all had communicated a set form of thanksgiving was said by the minister. Then the hymn of Simeon was sung by the congregation, who were then dismissed with the blessing. This form of service has been modified in various ways from time to time, but it remains substantially the type of service in use among the Reformed Churches of Germany, Switzerland, and France.

The Lutheran Church.—Luther was far more conservative than the rest of the Protestant Reformers, and his conservatism appeared nowhere more than in the service books which he drew up for the use of the church which bears his name. In 1523 he published a treatise *Of the Order of the Service in the Congregation*, and in 1526 he published the *German Mass.* Except that the vernacular was substituted for the Latin language, the old framework and order of the Roman missal were closely followed, beginning with the Confiteor, Introit, Kyrie Eleison, Gloria in Excelsis, &c. The text of this and other Lutheran services is given in *Agende für christliche Gemeinden des lutherischen Bekenntnisses*, Nördlingen, 1853. At the same time Luther was tolerant, and expressed a hope that different portions of the Lutheran Church would from time to time make such changes or adaptations in the order of service as might be found convenient. The Lutheran Churches of northern Europe have not been slow to avail themselves of this advice and permission. Most of them have drawn up liturgies for themselves, sometimes following very closely, sometimes differing considerably from the original service composed by Luther himself. In 1822, on the union of the Lutheran and Reformed (Calvinistic) Churches of Prussia, a new liturgy was published at Berlin. It is used in its entirety in the chapel royal, but great liberty as to its use was allowed to the parochial clergy, and considerable variations of text appear in the more recent editions of this service book.

The Swedenborgians, Irvingites, and other Protestant bodies have drawn up liturgies for themselves, but they are hardly of sufficient historical importance to be described at length here.

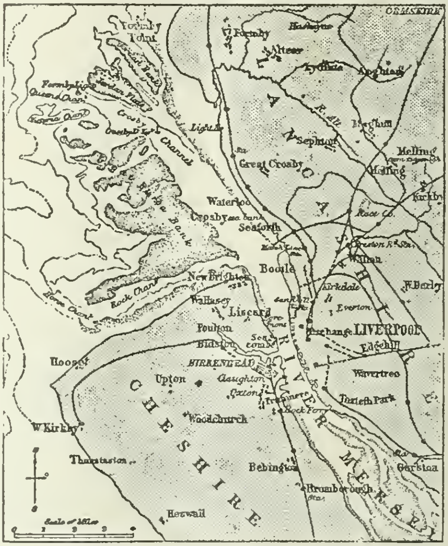
The Old Catholics, lastly, published a *Rituale* in 1875 containing the occasional offices for baptism, matrimony, burial, &c., and a form for reception of holy communion, in the German language. The latter is for temporary use in anticipation of a revised and not yet published missal, corresponding to the order of communion in English published March 8, 1548, in anticipation of the complete office in the Prayer Book of 1549. (F. E. W.)

LIUTPRAND (*c.* 922–972), Italian chronicler, was born towards the beginning of the 10th century, of a good Lombard family. The name is sometimes spelled Liudprand and even Luitprand. In 931 he entered the service of King Hugo of Italy as page; he afterwards rose to a high position at the court of Hugo's successor Berengarius, having become chancellor, and having been sent (949) on an embassy to the Byzantine court. Falling into disgrace with Berengarius, he attached himself to the emperor Otto I., whom in 961 he accompanied into Italy, and by whom in 962 he was made bishop of Cremona. He was frequently employed in missions to the pope, and on two occasions (968, 971) to Byzantium, to negotiate on behalf of the younger Otto (afterwards Otto II.) for the hand of Theophano. Liutprand died in 972.

He wrote (1) *Antapodoscos, seu rerum per Europam gestarum, Libri VI.*, an historical narrative, relating to the events from 887 to 949, compiled, as its name almost implies, with the object of avenging himself upon Berengarius and Willa his queen; (2) *Historia Ottonis*, unfortunately covering only the years from 960 to 964; and (3) *Relatio de Legatione Constantinopolitana* (968–969). All are to be found in the *Monum. Germ. Hist.* of Pertz, and in the *Rer. Ital. Script.* of Muratori; there is a recent edition by Dümmler (1877); and a partial translation into German, with an introduction by Wattenbach, is given in the second volume of the *Geschichtschreiber der Deutschen Vorzeit* (1853). Compare Wattenbach, *Deutschlands Geschichtsquellen im Mittelalter* (3d ed., 1873). Three other works, entitled *Adversaria*, *Chronicon* (606–960), and *Opusculum de vitis Romanorum pontificum*, are usually, but wrongly, assigned to Liutprand.

LIVERPOOL, a city and seaport of England, in the hundred of West Derby, in the county palatine of Lancaster, situated on the right bank of the estuary of the Mersey, about three miles from the open sea. The form of the city is that of an irregular semicircle, having the base line formed by the docks and quays extending about six miles along the east bank of the estuary, which here runs nearly north and south, and is about a mile in breadth. On the north the city is bounded by the borough of Bootle, along which the line of docks is continued. The area of the city is 5210 acres.

General Aspect and Features.—The subsoil of Liverpool is the Bunter stratification of the New Red Sandstone, overlying the Coal-measures, which rise up some distance to the eastward. In the lower districts there is a deposit of boulder clay, which has been extensively used for the manufacture of bricks. The sandstone rises in long ridges to the eastward, in the highest points about 250 feet above the sea-level. The city therefore lies on a continuous



Port of Liverpool

slope varying in gradient, but in some districts very steep. Exposed to the western sea breezes, with a dry subsoil and excellent natural drainage, the site is naturally salubrious, but neglect and perverseness have in past times done much to neutralize these advantages. The old borough, lying between the pool and the river, was a conglomeration of narrow alleys and mean houses packed together without any regard to sanitary provisions; and during the 16th and 17th centuries it was several times visited by the plague, which carried off many of the inhabitants. When the town burst its original limits, and expanded up the slopes beyond, a better state of things began to exist. The older parts of the town have at successive periods been entirely taken down and renovated. The streets of shops—Church Street, Bold Street, &c.—are equal in display to similar establishments in London. The commercial part of the city is remarkable for the number of palatial-looking piles of offices, built of hewn stone, principally in the Italian Renaissance style, amongst which the banks and insurance offices stand pre eminent. The demand for cottages about the beginning of the present century led to the construction of what are called "courts," being narrow *culs de sac*, close packed, with no thorough ventilation. This, combined with the degraded habits of a population brought together indiscriminately, resulted in a very high rate of mortality, to contend with which enormous sums have been expended in sanitary reforms of various kinds. The more modern cottages, erected on the higher grounds, are all that can be desired for that class of habitation.

Parks.—The public parks of Liverpool now form a prominent feature in the aspect of the town. The earliest, the Prince's Park, was laid out in 1843 by private enterprise. Sefton Park, the most extensive, containing about 400 acres, was commenced in 1865, and completed at a cost of £410,000. A large portion of the land round the margin has been leased for the erection of villas. Wavertree, Newsham, Sheil, and Stanley Parks have also been constructed at the public expense. Connected with Wavertree Park are the botanic gardens, with the usual plant houses, and a large and lofty palm house. The suburbs are rapidly extending, and those on the south contain many

Plan of Liverpool.

good private residences. A boulevard, about a mile in length, planted with trees in the centre, leads to the entrance to Prince's Park.

Public Buildings.—The old town has been so completely renovated during the present century that scarcely any of the public buildings date from an earlier period.

The earliest, and in many respects the most interesting, is the town-hall in Castle Street. This was erected from the designs of John Wood, the architect of the squares and crescents of Bath, and was opened in 1754. The building has since undergone considerable alterations and extensions, but the main features remain unchanged. It is a classical rectangular stone building in the Corinthian style, with an advanced portico in front, and crowned with a lofty dome surmounted by a seated statue of Minerva. The interior was destroyed by fire in 1795, and was entirely remodelled in the restoration. It now contains a splendid suite of apartments, including a ball-room about 100 feet by 60, approached by a noble staircase. The building is occupied by the mayor as the municipal mansion house. A range of municipal offices was erected in Dale Street in 1860. The building is in the Palladian style, of considerable extent and imposing design, with a dominating tower and square pyramidal spire.

The crowning architectural feature of Liverpool is St George's Hall, completed in 1854. The original intention was to erect a music hall suited for the triennial festivals which had been periodically held in the town. About the same time the corporation proposed to erect law courts for the assizes, which had been transferred to Liverpool and Manchester. In the competitive designs, the first prize was gained in both cases by Harvey Lonsdale Elmes. He was employed to combine the two objects in a new design, of which the present building is the outcome.

The structure is one of which the city may well feel proud, and notwithstanding some defects it will always hold a high and honourable place amongst the erections of modern times. It is fortunate in its situation, occupying the most central position in the town, and surrounded by an area sufficiently extensive to exhibit its proportions to the best advantage. Another advantage it possesses is that of size; there are few buildings in the country, forming a solid mass under one roof, which surpass it in dimension. The plan is simple in arrangement, and easily described. The centre is occupied by the great hall, 169 feet in length, and, with the galleries, 87 feet wide and 74 feet high, covered with a solid vault in masonry. Attached to each end, and opening therefrom, are the law courts. A corridor runs round the hall and the courts, communicating with the various accessory rooms. Externally the east front is faced with a fine portico of sixteen Corinthian columns about 60 feet in height. An advanced portico of similar columns fronts the south end crowned with a pediment filled with sculpture, with the inscription—

"Artibus, Legibus, Consiliis
Locum Municipia Constituerunt
Anno Domini MDCCCXLI."

The style is Roman, but the refinement of the details is suggestive of the noblest period of Grecian art.

The great hall is finished with considerable richness in polished granite columns, marble balustrades and pavements, polished brass doors with rich foliated tracery, &c. The organ, built by Messrs Willis of London, from the specification of Dr Samuel Wesley, is equal to any in the country for extent, power, and beauty of tone. Mr Elmes, a young architect of great promise, having died during the progress of the work, the building was completed by the late Mr C. R. Cockerell, R.A.

Next to the public buildings belonging to the city, the most important is the exchange, forming three sides of a quadrangle, adjoining the town-hall on the north side. The town-hall was originally built to combine a mercantile exchange with municipal offices, but the merchants perversely preferred to meet in the open street adjoining. This, with other circumstances, led to the erection of the new exchange, a building of considerable merit, which was commenced in 1803 and opened in 1808. It had scarcely been in use for more than fifty years when it was found that the wants of commerce had outstripped the accommodation, and the structure was taken down to make room for the present building, in which greater convenience has been attained, with considerable sacrifice of æsthetic effect.

The revenue buildings, commenced in 1828, on the site of the original Liverpool Dock, combine the customs, inland revenue, post-office, and dock board departments. It is a huge heavy structure, with three advanced porticoes in the Ilyssus Ionic style. Near by stands the sailors' home, a large building in the Semi-Gothic or Elizabethan style.

The Philharmonic Hall in Hope Street, with not much pretension externally, is one of the finest music rooms in the kingdom; it accommodates an audience of about 2500.

The group of buildings forming the free public library, museum, and gallery of art are finely situated on the brow of the slope opposite St George's Hall. The library and gallery of art are separate buildings connected by the circular reading-room in the middle. The latter possesses some novelties in construction, having a circular floor 100 feet in diameter without columns or any intermediate support, and a lecture-room underneath, amphitheatrical in form, with grades or benches hewn out of the solid rock.

Railways.—There are three passenger stations in Liverpool, the London and North-Western, the Lancashire and Yorkshire, and the combined station of the Midland, Great Northern, and Manchester and Sheffield. The rapid increase of traffic has led to large extensions of the North-Western, and a very large addition to the Lancashire and Yorkshire is in progress (1882). The tunnel under the Mersey now in course of construction will give access for the Great Western and Cumbrian systems into Liverpool.

Water and Gas Supply.—The original supply of water was from wells in the sandstone rock, but in 1846 an Act was passed, under which extensive works were constructed at Rivington, about 25 miles distant, by which a much larger supply was obtained. The vast increase of population led to further requirements, and in 1880 another Act gave power to impound the waters of the Vyrnwy, one of the affluents of the Severn. This scheme which, it is expected, will give a copious supply for many years to come, is now being carried out. The gas-works are the property of a company. Efforts have been made to effect a purchase by the city, but hitherto without success.

Administration of Justice.—The city has quarter sessions for criminal cases, presided over by the recorder, but the sessions are really held eight times in the year. The court of passage for civil cases is a very ancient institution, dating from the foundation of the borough by King John, originally intended for cases arising out of the imports and exports passing through. Its jurisdiction has been confirmed and settled by parliament, and it is now competent, by consent, to try causes to any amount. The mayor is nominally the president, but the actual judge is an assessor appointed by the crown. There are two police courts which sit daily, one presided over by the lay magistracy, the other by the stipendiary magistrate.

Ecclesiastical.—The parish, which was separated from Walton-on-the-Hill in 1699, contained two churches, St Nicholas, the ancient chapel, and St Peter's, then built. There were two rectors, the living being held in medieties. Of recent years changes have been sanctioned by parliament. The living is now held by a single incumbent, and a large number of the churches which have since been built have been formed into parishes by the ecclesiastical commissioners. St Peter's has been constituted the pro-cathedral, pending the erection of a more suitable building. Besides the two original parish churches, there are sixty-seven others belonging to the establishment.

The Roman Catholics form a very numerous and powerful body in the city, and it is estimated that from a third to a fourth of the entire population are Catholics. A large part of these are Irish settlers or their descendants, but this district of Lancashire has always been a stronghold of Catholicism, many of the landed gentry belonging to old Catholic families.

Charities.—These are numerous, and are maintained with no niggardly hand. The earliest foundation is the Blue Coat hospital, established in 1708, for orphans and fatherless children born within the borough. The building, erected in 1717, is a quaint and characteristic specimen of the architecture of the period. It now maintains two hundred and fifty boys and one hundred girls. There is an orphan asylum, established in 1840, for boys, girls, and infants, and a seamen's orphan asylum, commenced in 1858, for boys and girls. The Roman Catholics have similar establishments. The medical charities are large and flourishing. The royal infirmary has had a school of medicine attached, which has been very successful, and is now merged in the new University College. The medical charities are aided by simultaneous collections in the churches and chapels on "Hospital Sunday," the first Sunday in the year, the amount averaging about £10,000.

Literature, Art, and Science.—The free library, museum, and gallery of arts, established and managed by the city council, was originated in 1850. The library building was erected by Sir William Brown at a cost of £40,000. The Derby museum, containing the collections of Edward, the thirteenth earl, were presented by his son. The Mayer museum of historical antiquities and art was contributed by Mr Joseph Mayer, F.S.A. Sir Andrew Walker erected the art gallery which bears his name at an expense of £35,000. The Picton circular reading-room, and the Rotunda lecture-room were built by the corporation at the cost of £25,000. The library contains nearly 100,000 volumes. An annual exhibition of paintings has been established, the sales from which average about £12,000 per annum. A permanent gallery has also been formed, which is now being enlarged at a cost of about £12,000.

The literary and philosophical society was established in 1812, and still flourishes. There are also philomathic, geological, chemical, historic, and various other societies for the cultivation of almost every branch of knowledge and inquiry. An art club has been established with great success, and possesses an excellent club-house and gallery. The royal institution, established by Roscoe in 1817, possesses a fine gallery of early art, and is the centre of the various literary institutions of the town.

Education.—Elementary education has always met with cordial support in Liverpool, and is now carried on with vigour by the school board, supplemented by voluntary schools. For middle class and higher education there have existed for many years three institutions, which have been very successful, viz., the school attached to the royal institution, the collegiate institution in Shaw Street, and the Liverpool institute high school. A further effort has been successfully made resulting in the foundation of University College, the inaugural meeting of which was held on January 14, 1882. This college is affiliated to the Victoria university of the north-west of England. The sum of £135,000 has been raised by voluntary subscription, to which £30,000 have been contributed by the corporation. Seven chairs have been endowed, and professors appointed, and a suitable building has been provided.

Recreation and Social Life.—There are eight theatres, besides many minor music halls and places of amusement. The most fashionable and exclusive is the Philharmonic Hall, which is a large handsome building open only to proprietors, where concerts take place every fortnight during the season. The Philharmonic concerts, and the balls at the Wellington Rooms (the Almacks of Liverpool), afford the principal opportunities for the gatherings of the fashionable world. The Alexandra theatre, the new Court theatre, the Prince of Wales theatre, and Hengler's cirque are all that could be desired in point of decoration and the *mise en scene.* The minor houses are conducted on the whole with great propriety and success.

Population.—According to the census of 1881 (preliminary report) the number of inhabitants within the parliamentary and the municipal borough—the limits of which are conterminous—amounted to 552,425 persons, 271,640 being males and 280,785 females. At the end of the 17th century the population of Liverpool was 5145, but since then it has steadily increased as follows:—

1710	8,168	1811	94,376
1720	10,446	1821	135,000
1753	22,000	1831	205,572
1769	34,000	1871	488,845
1785	41,000	1881	552,425
1801	77,653		

If the boroughs of Bootle and Birkenhead, which are component parts of the port, are included, Liverpool has now a population of about three quarters of a million.

Trade and Commerce.—The progress of the commerce of Liverpool during the present century is almost without a parallel. In 1800 the tonnage of ships entering the port was 450,060; in 1880 it reached 7,933,620 tons. In 1800 4746 vessels entered, averaging 94 tons; in 1880 there were 20,249, averaging 440 tons. The only British port which can at all come into competition with Liverpool is London, the total trade of which, comprising exports and imports, amounted in 1880 to 16,479,108 tons, against 14,496,364 in Liverpool. A large proportion of this, however, is a coasting trade, indicated by the smaller size of the ships, averaging 240 tons each in London as compared with 440 tons in Liverpool. The coasting trade in Liverpool has rather fallen off owing to the superior advantages of railway traffic. The proportion of steamers to sailing ships has very largely increased of late years. The return for 1881 gives 5,534,462 tons of steam navigation to 2,379,466 tons in sailing ships. If we take the value of the imports as a criterion, London is far in advance of Liverpool, the values in 1880 being £141,442,907 and £107,460,187, but the London imports consist, to a great extent, of very valuable commodities, such as tea, silk, indigo, wines, &c., whilst the Liverpool imports principally consist of grain, food, and raw produce, the materials for manufacture. If we look at the exports the balance is reversed, Liverpool, in 1880, having exported the value of £84,029,651, against £52,600,929 from London. In the number of ships registered as belonging to the port, Liverpool stands first in the world, the tonnage belonging to Liverpool being 1,554,871, against 1,120,359 in London, and 1,005,894 in the whole of the ports on the Clyde.

The commerce of Liverpool extends to every part of the world, but probably the intercourse with America stands pre-eminent, there being five lines of steamers to New York alone, besides lines to Philadelphia, Boston, Halifax, Canada, New Orleans, &c. The size of the ships has greatly increased, having reached 8000 tons burden, with 10,000 horse-power.

The imports into Liverpool comprise produce of every description from every region under the sun. Cotton, however, is the great staple, almost the whole trade of the commodity centring here. Grain comes next, American and Australian corn occupying a large proportion of the market. Within the last few years an enormous trade in American provisions, including live cattle, has sprung up. Tobacco has always been a leading article of import into Liverpool, along with the sugar and rum from the West Indies. Timber, principally from Canada, forms an important part of the imports, the stacking yards extending for miles along the northern docks. At one time tea from China, and wool from Australia, promised to be imported with advantage, but the financial arrangements with London have drawn these trades almost entirely away. In regard to exports, Liverpool possesses decided advantages; lying so near the great manufacturing districts of Lancashire and the West Riding of Yorkshire, this port is the natural channel of transmission for their goods, and, if everything else fails, there are always coal and salt from Wales and Cheshire ready to make up a cargo. The consequence is that many ships, after discharging their homeward cargoes at London and the eastern ports, come round in ballast to Liverpool for an outward cargo.

Manufactures.—The manufactures of Liverpool are not extensive. Attempts have been repeatedly made to establish cotton-mills in and near the city, but have resulted in uniform failure. Engineering works, especially as connected with marine navigation, have naturally grown up, and have been carried on successfully on a large scale. Shipbuilding, in the days of the old wooden walls, in the early part of the present century, was active and prosperous, several frigates and sloops-of-war for Government having been built here, but the keen competition of the Clyde and the north of England drew away a large portion of the trade. There are now four shipbuilding establishments on the Mersey. In the year 1880–81 there were launched from these yards thirty-three iron ships, with a tonnage of 53,971 tons. At one period the soap manufacture filled a large space in the industry of Liverpool, but it has almost entirely departed. During the latter half of last century and the beginning of the present, the pottery and china manufacture flourished in Liverpool. John Sadler, a Liverpool manufacturer, was the inventor of printing on pottery, and during the early period of Josiah Wedgwood's career, all his goods which required printing had to be sent to Liverpool. A large establishment, called the Herculaneum Pottery, was founded in a suburb on the bank of the Mersey, and was carried on with success for many years, but the whole trade has long disappeared. One manufacture, established at an early period, still continues to flourish—the watch and chronometer trade. Litherland, the inventor of the lever watch, was a Liverpool manufacturer, and Liverpool-made watches have always been held in high estimation. There are several extensive sugar refineries, and two large tobacco manufactories.

Docks.—The docks of Liverpool on both sides of the Mersey are under the same trust and management, and equally form part of the port of Liverpool. On the Liverpool side they extend along the margin of the estuary 6½ miles, of which 1½ miles is in the borough of Bootle. The Birkenhead docks have not such a frontage, but they extend a long way backward. The water area of the Liverpool docks and basins is 333½ acres, with a lineal quayage of 22 miles. The Birkenhead docks, including the great float of 120 acres, contain a water area of 160 acres, with a lineal quayage of 9 miles. The system of floating docks was commenced by the corporation in 1709. With the advancing demands of commerce the docks were extended north and south. They constituted from the first a public trust, the corporation never having derived any revenue from them, though the common council of the borough were the trustees, and in the first instance formed the committee of management. Gradually the dock ratepayers acquired influence, and were introduced into the governing body, and ultimately, by the Act of 1856, the corporation was entirely superseded. Under the present constitution, the management is vested in the Mersey Docks and Harbour Board, consisting of twenty-eight members, two of whom are nominated by the Board of Trade and the rest elected by the dock ratepayers, of whom a register is kept and annually revised. The affairs of the board are of considerable magnitude. The revenue is derived from tonnage rates on ships, dock rates on goods, town dues on goods, with various minor sources of income. These amounted in the year ending July 1, 1881, to £1,226,497. The amount of debt outstanding is £16,284,881, for which a rate of interest averaging 4½ per cent. is paid.

Down to 1843 the docks were confined to the Liverpool side of the Mersey. Several attempts made to establish docks in Cheshire had been frustrated by the Liverpool corporation, who bought up the land and kept it in their own hands. In 1843 a scheme was privately concocted for the construction of docks at Birkenhead. Plans were prepared by Mr Rendel, C.E., the money subscribed, and arrangements made with the Admiralty,—the corporation being kept in ignorance of the proceedings. Application was then made by private individuals to purchase 200,000 square yards of land on the margin of an inlet called Wallasey Pool. The common council, which had been reformed in 1836, innocently fell into the snare, and in the ensuing session of parliament a rival scheme of docks for Birkenhead was brought out and passed. The great expectations which were entertained of their successful competition with Liverpool have been signally falsified. After a twelve years' struggle and litigation, the Birkenhead dock affairs had fallen into a hopeless state of insolvency, without any prospect of recovery, and in 1855 the docks were transferred to the corporation of Liverpool on payment to the bondholders of 13s. in the pound on their claims. Under the Act of 1856, settling the future constitution of the dock board, the Birkenhead docks were transferred to the Mersey Docks and Harbour Board. The result on the whole has been disastrous. The amount expended on the Birkenhead docks down to 1881 has been nearly 6 millions. The returns for this immense outlay do little more than defray the working expenses, the difference having to be made up from the revenue on the Liverpool side,—so that, in consequence of this unfortunate rivalry, the shipping frequenting the port is taxed to the amount of £270,000 per annum, which otherwise might have been remitted. The Birkenhead great float, of 120 acres, though it contributes little to the revenue, is valuable as a depôt for ships lying up, so as not to interfere with the working docks. In addition to the floating docks, there are in Liverpool eighteen graving docks and three in Birkenhead, and two gridirons on the Liverpool side.

The great landing stage of Liverpool is unique in its dimensions and utility. It was originally constructed in 1857, from the plans of Mr J. Cubitt, and greatly enlarged and extended in 1874, making the entire cost £373,000. The grand fabric had just been completed, and was waiting to be inaugurated by the duke of Edinburgh, when on the 28th July 1874 it accidentally caught fire, and, the timber being impregnated with kreosote, the flames spread with unexampled rapidity, and in a few hours the whole was destroyed. It was again constructed with improvements. Its length is 2063 feet, or about ⅖ths of a mile, and its breadth 80 feet. It is supported on floating pontoons rising and falling with the tide, connected with the quay by seven bridges, besides a floating bridge for heavy traffic 550 feet in length. The southern half is devoted to the traffic of the Mersey ferries, of which there are eight—New Brighton, Egremont, Seacombe, Birkenhead, Tranmere, Rock Ferry, New Ferry, and Eastham. The northern half is used for sea-going steamers, and for the tenders of the great "liners." The warehouses for storing produce form a very prominent feature in the commercial part of the city. Down to 1841 these were entirely in private hands, distributed as chance might direct, but in that year a determined effort was made to construct docks with warehouses around on the margin of the quays. This met with considerable opposition from those interested, and led to a municipal revolution, but the project was ultimately carried out in the construction of the Albert dock and warehouses, which were opened by Prince Albert in 1845. Other docks since constructed have been similarly surrounded. The Albert warehouses form an immense pile standing between the dock and the river, imposing from their huge dimensions, but otherwise the very incarnation of bald ugliness.

Grain warehouses on a large scale have been constructed by the dock board both at Liverpool and Birkenhead. The machinery for elevating, distributing, drying, and discharging is of the most complete and thorough construction. The rental received from the warehouses in the year 1880–81 was £240,394.

History.—There are no archæological difficulties attending the origin of the town, which is clearly defined by documentary evidence. The part of the country in which Liverpool is situated was not very distinguished in the earlier periods of English history. No Roman remains have been discovered within a considerable distance. Under the Saxons the site formed part of the kingdom or province of Deira, the river Mersey (Mœre-sea) forming the boundary between that kingdom and Mercia. During the Danish irruptions of the 8th century colonies of Norsemen made settlements on both sides of the Mersey, as is indicated by the names of the villages and townships in the districts. After the Conquest, the site of Liverpool formed part of the fief (inter Ripam et Mersham) granted by the Conqueror to Roger de Poitou, one of the great family of Montgomery. After various forfeitures and regrants from the crown, it was ultimately handed over by Henry II. to Warine, the keeper of the castle and prison of Lancaster. In a deed executed by King John, then earl of Mortaigne, about 1190, confirming the grant of this with other manors to Henry Fitzwarine, son of the former grantee, the name of *Liverpul* first occurs.

The name is spelt in a variety of ways, and much ingenuity has been exercised in the endeavour to explain its etymology. Probably the most plausible is the derivation from Cymric *Llyr-pwl*, "the expanse of the pool," or "the pool at the confluence," which exactly expresses the peculiarity of the original site. It is, however, open to the objection that the Welsh language had died out in the locality long before Liverpool was founded.

The immediate origin of Liverpool was owing to the following circumstances. After the partial conquest of Ireland by Strongbow, earl of Pembroke, under Henry II., the principal ports of communication were Bristol for the south and Chester for the north. The gradual silting up of the river Dee soon so obstructed the navigation as to render Chester a very unsuitable place of embarkation. A quay was then constructed at Shotwick, about 8 miles below Chester, with a castle to protect it from the incursions of the neighbouring Welsh; but a better site was sought and soon found. Into the tidal waters of the Mersey, a small stream, fed by a peat moss on the elevated land to the eastward, ran in an oblique direction from north-east to south-west, forming at its mouth an open pool or sea lake, of which many existed on both sides of the river. The triangular piece of land thus separated formed a promontory of red sandstone rock, rising in the centre about 50 feet above the sea-level, sloping on three sides to the water. The pool was admirably adapted as a harbour for the vessels of that period, being well protected, and the tide rising from 15 to 21 feet. King John repurchased the manor from Henry Fitzwarine, giving him another in exchange, and here he erected a castle on the usual Plantagenet plan of round bastions connected by curtain walls, with an inner ballium and buildings. He also founded a town by the erection of burgage tenements, one hundred and sixty-eight in number, and in 1207 he issued the following letter patent or charter:—

Carta Regis Johannis.

"Rex omnibus qui burgagia apud villam de Liverpul habere voluerint, &c. Sciatis quod concessimus omnibus qui burgagia apud Liverpul ceperint quod habeant omnes libertates et liberas consuetudines in villa de Liverpul quas aliquis liber burgemotus super mare habet in terra nostra. Et nos vobis mandamus quod secure et in pace nostra illuc veniatis ad burgagia nostra recipienda et hospitanda. Et in hujus rei testimonium has litteras nostras patentes vobis transmittimus. Teste Simon de Pateshill apud Winton xxviij die Aug. anno regni nostri nono."

Charter of King John.

"The king to all who may be willing to have burgages at the town of Liverpul, &c. Know ye that we have granted to all who shall take burgages at Liverpul that they shall have all liberties and free customs in the town of Liverpul which any free borough on the sea hath in our land. And we command you that securely and in our peace you may come there to receive and inhabit our burgages. And in testimony hereof we transmit to you these our letters patent. Witness, Simon de Pateshill, at Winchester, the 28th day of August, in the ninth year of our reign."

From the Patent Rolls and the sheriff's accounts we learn that considerable use was made of Liverpool in the reign of John for shipping stores and reinforcements to Ireland and Wales. In 1215 the town was garrisoned for the king during the rising which took place after the granting of the Great Charter.

In 1229 a charter of incorporation was granted by Henry III., authorizing the formation of a merchants' guild, with a hanse and other liberties and free customs, with sac and soc, toll and theam, &c., and freedom from toll in all the other seaports. Charters were subsequently granted by successive monarchs down to the reign of William and Mary, which last was the governing charter to the date of the Municipal Reform Act (1835). In 1880 when the new diocese of Liverpool was created, the borough was transformed into a city by royal charter.

The crown revenues from the burgage rents and the royal customs were leased in fee-farm from time to time, sometimes to the corporation, at others times to private persons. The first lease was from Henry III., in 1229, at £10 per annum. In the same year the borough with all its appurtenances was bestowed, with other lands, on Ranulf, earl of Chester. During the subsequent two centuries the fief was repeatedly forfeited and regranted, until it finally passed into the hands of John of Gaunt, duke of Lancaster, and from the accession of his son Henry IV. it merged in the crown. In 1628 Charles I., in great straits for means which were refused by parliament, offered for sale about a thousand manors, among which Liverpool was included. The portion containing Liverpool was purchased by certain merchants of London, who, in 1632, reconveyed the crown rights, including the fee-farm rent of £14, 6s. 8d., to Sir Rd. Molyneux, recently created Lord Maryborough, for the sum of £450. In 1672 all these rights and interests were purchased by the corporation.

Apart from the national objects for which Liverpool was founded, its trade developed very slowly. From £10 per annum, in the beginning of the 13th century, the crown revenues had increased towards the end of the 14th century, to £38—in modern currency about £570; but then they underwent a decline. The Black Death, the fatal scourge of the 14th century, passed over Liverpool about 1360, and carried off a large part of the population. The Wars of the Roses, in the 15th century, unsettled the north-western districts, and repressed all progress for at least a century. The crown revenues diminished from £38 to less than half that sum, and were finally leased at £14, 6s. 8d., at which they continued until the sale by Charles I.

Liverpool sent no representatives to Simon de Montfort's parliament in 1264, but to the first royal parliament, called in 1296, the borough sent two members, and again in 1306. The writs of summons were then suspended for two centuries and a half. During the 14th and 15th centuries nearly the whole of the returns of the sheriffs of Lancaster were to the following effect:—"There is not any city or borough from which any citizens or burgesses are able or accustomed to come, according to the tenor of the writ, by reason of their debility and poverty." In 1547 Liverpool, with the rest of the Lancashire boroughs, resumed the privilege of returning members. In 1583 the borough was represented by Sir Francis Bacon, the immortal philosopher and statesman. During the civil war the town was fortified and garrisoned by the parliament. It sustained three sieges, and in 1644 was escaladed and taken by Prince Rupert with considerable slaughter.

The true rise of the commerce of Liverpool dates from the Restoration. Down to that period its population had been either stationary or retrogressive, never exceeding about 1000 souls. Its trade was chiefly with Ireland, France, and Spain, exporting fish and wool to the Continent, and importing wines, iron, and other commodities. The rise of the manufacturing industry of South Lancashire, and the opening of the American and West Indian trade, gave the first impulse to the progress which has ever since continued. The importation of sugar led to the establishment of sugar refineries, which after the lapse of two centuries continue to form an important branch of local industry. By the end of the century the population had increased to 5000. The town burst the narrow limits within which it had hitherto been confined, and extended itself across the pool stream. In 1699 the borough was constituted a parish district from Walton, to which it had previously appertained. In 1709, the small existing harbour being found insufficient to accommodate the shipping, several schemes were propounded for its enlargement, which resulted in the construction of a wet dock closed with flood-gates impounding the water, so as to keep the vessels floating during the recess of the tide. This dock in Liverpool was the first of the kind, and was the parent of all the magnificent structures which have attracted the admiration of the world. The name of the engineer, Thomas Steers, deserves recording, as the author of the practical application of a principle already known leading to a world-wide utility, of a similar class to the adaptation of the railway by George Stephenson at a subsequent period.

About this date the merchants of Liverpool entered upon a traffic which, however questionable in point of morality, became very profitable during the remainder of the century—the slave trade, into which they were led by their connexion with the West Indies. In 1709 a single barque of 30 tons burden made a venture from Liverpool and carried 15 slaves across the Atlantic. Little was done during the next twenty years, but in 1730, encouraged by parliament, Liverpool went heartily into the new trade. In 1751 53 ships sailed from Liverpool for Africa, of 5334 tons in the aggregate. From this time the trade set in with such a steady current that it soon became one of the most lucrative branches of the commerce of the port. The voyage was threefold. The ships sailed from Liverpool to the west coast of Africa, where they shipped the slaves, and thence to the West India Islands, where the slaves were sold and the proceeds brought home in cargoes of sugar and rum. In 1765 the number of Liverpool slavers had increased to 86, carrying 24,200 slaves. By the end of the century five-sixths of the African trade centred in Liverpool. Just before the abolition in 1807 the number of Liverpool ships engaged in the traffic was 185, carrying 43,755 slaves in the year.

Another branch of maritime enterprise which attracted the attention of the merchants of Liverpool was privateering, which during the latter half of the 18th century was a favourite investment. After the outbreak of the Seven Years' War with France and Spain, in 1756, the commerce of Liverpool suffered severely, the French having overrun the narrow seas with swift well-armed privateers, and the premiums for insurance against sea risks having risen to an amount almost prohibitory. The Liverpool merchants took a lesson from the enemy, and armed and sent out their ships as privateers. Some of the early expeditions having proved very successful, almost the whole community rushed into privateering, with results of a very chequered character. When the War of Independence broke out in 1776 American privateers swarmed about the West India Islands, and crossing the Atlantic intercepted British commerce in the narrow seas. The Liverpool merchants again turned their attention to retaliation. Between August 1778 and April 1779 120 privateers were fitted out in Liverpool, carrying 1986 guns and 8754 men. The results, though in some cases very profitable, were exceedingly demoralizing.

During the whole of the 18th century the commerce of Liverpool kept steadily increasing in spite of external war and internal competition, and has so continued to the present time. The increase of the population supplies a fair index to the growth of its commerce.

The Municipality.—Under the Municipal Reform Act of 1835, the boundaries of the original borough were extended by the annexation of portions of the surrounding district. The city is divided into sixteen wards, returning three members each to the common council, with sixteen aldermen, making sixty-four in all. The wards were originally divided according to population, but the lapse of nearly half a century has so completely disturbed the proportions that, whilst some of the wards in the commercial localities have diminished in population, the Everton and Kirkdale ward, originally a rural suburb, now contains a population of 150,000, with a constituency of more than 20,000 electors. The electoral franchise, before the Reform Act restricted to the freemen, is still enjoyed by their successors, but their number is exceedingly small.

The arms of the city as set forth in the confirmation by the Heralds' College, in 1797, are described as follows:—"Argent, a Cormorant, in the beak a branch of seaweed called Laver, all proper, and for the crest, on a wreath of the colours, a Cormorant, the wings elevated; in the beak a branch of Laver proper." The supporters, granted at the same time are—"The dexter Neptune with his sea-green mantle flowing, the waist wreathed with Laver, on his head an eastern crown or, in the right hand a trident sable, the left supporting a banner of the arms of Liverpool; on the sinister a Triton wreathed as the dexter and blowing his shell; all proper." The motto is "Deus nobis hæc otia fecit."

The corporation of Liverpool has possessed from a very early period considerable landed property, the first grant having been made by Thomas, earl of Lancaster, in 1309. This land was originally of value only as a turbary, but in modern times its capacity as building land has been a fruitful source of profit to the town, a large proportion of the southern district being held in freehold by the corporation leased for terms of seventy-five years, renewable from time to time on a fixed scale of fines. The income from this source amounted in 1879 to £83,746. There was formerly another source of income now cut off. The fee farm rents and town dues originally belonging to the crown were purchased from the Molyneux family in 1672 on a long lease, and subsequently in 1777 converted into a perpetuity. With the growth of the commerce of the port these dues enormously increased, and became a cause of great complaint by the shipping interest. In 1856 a bill was introduced into parliament and passed, by which the town dues were transferred to the Mersey Docks and Harbour Board on payment of £1,500,000, which was applied in part to the liquidation of the bonded debt of the corporation, amounting to £1,150,000. The town dues at that time produced £132,592 per annum, which has increased in 1881 to £260,698. The markets produce an income of about £12,000 clear of expenses.

The council form the sanitary authority of the city, in which capacity they expended in the year 1880–81 the sum of £255,738, derived from rates. In the same year there was expended for lighting and watching, £75,263; for parks and places of recreation, £49,178; for town improvements, £33,192. These amounts are partly defrayed out of the corporate funds; the part for the constabulary is paid by Government, and the rest out of rates.

The mayor has an annual allowance of £2700, to sustain the dignity of his office and maintain the hospitality of the town-hall.

The city returns three members to parliament.

The see of Liverpool was created in 1880 under the Act of 1879, by the authority of the Ecclesiastical Commissioners, an endowment fund of about £100,000 having been subscribed for the purpose.

(J. A. P.)

LIVERPOOL, Charles Jenkinson, first Earl of (1727–1808), was the eldest son of Colonel Jenkinson, Walcot, Oxfordshire, where he was born 16th May 1727. He was educated at Charterhouse school and at University College, Oxford, where after a career of special distinction he graduated M.A. in 1752. Almost immediately on entering parliament as member for Cockermouth in 1761, he was appointed under-secretary of state under Lord Bute, and, as he soon shared equally with that nobleman the favour of the king, his political advancement was rapid and uninterrupted while the friends of the king remained in office. By Grenville he was in 1763 appointed secretary of state; in the Grafton administration he, in 1766, obtained a seat at the Admiralty Board; and from 1778 till the close of Lord North's ministry he was secretary at war. On the accession of Pitt to power in 1784, he became president of the Board of Trade, retaining office till Pitt's resignation in 1801. Besides direct political power he also enjoyed a large share both of substantial and honorary political rewards. In 1773 he became member of the privy council, and obtained the vice-treasurership of Ireland, which he afterwards exchanged for the clerkship of the pells; and from 1786 to 1802 he was chancellor of the duchy of Lancaster. In 1786 he was created Baron Hawkesbury, and ten years afterwards earl of Liverpool. He died 17th December 1808. Lord Liverpool was generally believed to be the chief political adviser of George III. His prudence, practical talents, and knowledge of the details both of home and foreign politics rendered him a specially safe and useful member of a cabinet.

He was the author of several political works, which display industry and discrimination, but, with the exception of his well-known *Treatise on the Coins of the Realm*, 1805, are without striking merits. His other writings are—*National and Constitutional Force in England*, 1756; *Treaties between Great Britain and other Powers*, 1648–1783, 3 vols., 1785; *The Conduct of Great Britain in respect to Neutral Nations*, 1785, 3 vols., 1801.

LIVERPOOL, ROBERT BANKS JENKINSON, SECOND EARL OF (1770–1828), son of the above by his first wife Amelia, daughter of Mr Watts, governor of Bengal, was born June 7, 1770. He was educated at Charterhouse and at Christ Church, Oxford, where he had Canning, afterwards his close political associate, for a contemporary. In 1791 he entered parliament as member for Rye, but he first held office in 1801 as foreign secretary in Addington's administration, when he conducted the negotiations for the abortive treaty of Amiens. On the accession of Pitt to power in 1804, he obtained the home office, and till his elevation to the House of Peers he acted as leader of the party in the House of Commons. He declined the premiership on the death of Pitt in 1806, and remained out of office till the accession of Perceval in 1809, when he again became home secretary. After the assassination of Perceval in 1812 he became prime minister, and retained office till compelled in February 1827 to resign by the illness (paralysis) which terminated his life, 4th December 1828. The political career of Lord Liverpool was entirely of a negative character so far as legislation was concerned; the only principle which regulated his statesmanship was persistent opposition to every kind of change, especially in the direction of increased religious or political liberty. From the beginning he strongly resisted Catholic emancipation, and he was also prominent in delaying the emancipation of the slaves. The energy of Castlereagh and Canning secured the outward success of the foreign policy of the cabinet, but in his home policy he was always unfortunate and retrograde. The Pains and Penalties Bill against Queen Caroline greatly increased his unpopularity, first originated by the severe measures of repression employed to quell the general distress, which had been created by undue taxation and was aggravated by blind adherence to protection. Though, therefore, actuated throughout by an honesty beyond all question, and though always commanding the sincere respect of his opponents by his dignified and considerate bearing, Lord Liverpool was destitute of wide and genial sympathies, and of true political insight, and his resignation of office was followed almost immediately by the complete and permanent reversal of his domestic policy.

LIVERWORTS. The Liverworts or *Hepaticæ* constitute a group of the higher *Cryptogamia*, allied to the mosses. Their shoots are either *thalloid*, in some genera (*Marchantia*) highly differentiated in structure, in others (*Anthoceros*) of simple homogeneous texture, with an upper and lower surface, the latter fixed to the ground by capillary rootlets, and generally margined with minute scales; or they are *foliose*, the central stem bearing on each side a row of leaves, consisting of one series of cells invested with a structureless epidermis, and destitute of nerves, such as prevail in the leaves of mosses. Frequently on the inferior aspect a third row of leaf-like scales is found, differing from the former, and known as stipules, bracteoles, or amphigastria. Hence the shoots, although typically trilateral, often appear bilateral. The reproductive organs of the *Hepaticæ* are of two kinds—sexual and asexual.

1. The sexual germs of the mosses and *Hepaticæ* were first described by Hedwig just one hundred years ago (1782). They consist, as in the higher plants, of germ-cells and sperm-cells. As the fronds approach maturity the terminal leaves become modified so as to form an involucrum, within which a special covering appears, the colesule or perianth, surrounding the pistillidia; this is tubular, conical, or compressed in form, with the mouth plicate and generally dentate.

On section of the colesule a number of minute flask-shaped bodies are found, attached to the apex of the stem, which have been named archigonia or pistillidia. After fertilization one of these enlarges, active cell formation proceeding from the central cell at the base, within which appears the germ-cell, which in time becomes the capsule, the ultimate contents producing spores arranged in fours, and elongated cells bearing within spiral filaments (elaters). Until the maturity of the spores, the sporangium remains at the base of the colesule, but at length the outer coat (calyptra) ruptures near the summit, and by the rapid evolution of the cells of the fruit-stalk (seta) the capsule is borne upwards. At this stage, which is of brief duration, the fronds look as if dotted with black-headed pins on white stalks. Released from pressure, the hygrometric action of the elater soon ruptures the wall of the capsule, which divides, in the majority of species, into four valves, and the spores are scattered around.

The antheridia are sometimes found imbedded in crypts within the substance of the thallus (*Riccia*), or in special receptacles either sessile or raised above the surface of the same (*Marchantia*). In the foliose *Hepaticæ* they are usually seated in the axils of modified leaves (perigonial), sometimes appearing beneath the fertile involucra (monœcious), or on special branches of the same plant (parœcious), or they occur on separate plants (diœcious). The antheridia are much smaller than the capsules, spherical or ovoid in form, and seated on a short footstalk. They are invested with a single coat of tabular cells. Before maturity they are greenish, but when ripe their colour turns to yellow. On pressure they rupture irregularly, and allow the escape of crowds of lenticular cells, which revolve actively under the microscope until the ciliated phytozoa within them are released.

The phytozoa of mosses were first figured by Unger (1834), who described them as consisting of a thick body, and a thin thread-like prolongation, which goes in advance when the body is in motion, and is spiral in form. Thuret has since shown that the so-called "tail" bears two long oscillating cilia. Hofmeister first observed the formation of the free germinal vesicle within the basal cell of the pistillidium as the direct result of fertilization.

II. *Asexual Germs.*—Beyond the true fructification, in the majority of *Hepaticæ*, certain bodies are met with, which are known as gemmæ, but which differ from each other in complexity and significance.

(1) In some *Marchantiæ* basket-like or crescentic receptacles are found, containing lenticular bodies, which, under favourable conditions, will produce new fronds.

(2) On the borders of the leaves, especially near the apex of the shoots, prolification from the ordinary cellular tissue is met with in most *Hepaticæ*, in the form of detached cells or tufts of such cells. These are generally described as gemmæ, but resemble more closely the *gonidia* of lichens, and probably aid in the diffusion of diœcious species, which from the absence of ♂ or ♀ plants would otherwise become extinct.

(3) Another process has been ascribed to gemmation, but has been more happily named by Dr A. Braun *rejuvenescence* (*Verjungung*). In decayed or apparently withered fronds, certain cells, after a period of rest, assume new activity and multiply so as to give rise to new individuals (*Anthoceros*, *Riccia*, &c.).

Distinction between Hepaticæ and Musci.—There is scarcely a character in the definition of *Hepaticæ* which might not refer to some genus of mosses, although he definition as a whole may be sufficiently distinctive, and practically there is no difficulty in distinguishing one from the other.

In *Musci* the urn-case or capsule generally opens by means of a lid, and the mouth is surrounded by a peristome divided into four, eight, or more teeth. A columella is nearly always present, and the spores ripen in a sac between the former and the walls of the capsule. From the early elongation of the fruit rudiment, the calyptra is ruptured at an earlier stage, the upper part investing the urn-case like a cap, during the development of the spores; the lower remnant remains at the base of the seta (which, as well as the capsule, is composed of more ligneous texture than in *Hepaticæ*) as the vaginula. The spore gives rise to a confervoid prothallus often extensively branched, and from this the leaf-buds arise. The leaves are imbricated on all sides of the stem, and the phyllotaxis is usually $\frac{1}{2}$, $\frac{2}{5}$, or $\frac{3}{8}$. The leaves are frequently strengthened by a midrib, and the rootlets are divided by numerous septa.

Habitat.—The *Hepaticæ* are cosmopolitan in range, and form a relatively important average of the alpine vegetation, being abundant in moist equable and insular places, *e.g.*, Ireland, Scotland, New Zealand. They are also met with in more tropical zones, such as South America, India, Java, and the West Indies.

Classification.

I. *Marchantiaceæ.*—Fronds thalloid, prostrate, furcate; epidermis pierced with curious stomata; inner section areolate, occupied by green gonidial cells, lower surface simply cellular, emitting long rootlets, papillose within.

(*a*) *Marchantieæ.*—Capsules aggregate on a stalked receptacle: *e.g.*, *Marchantia*, *Asterella*, *Fegatella*, *Dumortiera*, *Lunularia*, &c.

(*b*) *Targioniæ.*—Antheridia immersed; involucre like a split pea; capsule nearly sessile, below the apex.

(*c*) *Ricciæ.*—Antheridia and pistillidia immersed, the latter emitting the spores by the decay of the walls; spores without elaters: *e.g.*, *Riccia*, *Ricciella*, &c.

II. *Jungermanniaceæ.*—Capsule solitary terminal on the primary shoots or on short lateral ones, splitting into four valves.

* *Foliosæ.*

(*a*) Leaves *succubous*: *e.g.*, *Jungermannia*, *Scapania*, *Lophocolea*; &c.

(*b*) Leaves *incubous*: *e.g.*, *Lijennia*, *Frullania*, *Schisma*, *Lepidozia*, &c.

* * *Frondosæ*: *e.g.*, *Pellia*, *Blasia*, *Petalophyllum*, &c.

III. *Anthocerotcæ.*—Capsule horn or pod-like, opening by one or two valves, columella central, spores intermingled with deformed elaters: *e.g.*, *Anthoceros*, *Monoclæa*.

Uses.—At the present time the *Hepaticæ* are of little practical use to man. In the dark ages of medicine, when the doctrine of "signatures" was in fashion, the strongly-marked epidermic cells were supposed to resemble the structure of the liver, and the species were esteemed "a sovran remedy" in liver complaints. The *Hepatica fontana* (*Marchantia polymorpha*) of Casper Bauhine, "which grows near springs, wells, and watery places, very lowe, almost like a moss, and puts out flowers about June, not unlike *stars*," is wonderfully commended by Schröder, in those disorders of the liver which arise from too much heat (*English Dispensary*, 1733). A few species possess a pungent, bitter taste (*Porella*) resembling that of *Sedum acre*. Many also evolve a musky odour, observable in the woods and fields after rain, and incorrectly referred to the smell of moist earth.

Beyond the beauty of tint and outline, which light up many a dreary ravine, they supply abundant material for the microscope, enabling us by the translucency of tissue, and their easy preservation, so long as moisture is supplied, to study cell and leaf-structure, and the wonders of reproduction, as no other class will do.

Lastly, many fern-growers have of late included the *Hepaticæ* and *Musci* in their lists of favourites, the variety adding immeasurably to the interest of their collections. Most of the species are readily cultivated in a cold frame or fernery, the atmosphere of which must be kept moist and equable. In the renowned ferneries of Mr Backhouse of York, A. Stansfield of Todmorden, and the Glasnevin Gardens, Dublin, species have long been cultivated, many foreign to the climate, and introduced with foreign plants. (B. C.)

LIVINGSTON, Edward (1764-1836), American jurist and statesman, was born in Clermont, Columbia county, New York, May 26, 1764. He was a great-grandson of Robert Livingston, the first possessor under royal patent of "Livingston Manor," a tract of land on the Hudson, comprising the greater part of the present counties of Dutchess and Columbia. Having graduated at Princeton in 1781, he began to practise law in New York city, and rapidly rose to distinction as an advocate. He was a member of congress during 1794-98, and in 1801 was appointed United States district attorney for the State of New York, and while retaining that position was also elected mayor of New York city, then an office of high dignity and emolument. In the summer of 1803 New York was visited with a violent epidemic of yellow fever, during which Livingston displayed great courage and energy in his endeavours to prevent the spread of the disease, and to relieve the widespread distress. He suffered an attack of the fever in its most violent form, during which the people of the city gave many proofs of their attachment and anxiety. He recovered to find his private affairs, which he had neglected, in some confusion, and he was at the same time deeply indebted to the Government for public funds which had been lost through the mismanagement of a confidential clerk. Livingston at once surrendered all his property, and, having resigned his offices, removed to Louisiana, which had then just been ceded by France to the United States. He soon acquired a large law practice in New Orleans, and repaid the Government in full. Almost immediately upon his arrival in Louisiana he was appointed by the legislature to prepare a provisional code of judicial procedure, which was continued in force from 1805 to 1825. During the short war with England in 1814-15, Livingston was active in rousing the mixed population of New Orleans to resistance, and acted as adviser and aide-de-camp to Jackson. In 1821, by appointment of the legislature, Livingston began the preparation of a new code of criminal law and procedure, since widely known in Europe and America as the "Livingston Code." It was prepared in both French and English, as required by the necessities of practice in Louisiana, and, though substantially completed in 1824, and in greater part then adopted by the State, it was not printed entire until 1833. It was at once reprinted in England, France, and Germany, attracting wide interest and praise from the most distinguished sources by its remarkable simplicity and vigour, and more especially by reason of its philanthropic provisions, which have noticeably influenced, the penal legislation of several countries. Livingston was a member of congress during 1823-29, was afterwards senator, and for two years secretary of state under President Jackson. From 1833 to 1835 he was minister plenipotentiary to France, and conducted with success negotiations of considerable difficulty and importance. He died May 23, 1836.

See Livingston's *Life* by C. H. Hunt (New York, 1864), and his complete *Works* (2 vols., 1873).

LIVINGSTON, Robert R. (1746–1813), American statesman, brother of Edward Livingston noticed above, was born at New York, November 27, 1746. He graduated at King's College, New York, at the age of nineteen, became a practitioner of law, and, in 1773, recorder of the city, but was soon displaced by loyalist influence because of his sympathies with the revolution. In 1776 he was a member of the committee of congress which drew up the Declaration of Independence, and in 1777 was a prominent member of the convention at Kingston, which framed the first constitution of New York. Upon the adoption of that instrument in the same year he became the first chancellor of the State, which office he held until 1801, whence he is best known as "Chancellor" Livingston. He administered the oath of office to Washington at his first inauguration to the presidency in New York, April 30, 1789. In 1801 he was appointed by President Jackson as minister to France, and in 1803 effected in behalf of his Government the purchase from France of the vast territory then known as Louisiana, comprising the entire territory between the Mississippi and the Rocky Mountains, from the Spanish to the British possessions. This was, perhaps, the most important transfer of territory by purchase ever made, but none of those who participated in it realized its importance. Napoleon's agent obtained ten million francs more than he had been instructed to accept for the cession, and Jefferson and Livingston were at the time bitterly censured for rashly concluding so useless a purchase. In 1804 Livingston withdrew from public life, and after spending a year in travel in Europe, returned to New York, where he occupied his remaining years in promoting various improvements in agriculture. He also assisted Fulton in his invention of the steamboat. He died in February 1813.
