Knowing the grade, where will you sell? Bless me, how should I know? To be sure, I am writing this to try to tell you something about marketing; but, not knowing your selling talent, I can only tell you to study *yourself*. If you are a good salesman you can create a market where the other fellow says there is none. To illustrate: The producers round about a New York state city said the market was glutted, and that they could not move their honey at any price. Another producer from a hundred odd miles away dropped into town for a convention, and before sessions "kind of sauntered around town" as he put it, and took orders for a lot of honey to be shipped in from his place. He was a *salesman*. If you are not, then you can well afford to pay a very liberal commission to such a man to market your crop for you. Find out what you are.

Know your market. If you are a really sure-enough salesman, you will learn it before you have called on many people. If not, you must keep at it until you find out what sort of packages and kind of honey the market wants. This for selling to retailers. If selling to jobbers, *they* will determine whether they can use your honey, and they will bid as low as they dare. Then if you know the amount of crop and price level, you can jockey with them. If you don't know those things you take their price or keep your crop save in the rare years when the supply is far below the demand. And if the agricultural schools keep turning out a fresh bunch of beekeepers every year, those rare years will soon become as rare as hens' teeth. And it depends on the point

of view whether that will or will not be an evil.

Now, here is a secret. I don't tell it to any except a favored few, because I don't want to get the masses to plunging into the honey business. Among ourselves we all know what a bonanza honey-producing is; how a swarm of bees put in a \$4.50 hive will give 400 pounds of honey, which, if we retail it ourselves in any of the big cities, will bring us \$100, and that all we have got to do is to keep all the bees we can care for. When we allow for a poor season now and then, and for a lower price now and then just to crush some presumptuous competitor, you know, we can surely average \$75.00 each; and if we are smart, and hustle, we can take care of a thousand colonies without help—that of the wife and children doesn't count—so that the only problem which really confronts us is that of marketing. Now keeping this secret to yourself, and bearing in mind the great possibilities, you will more fully appreciate the vital importance of the selling, and to which I will now return.

Having found out what your crop is in quality, go out into the wilderness—of the city—and study the ways of the wild creatures. See what sort of packages are in use. There may be none; and then, oh rapture! there is a virgin field before you. But study packages, labels, etc., then get some for yourself.

I would tell you to get a nice jar and a neat label; but before I do, I will ask you what constitutes a nice jar and a neat label? Judging by much that I've seen in the various markets, I think very few honey-sellers have a clear idea of what is "nice" or "neat." Most labels are an agonizing jumble of type and color, very interesting curiosities of the lithographer's art, but no help at all in selling the honey. I don't care a rap what the label says, provided it only induces the observer to buy the package and test its contents. After that—if it is my honey—he will come back for more of the good things behind that label, and it is just there that I want my label to have an individuality which is exactly what the made-by-the-mile lithographed does *not* possess.

What have I to say about packages? What is your market? The average city market wants a glass package, smooth clean jar, smooth non-leakable top, and in sundry sizes. One store will use nothing but pounds; another a smaller, and another a larger size, and still another a mixture of two or more sizes. You never can tell till you try them out. Size of package is governed by the customary purchasing price

of the community. In one town, pounds retail for 15 cents; in another, for 30 cents. One store sells only for even nickels, while the next sells wholly on odd cents, as nine, fourteen, eighteen, etc.; and they measure your price by what the packages retail for.

One town will take dark-amber honey and give the top price for it; another wants light amber, while the next wants water-white. One wants mild, almost insipid honey, while the next wants something pretty rank.

Oh, this selling to the retailer is such a simple art! And even that simplicity is simplified when these sundry preferences exist between stores of the same town, and each store wants a different brand, and the salesman becomes insanely happy when on top of all this the buyers want all candying honey exchanged and all broken combs replaced. Oh, joy!

Possibly one of the best ways to learn the art of suiting the retailers is to go to work for a few score of them, perhaps buy for some of them at a profit-producing price. And that reminds me—do you know how much "profit" has to be added to your goods before the consumer gets them? Here are some of the costs between producer and consumer, supposing the producer sells his crop in bulk. Freight, cartage, and jobbers' expenses, minimum fifteen per cent; packages and packing, about ten per cent; "cash store" retail expenses, fifteen to twenty per cent; while a credit store's "overhead" may run to thirty-five or fifty per cent. Suppose your honey goes to the consumer in a pound jar selling for twenty-five cents; deduct from that, say fifty per cent just for expenses, then deduct what you think are the profits of these middlemen, and see how much is left for you. Can you afford to produce honey at that price? It depends on how much you produce at how much per pound. Do you know? Have you even a remote idea? Better find out before you get into the honey business very deeply. When you find out the cost of production, go into the cost of your marketing. You may find that the "overhead" expenses are up there like Damocles' sword ready to cut off all your profits on the slightest incautious move. Knowledge is said to be power; but it is also at times mightily disconcerting to our plans and pipe dreams. However, it is just as well to acquire a goodly bit of it at the start. The good wife and kiddies are less likely to be hungry and disappointed by and by. After you have learned all about what your local market wants, you will find it is so for only a little while; that it is constantly changing, and that, unless you are

awake and alert, some chap who is will crowd you out. The scramble for a living is just about as cold, heartless, and unfeeling in trade as it is among the animals. Sentiment, good fellowship, good will, kindly feelings, may be expressed, but orders are what the salesmen are after, and the chap who gets them is the one who counts.

When the competition gets keen, and prices drop and drop, what are you going to do? Hang on, drop prices and sell, or give up the business altogether? It depends on what you know of your business. If you are not thoroly informed, you are not in position to fight successfully for your living, and sooner or later you will go under. We have had all sorts of producing schemes and all sorts of appliances, and we have discussed these things until our voices are husky and our ink used up, but precious little have we heard of the cost of using said appliances or methods. We shall have to know pretty soon, for this honey business is getting down to brass tacks.

As consumption increases, prices will drop. Why? Oh! well, that is one of the economic laws which we have so far been unable to repeal. To explain it a bit—a lawyer would charge you for the explanation, but I won't, because I am already overburdened with the profits from the bees, and want you to be. To continue, when the demand for things increases, the production increases; more people enter the business, and very soon down go prices. Some fine day the dear public's fancy changes, demand falls off, and—well, only the strong and the astute weather the storm. And when you are put up against such conditions you will either holler for help or sit

down to live on the interest of your wealth. The strong and astute are those who have prepared themselves to meet the storms of competition, low prices, changing demands, etc., by piling up a reserve of capital, by learning all the arts of selling, by anticipating the consumers' demands—in a word, by being "forehanded." That term was given by our good old New England ancestors to the successful, thrifty, hardheaded ones among them. The homely virtue is as good today as then. Forehanded means more than the acquisition of worldly goods. It means the knowledge and thoughtfulness on which such thrift is based. I repeat, to get the knowledge of markets, of the kind of honey wanted, of the best packages, etc., go into the market, *buy* honey, taste it, study the packing, ask questions, follow the conventions, ask more questions, stop, look and listen, then move on and do it some more.

"They have eyes but they see not, and ears have they but they hear not." If you are both deaf and blind to what is about you, for your own sake and for the sake of the rest of us *hire a salesman*. Do you say that you cannot afford to? Then pool your issues with your fellow-craftsmen; go into a marketing association as some of the Colorado beemen have done, and as so many fruit and other specialists have done. To be sure, you will have to yield to the majority; but most of the time the majority is pretty nearly right. Co-operation is a sadly overworked word, but a very much underused fact. Be as willing to yield to others as to express your own views; *get together* and *pull together*. Perhaps you are doing very well going it alone; but in the long run you may do a lot better "running with the pack."

Providence, R. I.

## THE NECESSITY FOR ADEQUATE GRADING

BY JOHN W. LOVE

The attitude expressed in the bromide. "We are beekeepers, not salesmen," is all very well for the man who keeps bees as a backyard hobby; but the honey-producer who depends on his colonies for a living cannot afford to neglect the principles of marketing farm produce. Some very important developments have taken place in this new science of selling, and more important advances are due in the near future.

The preparation of a package has long been recognized as a basis of success in business of any kind. It would be impossible for manufacturers to deal with distributors without having between them a clear

understanding on sizes, grades, and packages. Yet farmers have been slow to grasp the significance of this principle. They have continued to send to market apples of different sizes in baskets of varying capacity, strawberries in crates of odd dimensions, and comb honey of widely different grades in the same lot.

If the dealer is to quote a price he must know exactly what he is getting; and before transactions can be placed on a permanent basis of confidence he must know that what he receives will be strictly true to grade. It is impossible to make much progress until the buyer and seller discuss the com-

modity on the same terms. Standardization of packages and contents is also necessary before marketing information can be disseminated.

In this direction a beginning has been made in the adoption of grading rules, such as those of the National Beekeepers' Association; but outside of the successful co-operative associations very few honey-producers give adequate attention to this important matter. The situation has been the same in apiculture as in fruit or cotton growing—the producer has relied upon the buyers to make the classification by competitive bidding. It does not work out this way, however, as investigations by the Bureau of Markets have shown.

It is true that a product of high grade will sell itself, albeit with some loss if the sizes of packages are not uniform. The trouble lies with low grades, culls, and mixtures. These are ruinous to the whole market, whether they are cotton bales, grapes, or sections of honey.

The public is ready to pay good prices for the product which is uniform in quality, size, and package. Consumers are quick to appreciate a commodity of uniform high grade, and are willing to pay prices which will be remunerative to the producer. This has been demonstrated in the success with which standardized syrups, cereals, and canned vegetables have sold at prices three times those paid to the producer.

#### NEW HONEY STANDARDS COMING.

Since the net-weight law went into effect loud protests have gone up from beekeepers who object to the trouble it makes in stamping the weight on the sections. The new law makes for standardization, however, and so must be considered a step in advance. The only drawback is that standardization has not yet gone far enough. It does not yet include sizes of sections and grades of honey.

Perhaps further advances in this direction are premature, at least until some of the agitation against the present law quiets down; but more detailed standardization on the part of the Government is coming, and the sooner it comes the better for the retail honey market.

What will be the nature of the new legislation? Congress has established the standard apple-barrel which now has the same legal status as the bushel. At present, standardization of apple-boxes, berry-crates, and cups is under consideration. It is not unlikely that the Government will undertake to define sections for comb honey in the same law. Ample time will be given, of course, for the beekeepers to use up sections of odd size. The form or forms standardized would be those in most common use.

This standard would be enforced in the same way as the standard apple-barrel. Bees would still have the right to build comb in any other thing; but the producer could not sell the product at a price per section unless its dimensions conformed to the government rule. Congress has the right to enact such legislation under the weights and measures provision of the Constitution. It would be applied without regard to whether the business is interstate or not.

The Government can never be expected to accomplish as much for honey-producers in this direction as they can do for themselves thru co-operative effort. Such standardization as contemplated would not be as effective as the Colorado Honey-producers' Association enforces among its members, for example. But it would be something, at least, and would probably make possible more extended co-operative organization in the craft. This would mean larger profits for the individual producer.

Cleveland, O.

## SELL DIRECT OR TO THE RETAILER

BY CHARLES H. CHESLEY

The small honey-producer can often dispose of his product thru the agency of some local grocer; or in case he has too much for one merchant to handle, two or more can be induced to handle the output. There is usually more money for the producer by selling to the retailer direct than in dealing with a commission house. Of course, when the output is fairly extensive it may be necessary to do business with the commission man.

The honey market is one that can be

developed in many communities. Thus one producer in a community where beekeeping is rather uncommon had a small circular printed, describing the uses and valuable qualities of honey. This was left on the counter of one of the main groceries. On the bottom of the circular was announced the fact that "our product is for sale by John Smith & Son." It was stated that this more than doubled the sale of honey in that village in a few weeks.

In selling honey in the home market (or

anywhere else), careful grading is necessary. The product must, in all cases, be exactly what it claims to be. This is even more important in the home market than when selling to a commission house, for future sales depend on satisfying the customers.

Endeavor to have the grocer make it a point to push the sale of your honey. In order to do this it will, of course, be necessary to allow him a liberal margin of profit. It is better to do this, in most cases, than to attempt to sell the product direct; and even then you will probably realize more than you would from the commission merchant in the city.

One man of the writer's acquaintance,

whose whole business is beekeeping, sells his honey almost entirely to consumers, having regular customers in three or four small cities. Of course he can do little marketing in the busiest seasons; but he sells a good deal at times when the bees need no attention. This man sometimes finds he has more than he can sell to the retail trade, and then he drives to a village two or three miles further away, and disposes of it to the retail merchants. In the towns where his regular customers live he does not attempt to do business with the retailers, as they naturally know him and feel somewhat prejudiced against him. Fortunately for him, he lives in a locality where thriving manufacturing villages and cities are scattered thickly.

East Barrington, N. H.

## PUT YOURSELF IN THE CUSTOMER'S PLACE

RUTH C. GIFFORD

We find that the easiest way to sell honey is to give the customers just what they want. Perhaps you think these kinds of customers are cranky. If they are, they are merely like everybody else. All persons are cranky if you know 'em. Besides, these customers generally use a lot of honey, and their trade is dependable.

As soon as the honey is off the hives, and cleaned, it is sorted, and the cases immediately packed for the customers who have likes and dislikes. Some prefer the pure white honey; others want the light and dark mixed. They claim it has a better flavor. Then there are some who don't think the light honey is fit to eat, and refuse to buy anything except the very dark.

The frequent request that puzzled me most was for sections that have no honey in the row of cells next to the wood. On inquiring I received a very interesting reply. In nearly all homes the honey is cut out of the wooden section before it goes on the table. Consequently the majority of the family never see how attractive the section looks with the cells neatly sealed close up to the wood. When honey is prepared for use from

these pretty sections, sealed cells have to be cut; so when it reaches the table the edges of the comb look smeary, and some honey is running over the plate. If the outside row of cells is empty the honey can be removed from the section so it will look very attractive when it reaches the table. There will not be a single drop of honey in sight until it is passed to the first hungry honey-eater. Now, when we have company and want it to look extra nice we always select a section which has no honey in the row of cells next to the wood, and the way people admire it amply repays.

Ruth C. Gifford's carrying-case from which she retails comb honey.

Sending out sections containing pollen is one thing against which we guard most carefully. The sections are always sorted in front of a window, where even a small amount of pollen will show dark thru the section. Nowadays people are not educated (?) to pollen, and the first bite into it by an innocent person is a sure guarantee of a lost customer.

A large part of the honey is sold in cases holding a dozen sections. We have never tried larger cases, because it would be useless. Some people even say these cases are too large.

Of course quite a number of people don't buy even a twelve-section case; so for supplying them we use twelve-section retail cases. In them are six section-holders, each containing two sections instead of four as in the supers. They also have division-boards. When one section is left alone in this length of holder it will not jolt around enough to damage it. The ends of the section-holders rest on cleats, so any leaking honey will go into the bottom of the case. Before the boards are nailed on the bottom, a piece of white table oilcloth is fastened on it, and then the boards on top of that.

In the lid, the boards are fastened together with strips of tin. The lid is perfectly flat on top, and is covered with tin or heavy building-paper. It has a cleat around the edge on the under side. After this case is completed it is stained inside and out a dark brown, and given two coats of water-proof varnish. When it is soiled it is wiped with a damp cloth, and even the shiny white oilcloth in the bottom of the box is soon as clean as ever. We have used this kind of case for several years, and it has given perfect satisfaction. It is needless to say the sections themselves are scrupulously clean. In every way we do all in our power to make the honey attractive.

If you have honey to sell, try to put yourself in the consumer's place, and imagine just how it would appeal most to you. Then fix it that way. For instance, if you value your trade *don't* wrap cases or sections in newspaper. Leave them unwrapped first. However, they are much more attractive in regular wrapping-paper.

I hear some one ask, "Does all this pay?" It most assuredly does. We have always had more demand than honey, and at good prices too.

North East, Md.

## I AM NOT A SALESMAN

BY G. C. GREINER

From observation I know that beekeepers as a rule greatly neglect the most vital part of our pursuit. The financial success of all our beekeeping efforts hinges on the sale of the product. If we do not put forth the necessary efforts to increase our sales, all the increase of our crops will benefit us very little. In past years I have not done my best in this direction; and today I am not pushing things as I might. The only excuse I have for this neglect is that I am not a natural-born salesman. It goes against my nature. With the long experience of producing and selling honey I can do fairly well after the ice is once broken; but from choice I would rather stay in my honey-house or among my bees than start out into a section where I am not already acquainted.

Early this fall I received a postal card from one of my old customers who had moved from his former home to a new section of the city. The card requested me to deliver his usual winter supply of honey on my next market trip or whenever I could make it convenient to call. When I stopped at their house the lady of the house came to my wagon and selected quite a quantity of my goods; and while we were chatting

the lady of the next residence joined us with the intention of examining the contents of my wagon. She, too, made quite a purchase. Before she left the wagon a little girl stepped up to me and said, "Mr. Greiner, mamma wants you to stop at our house (the third in the row); she wants some honey too." This shows that people will buy honey if it is offered to them in attractive form, and made convenient for them to procure it, when otherwise they would never have thought of honey. If I had stopped at every house the length of the street, undoubtedly the majority of the inhabitants could have been induced to make a purchase. But I had been at the market, and was nearly sold out.

A neat attractive label is in many instances the means of increasing sales. It should not be too large to hide the contents of a glass package, but sufficiently conspicuous to attract the notice of the buyer. At our last summer's gathering of beekeepers I had a little discussion with one of our prominent members on this subject. He claimed it did not pay to go to the trouble and expense of using labels. He said he had his name pressed on his bottles for one

thing, and too many of the labels came off before the honey got to the consumer any way, so he decided not to use them any more. I cannot agree with our friend. It is true that once in a while a patch of labels does not seem to stick as well as at other times. When we are liquefying in cans a few may come off; but they are easily replaced, and the businesslike appearance of our goods compensates for the little trouble. A neat tasty label is certainly a great improvement, and helps sell our honey for various reasons. Its object is at least threefold. First, the guarantee being on the label, it insures the buyer unquestionable purity of the article. Second, the name convinces the purchaser that we are the actual producers—a conviction which again produces confidence in our goods; and, third, as I said before, the neat appearance of our ware attracts the attention of the passing crowd.

Time and again I have had people take up a can of honey, and, after examining the label, say, "That is the honey I want." Others ask, "Are you the Mr. Greiner yourself who produces this honey?"

When answering in the affirmative, a sale invariably follows. It seems to give a certain satisfaction to buy direct from the producer. People have less confidence in the genuineness of the article after it has passed thru three or four different hands.

That other branches of industry consider attractive labels of great importance can be seen every day when we step into our groceries and drugstores. All the shelves are lavishly decorated with goods of all descriptions nicely labeled. Why should beekeepers neglect their own interest and fail to improve the appearance of their goods when it adds so much with comparatively so little expense?

Another feature which the majority of beekeepers greatly neglect, and which in

many instances would increase the sale of their honey, is an attractive display at fairs, carnivals, and other public exhibitions. Until very recently I have been one of the "doubting Thomases" myself. I was laboring under the wrong impression that it does not pay. My first attempts along this line, in which I was interested many years ago, did not show any adequate results for the time and trouble expended. Besides, being otherwise engaged, I could not spare the time to attend properly to an effort of this kind. But since I have moved to my present home, conditions have been more favorable in regard to this matter. Having severed myself from nearly all business connections except beekeeping I could have managed to set aside the necessary time for this purpose; and my locality, being one of the best in the country in regard to the production of an extra-fine quality of honey, the effort of making a fairly passable display at fairs would not have inconvenienced me very much. And why did I neglect it? Simply shortsightedness. The old impression, "it does not pay," kept me from availing myself of the opportunity.

Recently it happened that the progress of our little burg, the building-up of the place with the rapidly increasing number of inhabitants, induced the men at the helm to propose and start a so-called "harvest festival" in the form of a general agricultural fair. Being a tax-payer and therefore more or less interested in public doings, I decided to contribute my mite toward the success of the undertaking by way of a little honey exhibit. I did not expect any direct financial gain out of the affair, and the result was, therefore, all the more gratifying when on my first market-trip afterward a lady accosted me something in this way: "If you are the exhibitor of that honey I saw at the fair, and you have any more, I should like to get a crate just like it."

La Salle, N. Y.

## WHAT I HAVE LEARNED IN SELLING MY OWN CROP

BY WALTER GARABRANT

I am situated where most of the honey customers are well-to-do, and many of them are wealthy. When I started I was located on a by-road; but for the last ten years I have been on a main macadam road. Since the advent of so many autos there are a few more transient customers who sometimes come again. I have always kept a small sign "Honey for Sale" in plain view of passers by, and the apiary may be seen from the road.

Salesmanship is almost a profession at the present time. Doubtless it needs to be if one undertakes to fake the public for a swindle. But almost all producers of small quantities of honey could be their own salesmen to advantage if they would give it some consideration. On the average, perhaps, they would be about as successful salesmen as apiarists if they would put forth reasonable effort along this line.

My honey is sold both at retail and

wholesale. When the crop is small it nearly all goes at retail. When larger, only a fourth to a third goes at retail. We have always peddled most of our farm products, and honey sales have been made mainly in connection with the sales of other produce. When we sell at wholesale it is usually direct to the retail merchant, not to a middleman.

It has always been one of our principles to sell to the nearest buyer who will pay the market price. This is sometimes our nearest neighbor. Thus we save time, transportation, and risk of lost payment, since we know the reliable buyers. This also relieves the larger markets, and gives better distribution. We have always tried to give a buyer what he wants or needs, sometimes refusing to sell when we knew it would not suit, or that it would give dissatisfaction later, and probably result in the loss of a customer. I cannot recall losing any of our customers because of dissatisfaction.

I am known as a "dear man," not as a "cut rate." Sales at retail are made at the best or average retail price for the quality; at wholesale at the best market price. Prices are usually set by the local markets, but sometimes by the larger city quotations in the papers. In this way we are on good terms with the stores and business men in town, and we can sell as we like. Because of lack of time I have never made a regular business of peddling honey in the large town where the large part of my wholesale sales are made. I believe a good thoro peddling of honey once a year at least would increase the honey sales as a whole for the stores. I have started a good many customers by an occasional sale.

I have a few regular customers in town who take honey when supplied with other produce. I have never had trouble in wholesaling my honey, both comb and extracted, at the stores, and usually at prices higher than the New York quotations. I could sell more if I tried. To start a new wholesale customer who is in doubt, or does not want to buy, if reliable I leave honey for sale on trial. I have never had any returned. I always sell for cash at the stores except in a few cases where the honey is delivered by others.

I have never advertised honey. Why should I when I cannot supply the present demand? However, I have always been ready to talk about bees and honey, and give any interesting facts about them. This may not have increased sales, but it has been at least the means of getting most of the storekeepers to take better care of their honey, and keep it on display.

My oldest record of sales is dated 1898, when the crop was about 1000 pounds. Since then the crop has varied from 400 to 2700 pounds. I know the average price per pound of that first crop was much less than of late years. I still have many of the same customers, both wholesale and retail. Some of them come back voluntarily, or send orders. A good many I keep after, by a notice of the new crop, or inquiry of some kind as to what they want. Many I call upon when the new crop is ready. I get advance orders from the storekeepers when I can; but most of them are regular customers, and their demand is about regular. The rest of the orders are taken by chance.

I have one retail route that I go over once in the early fall, and twice if time permits. This trip runs from 100 to 200 lbs. for the day's work. On this trip I am often able to dispose of the odd sections that do not ease up well with the main lot. At first the customers on this trip took mainly comb honey; but the last season and the one before they took nearly all extracted, in jars. The demand changes—due, principally, to the more attractive appearance of the jars and the more convenient form for using a little and saving the rest for later use.

I have always had some good customers for such poorly filled and poorly capped sections that are too heavy to use profitably as baits. These are sold by weight at the wholesale price. Price tells here. It is seldom necessary to change customers for this grade often, and but little trouble to find a new one. In this way hurting the store trade with second-grade goods is avoided.

I have nearly always sold my good section honey by the box, always at retail. I consider it less apt to make the public critical on this point. However, I always grade carefully, and vary the price to fit the grade, especially to the wholesale trade. Thus a lighter section may sell, in a short season, for the same price as a better weight when the sections run heavy.

Enough dark honey is bottled to supply the demand in that form. The rest is sold in 2 x 4 quart tin cans. Because dark honey is cheaper, it always finds some sale, mostly to neighbors. A few prefer the flavor of the dark honey. I have also a considerable demand for two-quart cans of white honey. Many of these are sent by parcel post.

Sometimes it hardly pays to retail from the standpoint of profit alone; but the honey must be sold. Retailing relieves the wholesale trade, and usually stimulates and creates a demand for honey.

My principal honey-flow is from the

clovers—white, alsike, red, second bloom, sweet clover, of late years, and several seasons we have secured some from alfalfa. The season ends with the sumac, which is often the heaviest part of the flow. I have always made it a practice to get my comb honey off with as little travel-stain as possible. The extracted I want good and ripe, but not too heavy and sticky. It is stored in a good hot room until after the fall market. I have had the thermometer go to 110° F., generally 70 to 90. What I carry for winter is put in a warm dry room in the house. Doubtless the quality and flavor of the honey have much to do with repeat orders, the tastes and opinion of quality differ very much.

The same label, and also a distinctive one, I find, is also a help in holding trade for the stores. Every section is scraped thoroly

clean inside and outside and usually stamped on the top as a guide to keep right side up. Cartons are used on all retail trade, but not on all sold at wholesale.

To summarize:

Sell to the nearest obtainable customer or market.

Never be "grumpy" if a buyer says no. Get the best market price—don't cut.

Don't retail at wholesale prices. It's a waste of time and labor.

Give customers what they want or what you believe will suit them. Put the honey in the best marketable shape and appearance, but grade honestly. If the demand is short or lacking, create it in some way. Talk about honey and bees to any one who may show the slightest interest.

Be careful to keep up the quality of your honey.

Chester, N. J.

## MARKETING HONEY LOCALLY

BY JOSEPH GRAY

Variety is the spice of life. In years past I have paid considerable attention to an attractive and varied display of honey; but the purpose of this article is confined to supplying the local needs. When I see both comb and extracted honey brought 100 miles to be sold in this valley, while we who live here market at wholesale 500 miles or more distant, I think it is time to sit up and cater to the home trade. The reasons for this neglect are that no one will trouble with sections; and then, second, it is cheaper, if you own 1000 colonies, to buy in bulk by the carload, and sell in bulk. When I came into possession of an apiary I figured that, as I had to proceed on a smaller scale, the difference between 5 cts. wholesale and 7½ cts. to local buyers for extracted was worth the extra labor involved, also the production of a few sections in extracting-supers suitable for the local trade.

I present your readers with my label, and what it stands for as follows:

I have spent considerable time getting up labels. Let us pick this label to pieces:

1. Locality is not too prominent, but sufficiently so to attract attention. This is an alfalfa region, and the day is here when an American will purchase an article for what it is, and reject it if not so labeled. I try to build up an honest trade, and therefore I give prominence to the words alfalfa honey.

2. Ownership is not too prominent, and yet prominent enough to back up the guarantee.

3. The guarantee of purity and quality. I am at all times open to inspection to show that care and cleanliness are exercised to produce a pure article of standard quality. It is not my purpose to pit alfalfa honey against sage or orange, but to create and hold a local market for alfalfa honey.

NOTE: Pure Honey will Granulate or Candy. Canded Honey is an agreeable change from Liquid Honey. To restore Honey to its liquid condition, place the can in a pan of water heated to scalding (150 degrees), and allow it to remain until the Honey is liquid.

4. The net weight is a simple statement to comply with a wise law and ensure the customer's confidence.

5. The note is to enlighten a customer. Is there still ignorance as regards honey?

A word about cans. I have two kinds. One I like and one I do not. In judging displays of honey, 20 points out of 100 were allowed for the get-up of a display from the business standpoint, and often it is the little details that add to the effect as a whole. I prefer a can with a large friction top and an ear soldered for the bail under the top seam. A non-rusting soldering-flux should be used. I do not like a can with a small lid, nor do I like to see considerable rusted surface about the ear from the use of acid in soldering. It gives the can a second-hand appearance.

Salesmanship is an art. Never let an

opportunity go by to place a simple statement to educate a customer. Above all, don't make their ignorance a laughingstock to others.

The art of selling to the grocer or to consumers is a good deal one of locality. If you have time to spare, the latter plan may pay; or if you are running a milk-wagon it may pay.

The producer is not the only one. The man who distributes and the man who sells over the counter need their share. Local sales from home are limited. Let us be charitable to the man who markets for us.

Heber, Cal.

## AS GLIMPSED THRU THE CAMERA

Good Appearance after all, is one of the Best Selling Points

BY H. H. ROOT

The discussion on scraping or sandpapering sections between Dr. C. C. Miller and our Mr. J. E. Gayer, given on pages 655 and 656 of our August 15th issue for last year was very interesting to me, for the question of removing propolis from comb honey is a subject to which I have given considerable thought. I have tested a number of different power devices for doing the

work, including different forms of sand-wheels and sand-belts, but have always decided that a plain flat-faced pulley covered with sandpaper, with means for renewing the paper quickly, furnishes the simplest and best method of cleaning sections. While it might be strenuous exercise, I believe such a cleaner could be run by foot power. I tested A. E. Shore's cleaning-device, pic-

A corner of a section of honey enlarged to show the dust of wood and propolis scattered over the surface of the cappings. This trouble is caused by carelessness in cleaning the propolis from the wood.

tured on page 591 of the July 15th issue, and Mr. Gayer tested it also, but neither of us liked it as well as the simple sandpaper-covered pulley. I have also tried revolving wire brushes; but the wire soon gets dull or fills up with propolis, and has to be renewed, and the renewal of a wire brush amounts to more than the renewal of the sandpaper on the surface of the pulley.

But in this article I did not start out to discuss all the different methods of cleaning sections. I merely wanted to picture a result very common—more common than one would believe—of improper sanding of sections. (I am not sure that the trouble is always due to sanding. Careless scraping might produce the same result.) I refer to the cleaning of sections, especially plain sections, in such a way that the dust of the wood and propolis is scattered around over the surface of the comb, making the cappings look "fuzzy," and the honey itself, in the occasional open cell, very much speckled. A magnifying-glass shows clearly the minute particles of wood and propolis, sometimes not so very minute either.

Last summer Mr. Gayer showed me case after case of honey, almost any section of which, if one examined it closely, showed this same appearance. I picked out one which was bad, tho not as bad as some others that I have seen since, and made a photograph of it. Some may think this illustration exaggerates the appearance of the honey. As a matter of fact, while I tried to exaggerate it by enlarging, and by getting the light just right to show the dust to the best advantage, the honey itself looked far worse than this picture.

If a plain section is laid down flat on sandpaper, and moved back and forth in order to clean the edges of the section, the surface of the honey is almost sure to get pretty well covered with this dust. In a warm dry room the frictional electricity generated no doubt helps the dust to cling to the comb. To be sure, if every particle of dust on a section of honey could be carefully removed and put together in a little heap in a spoon it would not make a pile large enough to be noticed perhaps, even if it were all swallowed at once; and yet that dust scattered over the cappings makes the honey look bad, if one takes the trouble to look at it very closely, and that is the principal reason why the practice should be avoided. With beeway sections the dust feature is never quite as bad. At the same time (and let me whisper this so Dr. Miller will not hear it) I had the opportunity last fall of looking at some of Dr. Miller's own comb honey, and I found some dusty sec-

It is never good practice to ship bulged comb honey; and putting bulged honey in with good honey in the same shipping-case is inexcusable.

tions! I tried desperately hard to find a section bad enough to photograph, but could not, so I shall have to assume that Dr. Miller knows what he is talking about, for beeway sections at least.

Summing up the whole matter, it seems to me that the practice of laying plain sections down on sandpaper in order to clean the edges should be condemned. A better way is to use some sort of scraper for the edges of plain sections, and no doubt even of beeway sections, unless the operator is careful. Of course, the edge of the beeway, if badly propolized, has to be scraped any way if one wants his comb honey to look presentable.

#### FANCY AND CULL HONEY IN THE SAME SHIPPING-CASE.

The second illustration shows a couple of sections taken from a shipment of very

Five different styles of foundation starters.

fine comb honey—at least most of it was fine. The only bad thing about it was that every now and then a badly bulged or one-sided section was slipped in along with the good honey. Both of these sections were taken from the same shipping-case. Wherever this is done the surface of the comb of the bulged section is nearly always bruised as well as the section next to it. Bulged comb honey ought to be considered “unshippable;” at any rate, it should never be shipped with good honey. Aside from the bad practice of injudicious grading, shipping honey like this with good honey always makes trouble. The one mistake spoils two sections.

If shipping bulged comb honey were a rare practice, calling attention to the matter in this way would be foolish; but instead of being rare it is, unfortunately, very common. In most cases I suppose it is not intentional; but, like all other unintentional mistakes, bad results follow just the same.

#### WHAT IS THE BEST-SHAPED STARTER?

The third illustration shows five sections fitted with foundation—from starter to full sheets—and also a top and bottom starter. Every form of starter there represented has

its own advocate; but personally I feel that the last plan, that is, the double starter, as originated and recommended by Dr. Miller, has the most points in its favor. There is no question but that more producers are using double starters every year. It takes more time to put in the extra starters, it is true; but it is time well spent. Many do not use the right sizes. In giving the right sizes I can do no better than to take Dr. Miller's words from “Fifty Years Among the Bees.” Speaking of super foundation,  $3\frac{7}{8} \times 15\frac{1}{2}$ , he says, “This size is just right to make four top starters  $3\frac{1}{4}$  inches deep and four bottom starters  $\frac{5}{8}$  inch deep. Occasionally a bottom starter of this depth makes trouble by lopping over, but not often, and a shallower starter is more likely to be gnawed down by the bees. Moreover, I think the deeper the bottom starter the more properly the two starters are fastened together.

With two starters of this size, and a  $4\frac{1}{4}$  section, there should be a space of  $\frac{1}{8}$  inch between the two if it were not that the space is made larger by the melting-away of the edges of the starters when they are put in the section.

The result of leaving old sealed honey in bait sections. The finished product is patchy and discolored. The photograph does not tell the whole story, for the old honey looked its age and more too. Sealed honey in bait combs should be uncapped, and the comb shaved down quite thin.

## NEW DESIGN NEEDED FOR COMB-HONEY CARRIERS

BY F. GREINER

For some years I have been shipping my comb honey without the use of carriers for the shipping-cases for the reason that I have been enabled to load whatever the number of cases I wanted to ship in thru cars with fruit being shipped from this point in ear lots. I have quite a quantity of the carriers on hand, but I make use of them only on rare cases.

The supply dealers are not aware, it seems, that a different ruling is in force now as to these carriers. The fact is that the railroad companies in the East will not accept such carriers as are now listed in the new price lists of 1916. The old design was all right up to the fall of 1915; but at this time the carrier must be enclosed all around—in other words, it must be a tight box. I was put to the trouble of unpacking a small shipment last fall and remodeling the carriers to meet the requirements. Another beekeeper here had to unpack his whole crop and fix the carriers over, making him a very unpleasant and laborious job, to say nothing of the extra amount of lumber that had to be used.

Our transit companies get some funny ideas into their heads sometimes—for instance, the ruling now in force on egg-crates. These must be just so—regular style, nothing coddled up will be accepted. I attempted to ship a crate a few days ago which had been remodeled from a substantial lemon-box. The express office called me up and told me that I must come back and repack the eggs into a regular style of crate. Manufacturers of carriers will do well to see to it that their carriers conform to the rulings of the railroad companies.

### HARMONIOUS COLORS FOR LABELS.

For honey-labels of any size, particularly

for tin packages and pails, a white and yellow background with black printing harmonize well. Let the white paper be covered all over with light-yellow bees—no sharp dark lines in the bee—white lines drawn all thru the bees, to make the bees not inconspicuous, but to appear, from a little way off, as a very light yellow with the white paper. Upon this paper should be printed in very large conspicuous type the word "Honey" so when a pail or can stands on the grocer's shelf it may be easily read from a distance. The less other reading on the label, the better; but the name and address of the producer as well as the number of pounds or ounces should be given. Such labels might be made of any size, from very small, suitable for section boxes or small tumblers, up to 60-lb. cans, etc. They should not be very expensive.

A straw skep could also be used in the manner above mentioned for a background in lieu of the bee. For honey labels nothing could be more appropriate.

### SENDING GRANULATED HONEY BY PARCEL POST.

There is nothing to hinder the shipping of granulated honey in tin—possibly in paper also—by parcel post. I have not dared to send liquid honey in this manner, altho put up in friction-top tin pails.

We must guard in every possible manner against the possible soiling of other mail matter with honey. A package of comb honey was retained in our postoffice here because of the leakage. It is not practical to ship comb honey by parcel post except when put up in tin and tightly sealed. Comb honey will always be badly broken in transit when shipped by parcel post.

Naples, N. Y.

## MARKETING HONEY ON RUBBER TIRES

BY LEWIS L. WINSHIP

During the season of 1915 I produced about 500 pounds of honey in all—a little more than 400 pounds of which was extracted. About half the extracted, and all the comb, was sold at home.

As we own an automobile, and were selling other things from house to house, I hit upon the idea of carrying a few dozen jars of honey. This plan did not occur to me until the latter part of August; and from that time on, ten or twelve dozen jars of honey were a regular part of our load. I

sold these jelly-jars of honey, holding an average of eight ounces, for 90 cents to \$1.25 a dozen. They moved readily; and at nearly every store where they had none on hand I made a sale. These first sales were necessarily small—only a dozen or two in a place. I was counting on only the one sale; and wherever I sold any I took the name of the firm for future reference.

My own honey was soon sold, and I saw that I would have to buy outside honey if my side line was continued. I ordered 120

pounds for a trial, and soon saw that an order of that size was only a drop in the bucket. I forthwith ordered four cases more, and about a week later we had a breakdown on the road which wound up my wholesale honey sales for 1915.

From this method of selling honey I learned that:

A neat label attracts attention.

Bright tin caps are preferable to old rusty ones.

Price cuts a small figure if the honey is irresistible in appearance and taste.

Dark honey can be bottled and sold, if agreeable in taste.

A majority of retailers are ignorant regarding honey.

In regard to the latter I found that many up-to-date storekeepers thought extracted honey was spoiled when candied. Many of them said they would try a dozen jars of honey if I would guarantee it not to candy.

Against this condition I was obdurate, and explained that all extracted honey would candy in time. When I told them that this candying was a good test of its purity, I suspect a great many doubted my sanity. If not, they certainly looked as tho they did. I also explained how easy it is to reliquefy this candied honey; and probably by telling this fact I killed some sales, for many would take no more when they found they could liquefy what they had.

I have sold considerable honey around home in one-gallon tin cans; and I find that the only objection to this is the spoiling of the appearance of an otherwise beautiful product.

I have peddled some honey, but find that ten cents is all one can ask for an eight-ounce jar. For nearly all I have sold wholesale I have received \$1.25 a dozen. According to this I am losing five cents a dozen by peddling it. This certainly does not make

me feel like peddling honey when I can get \$1.25 a dozen wholesale.

From now on I think that I shall confine my efforts to selling from an automobile. By doing this I can sell ten or twelve dozen jars a day; while by peddling, three dozen is quite a day's work. Of course, after one gets his home market educated to use only his own honey he may be able to sell in larger quantities. At present the high prices of everything are tending to make people buy all their commodities in smaller quantities. Years ago, when people bought their winter's supply of potatoes and other things in one lot they were cheaper. Now they buy a peck of potatoes at a time, and pay from two to three times what they would by purchasing in bushel lots. The same thing applies to honey, and few people buy a winter's supply at once. The reason for this is obvious; few people have the ready money to lay in a winter's stock of anything. I had only one customer last season who purchased more than a gallon can. He purchased eighteen pounds, and no doubt thought he was buying a supply for life.

If all consumers would use as much honey as the beekeepers themselves, marketing honey would be simple. Last summer, when I took off honey I reserved 55 pounds of extracted for our own use, and in a short time little was left. We have a family of nine honey-consumers, and very little in the way of honey escapes.

My average profit per dozen was 50 cents. Possibly this profit will vary slightly with different localities on account of different prices per pound for honey. Perhaps some beekeepers may feel that it is worth the fifty cents per dozen to bottle and haul the honey around the country. If breakage were bad it probably would take all the profit, but I have yet to break the first jar.

Springville, N. Y.

## SELLING A CROP BY SAMPLE; HOME TRADE VS. WHOLESALE

BY GEORGE DODDS

We started the season of 1915 with 45 colonies (35 fair to good ones, and 10 weak ones). The 35 stronger colonies we ran for honey, and the weaker ones for increase. About 20 colonies were run for extracted honey, and 15 for comb. The white crop amounted to 1850 lbs. extracted honey, and 1000 sections. The buckwheat flow was a total failure, and I had to feed for winter.

As this was the first time I ever produced any extracted honey I had to do some figuring to get rid of it at any price at all, as I had no call for this kind of honey. First,

I ran a small advertisement in our home paper to let people know I had extracted honey. About the last week in August I inserted the following:

### A TON OF HONEY FOR SALE.

Bring a container on or before Sept. 5 and get your winter's supply of white extracted honey direct from the tank at 10 cts. per lb. A valuable honey-recipe book given with every order. After that date old prices will prevail—5-lb. pail, 60 cts.; 10-lb. pail, \$1.10; also comb honey by the section or family size case (15 sections).  
GEO. DODDS.

During the ten days previous to Septem-

ber 5 I sold about \$75 worth of extracted and comb honey, the neighbors bringing all kinds of containers, but mostly one and two quart fruit-jars and gallon maple-syrup cans.

In about two weeks the following was inserted:

READ  
Prov. 24:13, and heed the divine command.  
GEO. DODDS.

This one furnished plenty of comment, as we heard from it a great many times. Every one had to look it up at once upon seeing it.

As I am not able to get out among the people to sell honey I had to think of some other means, as the advertising was not bringing many sales; even the wording was changed often. I sent samples to many places, but none wanted extracted honey at even a reasonable price. The best offer was 6½ cts., delivered in Cincinnati. This would mean about 5 cts. clear above containers and freight. I thought that good white honey ought to be worth more than this, so I ordered several gross of No. 40 bottles and corks and had the following label printed.

I AM A SAMPLE OF  
DODD'S EXTRACTED CLOVER HONEY.  
Taste and note my delicious flavor. I am put up in 5-lb. and 10-lb. pails at 60 cts. and \$1.00 respectively. Phone 112-2 or drop a card to Dodd's Apiary, Cambridge, N. Y., and your order will receive prompt attention.

I next filled a good supply with honey and handed them out to any one interested and to many who were not, and from the latter I secured many of my best customers.

This plan began to move the honey quite rapidly, as I would always have some of the

samples with me; and if some one would happen to be going to the city I would give them several to hand out, explaining how we would mail the pails crated, and what the postage would be. The result was that quite a number were sent to neighboring cities; and several, thru friends, were sent to New York. Many times one sample sold several pails. The beauty of it was, the sample and label did all the business, no explanation being needed.

Today, January 12, I have but four five-pound pails left. This means that 1700 lbs. was sold at home, or mailed, at between 10 and 11 cts. above the price of the container. The remainder was shipped away at 9 cts. in 5-gallon cans.

Now for the gain over selling at wholesale at 5 cts. net per lb: 1700 lbs. at 5 cts. \$85. The 1700 lbs. at home brought \$175; \$175 less \$25 for advertising, bottles, corks, labels, and honey (for filling the same) left \$150 for the honey instead of \$85—a gain of \$65 in money, not counting my work, and I have about two gross of the bottles left for another year. There is one thing that will offset my work, and that is worth more than \$65 too. That is, the customers I have for future years, as many of them are people who seldom if ever bought comb honey, and have now had from one to five 10-lb. pails. One family has had fifteen 10-lb. pails besides some comb honey. It will not be as hard for me to sell double the amount another year, as last year was my first year in producing extracted honey.

Many will probably say that my price was too low for honey to the consumer, and no doubt it was; but considering the market I think it was the proper time to work up a trade at home, even if it has to be done at somewhat of a sacrifice.

Cambridge, N. Y.

## SELLING EXTRACTED HONEY BY PARCEL POST

BY J. B. MASON

With a great deal of interest I have read the various articles on this subject that have appeared in the different bee journals. I spent good money in finding out what price would be attractive. Of course, there is a difference in different localities. I also spent some money in finding the size package that takes the best, and proved to my own satisfaction that it is not the smallest package, and yet the small packages are kept on sale in all cities and towns. The impression is that the honey in them is "store honey."

After trying the small packages I decided

to give the quart screw-cap cans a trial. In a few papers I advertised in the classified columns, and got returns enough to set me to studying. I finally had the following ten-line electrotype made and used it in a few papers.

EAT MAINE HONEY.  
3 lbs. Clover Honey by Parcel Post anywhere  
within 600 miles, 60 cents.  
J. B. MASON,  
Mechanic Falls, Me.

On the left was a picture of a bee and on the right a can of honey. It took like

wild fire, for orders came with a rush. There were also a large number of repeat orders from people who said that the honey was the best they ever tasted.

In the last two months I have received over one hundred orders from one religious paper, having but a small circulation. I attribute this success to the fact that the advertisement showed at a glance just what would be sent—the two-quart screw-cap can. This advertisement has not only sold honey in these packages, but in ten-pound pails and five-gallon cans. It has also sold comb honey.

A plan like this does not end in one season. The people are educated to eat honey, and I am sure that there are many families to whom I have sent honey in this way that have not been in the habit of using honey heretofore.

I am writing this in the hope that the beekeeper who has produced a few thousand pounds of table honey may have a way in which he can get the most out of his crop, and at the same time develop the home market.

Mechanic Falls, Me.

## MOVING A COLONY TO PREVENT SWARMING

BY J. D. HULL

We have been producing comb honey only for the last four or five years. Last season we had eight out-apiaries besides the home yard, the furthest being sixteen miles from home, and the nearest about two miles. We have three Metz cars that we use for traveling, hauling supers, etc. We have one car fixed into a light truck.

We try to get around to each yard every five or six days during the swarming season, and look into every colony that is strong enough for swarming. We do this by tipping the hive up so we can look for queen-cells in the bottom of the hive. If any such cells are started, nine times out of ten we find them on the bottom of the combs.

We used to follow the shaken-swarm plan, but have discarded it of late years, as it took too much time and work. For the last three or four years we have been practicing moving to stop swarming. When we find a colony that has the swarming fever we move it to a new stand and put one in its place that has not got the swarming fever, leaving all of the supers from the colony that was getting ready to swarm on the one we put in its place. If we can we let two or more field forces enter the one colony that has not got the swarming fever.

We always put all of the supers on this last colony with usually an extra empty one or two on top. When the first super is one-half to two-thirds full, the empty one is put under it, and an empty one is always kept on top.

Last season was a fair one. We got about two cases to the colony, spring count, with an increase of about 200 colonies. We put 500 in winter quarters last fall. Practically all of the work thru the honey-flow and swarming season was done by myself, as my brother, who is in partnership with me, has charge of the farm where we live.

This way of treating colonies for swarming will usually stop them for about one week. If I find the bees are getting ready to swarm, on our next visit they are given the same treatment again. This way takes much less time than any way we have found yet. In this way I work two, and frequently three yards a day.

Honesdale, Pa.

## THE DEATH SONG OF THE WORKER BEE.

BY GRACE ALLEN

They will say I have died, but I know  
I have lived! The life fled  
While I claimed it and loved it so,  
I shall love it until I am dead.  
I have crowded it full of delight,  
Of labor and zest and the flight  
Of dream-driven wings in the sun;  
For lives that are yet to be  
In the days that I never shall see,  
I have thrilled to my work—and won.

In the odorous heart of the hive  
What days I have known!  
The still-looking larvæ so live—  
I nursed them until they were grown;  
Or, hanging so hushed by the wall,  
I builded it waxen and tall;  
Then out thru the maze of the light—  
For you, all you coming ones, you!  
Went plunging and veering so true  
To the flowers out of sight.

Swift workers, who hum as you pass,  
I have crawled off to die;  
Here, out of your way, in the grass,  
With wings feebly fluttered, I lie.  
All ragged these wings now and worn,  
But what dreams-coming-true they have  
borne  
Home—thru the sun!  
Ah, Death! tho you silence my song,  
I shall live—I shall live ages long  
Thru the deeds I have done!

# Heads of Grain From Different Fields

THE BACKLOT BUZZER

*Beats all the way the bees are working this summer. Mother says she don't know what to do, for the artist hasn't left enough space in this picture for more than two more supers.*

## Bees an Aid to Honey Sales.

A public demonstration in front of a grocery, showing a case of bees, with an interesting continuous talker on the life of the bee, will always draw a crowd of interested listeners who will take the wonderful statements of the beeman and tell these tales to their friends, that they may come, see, and hear.

The queen will always be found interesting, and the people will want to see her. The wonders of nature interest people when they can get the knowledge in an easy way. Some will go to the books to verify the statements. Should the sample of honey please, they come for more and for a larger quantity. Then they give some to their friends, and tell of the wonderful find.

The talker explains that the bees visit flowers, gather nectar, which, before being placed in the comb, must be evaporated—that is, ripened by the heat of the hive, and all water removed.

Groceries are poor places to sell honey, as the clerks lack the interest and energy to talk friendly with the public, and never know enough to tell of the food value of honey nor to keep the honey and jars looking bright and clean so as to be inviting. Therefore honey is sold only to regular users, and they gradually fall away.

Labels, to be a help to honey sales, should be plain, as a beeman's work should look. Flashy labels give the appearance of a manufactured article, and the government guarantee has a wrong effect on sales.

One of the largest packers of honey in Los Angeles twenty years ago sold from the 60-lb. can, but was induced to pack in jars. Now his sales are \$50 a day, or 1000 cases a year. Every jar sold makes a friend of the buyer, and is a standing advertisement for the store—a powerful aid in the development of the business generally.

Los Angeles, Cal. S. K. Bennett.

## This Plan would Sell Honey Anywhere.

Last September I had a lot of extracted honey left over—ripe, rich, and fragrant, but very dark. I should have been glad to get 5 cents a pound for it; but I sold it all for about 8 cents a pound, and could have sold more. This is how I did it:

I took about three dollars' worth of short advertisements in three local papers, and paid for them in honey (extracted) at ten cents. I suggested that the readers would be interested in the strange natural history of the honeybee, and the papers gave me all the space I wanted.

I also shipped some to Mobile, and spoke to the editors of the Register, one of the biggest and best papers in the South, and they were glad to get the articles. Then I gave the sale to just one firm which advertised the fact, and the honey soon vanished. It was only a few hundred pounds all together, but the experience was illuminating.

Mobile, Ala. H. A. Moody, M. D.

## Cells Completely Covered with Comb.

I had prepared a Hoffman frame for raising some queens from brood of two choice queens. The frame had a strip of brood foundation in the upper part, then a thin bar about midway, coated with wax on which the cell cups were fastened with wax. Royal jelly was put in each, and young larvæ introduced as near two-day larvæ as I could get. Just as I got the bar prepared, a large swarm came from one of my best hives. I had trouble in getting it, because it settled in the fork of an apple-tree. I sprayed the bees with water and removed two-thirds of them into a half-bushel basket, and emptied them in front of a colony with queen-cells only. Most of the bees refused to go in. The queen must have gone in but was killed. Within two hours practically all the bees of the swarm had gone back to the old stand. It was a bouncing colony. I opened it up carefully, cut out every queen-cell, and introduced my queen-cell frame. I thought I had a choice place. The next morning the bees had drawn out six cells beautifully, and the larvæ had tripled in

size over night, it seemed. I noted the date and closed the hive.

When I opened the hive again, five of the queen-cells were enveloped in comb until they were as large as walnuts and spherical in shape. You could not see the queen-cells at all, and no one could have guessed they were there. The sixth cell was the center of a beautiful piece of drone comb filling the whole space to the bottom-bar.

In looking thru the hive I found three queen-cells built up from their brood. In disgust I removed my carefully prepared queen-cell frame and proceeded to investigate my balls of comb. There was a nicely developed queen in three of them. The others, for some reason, had not developed. It may be that I injured the larvæ in grafting. The foundation above was drawn out, and filled with honey.

Yesterday I gave this colony ten cells on the same frame, and now they can raise no queen-cells from their own brood. This morning they have seven as fine queen-cells as I ever saw, the larvæ growing finely. I wonder what they will do this time. I hope they will make no more walnuts with queens as kernels. H. B. Arbuckle.

Maxwelton, W. Va.

#### What is a Strong Colony?

Some of my colonies had ten full frames of brood, and I felt quite proud of them. I examined a lot last week owned by a neighbor, and one queen had thirty-five frames of brood! I want to know what big beemen call strong colonies.

St. Albans, Vt.

A Beginner.

[Any queen that would keep ten combs full of brood should be called a good queen, and her colony would certainly be a strong colony. Those who use twelve-frame hives expect a queen to keep at least twelve combs of brood. Occasionally there is a report from a beekeeper who expects his queens during the early part of the honey-flow to have two ten-frame brood-chambers pretty well filled with brood. A good deal depends upon the size of the colony, number of nurse bees, strain of bees, age of queen, etc. A queen that had thirty-five full-size combs full of brood would certainly be some queen.—Ed.]

#### Honey to Moisten Gummied Labels.

Dr. Miller's recommendation to have the label long enough to reach around the pail and lap over would be excellent if there were no other way to make a short label stick. One drawback to the doctor's method is this: A label that would fit a five-pound pail would be worthless for a sixty-pound can or for one-pound glass jars.

I use a gummied label, the dimensions of which are about 3 by 4 inches, and I use it on any size of package. It is true, the gum alone is virtually worthless so far as securing any adherence to the tin is concerned. But by using a stiff brush to smear a thin

coat of warm honey over the gum, the label will stick, not only till the cows come home, but until these same bovines become superannuated. The philosophy underlying the phenomenon is that with any paste or gum with which I am familiar the power of adhesion decreases as the temperature goes down; it does not require a very low temperature to cause the label to curl up and fall off. But with the honey the colder it gets the tighter it sticks, and it adheres about as well in a high temperature as the gum commonly used.

I have never tried the use of honey on an ungummied label. It is but little more trouble to anoint the gum with honey than to moisten it with water, and it does obviate the everlasting necessity of resticking labels.

Has any one tried to compound a paste with honey as one of the ingredients?

Kansas City, Mo.

D. D. Downing.

[Honey with ordinary flour or starch paste makes a mixture that moulds easily. Used with the prepared pastes it is very satisfactory.—Ed.]

#### Wings Not There to Clip.

Tell Dr. Miller that if he had understood me properly, page 521, July 1, I am sure he would not have any reason for not being "on speaking terms with me." I did not compare him to a queen. I have never accused him of being regal. If he were a queen I am sure it would not be necessary to clip his wings, for he has none; and if I were at the clipping business with him, and wanted to keep him from getting away, I would, in spite of all the plea he has made, never stop at clipping off one leg. I would take both, and then I have no doubt the bees would have the good sense to supersede him in a very short time. See Stray Straws, July 1.

R. F. Holtermann.

Brantford, Ont., Can.

#### More Super Room Needed.

Will I be liable to need an extra super on hand to care for a new swarm of bees from either an old colony that put out a new swarm of bees June 30, 1916, or from the new swarm of June 30, 1916? If so, how many new hives am I liable to need for said bees during this season?

O. S. Bancroft.

Bradford, N. Y., July 5.

[The first swarm will not be likely to cast another swarm this season; but the old colony, unless watched, may send out a second, third, or even a fourth swarm. The first swarm may need an extra story of room for the storage of surplus, and the old colony also may need extra room if the second and third swarms may be kept back, which is usually done by destroying the queen-cells.

From your statement you had better have two extra supers, one for each colony. We would advise full sheets of foundation for either extracted or for comb honey.—Ed.]

A. I. Root

## OUR HOMES

Editor

For God so loved the world that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life.—JOHN 3:16.

And John answered and said, Master, we saw one casting out devils in thy name; and we forbade him, because he followeth not with us. And Jesus said unto him, Forbid him not; for he that is not against us is for us.—LUKE 9:49, 50.

The first text is an old familiar one. In fact, it has headed my Home papers several times in the past forty years. Just now I wish to call attention to that word *world*—for God so loved the *world*. Does that word “world” mean this beautiful planet on which we live—hills and mountains, fertile valleys, etc.? Not so. It means mankind, humanity, the human race. Somebody said recently there would not have been any world nor any planet had it not been for the purpose of furnishing a place for humanity to live. God loves humanity, and he wants humanity to have everlasting life. How little do we comprehend the full import of the words *everlasting life!* The dear Savior said, as you may recall, “Whosoever liveth and believeth in me shall never die.” I wonder if we think of this verse enough, and realize what it means. If God our creator loved the world, and still loves it, we ought also to love the world, to love humanity, and to love our fellow-men; and when we in our feeble way undertake to help in the great work of raising humanity, we get a thrill and a joy that we can get in no other way.

Just a day or two ago my youngest daughter came up with a fine-looking man by her side, and asked me if I knew him. He was well dressed, looked smart and bright, and something in his face recalled years ago. But I could not catch on until he explained a little. When he said that he was Ransom Murray I began to understand. In these Home papers about thirteen years ago I told about finding a boy in our Medina jail who was almost twenty years old, and could neither read nor write. His offense was for climbing on a freight-car and stealing a ride. He was soon let out, and went to work for the A. I. Root Co. When I told about it in Our Homes my daughter Carrie, who was a teacher then, volunteered to teach him to read and write, and a little later he united with our church, and now he is a bright, skillful, intelligent, and useful man. What a thrill it gave me as I realized the outcome of a little help and a little good advice at a critical time in a boy's history! Let us now digress a little.

Yesterday, July 14, was a red-letter day to me. I was coming home from the “cabin in the woods” in northern Michigan, and I was in a hurry to get home; but when I got into Detroit and learned that the boats did not run to Cleveland on Fridays I was considerably disappointed. Then I remembered similar cases when my plans had been interrupted and I had asked the dear Savior to guide my erring footsteps and show me *his* plans and what he had for me to do. I soon found some good friends whom I had learned to know and love down in our Florida home. They were located in the suburbs, and were very glad to take me with their little Ford automobile, among other things, to see where the Fords are made, or the “tin Lizzies,” as somebody has nicknamed them. While we were discussing the Ford enterprise my good friend Mr. Flower told me something as follows. He said he was not sure he had the details all straight. I presume all the world knows that one of Mr. Ford's special hobbies is to make good men out of bad men. Right here let me give you a little clipping from one of the little books sent out by the Ford company. It will be a good introductory to my story:

## THE FORD IDEA IN EDUCATION.

The impression has somehow gotten abroad that Henry Ford is in the automobile business. It isn't true. Mr. Ford shoots about fifteen hundred cars out of the back door of his factory every day just to get rid of them. They are but the by-products of his real business, which is the making of men. William Carey, cobbler and missionary, asked as to the nature of his business, said: “My business is extending the kingdom of God, but I mend shoes in order to provide money to carry on my work.” Mr. Ford's business is the making of men, and he manufactures automobiles on the side to defray the expenses of the main business.

What an idea that is, friends!—the making of automobiles is only a “side issue” to Ford's lifework.\* I think I have told you several times that when I first got up to speak in a union meeting I said something like this to our Medina friends:

“My friends, you all know I have always been a very busy man, and I propose to be a very busy man still; but, God helping me, henceforth I mean to be busy for Christ Jesus first and for A. I. Root afterward.”

You see my declaration then was that my little factory, then just starting for supplying beekeepers and taking their money, etc., was to be a side issue to the main business

\* I clip this from a Ford pamphlet:

Henry Ford once remarked that making automobiles was merely a side line with him, that making men was his real job.

of spreading the glad tidings of God's love; and may God grant that it may be the same after I am dead and gone, for it is my aim to build up first "the kingdom of God," and a great business second. Well, now for the story told me by friend Flower. It may be fiction, but I give it for what it is worth.

He said one of the greatest and most useful men in that company of over thirty thousand came to Ford's attention years ago something in this way. The fellow had succeeded in defrauding the Standard Oil Co. of a good many thousand dollars. He was convicted, and sentenced to ten years in the penitentiary. They proved it against him, but he had so skillfully manipulated the books and covered his tracks that even expert accountants could not tell *how* he did it. They puzzled over it in vain, and finally offered to remit the sentence and set him free if he would divulge the secret—that is, the plan he had worked out to swindle the great corporation. Ford heard of it, and thought that a man of such ability should be of at least *some* use to the world, and so he employed him; and as he made himself useful in developing Ford's business his wages were increased. But he was restless, and wanted to cut loose so he could use his talents in a wider way. But I think Ford finally offered him \$50,000 a year to stay at his plant. But he refused to take even so princely a sum; but as a sort of joke he told Ford he would go on without any salary if he would allow him a dollar for every automobile they put out. Now, friends, you can see something of the outcome. When they succeeded in making a million automobiles this ex-convict got a million dollars.\*

Well, friends, about a year ago I wrote the Ford company that I saw an automobile dealer in the great city of Akron who sells perhaps hundreds of high-priced machines, and he advised me to buy a Ford if I wanted to go by land to Florida; and he said this, even tho he had never dealt in Ford's machine in any way. I gave it in substance in GLEANINGS, and a copy of it was sent to Ford's people. This little inci-

\* Just think of it, friends. Here was a man whose talents and ability astonished the world, and yet he might have been doomed to spend ten of the best years of his life in the penitentiary. The trouble was that he had made the mistake of devoting his wonderful ingenuity to the robbing of a great multi-millionaire syndicate instead of doing something to bless and benefit his fellowmen. The boy I have mentioned, who could neither read nor write when he was almost 21 years old, did not seem to get on well with his teachers. If I remember correctly he had been told there was no use for him to go to school, for he did not learn anything. When my daughter Carrie took him in hand he did seem a little peculiar, and yet in a short time he was able to write a letter to his poor old mother, who had not heard from him in years.

dent introduced me to the manager of the advertising department. By the way, the Ford people have never given us any advertising; and I told their advertising agent, Mr. Russell Munro, that on the whole I was rather glad they had not given us any, because no one could now say that the write-up I gave them was in any way, even indirectly, paid for. Let us now get back to the humanity which "God so loved."

After I had become somewhat acquainted with the manager they called in an expert and gave him orders to "show Mr. Root everything he wants to see, and answer all his questions." This expert who went along with me was Mr. A. Lee McKay, the "court-esy manager." I told him I wanted permission to give them full credit in print. Perhaps I should explain that great crowds of people are being taken thru the works day after day by one or more guides; but instead of sending me with the crowd they gave me a personal guide; and it was a little tough on the guide, not only because I am a little deaf, but because I am an old man. He had to take my arm and twist me around thru the machinery, and then shout in my ear to make me hear. By the way, years ago when I used to take my good old mother thru our factory she did not care very much about the new automatic machinery, but she was greatly interested in looking into the smiling faces of the boys and girls who were running the machinery; and on this wonderful trip on that afternoon I honestly believe it is true that, while I was interested in the wonderful machinery, I was more interested in the great streams of humanity that were before my eyes constantly. Just think of it! There are something like 30,000 people employed in that great pile of factories, and they are mostly married men, because the preference is to give a place to men with families or boys who have mothers to support. That is a part of the Ford management.

Friday, July 14, was a terribly warm day in a good many places as well as in Michigan; and the first thing that interested me was their plan for supplying pure air, and to have the air as cool as possible. Their apparatus for supplying pure air free from dust, and sufficiently moist, is perhaps ahead of anything else in the world. Next come their arrangements for supplying *pure cold water*. In many places the workmen are obliged to work with artificial heat, say in handling furnaces and hot metals, and also in the japaning department. Well, there are great glass bottles full of cold pure water everywhere; and every workman, big or little, has a drinking-cup

in his pocket. The bubbling fountains we see in so many places are all right; but with such crowds as they have here it would be next to impossible. These water-bottles are not only located handy to everybody, but a boy with a cart holding six bottles is all the while traveling around the room ready to replace any empty jar. I clip from one of their books as follows:

There is a department, enrolling about 500 men, whose duties are to keep the floors swept clean, the windows washed—in fact, to keep the sanitary conditions surrounding the workmen as nearly perfect as possible. The floors of the entire plant are scrubbed at least once a week with hot water and a strong solution of alkali, which removes the grease. Another department, of about 25 men, does nothing but paint the walls and ceilings of the factory, keeping everything fresh and clean.

As light is a very important matter, not a pane of glass in that great institution is suffered to get the least dusty. My good friend, let us pause a moment. How are the windows to your barn, workshop, poultry-house, or any other building you may have at just this minute? If this Ford concern can afford to keep every pane of glass scrupulously clean in their great establishment, how is it with you?

Notwithstanding the fact that Mrs. Flower was with us on that trip, I told Mr. McKay there was just one thing more that interested me as much as anything else—their public-comfort room or closet arrangements for men. He made the remark that if I saw one of them I saw the whole of them. Said he, "Here is one right here. Let us look at it."

By the way, these toilet rooms are supposed to be within a few steps of every one of the 30,000 workmen. Shall I tell you why I especially wanted to see the men's toilet or lavatory, as it is sometimes called? I especially wanted to see if there was any tobacco juice squirted off in the back corners where it would be a hard matter to get at it with a broom or scrubbing-brush. I wonder if every man in the employ of the A. I. Root Co. will read this. I hope so. Well, I guess I did see a few traces of tobacco or stains where there *had been* tobacco spittle. But the room was far in advance of what you see in hotels, railway stations, and a dozen other places. You will remember in that printed extract at the beginning of this paper there is an intimation that making automobiles is a side issue. Now keep that in mind while we go on.

In such a great establishment, with complicated and expensive machinery, it is almost an impossibility to prevent injury entirely; and I was greatly pleased—in fact, I felt like thanking God when I was

ushered into a large spacious room beautifully lighted, and kept scrupulously clean, where were half a dozen physicians and surgeons provided with every up-to-date appliance for caring for sick or injured people. While we were there two men came in, each one having a mangled or cut finger. The workman loses no time when he is accidentally hurt in this way, and he pays no fee to the doctor. I have not time here to tell you all they do for the physical comfort and for "safety first," as has been so often expressed.

Now hold your breath while I tell you something else. They have in that great establishment men from all parts of the world, and, if I make no mistake, the guide said that at least *one hundred different languages* are spoken here, and they often come to work with no other language than their own. How can you teach men to work with dangerous machinery if you cannot talk to them? To remedy this handicap they have an English school, and this school is going on all the while. Pay-day is going on all the while; and as they work in eight-hour shifts a great part of the factory is going on day and night. By the way, a great and wonderful new factory is now in process of construction to give place to *other thousands* besides the 30,000 already enrolled. Well, that English school pleased me about as much as any other one thing. The teacher was one of the crowd. He had on his overalls like the rest. While we were there he gave them a sentence to repeat after him, and I think it was this:

"The Ford Motor Co. have in their employ 30,000 people." He spoke slowly and distinctly, the most of his audience also speaking slowly and distinctly, and managed to follow him pretty well. The word "employ" seemed to be hard for their tongues, or at least some of them, and he said it very slowly many times over. Then, pointing to a certain person, he said, "I want you, my good friend, to speak that word *employ* all alone;" and after he had made him utter it fairly well he had the whole crowd follow. Now, this teacher had a special gift for teaching his fellow-men. His gesticulations and shouts and comical grimaces made me think of Billy Sunday. Oh what a glorious undertaking is the one I have just mentioned, to take an average crowd of foreigners coming from all parts of the world, and teach them a common language, including old men! My good father used to remark humorously, especially when he was getting old, "It is a hard matter to teach old dogs new tricks." Well, I begin to realize it just now, espe-

cially when my grandson is trying to teach me to run a Ford automobile.

Now, here is one other thing that pleased me greatly. We went into one room 800 feet long and perhaps 200 feet wide; and the piles of machinery, belts, and wires, made it look like the tangled forest up around that "cabin in the woods." Well, amid all this machinery were human beings so thick they made me think of bees at the front of a hive on a mid-summer day. Why, there were just clusters of men and boys so close together you would not think they could work. But they did work with such a vim that I asked if they were employed by the piece. I was told there was no piece-work in the whole establishment. My informant said that, while there were some good things about the piece system, it was so liable to start jealousy and ill feeling they had decided against it. I told him it was much the same way in our establishment of between 200 and 300 hands. Well, now, I made a little inspection of those boys and men crowded like bees in a hive. Come to look carefully, each man did one particular thing. For instance, one part of the automobiles that was being put together was located on a long stand or table, and this was pulled along slowly by means of an endless chain. As it passed, each man did something to it. For instance, one man had a box of burrs. These he put in place and turned them down hard and screwed each burr tight with an appropriate little wrench. The next added something else; and it was all so timed and managed that all were kept busy and nobody had to wait. In fact, they had to hustle sometimes to get their part finished before the machine had passed and the next one had come along. Now, you might think it would be monotonous to do the same thing over and over hour after hour and day after day. But to my surprise each man looked well and happy. Right here a great lesson comes in. These workmen are happy, and *do* enjoy their work. The things I have been telling you about, the looking after his health and comfort, is the secret. Added to it all, the institution is now "profit-sharing." Each person is a part of the institution. If it prospers, *he* prospers. If I remember correctly, they have, at least some of the time, been enabled to turn out a finished machine for very minute of the day and night.

By the way, the appliances to obviate the necessity of heavy and tiresome lifting are a wonderful feature of the institution. One of their workshops is six stories high; and away up under the roof is a traveling crane that moves the whole length (I think 800

feet) of the big room. Under this is a second traveling crane that runs back and forth at right angles; and then there are grappling-hooks that will go down to any story and pick up a load and deposit it where wanted. This system of mechanism picks up every box of materials and lays it down right where the workmen want it. In this way the workman is spared fatiguing work that has formerly been supposed to be unavoidable all over the world. A good many of the materials slide down on an inclined plane just where they are wanted. For instance, at one point the rubber wheels came down and were slipped on to the machine. Then it was pushed along until it came on to some revolving rollers in the floor. This set the wheels revolving, which cranks the machine so the engine can be tested. If everything went all right, a boy hopped on to the chassis, or the auto without a top, and ran it under a certain platform. When he got to the right spot he hopped off and the top was let down by this traveling crane, and dropped into place so quickly and surely that it almost seemed like sleight-of-hand. I said to my guide, "Why, Mr. McKay, the stories in the Arabian Nights are nowhere compared with what we see going on in this department." I asked him if it was possible for the men to get along without jealousy, bickering, or fault-finding, or things of that kind, that are so common. He said the secret of it was they tried to cultivate such relations between employer and employee that they were all loyal to the institution.

By the way, if this Home paper should be the means of inducing everybody to try to go to work for Ford, let me tell you there are ever so many thousands of applicants waiting for a place all the while. In regard to intemperance, there is very little of it, because it is understood that a man necessarily loses all chance of promotion and also *his place* if he comes to work showing any symptoms of booze. Our readers already know what Ford has done to discourage the use of cigarettes. In fact, this Ford institution is to me another reminder of what I have so often been telling you of late, that "God's kingdom *is* coming;" and it is coming thru means that have been brought to bear thru our great business centers and the factories as well as thru our churches and religious organizations. Whatever may be said of Ford's theological views, he certainly loves his fellow-men; and his great work, therefore, is along the line of our beautiful text that "God so loved the world."

Just a word about our second text. So

far as I have learned, Mr. Ford is not a member of any church. I hope I am mistaken about this; but the general impression seems to be that he is not connected with any body of Christian people. And yet we find him doing a reform work among people of every nation of the world that perhaps has never before been paralleled. He loves his fellow-men. He has been all his life untiring in striving to educate and uplift them. In connection with that great enterprise he has sent doctors and trained nurses into the homes of his workmen; he has taught the mothers how to care better for their children; he has looked after their sanitary surroundings, and in short he has been doing a sort of missionary work perhaps never before undertaken by any man in any organization. What shall we say? The verses I have given from that 9th chapter of Luke seem to me to hit the matter exactly. There are many strange things in this world of ours. Altho Mr. Ford may not be a follower of the Lord Jesus Christ, he has never, so far as I know, spoken against him; and the Master said, as I understand it, "Forbid him not;" and, again, "He that is not against us is on our part." My opinion is that Mr. Ford has been and is even now laying up *treasures in heaven as well* as here on earth, and perhaps he does not know it. Again, I am reminded of the passage where the people say, "Lord, when say we thee a hungered, or athirst, or a stranger, or naked, or sick, or in prison, and ministered unto thee?" The answer was, as you may recall, "Verily, I say unto you, Inasmuch as ye have done it unto one of the least of these my brethren ye have done it unto me."

~~~~~

HAVING SUNDAY ON SATURDAY; SOMETHING ABOUT TEMPERANCE WORK.

On page 337 of our issue for May 1 I suggested some reasons why people all over the world could not have the days of the week at the same period of time wherever they were; and in reply to what I said, a good lady writes as follows:

We take GLEANINGS and enjoy it very much; also our bees. I read every word of your paper, especially Our Homes, etc. I notice you often write under the heading, "God's Kingdom Coming." It is coming, but not in the way many think.

My dear sir, you place yourself in the class spoken of in Ezekiel 34, when you give nearly a column of your bee journal as to which day is Sunday. If you will go to a standard cyclopedia you can get the origin of Sunday. Seventh-day Adventists do not try to have Sunday on Saturday. Your argument is very old. I am an old woman, and I have heard it before; but it is not as old as God's law given at

creation, reiterated at Sinai, and kept by Christ and his apostles for nearly 400 years.

I have been blessed by obeying God rather than man-made laws regarding Sunday, and I am not alone. God is calling out a little flock, without spot or wrinkle, to receive him at his coming. It is my greatest desire to be one of that little company. If I were where the day of the week was disputed I would keep *the day before the one decided upon* as Sunday by the majority—always the sixth day from Sunday.

The *Temperance Annual*, gotten out by the Seventh-day Adventists, publishers, got the credit for saving Maine at the last election. Thousands of these are used by all classes of temperance workers. I send you a copy, also copies of other papers at hand, that you may see Seventh-day Adventists are trying to do their share in temperance work. I have marked the margin at the top of each copy, that it may save your time. I enjoy your talks on simple living, for Seventh-day Adventists *lead* the simple life.

Do you know that the renowned D. L. Moody accepted God's law regarding the sabbath at the last?

May God help you is the prayer of an humble reader.

MRS. B. L. PERRY.

Nevis, Minn., May 18.

In the article referred to, I said I had had but one reply to my suggestion that we call Monday the first day of the week so as to get rid of the inconvenience of having different days for Sunday. The good lady who writes the above gives us a little more light on the subject if I understand it. She says wherever there is a dispute as to which day should be Sunday, *she* would keep the *day before* the day agreed on by the majority.* At first I was inclined to think this indicated a contrary spirit, or a disposition to disagree or stand out against what the majority might agree on; but in praying for a little more charity for a lot of good people, I was led to look at it in this way: These people may honestly believe that God calls on them, and perhaps all of us, to remember and respect (as a day of rest) what is ordinarily called the seventh day instead of what pretty nearly the whole wide world calls Sunday. Let me remark right here that near our Florida home one bright Sunday morning, when everybody was on the way to church, I saw one neighbor who was painting his fence fronting the street. As he was a new comer the question came up, "Is this man particularly anxious that everybody may know that he has no

* I hope our Advent friends will not feel hurt when I say that since the above was in print I saw an account somewhere of a certain Scotchman who was always pulling against the good people of his church. On one occasion a strong effort was made to have a particular motion declared unanimous, but the Scotchman stood out as usual; and then they tried to have him unite with the rest so that they might go on with their work. But he became so stirred up that he arose and said, "Brethren, I want you to understand that, so long as I am a member of this church, there is never going to be anything 'unanimous.'"

respect for Sunday and for Christian people, or does he wish by this act to let everybody know that *he* is a Seventh-day Adventist? I shall have to confess that I did not take pains to inquire whether he was an Adventist or not; but I cannot help thinking that his act was not only unwise, but for a stranger just coming into the neighborhood, it was also unchristianlike.

And now I want to say a good word for the Adventists. This good lady has sent me a copy of the *Youth's Instructor* for 1916.* I called attention to this annual about a year ago, and want to say again that I think it is about the best and most finely gotten-up *temperance periodical* I ever saw. The first article, with beautiful illustrations, is by former Governor J. Frank Hanly, of Indiana; and it is well worth the price of the magazine. I have heard Mr. Hanly make several addresses, and I have had some good talks with him; and my opinion of him is that he is one of the wisest and most level-headed temperance and Christian workers we have in the whole wide world. In a wet-and-dry contest I cannot think of any better literature to distribute than this *Youth's Instructor Temperance Annual*. It can be had as below:

THE YOUTH'S INSTRUCTOR, Review and Herald Publishing Association, Takoma Park Station, Washington, D. C.

THE FLORIDA EVERGLADES; A BRIEF TRIP THRU A PART OF IT BY OUR OLD FRIEND, W. C. GAULT.

Mr. Root:—Nettie and I took a trip down thru the southern part of the state in April. We went by rail to Ft. Myers, thence up the river to Labelle, thence motored across thru a wild part 21 miles to where we could again get a boat. We stopped at Moore's Haven in the Everglades—a lovely spot. Moore is a Chicago man, and owns 100,000 acres of this rich land, and is getting things fixed up to suit him. I suppose he has plenty of money in the bank and some in the pocket. I didn't feel sorry for him, but I *did* pity the poor fellow that had invested in ten acres with no money, either in the bank or pocket, and could not sell a vegetable. We went from there to Rita Island in Lake Okeechobee, and from there to one of those big drain canals which lead to the east coast at Ft. Lauderdale. It was a wild-looking place thru that sawgrass—very few birds or animals, but lots of alligators. The grass was very dry when we were there, and we saw some large fires. In one place the fire was heading toward the canal. A poor little rabbit out of breath jumped right into the canal to get rid of the fire. In another place we saw a wildcat that seemed to hesitate about going in the water, and climbed up a small bush that was green and sat there, not knowing what to do next. We were going ten miles an hour, and soon left him. The canal is 60 feet wide and 61 miles to the head waters of New River, where there is a pair of locks. We stayed over Sunday at Ft. Lauderdale, then came up the east coast to Palm-

Beach. I wasn't struck with the place—no conveniences, and a certain air of "all of self and none of thee."

I didn't see a place in all the route for which I would like to exchange our quiet little home in this lovely sunshine city. We saw some wonderfully rich land in those Everglades, but I felt that the other fellow might have it and I would stay where we had some privileges—neighbors and friends. I think that some time that country will be drained and cultivated, but it will take time and lots of money, and the fertility will have to be kept up. I have had some experience with muck land. We didn't see a trolley car from the time we left Tampa till we got back there, and didn't hear the toot of a locomotive from the time we left Fort Myers till we reached Ft. Lauderdale—48 hours.

The tourists have about all left, and some of them from Ohio write of the cold wet season. We are having lovely weather and lots of nice ripe melons and peaches. We have a few nice hens, and they continue to pay tribute. All of the good things are not in Florida, but there are a good many, and one must stay thru the summer in order to enjoy them.

St. Petersburg, Fla., June 12. W. C. GAULT.

The above was evidently not intended for print; but there are several points in it that many will be interested in. Think of one man owning *one hundred thousand* acres. Well, if this friend has money enough to open up and develop that new region, his work may prove to be a blessing to humanity. Just a word of explanation about the poor fellow who had only ten acres and no money, etc. I take it the reason he could not sell his vegetables was because he was so far away from the market or shipping-point; and this is a mistake that has been made several times in Florida. Unless your grove or truck-garden is convenient of access to some shipping-point or town or city, it may cost more for transportation than the crop amounts to, especially where the stuff has to be hauled thru deep sandy roads. The new hard roads that are now being built all over Florida are going far to help this state of affairs. The same trouble has been experienced to some extent by beekeepers, who, after having secured an abundant crop of honey, have found it not only difficult but expensive to get it to a railroad station or boat-landing.

"CHARITY SUFFERETH LONG, AND IS KIND."

On page 503, June 15, in speaking of the dispute in a Pullman car, I had something to say about Christian courtesy; and I have often wondered why people, in using the telephone, so frequently become not only impatient but uncivil. You may ask the question right here, "Mr. Root, are we to understand that *you* are always gentle and kind when you use the telephone?"

To which I answer that, on account of my deafness, I seldom try to use the telephone; but I am often obliged to listen to

* If you regard this paper of real worth as a temperance agitator and educator, send at least one dollar for twenty-five copies to give to others. Twenty-five cents will bring you five copies.

others, and sometimes I venture a remonstrance against hasty words. Now, here is something from our good old friend the *Sunday School Times* which hits the matter to a dot. Read it, and see if it hits you, my good friends.

ANSWERING THE TELEPHONE.

To rebuff a visitor is neither courteous nor Christian. Most of us pride ourselves on the fact that we would not do such a thing. Yet telephone discourtesy is one of the commonest and one of the strangest events in the everyday life of both Christians and other ordinarily courteous folks. Stop and think a moment; with what tone of voice do you answer the telephone if the bell rings at a moment when you would rather not be interrupted? An amazingly large proportion of well-bred and well-mannered Christian people make their first word of reply to the phone call in a tone either of noticeable impatience or of curtness or of weariness. Let those same persons be addressed by a friend entering the room unexpectedly, and they would not think of greeting him in any way except that of courteous, inviting welcome, even if they did not feel "welcoming" inside. Yet over the telephone they abandon that tone and spirit whenever they feel like it, and they do not realize what a sharp rebuff it means to the unknown caller at the other end of the wire. The simple test is this: do we answer the telephone exactly as we greet our friends face to face? If not, let us be properly ashamed of ourselves, and never fail that way again.

While making the above clipping from the *Times* I found something right below it which it seems to me must have a place. A good many times in this busy life of mine when I have worked hard to accomplish

something—yes, may be I have worked for months and years, and, after it was done, instead of giving me credit the great busy world gave credit to somebody else. I used to feel hurt at such times, and perhaps got a little sour toward the world. But I believe I have mostly gotten over it. Now below is that second item from the *Times*:

WHOSE RECOGNITION?

Can we be happy when we are ignored? Not if our chief happiness comes from our interest in self. But if that is our idea of happiness, we are satisfied with a poor counterfeit of the real thing. We have yet to know the meaning of the joy that is centered, not in what we are, but in what Christ is. Joy for the first time begins in any one's life when Christ has become the whole in his actual life and being. Charles E. Scott, of China, punctures a common failing when he says: "When one is in Christ, how silly and inordinate it is to waste any time or strength in trying to get 'recognized.' And what joy it is to try to get Christ recognized! My experience is that, the closer I live to him, the more it is a matter of indifference whether I personally get credit from fellow-workers for things accomplished or not." To be in Christ is to be dead to self. So the struggle for self's recognition ceases after our burial with him into death, that in all things he may have the pre-eminence.

In answer to the question, "Can we be happy when thus overlooked?" yes, we can even "rejoice and be glad" because an opportunity is afforded us to show forth a Christlike spirit. Charity, you will remember, not only "beareth all things," but "seeketh not her own."

HIGH-PRESSURE GARDENING

SWEET CORN FOR POULTRY; SWEET CLOVER SPORTING; HIGH YIELD OF POTATOES.

Mr. Root:—On page 562 you have an item on sweet potatoes and peas preventing hens from laying. I have often heard that sweet corn would stop hens from laying, but have fed my White Wyandottes Golden Bantam almost exclusively for months at a time, and they laid well, and found also that they preferred it greatly to common Dent corn, as they would pick out all the Bantam and leave the Dent on the ground.

You mention a period between old and new potatoes. I usually have old Carman No. 3 away after new potatoes, in a common cellar, in fine condition even up to September 15 one year. We eat them "skins and all."

Last summer I told you of a remarkable plant of sweet clover, and promised you seed. It grew over seven feet tall from seed planted April 15, with large thick leaves ten times as large as the common; but it was an annual variety, or annual sport, and died, dead as a ragweed. I picked off its few attempts at blossoming, or it might have seeded, and proved of value; but I fear frost would have killed it before doing so. It is odd, too, that its root was very small as compared with common sweet-clover plants of the same age. I am certain some plants with much smaller amount of stems and foliage had roots ten times as large. I regret its loss.

I planted seed of sweet clover taken fresh from plants last August, and they are now over six feet

tall, and blossoming. Alfalfa planted at the same time is only about two feet high—in blossom too.

Mr. Baldwin's thoughts on different names for the same plants are interesting. I came from Sidney, Ohio, in June, 1907, and have found names of plants here in many cases different from Ohio. I wrote you once about poke of Ohio being called skoke here, while poke is a swamp plant which grows in company with skunk cabbage, and is said to be poisonous. What we know in Ohio as lamb's-quarter is here called pigweed, but is used for greens. Dogfennel is here called Mayweed; timothy is herd's-grass; sycamore-trees are buttonball. I have heard them called buttonwood in Ohio.

We have a potato here known locally as Double Yelder, deemed by many as superior to any other in quality. It is good at digging-time. Last fall I found one hill with 35 potatoes, which I saved carefully to plant this spring. On examining this spring one was scabby, and discarded. The remaining 34 weighed 54 ounces at planting time; 23 were planted whole, and 11 cut to two pieces, planting 45 hills. I like undersized potatoes for baking or boiling, for eating "skins and all." By selecting those hills containing the largest number of potatoes when digging I have reduced the size of my strain of Carman No. 2, while increasing the number in the hill.

Packer, Ct., July 5. E. P. ROBINSON.

Friend R., I am glad to know that sweet corn is preferred by poultry. I feel sure it must be more nourishing, and I could hard-

ly believe it would prevent laying. I very much regret your loss of the "sport" sweet-clover plant. So far there seems to have been but little attention paid to improving varieties of sweet clover. I believe it is true that the Carman No. 3 potato has the remarkable property of keeping in good condition when most other potatoes are unfit to use. I suppose, of course, you keep the sprouts rubbed off. Where potatoes of any variety are inclined to grow too large, this can be corrected by planting close together. In order to get potatoes extra early, down in Florida we plant good-sized tubers, and plant them whole. So many stems come up that this has the effect of growing a large number of small potatoes. These small potatoes are just right to cook whole with green peas.

FREEMAN POTATOES; ALSO A KIND WORD
FROM AN OLD FLORIDA FRIEND.

My good friend who writes below applied to me for some Freeman potatoes; but I was unable to find them at so late a date as the last of June. The letter below explains itself:

Mr. Root:—Your very kind letter of June 30 and the letter of previous date in regard to Freeman potatoes was duly received, and your efforts, I assure you, are very much appreciated. I had no intention of putting you to so much trouble in the matter; but I did want that particular variety of potato, and had the impression that it could be obtained in Medina. I agree with you that so good a tuber should be preserved. I regret to learn that Mr. Green has passed on, of which I was unaware until the receipt of your letter.

As Maule, of Philadelphia, advertises them in his catalog, I infer he usually carries a supply early in the season, so don't make any further special effort to find them. My conscience troubled me a bit when I first wrote your company for fear the request would be referred to you personally, for I am fully aware of what a busy life you still lead and the many demands upon you.

I read all that you write in *GLEANINGS*, and am greatly interested in your Florida experiments in different lines. I think you are prolonging your life and usefulness by spending the winters in that state. My chief regret is that you did not select the southeast coast, where my permanent home is, tho I bought a little place here in Rye for a summer home, and have some fruit-trees. I make a vegetable garden and keep a few hens. I had a cow last summer, but find it less work and more economical to buy milk, butter, and cream since I am here only half of the year.

Rye, N. H., July 8.

WALLACE R. MOSES.

The Freeman is not only quite early, but for quality I think it is equal to any. Our good friend Moses, who writes the letter above, has a northern home several miles from any express office, and wants his potatoes by mail—something like our old cabin in the woods, as I take it.

SUNFLOWERS FOR BEES, AND SOME OTHER
THINGS.

The following letter explains itself:

Inclosed is an article on sunflower that I intend sending long ago. I am sure I read in *GLEANINGS* some time last year that very little honey is obtained from the cultivated sunflower. Now, this is our main honey crop, and nice honey too. Is that another case of locality, or is it on account of the vast acreage? Seed is used for making salad oil.
Manteca, Cal. ERNEST E. WARREN.

MANTECA SHIPPED LARGER SEED CROP THAN U. S. IN 1909; E. POWERS SOLD 1275 TONS OF SUNFLOWER SEED THIS YEAR; WHOLE CROP OF UNITED STATES IN 1909 WAS 1117 TONS ACCORDING TO U. S. REPORT, WORTH \$76,000 AT 3 CENTS PER POUND.

E. Powers has shipped 1275 tons of sunflower seed this season. The largest shipment of previous years has been 215 tons. But preparations were made to handle 600 tons this season, while the actual output more than doubled the expectations.

In 1909 California produced 120 tons of sunflower seed, and the output for the whole United States, as given by the year-book of the Department of Agriculture for the year 1909 was 1117 tons, or 153 tons less than the Manteca section produced this year.

When reduced to a matter of dollars and cents, figured at 3 cents per pound, the sunflower crop of the Manteca section amounted to \$76,500. Mr. Powers paid out over \$60,000 to sunflower-seed and grape-growers during the month of October.

My good friend, wherever sunflowers, mustard, or any other crop is grown largely, as in the case you mention above, by all means locate an apiary near by. A few days ago a subscriber asked the best kind of mustard to plant, especially for bees. I told him it would not pay him to plant mustard nor anything else exclusively for honey; but wherever there are large fields or special localities devoted to growing such things as sunflowers, mustard, etc., in the general market, there is the place for the wideawake beekeeper to start an apiary. I am glad to know that the large amount of oil in sunflower seed is being appropriated as an article of food.

THAT "POT OF GOLD," AND WHERE TO FIND IT.

The following is clipped from the opening article in *Good Health* for July:

Somewhere in summer is health. It will not come to you unbidden. You must search for it in the great outdoors.

You will find it in your garden—at the business end of a hoe handle.

Do not spend time and money at summer resorts that will only disappoint you. The pot of gold does not lie at the other end of the rainbow, but at this end, in your garden.

I wish to put in a good emphatic amen after the closing sentence.

The pot of gold is right near by; and it is in your garden or back yard. If you do not find the gold you can most assuredly find health, and this is of infinitely more value than gold.

TEMPERANCE

HAVING IMPORTANT OFFICES FILLED BY GOOD MEN; IMPORTANCE OF THE PRIMARIES.

Perhaps one of the greatest troubles that beset us as a nation is the fact that bad men *keep* getting into important offices. The temperance people sometimes take it for granted that a man is on the dry side and not only vote for him but work for him, only to discover later that they have been humbugged. Just now, here in Ohio, and I presume in other states as well, people are wanting you to vote for them. As a rule, I personally do not believe very much in voting for any man who goes about soliciting votes. Before I vote for any man I want to know something about his past record: and on the wet-and-dry question, unless a man can come right out before the people and declare, without fear or favor, that he is on the dry side, I would have nothing to do with him. The *Rural New-Yorker* says when a man tells you or writes you that he "will take the matter into consideration," turn him down. This, of course, refers principally to the temperance question. The time when such moral questions need "consideration" has gone by. That is our greatest trouble—apathy and indifference. The *American Issue* gives the figures to show what a shameful per cent of professing Christians and church members forget or ignore the importance of the primaries. As a consequence, when election time comes they are more or less helpless. The liquor party, on the other hand, are on the alert, and fully alive to the importance of being on hand *all* the time. As a result, when we come to count our votes after election there is a widespread consternation to understand how it is that there are so few *good* people and so many *bad* people. It isn't true that the bad outnumber the good, but it *is* true that an alarming part of our good and intelligent people get stupid and indifferent when they ought to be wideawake and doing their best at the primaries to head off the one who, "as a roaring lion, walketh about, seeking whom he may devour."

August 8 is primary day in Ohio.

THE SAD CASE OF SEATTLE, WASH.; ITS "DEPLORABLE CONDITION" UNDER THE DRY REGIME.

Mr. E. H. Sargent, a Medina boy who for several seasons had charge of our apirary, and who is now a prominent man at Fort Casey, Wash., has just mailed us a copy of the Sunday edition of the *Seattle*

Times (28 pages), largely taken up by telling of the blessing which has come to Seattle since it has been voted dry. You may have seen notices in various periodicals (that is, periodicals that accept such notices, even on their advertising pages) of the "deplorable results of prohibition in the great Northwest," "miles of empty stores," etc. Well, now, this editor of the *Seattle Times* was a wet man, and the *Times* was a wet paper. But it is almost laughable to see him turn around and own up that he was wrong. We have space for only a few of the headings found on the first page.

SIX MONTHS UNDER DRY LAW PROVES FALSITY OF LIQUOR MEN'S CHARGES.

SUICIDES AND MURDERS DECREASED BY HALF SINCE JANUARY 1; POLICE ARRESTS DUE TO LIQUOR VIRTUALLY CUT IN TWO, AND BUSINESS MEN REPORT TRADE GAINS.

Well, we've had six months of prohibition, and I can't find those miles of empty stores.

On page 16 I find the following:

The *Times* admits it was wrong when it said during the campaign against prohibition that the enforcement of the statute would mean miles of empty stores in Seattle, reduced bank clearings, reduced bank deposits, reduced rentals, reduced realty values, and general business depression. Six months ago the law went into effect. *None of the dire things prophesied for the first half of the year 1916 has occurred. On the contrary, Seattle has prospered wonderfully.*

May God grant that more editors will find themselves mistaken, and have the grace and Christian courtesy to *acknowledge* they were mistaken, as has the editor in the above.

BREWERS ADVERTISING FOR THE NAMES OF BOYS, ETC.

On page 422 I copied a letter from the Hollister Distilling Co. But the *Manatee River Journal*, published at Bradentown, Fla., "goes one better" on the advertisement I gave. Here is the way they tell it:

The following notice tells what's wanted by the saloon:

WANTED.—One hundred boys for new customers. Most of our old customers are rapidly dropping out. Ten committed suicide last week. Twenty are in jail, and eight are in the chain gang. Fifteen were sent to the poorhouse. One was hanged. Three were sent to the insane-asylum. Most of the rest are not worth fooling with—they've got no money. We are just obliged to have new customers—fresh young blood—or we'll have to shut up shop. Don't make any difference whose boy you are, we need you. You will be welcome. If you once get started with us we guarantee to hold you. Our goods are sure. Come early—stay late. Opelika Saloons, Proprietors.

Better Queens and Bees for Less Money

20 years of select breeding gives us bees and queens of highest quality---Queens for Honey production---Queens of unusual vitality---Queens that successfully resist European foul brood

Our select colonies for breeding purposes, larvae, and select drones are those of the highest standard, the choice of over 1000 hustling honey-producing colonies of pure Italian bees. These select colonies are located at such a distance from all other bees as to assure pure mating, and thus effective use of our select drones. The larva we use in grafting is as small as can be seen and handled, having just come out of the egg. These are placed in cells, which in turn are placed and nourished in strong ten-frame colonies, which, when honey is not coming in sufficiently, are heavily stimulated by feeding. Thus we get large well nourished cells, which in turn produce large, long-lived, and hardy queens that give workers unexcelled for honey production. We use no baby nuclei. All our queens are hatched and reared in strong three and five frame full-dph hives. Thus natural conditions are preserved, and the best queens produced.

Price List of Our Three-banded and Golden Italian Queens. Ready by Return Mail.
 Untested.....50 cts. each or \$45.00 per 100 Tested.....\$1.00 each or \$ 90.00 per 100
 Select Untested...65 cts. each or 60.00 per 100 Select Untested...\$1.25 each or 115.00 per 100
 All queens are warranted purely mated. Wings clipped free of charge.

Price List of Our Swarms of Bees for Fall Increase.

1-lb. swarms with select queens..... \$1.75 2-lb. swarms with select queens..... \$2.50
 3-lb. swarms with select queens..... 3.50 5-lb. swarms with select queens..... 5.00
 All orders filled at once or as desired.

We have no disease of any kind. Satisfaction we always guarantee.

M. C. Berry & Company Hayneville, Alabama

Italian Queens with a Record of 30 Years

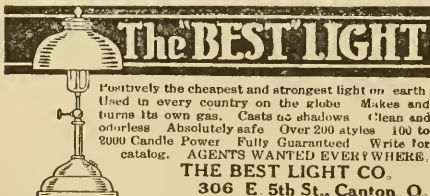

Leininger's strain of Italian bees and queens have been carefully bred for 30 years; for gentleness and honey-gathering qualities are unexcelled; 95 per cent pure mating guaranteed. Queens ready June 1. Untested, each, \$1.00; 6, \$5.00; tested, \$1.50; 6, \$8.00.

Fred S. Leininger & Son, . . . Delphos, Ohio

DOOLITTLE & CLARK

Italian queens are what you want for fall requeening. Try them! Prices: \$1.00 each; \$5 for six; \$9 per dozen.

Marietta, New York

HONEY AND WAX FOR SALE

FOR SALE.—Clover extracted honey.
F. W. MORGAN, Zumbro Falls, Minn.

NEW ORANGE-BLOSSOM HONEY.—Two 60-lb. cans, \$9.75. Sample bottle by mail, 10 cts.
OTTO LUHDORFF, Visalia, Cal.

Clover honey, extracted, in 60-lb. cans; comb in $4\frac{1}{4} \times 1\frac{3}{4}$ sections. Write for prices, etc.
E. L. LANE, Trumansburg, N. Y.

FOR SALE.—Choice comb and extracted honey; also about 90 colonies bees with all fixtures.
J. G. CRISLER, Walton, Ky.

Choice new-crop white-clover extracted honey in new 60-lb. tin cans, the bargain of the season; sample, 10 cts. D. R. TOWNSEND, Northstar, Mich.

FOR SALE.—Clover honey (1916 crop), excellent quality, in new 60-lb. cans; also 5-lb. and 10-lb. pails. Sample, 10 cts. May be deducted from first order.
DODDS' APIARY, Cambridge, N. Y.

FOR SALE.—All sweet-clover honey in 60-lb. cans, two cans to a case, 7 cts. per lb.; also comb honey in $4\frac{1}{4} \times 1\frac{1}{2}$ -inch sections, f. o. b. cars.
JOE C. WEAVER, Cochrane, Ala.

FOR SALE.—Raspberry, basswood, No. 1 white comb, \$3.00 per case; fancy, \$3.25; 24 Danz. sections to case; extracted, 120-lb. cases, 9 cts. per lb.
W. A. LATSHAW Co., Clarion, Mich.

New clover honey; comb runs from No. 1 to fancy, \$3.50 per case; No. 2, \$3.00 per case of 24 sections, six cases to carrier; extracted clover, 9 cts., two 60-lb. cans to case.
H. G. QUIRIN, Bellevue, O.

Saw palmetto honey, thick and delicate; case of two 60-lb. cans, \$5.00. Also best seagrape and mangrove honey, 7 cts. in cans or 6 cts. by the bbl. Sample, 10 cts., to be applied on order.
A. E. AULT, Bradentown, Fla.

RASPBERRY HONEY.—Thick, rich, and delicious, put up for sale in 60-lb. tin cans. Price \$6.00 a can. Sample by mail for 10 cts., which may be applied on any order sent for honey. Write for price on large lots.
ELMER HUTCHINSON,
Rt. 2, Lake City, Mich.

FOR SALE.—Beautiful white-clover extracted honey, left upon the hives until after the close of the season before extracting, then put up in new 60-lb. net tin cans. The fact is, we have studied out a system of extracted-honey production whereby exquisite quality is secured at the expense of quantity. Just a little more money will buy this rich, ripe, well-ripened stock than is required to buy "just ordinary" stock. Inclose 10 cts. in stamps for a large sample that costs us 25 cts. to send, and be convinced of the superior quality of this stock. Address the BEEKEEPERS' REVIEW, Northstar, Mich.

HONEY AND WAX WANTED

Beeswax bought and sold. STROHMEYER & ARPE Co., 139 Franklin St., New York City.

WANTED.—Comb and extracted honey, in car lots and less carlots. J. E. HARRIS, Morristown, Tenn.

WANTED.—Comb honey; fancy and No. 1 qualities; $4\frac{1}{4}$ square by $1\frac{3}{8}$ sections preferred. Also white extracted honey, carload or less; quality.
HOFFMAN & HAUCK, Richmond Hill, N. Y.

BEESWAX WANTED.—Until further notice I will pay for good yellow wax 28 cts. cash or 30 cts. in trade for queens delivered here.
W. D. SELLERS, 242 Pine St., Lancaster, Pa.

WANTED.—Your own beeswax worked into "Wend Process" foundation at reasonable prices.
SUPERIOR HONEY Co., Ogden, Utah.
"Everything in bee supplies."

FOR SALE

FOR SALE.—A full line of Root's goods at Root's prices.
A. L. HEALY, Mayaguez, Porto Rico.

HONEY LABELS.—Most attractive designs. Catalog free. EASTERN LABEL Co., Clintonville, Ct.

SEND TODAY for samples of latest Honey Labels. LIBERTY PUB. Co., Sta. D, box 4-E, Cleveland, Ohio.

FOR SALE.—165-lb. honey-kegs at 55 cts., f. o. b. factory.
N. L. STEVENS, Venice Center, N. Y.

Get our new Rubber Stamp Catalog.
ACME PRINTING Co., Medina, Ohio.

For select queens add 25 cts. each to the above prices. For queens in quantity lots, or bees by the pound, write for prices. ROBT. B. SPICER, Rt. 181, Wharton, N. J.

Hollopeter's strain of three-banded Italian bees and queens now ready. Bees, a full pound of the right kind for business, with young laying queens, 1 pkg., \$2.25; 6 pkg., \$12.50; 2-lb. pkg., with queen, \$3.25. Queens, bred for business, untested, each, 75 cts.; 12, \$8.00. Safe arrival in good condition guaranteed. Health certificate with each shipment. Circular free.

J. B. HOLLOPETER, queen-breeder, Pentz, Pa.

PURE ITALIAN QUEENS.—Golden or three-banded, by return mail. All queens are warranted purely mated. They are large and long lived. They have proven themselves highly disease-resistant in many localities. One select untested, \$1.00; 6, \$4.25; 12, \$8.00; 100, \$60.00. Tested, \$1.25. Bees by the pound, nuclei, colonies. Safe arrival and satisfaction I guarantee. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

Famous Howe's, Root's, Moore's, Davis' select strain of honey-gatherers, disease-resisting. None better for all purposes. Untested, one, 75 cts.; doz., \$7.50. Select untested, one, \$1.00; doz., \$9.00; ½ doz., \$5.00; tested, \$1.25; doz., \$10.00; select tested one, \$1.50; ½ doz., \$8.00; extra select, \$2.00. Bees by the pound, \$2.50 with queen. Honey crop short. Will have plenty of bees in June.

H. B. MURRAY, Liberty, N. C.

Special on fine queens for my birthday.—I shall be 39 August 7. Orders dated to me for that day will be filled any time from then on at 50 cts. each or \$45.00 per 100. Pure mating, no disease, safe arrival guaranteed; three-banded only; no goldens.

First of all, I want to say your queen is all as a breeder. I have about 75 of her daughters, and their energy is unlimited, and, of course, that is the most important point. JOE C. WEAVER, Cochrane, Ala.

Breeders, \$5.00 each; tested, \$1.25 each. If you have requeening to do, try some of my queens. I really think they are extra.

CURD WALKER, queen-breeder, Jellico, Tenn.

Leather-colored "Nutmeg strain" queens, \$1.00; \$10.00 per dozen. Tested, \$1.50. Special price on large lots by return mail.

A. W. YATES, 3 Chapman St., Hartford, Ct.

ITALIAN QUEENS.—Northern-bred, three-banded, highest grade, select untested, guaranteed. Queen and drone mothers are chosen from more than 600 colonies, noted for honey production, hardiness, prolificness, gentleness, and perfect markings. Price after the first week in August, one, 75 cts.; 12, \$7; 100, \$50. Send for circular.

J. H. HAUGHEY, Berrien Springs, Mich.

The bargain of the season—listen: *The Beekeepers' Review* to new subscribers is \$1.00 per year. Ten three-banded Italian untested queens at 50 cts. each would be \$5.00. *The Review* for the last four months of this year would be 33 cts., total \$6.33. Send us \$5.00 for the *Review* 16 months, beginning with the September number, and receive 10 untested queens, mailed you direct from our breeder in Mississippi. To get this exceptional bargain, address all orders to *The Beekeepers' Review*, Northstar, Mich.

LEATHER-COLORED ITALIANS.—Large, vigorous, three-band Italian queens that have proven that they can stand a severe winter, last winter being a test for them. For size, beauty, gentleness, and honey-gathering qualities they will surprise you. If you have foul brood, try them. It will be half the fight. All queens are guaranteed for a period of one year from date received. If you have a special case of introduction state your case, and I will advise you how best to proceed. If they fail to please you, you get your money back. Prices: 1, \$1.00; 6, \$5.00; 12, \$9.00. No foul brood in my apiary nor near me.

W. D. SELLERS, 242 Pine St., Lancaster, Pa.

BEE SAFETY --HOW?

—By ordering Murry's queens. I have testimonials on file that my strain of bees are strongly resistant to European foul brood, Isle of Wight disease, and paralysis. Plenty of queens ready to ship on short notice from now till Nov.

1. Safe arrival and satisfaction guaranteed. No disease of any kind in my apiaries. Three-banded Italians and Goldens. Untested, one for 75 cts.; six for \$4.00; any number over that, 62½ cts. each. Tested, one for \$1.00; six for \$5.00; over that, \$10.00 per dozen.

H. D. MURRY
Mathis, Texas

45c--Golden and 3-banded Italian Queens--45c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested, one, 45 cts.; 12, \$5.00; 100, \$40.00. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. 1 lb. bees, \$1.25; 2 lbs., \$2.00; 1-fr. nucleus, \$1.25; 2-fr., \$2.25. Full colony, 8-fr., \$6.00; 10-fr., \$7.00. No queens at these prices. The Italian strain of bees have proven themselves able to resist foul brood to a greater degree than any other strain, and they are, therefore, the strain to buy if you have foul brood in your locality.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

To inquirers:—I am rearing no queens for sale, but am keeping *The Stover Apiaries* supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.

C. C. Miller, Marengo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 or \$5.00; Untested, 60 cts.; 12 for \$6.00. Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00. Will replace inferior queens.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

The Stover Apiaries, Mayhew, Mississippi

Queens--Queens--Queens. We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

Zanesville Service Still Available

Effective August 1, the Zanesville Bee-supply Agency will be under new management on account of my acceptance of a position in the Home Offices of The A. I. Root Co. at Medina. On and after this date Mr. A. M. Moore, of the Central Ohio Supply Co., will be in charge.

I want to take this opportunity to thank the many customers and friends whom it has been my pleasure to serve during a number of years for the measure of success and consequent promotion they have made possible. It is my earnest desire still to remain in touch with them. Let me bespeak for Mr. Moore the same good treatment accorded me.

As heretofore, a full line of the best bee supplies will be carried in stock. The new warerooms will be very accessibly located in the Townsend Building No. 7 Main St. Please note the change from our present location on Third St.

E. W. PEIRCE.

Orders and all communications other than those intended for E. W. Peirce personally (which should be addressed to Medina) should be mailed to

CONVENTION NOTICES

The Western New York Honey-producers' Association will hold its annual basket picnic and field meeting on August 12, 1916, at the home and apiary of Roy Wisterman, at Dysingers Corners, N. Y., which is located on the Lockport-Akron macadam road 6 miles southeast of Lockport or 10 miles northwest of Akron, or 4 miles south of Gasport. A good program is in preparation, and an enjoyable time is anticipated. Bring your friends, your veil, and don't forget your basket lunch. All beekeepers welcome.

WILLIAM F. VOLLMER, Sec.

Akron, N. Y., July 15.

The Eastern New York Beekeepers' Association will hold a field meeting and basket picnic at the apiary of the president, W. D. Wright, at Altamont on Aug. 11. Mr. C. P. Dadant, of the *American Bee Journal*, is expected to be with us, and address us on the past, present, and future of the National Beekeepers' Association, besides other topics. There will be two sessions. All beekeepers are invited.

S. DAVENPORT, Sec.

Indian Fields, N. Y.

TRADE NOTES

REGULAR AND SAFETY SHIPPING-CASES.

Because of the great increase in the cost of paper in all forms we find it necessary to advance prices of the regular 24-lb. shipping-case \$1.00 per 100, and of the safety cases, including safety cartons, \$4.00 per 100. In 100 24-lb. cases there are 2400 safety cartons. The price of these cartons is advanced \$1.50 per 1000, which makes the increase for cartons alone \$3.60 per 100 cases. There is, besides, the drip paper and corrugated pads, which are now costing considerably more. These pads cannot well be dispensed with. In fact, where cartons of some kind are not used, there should be divisions in the case to protect the comb honey properly for safe shipment. See editorial on this subject in this issue.

GLASS HONEY-PACKAGES ADVANCED.

Increased cost of materials affects glassware to such an extent that we are obliged to announce higher prices on the various glass packages listed in our catalog. The taper-panel jars are advanced 10 cts. a case, making the new price for ½-lb., 90 cts. per case; 6 cases, \$5.10; 1-lb., \$1.10 per case; \$6.30 for 6 cases. The round Federal and Tiptop jars are also advanced 10 cts. per case, making the new prices as follows:

Federal jar, \$1.20 per case of 2 doz.; 6 cases, \$6.90
15-oz. round jar, 95 cts. per case of 2 doz.; 6 cases, \$5.40.
16-oz. round jar, \$1.00 per case of 2 doz.; 6 cases, \$5.70.
½-lb. Tiptop jar, \$1.10 per case or \$5.50 per crate of 1 gross.
1-lb. Tiptop jar, \$1.20 per case or \$6.00 per crate of 1 gross.
6½-oz. tumbler, \$1.00 per case of 4 doz.; \$7.50 per bbl. of 40 doz.

PREMIUM AND SQUARE JARS.

We still have 75 to 80 doz. of 1-qt. Premium jars which we offer, to close out, at 60 cts. per doz.; \$6.00 per gross. There are one dozen in a paper carton. If crated for protection in shipping, add 50c. a gross.

We have several gross of 1-lb. square jars with spring-top fastener similar to the Tiptop jar. These are worth 75 cts. per gross more than jars with cork. We offer them, to close out, at \$5.50 per gross, packed 6 doz. in a case. In our New York and Philadelphia offices we have a surplus stock of 2-lb. square jars packed 6 doz. to a case. These we offer, to close out, at \$7.50 per gross; also a limited quantity of 1-lb. with cork at \$5.00 per gross; ½ lb. at \$4.00, and ¼ lb. at \$3.25.

TIN HONEY-PACKAGES.

New quotations received on tin cans and pails are very much in advance of former prices. We are fortunate in having a supply of 5-gallon cans, bought

before the advance, so we can continue for some time yet furnishing these cans at the present list price. We are obliged to name higher prices on the friction-top cans and pails for shipment direct from Chicago or Baltimore as follows:

2-lb. can, 500 to crate, \$16.00 per crate; 90 cts. per case of 24.
2½-lb. can, 462 to crate, \$17.00 per crate; \$1.05 per case of 24.
3-lb. can, 420 to crate, \$18.00 per crate; \$1.20 per case of 24.
5-lb. pail, 200 to crate, \$13.00 per crate; \$1.00 per case of 12.
5-lb. pail, 50 to crate, \$3.75 per crate.
10-lb. pail, 100 to crate, \$10.50 per crate; 80 cts. per case of 6.
10-lb. pail, 50 to crate; \$5.50 per crate.

THE A. I. ROOT CO., Medina, Ohio.

Special Notices by A. I. Root

PAYING BEEKEEPERS A VISIT.

I am now planning an automobile trip from Medina to Springfield, Ohio, about the time that this journal reaches you, or a little later; and along the route I might make some of the readers of GLEANINGS a call of twenty or thirty minutes if they will tell me briefly on a postal card how to reach them—that is, those of you who are along the line, on my way going or coming. Therefore if you would like to see your old friend of the Home papers for a few minutes, just send in your postal card about as soon as you get this.

"EVAPORATED" HONEY—WHY NOT?

Something like forty years ago Mrs. Root put some honey into a shallow pan in the oven and let it stay with a moderate heat until the water was evaporated or driven out until it was a sort of candy. I remember the circumstance because of her remark that it was so "wonderfully delicious" that she and the children ate every bit of it, and did not save a particle for "papa," but she added that she would make some more for me to try. Now, I think we all decided it was greatly superior to common honey; but I think the matter was dropped because it was sticky, and stuck the jaws together, etc. Since then at various times the matter of "honey candy" or honey evaporated until it is very thick has come up. Our friend Root, down in Florida, used for years a solar evaporator consisting of glass sashes placed over a box of shelves to hold the bottles of honey; and by this means we can, in time, get honey of almost any density.

One thing that brings the matter up just now is that I have just been considering that if we could get rid of the water in honey, or at least a great part of it, there would be a great saving in the matter of shipping. What is the use of paying freight or express charges on water? We have evaporated peaches, apricots, nectarines, and all sorts of fruit, and this effects a great saving in two ways: First, we get rid of the water; and, second, we dispense with the glass or tin containers that must be used with all canned fruit. Now, why can we not do the same way with honey? Howard Calvert, the father of the baby pictured in our last issue, has submitted to me some samples of honey candy. Some of it, made of pure honey and nothing else, is hard and brittle like a stick of hoarhound candy; but in the warm damp atmosphere of this weather it soon becomes sticky on the outside, and unpleasant to handle. I am told the only remedy is to coat it with chocolate. In this way it can be handled and shipped like ordinary candy; and I believe I prefer it to any candy I ever tasted. Even some of it that was a little overheated has a delicious taste similar to caramels; and my impression is (this 26th day of July, 1916) that in the near future a great industry will be built up in shipping honey in the solid form. Even if it should be necessary to coat the outside with chocolate or some similar healthful food, even then the saving in freight and the saving in glass and tin packages would be enormous. If any of you can furnish evidence of what has already been done in this direction, I shall be very glad indeed to get it.

Bellevue, Ohio

W. H. Laws Talking Queens

We have taken care of every queen order the present season, altho more than 2000 queens were mailed from the Laws yard in past 60 days, but in order not to get swamped we had to withdraw our ad. from GLEANINGS.

We are well supplied with queens, both tested and untested, also as fine a lot of breeders as possible to produce. Any of these can go out by return mail. Samples of live bees from my breeding queens will be mailed free to prospective buyers on request.

The time is approaching when every beekeeper should see that his colonies are supplied with strong young queens for another season. To do this you will need a first-class breeding queen now, or make your arrangements with me for queens to be introduced near the close of your honey-flow.

Prices as follows: Untested, each, 75 cts.; 12, \$8.00; 100, \$60.00. Tested, each, \$1.00; 12 for \$10.00; 100 for \$75.00. Breeding queens, \$5.00 each; six for \$25.00.

W. H. Laws, Beeville, Texas

QUEENS

Our July, August, and September SPECIAL PRICE on untested leather-colored queens--- a bargain never offered to the American beekeeper before.

Prices on 1 to 10 queens, 50 cts. each
 " 11 to 25 queens, 45 cts. each
 " 26 to 100 queens, 40 cts. each
 " 101 to 1000 queens, 38 cts. each

Safe delivery. If not satisfied, return queens and get your money back. The Root Company, The American Bee Journal. Dadant & Sons. any mercantile agency, and others will tell you who we are.

The Penn Company . . Penn, Miss.

Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

	June and July	August and later
Select Tested Queens	1 for \$1.75; 12 for \$19.25	1 for 55 cts.; 12 for \$ 6.00
Tested Queens	1 for \$1.05; 12 for \$12.00	1 for \$1.00; 12 for \$10.75
Untested Queens	1 for 60 cts.; 12 for \$ 7.00	1 for \$1.65; 12 for \$18.00
Very best queens for breeding, \$3.00.	1 lb. bees in package, \$1.25;	2 lbs. in package, \$2.00.

Add price of queen. If any of our untested queens should prove to be maimed we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

W. D. ACHORD, FITZPATRICK, ALABAMA

EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

The A. I. Root Company . . . Medina, Ohio

Special Bargains in Shipping-cases

With the bonntiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

- 8 crates of 50 each, 9½-inch, 2-row, at \$4.00 per crate.
- 20 crates of 50 each, 10-inch, 2-row, at \$4.00 per crate.
- 15 crates of 50 each, 6¼-in. 3-row, at \$4.00 per crate.
- 56 crates of 50 each, 12-lb. cases, at \$4.00 per crate.
- All of the above have either 2 or 3 inch glass, and take 12 sections 4¼ x 1¼ x 1½ plain.

- There are also for the same size section, packed 10 in a crate:
- 12 crates of 10 each, 9½-in. 2-row at 85 cts. per crate.
 - 4 crates of 10 each, 6¼-inch 2-row at 85 cts. per crate.
 - 4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.

- For the 4¼ x 1½ beeway section we have:
- 15 crates of 50 each, 15¼-inch 2-row, for 15 sections, at \$4.50 per crate.
 - 9 crates of 10 each, 15¼-inch, 2-row, for 15 sections, at 95 cts. per crate.

- 15 crates of 50 each, 11¾-inch, 2-row, for 12 sections, at \$4.00 per crate.
- 8 crates of 10 each, 12-lb. safety cases with cartons, at \$1.20 per crate.
- 5 crates of 10 each, 8-inch, 3-row, for 12 sections, at 85 cts. per crate.
- 2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate.

- For 24 sections, 4¼ x 1½ plain:
- 1 crate of 25 each, 9½-inch, 4-row, at \$4.00 per crate.
 - 2 crates of 10 each, 9½-inch, 4-row, at \$1.75 per crate.
 - 3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.

- For 12 sections 4 x 5 x 1½:
- 33 crates of 50 each, 3-row cases, at \$4.00 per crate.
 - 3 crates of 50 each, 3-row for 15 sections, at \$4.00 per crate.

- For 12 sections, 3¾ x 5 x 1½:
- 6 crates of 10 each, 3-row cases at 85 cts. per crate.

ADDITIONAL SHIPPING-CASES AT BRANCH OFFICES.

At Washington, D. C.

- 3 cases, 10 each, 12-lb. cases for 4¼ x 1½ sections, at 85 cts. each.
- 7 cases, 10 each, 12-lb. cases for 4¼ x 1½ sections, at 85 cts. each.
- 3 crates, 50 each, 12-lb. cases for 3¾ x 5 x 1½-inch sections at \$4.00 per crate.

At Mechanic Falls, Me.

- 5 packages, 10 each, 12-lb. safety-cases for 4¼ x 1½ sections, including safety carton, at \$1.20 per crate.
- 2 crates, 10 each, 12-lb. cases for 4¼ x 1½ sections at 85 cts. per crate.
- 3 crates, 10 each, 12-lb. cases for 3¾ x 5 x 1½ sections at 85 cts. per crate.
- 2 crates, 10 each, 12-lb. cases for 4 x 5 x 1½ sections at 85 cts. per crate.
- 2 crates of 10 each, 12-lb. safety cases for 4 x 5 x 1½ sections, including safety cartons, \$1.20 per crate.

We also offer the following glass jars, to close out at special prices, subject to previous sale.

At New York Branch.

- 4 bbls. of 7-oz. tumblers, 24 doz. to barrel, at \$5.00 per barrel.
- 11 gross of 2-lb. square jars with cork, 6 dozen to case at \$7.50 per gross, \$4.00 per case.
- 13 cases of 2 dozen each, ½-lb. square jars with cork, at 90 cts. per case.

At Philadelphia Branch.

- 1 gross ¼-lb. square jars with cork, at \$3.25.
- 10 cases ¼-lb. square jars with cork, 75 cts. case of 2 dozen.
- 1 gross ½-lb. square jars with cork, at \$4.00.
- 8 cases ½-lb. square jars with cork, 90 cts. case of 2 dozen.
- 4 gross 1-lb. square jars with cork, \$5.00.
- 3 cases 1-lb. square jars with cork, \$1.10 case of 2 dozen.
- 5 gross 2-lb. square jars with cork, at \$7.50.
- 37 cases 1-lb. Simplex jars, 2 dozen per case, at \$1.30.

At New York Branch.

- 1 crate 50 2-row and 1 crate of 50 3-row 12-lb. cases for 4¼ x 1½ sections at \$4.00 per crate.
- 1 crate 50 15-lb. cases for 4x5x1½ sections, at \$4.00 per crate.

At Philadelphia Branch.

- 8 crates, 50 each, 12-lb. cases for 4¼ x 1½ sections at \$4.00 per crate.
- 10 crates of 10 each, same, at 85 cts. each.
- 13 crates, 50 each, 12-lb. cases for 4¼ x 1½ sections at \$4.00 per crate.
- 9 crates, 10 each, same, at 85 cts. per crate.
- 4 crates, 50 each, 24-lb. cases for 4¼ x 1½ sections at \$8.00 per crate.
- 4 crates, 10 each, same, at \$1.70 per crate.
- 4 crates, 50 each, 16-lb. cases for 4¼ x 1½ sections at \$4.50 per crate.
- 1 crate of 10 12-lb. cases for 4 x 5 x 1½, at 85 cts. per gross.
- 7 crates, 50 each, 12-lb. cases for 3¾ x 5 x 1½ sections, at \$4.00 per crate.
- 5 crates, 10 each, same, at 85 cts. per crate.

At Mechanic Falls, Me.

- 5 gross ½-lb. square jars, with corks, at \$4.00 per gross.
- 29 cases of 2 dozen each, Simplex or Federal 1-lb. jars at \$1.10 per case.

At Washington, D. C.

- 1 bbl. 12 dozen 1-lb. No. 25 jars at \$5.00 per bbl.
- 3 bbl. 12 dozen 1-lb. Simplex jars at \$5.25 per bbl.
- 2 crates 12 dozen 1-lb. Simplex jars at \$5.00 per crate.
- 1 case 2 dozen 1-lb. Simplex jars at \$1.10 per case.

These are fine for exhibition purposes.

- 8 dozen ½-lb. Hershiser jars with nickel tops at 50 cts. a dozen.
- 11 doz. 1-lb. square Hershiser jars with nickel tops at 65 cts. a dozen.

THE A. I. ROOT COMPANY, Medina, Ohio

SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

Shipping-cases in Flat, without Glass

No. 1.	holding 24 sections, 4¼x1 ¾, showing 4.	10, \$2.00; 100, \$18.00
No. 3.	holding 12 sections, 4¼x1 ¾, showing 3.	10, \$1.30; 100, \$11.00
No. 1½.	holding 24 sections, 4¼x1 ½, showing 4.	10, \$1.90; 100, \$17.00
No. 6.	holding 24 sections, 3 ⅝x5x1 ½, showing 4.	10, \$1.80; 100, \$16.00
No. 8.	holding 24 sections, 4x5x1 ¾, showing 4.	10, \$1.80; 100, \$16.00

Shipping-cases with Glass.

		with 3-inch glass	with 2-inch glass
No. 11.	Same as No. 1.	Nailed, 35c; in flat, 1, 25c; 10, \$2.30; 100, \$21.00.	100, \$20.00

HONEY GRADING RULES

GRADING RULES OF THE A. I. ROOT COMPANY, MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the ease excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides and not less than two-thirds of the way around, and not more

than 60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.
Honey in badly stained or mildewed sections.
Honey showing signs of granulation.
Leaking, injured, or patched-up sections.
Sections containing honey-dew.
Sections with more than 50 uncapped cells, or a less number of empty cells.
Sections weighing less than the minimum weight.
All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.
Honey contaminated by excessive use of smoke.
Honey contaminated by honey-dew.
Honey not properly strained.

YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

Golden and Three-band Italian Queens . . . 45c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested, one, 45 cts.; 12, \$5.00; 100, \$40.00; tested queens, 75 cts. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. The Italian strain of bees have proven themselves able to resist foul brood to a greater degree than any other strain, and they are, therefore, the strain to buy if you have foul brood in your locality.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.

C. C. Miller.
Marengo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested, 60 cts.; 12 for \$6.00. Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00. Will replace inferior queens.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

LOCKHART'S SILVER-GRAY CARNIOLANS.

"LINE BRED" for the past 30 years. They are VERY hardy, gentle, prolific, great workers, and builders of VERY WHITE combs, and use mostly wax in place of propolis. Untested queen, \$1.00; six for \$5.00; dozen for \$9.00. Select untested queen, \$1.25; six for \$6.00; dozen for \$11.00. Tested queen, \$2.00; six \$9.00; dozen for \$15.00. Select tested, \$3.00. Best breeder, \$5.00. Extra select, the very best we have, \$10.00. Safe arrival guaranteed in United States and Canada. No foul brood here.

F. A. LOCKHART & CO., Lake George, N. Y.

GENTLEMEN:—Enclosed you will find \$1.25 for a select untested Carniolan queen. I have bought Carniolan queens from Texas and other places, but they don't compare with your "Line Bred" strain.
Homer, N. Y., July 27.

Yours truly, M. H. FAIRBANKS.

F. A. LOCKHART & CO., Lake George, New York.

Queens--Queens--Queens. We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

\$1.00 per year. When paid in advance: 2 years, \$1.50; 3 years, \$2.00; 5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60c per year postage.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. Notice is given just before expiration. Subscribers are urged, if unable to make payment at once after expiration, to notify us when they can do so. Any one wishing his subscription *discontinued* should so advise us upon receipt of the expiration notice; otherwise it will be assumed that he wishes GLEANINGS continued and will pay for it soon.

HOW TO REMIT. Remittances should be made by draft on New York, express-order or money-order, payable to the order of The A. I. Root Co., Medina, Ohio. Currency should be sent by registered letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

FOREIGN SUBSCRIPTION AGENTS.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents at the prices shown:

PARIS, FRANCE.—E. Bondonnau, La Korrigan, Avenue de la Gare. A Juan-les-pins, France. *Per year, postpaid, 8 francs.*

GOODNA, QUEENSLAND.—H. L. Jones. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/7 p.*

DUNEDIN, NEW ZEALAND.—Alliance Box Co., 24 Castle St. *Per year, postpaid, 6/7 p.*

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

ALBANY AND SCHENECTADY.—The crop of white honey will be a good one in this section. Producers are offering plenty of extracted already, but not much comb honey is ready for market yet, and weather conditions are not favorable for selling the latter. To quote prices now would be to guess at what they may be later on.

CHARLES MACCULLOUGH.

Albany and Schenectady, Aug. 3.

CHICAGO.—The new crop of honey is arriving, but so far no sales have been reported. This, probably, is owing to the extreme heat of the past two weeks, which debars sales. There is still quite a quantity offered for sale of the crop of 1915; and until this is out of the way, and the weather changes there will be little if any movement. Beeswax remains at 28 to 30.

Chicago, Aug. 3.

R. A. BURNETT & Co.

KANSAS CITY.—On account of the extremely dry weather, the honey-flow has stopped, but there is quite a surplus of new comb honey on the market. Strictly No. 1 white comb honey in 24-section cases is selling at \$3.25 to \$3.40 per case; No. 1 amber comb honey, \$3.00, and No. 2 amber at \$2.90 to \$3.00. Strictly fancy white extracted honey is selling at 8 to 8½, with a good demand. The demand for comb honey is only fairly good.

C. C. CLEMONS PRODUCE CO.

Kansas City, Aug. 5.

NEW YORK.—There are no prices established as yet on the new crop of honey, comb as well as extracted. From reports we have thus far received it seems evident that a good crop of white honey has been produced in the eastern and middle states, whereas California reports a very short crop, especially of sage honey. The old crop is pretty well cleaned up with the exception of West India, which is arriving in large quantities, and there seems to be an unlimited supply.

New York, Aug. 5. HILDRETH & SEGELKEN.

ST. LOUIS.—There is no change in this market since our last quotations. Comb honey is still very dull, and so far very little new is arriving. Southern extracted honey in barrels and 60-lb. cans is in good demand, and receipts are meeting ready sale. We quote amber extracted in barrels from 5½ to 6; in 60-lb. cans, from 6 to 6½, according to quality and quantity. Comb honey is ranging in price from \$2.50 to \$3.25 per case. Beeswax brings 29 cts. for pure; inferior, less.

R. HARTMANN PRODUCE CO.

St. Louis, Aug. 5.

DENVER.—New crop comb honey is selling in the local market at the following jobbing prices: Fancy, per case of 24 sections, \$3.38; No. 2, \$3.15; No. 2, \$2.93. White extracted, 8½ to 8¾ cts. per lb.; light amber, 8 to 8¾ cts. per lb., and amber, 7 to 8 cts. per lb. We pay 26 cts. per lb. in cash and 28 cts. per lb. in trade for clean, average yellow beeswax delivered here.

WM. LOSSING.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

WHY IS THIS TRUE? BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who "has been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis Sections in a season, and has not found one section in the whole lot that was not perfect. Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.

G. B. Lewis Company, Watertown, Wisconsin

Catalog on request giving nearest distributor.

DO YOU WANT Your Bee Supplies Shipped Promptly?

EDITORIAL

Excessive Freight on Comb Honey

WESTERN beekeepers having comb honey to ship in less than carload lots should write to R. C. Fyfe, chairman Western Classification Committee, Chicago, Ill., protesting the new classification effective Sept. 1. See editorial in last issue.

Our Cover Picture

IN most localities an ideal place for bees is that where there is partial shade. Dense shade, however comfortable it may be for the beekeeper, is not advisable so far as the bees are concerned. The picture on our cover shows three colonies kept for experimental purposes under the shade of guama trees (*Inga laurima*). In the background are shown a few yucca plants. These bees are part of the apiary of Rafael Vidal, Mayaguez, Porto Rico, whose interesting article appeared in our May 15th issue, page 409.

The Possibility of Bees Carrying Blight Germs from One Apiary to Another when Trees are out of Bloom

THE following letter received from Prof. H. A. Gossard, referring to our editorial on page 584, will explain itself.

I was quite interested to read your editorial comment on my reply, and find that you are again mistaken in supposing that I think bees carry blight to any great extent except when the trees are in bloom. However, it is not impossible that these might carry the blight germ from one aphid colony to another when trees are out of bloom, or at times when bloom is scarce and the bees are very busy collecting honey-dew. Possibly they do not visit the apple aphids to any great extent for this purpose. The blight germ will live for ten successive days in aphid honey-dew on a leaf that is moderately shielded from sunlight, and will survive even when the leaf has apparently become perfectly dry for at least one day. We have some evidence, not wholly conclusive, that the germs multiply in honey-dew as they do in nectar and in the sap of the

tree. Various species of flies and nectar-loving wasps visit the honey-dew more numerous and constantly than do the bees, and are, therefore, much more apt to become carriers in this manner.

I am also very sure that the apple orchardists of many surrounding states will disagree emphatically with your statement that blight is not to be feared to any extent on apple-trees. I am sure that fifty per cent of our orchardists would state very vehemently that, for the past three years, blight has been a greater threat to apple orchards in Ohio than any other bacterial or fungus disease or insect pest. However, I have regarded this as, in all likelihood, a temporary condition—simply a wave that sometimes comes, and that, after two or three seasons, subsides to its old status. During the present season the amount of blossom blight has hardly been beyond the ordinary—in fact, I am inclined to think that, in the state as a whole, it has been less than ordinary.

H. A. Gossard, Entomologist.
Wooster, Ohio, July 27.

The Ohio State Beekeepers' Field Meet at Medina, Aug. 25 and 26

IT has been definitely decided by the officers to hold the next Ohio field meet at Medina on Friday, Aug. 25, and the morning of the 26th. No definite program has yet been arranged. While there will be papers and addresses, the principal work in hand will be practical field demonstrations at the home yard and at the queen-rearing yard among the basswoods. New and modern apparatus for taking extracted honey will be shown on the afternoon of the first day. A power extractor, steam uncapping-knife, honey-pump, and capping-melters will all be shown in practical operation. About a thousand pounds of honey will be extracted to give one an idea of the entire method of procedure. Smaller machines will also be exhibited.

An opportunity will also be given to witness the operation of bottling honey and of making comb foundation. Arrangements will be made to carry visitors to a

few of the outyards, and lunch will be served at noon of the first day.

The operation of rearing queens from start to finish will be demonstrated at the queen-rearing yards among the basswoods.

All are cordially invited to be present at this field meet, whether they live in Ohio or some other state.

It is expected that Dr. E. F. Phillips, of the Bureau of Entomology, Chief Inspector N. E. Shaw, of Ohio, and other prominent beekeepers, will be present. Possibly and probably one of the Dadants will be with us.

The Color of Pollen from White Clover

ON page 521, in his regular department, Dr. Miller raises the question whether Mr. Lovell, in his article on page 477, has properly indicated the color of pollen from white clover. Mr. Lovell replies as follows:

Mr. Root:—I have just read Dr. Miller's remarks, page 521, on the color of the pollen of white clover. My article was written in the winter, when there was no opportunity to examine personally the color of white-clover pollen, and I was confident that I had seen it stated that it was greenish yellow. This afternoon I have been studying the color of the pollen, both in the field and under the microscope, and my results lead me to believe that Dr. Miller has considered the matter chiefly from the hive end.

The color of the pollen on fresh anthers which have recently opened is not brown, as Dr. Miller says, but yellow, as in the case of many other flowers. Under a lens, with the light falling on it, the pollen has a golden sheen similar to gilt tinsel. In the field I noticed that a number of bees had small balls of brown pollen in the pollen-baskets. If this was collected from the white clover it must be remembered that it was moistened with saliva and perhaps other glandular secretions, and manipulated by the fore and middle legs before it was deposited in the baskets, which might easily give it a color different from what it has in the anthers. Did Dr. Miller examine the pollen in the anthers of fresh flowers?

If you will examine a head of white clover you will notice that there are no anthers exposed—they are all enclosed in the carina, or keel. When a bee alights on a flower and pushes down the carina and wings (alæ) the anthers and stigma protrude and strike against the under side of the body of the bee. When the bee flies away, the anthers again return within the keel. It is, therefore, not an easy matter for a bee to collect pollen directly from the anthers of white clover. Of the bees sucking on white clover, which I watched this afternoon, not a single one attempted to gather pollen. Many of

them had no pollen on the thighs; but a few, as stated above, had small balls of brown pollen in the baskets. Whether this was white-clover pollen I cannot yet say definitely. I then watched the bees flying into the hives, as they returned from the field by hundreds. The white-clover flow is here at its height. Many, very many, of these bees brought in no pollen; others had balls of yellow pollen which may or may not have come from the blossoms of white clover. A single floret of white clover yields only a small amount of pollen. This may be rubbed off on the ventral side of the bee, which is then able to gather it. How far does it do so? Has Dr. Miller examined the pollen in his hives under a microscope? Is he certain that white-clover pollen is as abundant as he supposes?

The yellow pollen which I noticed on certain bees flying into the hive seemed to me a different shade from that of white clover.

John H. Lovell.

Waldoboro, Me., July 5.

Honey-crop Conditions and Prices; the Effect of the Drouth

HAD it not been for a general drouth which set in the last of July, there would have been an enormous crop of clover honey. As it is, there has been a large yield in many localities in spite of the shutting off of the nectar supply. In some others the dry weather stopped the flow just when it was getting ready to make a good showing in the supers. In still others it checked the flow just as it started. Taking everything into consideration, in all probability the clover crop will be much larger than that of last year, but probably no larger than it has been some other seasons.

The best clover flow seems to center around Michigan. From that state reports are universally favorable. With some exceptions they are good in Wisconsin, Minnesota, Illinois, Iowa, Kansas, Missouri, Ohio, Pennsylvania, New York, and all the New England states. In all of the territory named (and that covers the largest part of the clover area) there have been some partial and complete failures; but we believe we never encountered a season when the reports were more uniformly favorable throuth the clover area than this year of 1916.

The drouth is so severe in some localities that it may kill off the clovers this fall. If so there may be a possible failure of clover for next year. This means that if prices on clover honey go too low, and the beekeeper can afford to do so, he will hold his crop over for next season.

Reports from the western territory com-

prising the alfalfa and mountain-sage country, are somewhat meager and scattering. There were very heavy winter losses in Montana. Many colonies were so weak that they were in no shape to catch a flow, even if it had come. In many portions of the state it did not come, so we shall not expect much from Montana.

In Nevada according to one report late frosts injured the alfalfa, and there will be only from a third to a half of a crop of alfalfa. Around Reno the main flow, starting about July 3, is already gone.

In Colorado the few reports we have received indicate from a light to a fair crop.

In Arizona and Imperial Valley, California, the yield has been below normal. Some of the largest beekeepers in Imperial Valley are discouraged. Further north in California the crop has been estimated at from one-fourth to one-half of a crop.

The possible and probable shortage of honey in the West, comprising the irrigated districts, the severe drouth in the East, with the prospect of clover being short next year, may have and should have a tendency to hold up prices, altho if reports are correct it is evident they will sag below those of last year. During the middle and fore part of July it looked as if prices on both comb and extracted clover honey would go down to a low level. Buyers were very shy about making offers. In one case a buyer refused to make any offers, and finally, after repeated requests to name some figures, he mentioned six cents on a fine article of extracted. The buyer made this low offer expecting it would be turned down as he did not wish to buy then; but he was snapped up instantly with a carload, with the offer of more at the same price. This has had a tendency to demoralize prices; but the drouth has given prices an upward boost and beekeepers are more hopeful.

TRAVEL-STAINED COMB HONEY.

The market is still well stocked with a fine grade of comb from last year. The new crop is now ready to be delivered, and it is reasonably certain that the prices will be easier.

Probably some of the comb honey this year will be travel-stained because the clover yield, owing to the rainy weather followed by drouth has been irregular—a little every day, then stopping entirely, and then starting briskly. With conditions like this where the flow is slow, there is almost sure to be some travel-stained comb honey.

Our readers are requested to send in their postal-card reports. Indicate what the final yield has been, and what prices are being secured. In mentioning prices,

be sure to say whether they are retail, wholesale, or jobbing.

Later.—Some good rains have followed, and the drouth seems to be broken for the time being.

The Isle of Wight Disease or Bee Plague in Ohio

THE bee-inspectors of Ohio have found in several of the apiaries in southern Ohio and in the western part of the state a disease among the adult bees resembling bee paralysis or Isle of Wight disease. In some cases the colonies have been considerably reduced in strength, right in the midst of the honey-flow. Some scare headlines in the daily press have appeared, referring to a certain bee plague.

In our issue for July 15, page 583, we mentioned the fact that Mr. C. H. Boccock, of Newmarket, England, who had been investigating the Isle of Wight disease for the Board of Agriculture of Great Britain, had come to this country to discover whether we had the same or a similar disease here. On the very morning that the scare headlines concerning the bee plague appeared in our daily papers Mr. Boccock arrived in Medina. At the earnest solicitation of Dr. E. F. Phillips we drove with Mr. Boccock over to Weston, Ohio, where we met by appointment not only Dr. Phillips, but Bee Inspector N. E. Staw, of Ohio.

This Weston apiary is owned by one of the assistant inspectors, Mr. A. C. Ames. Unfortunately for the purpose of this investigation the disease had almost disappeared at the time of our visit. In fact, it has been in the habit of coming and going. Sometimes the disease will nearly disappear, and then return with all its former virulence. Mr. Ames, altho situated in a favorable locality, had estimated that his crop of honey had been materially reduced on account of the heavy losses from his hives. On some occasions a number of dead and dying bees were scattered all over the vicinity—so much so that the dead and dying bees attracted the attention of many people who were not beekeepers. "You can imagine," said Mr. Ames, "that when other people find dead and dying bees all over the ground, within a short distance of the apiary, the situation is somewhat serious."

Mr. Phillips and one of the bee-inspectors reported finding a similar trouble at several of the southern apiaries that he had inspected.

On arrival at the Ames apiary we repaired to the beeyard. As already stated, the disease had all but disappeared; but

there were several specimens of diseased bees scattered at the entrances of some of the hives. They made a vain attempt to fly, and appeared to be in great distress. There were no symptoms of bee paralysis; and the trouble, whatever it was, appeared to be different from anything else that the average beekeeper in this country encounters. There were numerous dead bees in front of the entrances of nearly all the hives; but neither the dead nor dying look any different from the ordinary normal bees. Beyond the conditions of apparent distress and disposition to leave the hives, there seemed to be nothing wrong. Mr. Bocoek examined the bees very carefully. He was entirely of the opinion that it was not bee paralysis such as he had seen in various parts of the United States, but he thought the bees showed the initial symptoms of Isle of Wight disease.

Some specimens of the bees had been sent to Dr. Phillips to be examined by his bacteriologist. An examination of the intestines showed that they were destroyed. But in only *one bee* was *Nosema apis* found. All the rest showed none.

When Mr. Bocoek was in Washington he and Dr. Phillips examined a colony of bees in Maryland that was badly affected with paralysis. In fact, according to Dr. Phillips, it was a typical case of American bee paralysis; but not in any one of the affected bees could *Nosema apis* be found.

At the Ames apiary, at the time of our visit, the bees were working briskly on red clover. They had so nearly recovered that they were storing honey in supers. Some of the colonies were two and three stories high, and appeared to be in a high state of prosperity. Had our attention not been particularly drawn to the situation, nothing abnormal would have been noticed; but that there had been trouble was very apparent. If it is Isle of Wight disease it must have been waging a losing fight against bees which were nice Italians.

THE ISLE OF WIGHT DISEASE IN GREAT BRITAIN.

Mr. Bocoek reports that it is his opinion this disease has destroyed 80 per cent of the bees in England. It has made particular inroads in Hampshire, Berkshire, Cambridge, Suffolk, Norfolk, and Essex counties. It has spread from southern England clear up thru the whole country. So far there seems to be no remedy, and the bees die off by the thousands in and out of the hives. It has been discovered that some strains of bees are much more resistant than others. The black bees of Great Britain fall easy victims. Mr. Bocoek and

his associates have observed that Italians show most resistance, and he is somewhat of the opinion that the American Italians would hold the Isle of Wight disease in check.

It is possible that some apiaries in Ohio and elsewhere have had the Isle of Wight disease; but so far no apiaries have been completely wiped out, and practically all of them, sooner or later, have entirely recovered. If the Italians are more resistant to the Isle of Wight disease—and we know they are more resistant to American foul brood—it will afford a great deal of encouragement not only to our American beekeepers but to the British as well.

While *Nosema apis* has been found in the intestines of the Isle of Wight diseased bees, the very fact that the same organism is found in healthy bees leads to the opinion that it is not the only cause.

It is well known that the germs of pneumonia may reside in some human beings that are resistant, but cause an immediate outbreak of the disease in other persons to whom these germs are communicated. If *Nosema apis* is the primary cause of the Isle of Wight disease, then apparently it has no effect on some strains of bees, particularly on a vigorous strain of Italians. On the other hand, it is possible that *Nosema apis* has to work in conjunction with some other organism before the actual Isle of Wight disease makes any headway. There is much to be learned of this peculiar malady that has wrought such destruction in Great Britain; and if Mr. Bocoek shall be able to throw any light on the proposition he should and will receive the thanks of both American and British beekeepers.

In this connection it should be stated that *Nosema apis* is not a bacterium but a protozoan. It is, therefore, much more difficult to handle. Whatever it is, it seems to act on the inner lining of the intestines of the bees. In some cases it breaks down the tissues altogether.

From the various reports of the peculiar disease that has attacked adult bees, it is apparent that there is something in the United States that is not the same as bee paralysis; but the very fact that the trouble, whatever it is, disappears in the second season shows either that we do not have the Isle of Wight disease, or that *that* disease is not able to make any serious inroads among the American Italians; or it may be possible that our climatic conditions are enough different to make serious inroads of the disease impossible in *any* strain of bees.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

ALLEN LATHAM, in speaking of rearing queens, p. 593, you mention "the employment of a full colony of bees for some days" as a matter of expense. "In this locality" it isn't a matter of any expense at all, for during the busy season there are always colonies doomed to ten days' queenlessness to keep them from swarming.

P. C. CHADWICK, I accept your correction, p. 587. It wouldn't do at all to set out cappings as a free-for-all lunch in any foul-broody locality. But the bees can clean them up without any such exposure, by the plan given by H. H. McIntyre, p. 596, or something similar. But I can't agree that the worst feature is the danger of starting robbing. I'd rather have robbing started than foul brood; and anyway it wouldn't start robbing "in this locality." [We are glad to get your indorsement of the McIntyre treatment of cappings. It seems to us that the plan is excellent.—Ed.]

THE doctrine is advanced, p. 517, that when it is uncertain whether a virgin is present, the thing to do before risking a laying queen is to give a frame of brood to see whether cells will be started. I've practiced that no little, and have also practiced giving young brood to a nucleus having a virgin, so as to hurry up her laying. But some New England beekeepers objected that that was a pretty sure way of losing the virgin, and I'm afraid they are right. At any rate I found that more virgins disappeared a year or two ago in nuclei to which I gave brood than in those I let alone. I wonder how others have found it. [It is our practice to give young brood in colonies that we suspect to be either queenless or having only a virgin. Rather than keep the colony queenless longer, we desire to introduce a laying queen. But it would be quite useless to attempt it unless we knew positively that the colony was without a virgin, which fact is determined by the building of cells. We would rather lose the virgin than to start laying workers.—Ed.]

IF you do a good job of looking for cells and cell-cutting, and have your queens' wings all clipped, and do it regularly once every week or ten days, you will be absolute master of the swarming problem so far as comb-honey production is concerned," says W. A. Latshaw, p. 608. I can imagine with what eagerness some beginner will say, "That's just what I want. How easily I

can prevent swarming!" And then the bitter disappointment when he finds his bees swarming out, possibly the next day after he has carefully cut out every queen-cell. It is within the range of possibilities that Mr. Latshaw has a strain of bees that can be kept from swarming by cell-cutting; but the average beginner—indeed, I think the average veteran—has no such bees. For a great many years I have practiced cell-cutting, and I don't think I could be induced to give it up. I have tried to encourage every tendency toward a non-swarming race of bees. Each year I have a good many colonies that go thru the whole season without swarming that would be practically certain to swarm if I didn't kill cells. But I'm sorry to say that I have a much larger number that, without any other treatment, will go straight on to swarming, in spite of all the cell-cutting I may do. So long as I find upon each round nothing beyond eggs or very young larvæ, I keep on cutting cells. But if I find cells sealed, or nearly ready to seal, I know that cutting them out will do no good, and that if I trust to cutting out such cells such a colony will be practically certain to swarm, possibly inside of a week, possibly the next day, with only eggs in cells. Cutting cells delays swarming, in some cases prevents it, but cannot be relied on in the majority of cases. [We quite agree with you, doctor. We kept swarming fairly well under control this season, but the boys were instructed to cut out the cells when they were just started, and to keep on cutting them out every seven days. They were further told that if the cells got well under way, honey conditions fair, and weather hot, the swarming would probably take place in spite of the cutting. Like yourself we cut out the cells anyway, gave lots of room and bottom ventilation.]

The great trouble is, beekeepers let the season and the bees get ahead of them. In bee culture there are certain things that must be done at a certain time. Mr. W. A. Latshaw probably had conditions that were favorable, and very possibly and probably he cut out the cells when they were very young. But if he has since had a season like this one he will probably come to the conclusion as did one of our outyard men who came in one day very much disgusted, saying cell-cutting was "no good, as the bees go on swarming just the same." Further investigation showed that cells were pretty well advanced, and swarming well under way.—Ed.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

My observations agree with Dr. Miller as given on page 469, June 15, that queens very decidedly prefer old comb to new, especially in early spring. After the weather is hot it does not seem to make so much difference.

* * *

More clover in bloom than I ever saw before in one year. I think I have seen just as much white clover before, but now it is white and alsike. I never saw an alsike-clover blossom till after I was twenty-eight years old.

* * *

Riding thru a large fruit-farm recently where cherry-trees had been set between every other apple-tree, I couldn't help noticing how much more heavily the trees were loaded with fruit as we came near where the bees were placed in the orchard.

* * *

There is a difference of opinion as to the advisability of our country making large expenditures in preparing to meet an imaginary enemy. But there is but little question as to the wisdom of the beekeeper being prepared for the flow of honey when it comes. I believe in this kind of "preparedness."

* * *

Swarmed, swarm, swarming! I never knew such a year. Bees began the latter part of May, and they are still vigorously at it, July 16, and it looks now as tho they would keep it up till August or September. If honey had been stored in proportion we might rejoice: but it was too cold and raw till June 23, since which honey has been coming in in a pleasing way.

* * *

I was pleased with the editorial in GLEANINGS for June 15, on "Exaggeration in Advertising;" in fact, I was delighted. It cannot be denied that, during the last year, there has been more or less advertising that was no credit to the advertisers nor to the journals publishing them. It is a source of pleasure to know that this sort of thing is to be cut out in the future, and that the brakes are on with a vim.

* * *

Dr. Miller, on page 427, June 1, refers to drones reared in queen-cells, or, rather, an attempt of bees to rear a queen from drone eggs or larvæ. We run across such, I believe, every year, and sometimes many of

them. I have never known a drone larva to be exchanged for a worker larva: nor have I ever known such to hatch, altho the drone larva in such cells seems to reach nearly maturity before it dies.

* * *

I am much interested in that new edition of the A B C and X Y Z of Bee Culture. At first it was the A B C book; and when it had grown older and larger it became the A B C and X Y Z book. Now, isn't it about time it lay aside these juvenile and youthful names and take on the more mature and dignified name of "Encyclopedia of Bee Culture," which it really is? I am astonished at the amount of information it contains when I look it over, and it is a pleasure to recommend it to beginners seeking information.

* * *

Mrs. Allen, p. 428, June 1, expresses her amazement that the tradition of the necessity of informing bees of the death of any member of the family is still believed by many persons. This is an old and instructive tradition or superstition, as we may call it. How did it start, and why has it been handed down from generation to generation? In earlier ages, when less was known of bees than at present, some one died; his bees were neglected, and they, too, many of them died. Many such cases may be remembered by some one who then tries to account for it. It may have been suggested that, as bees were very wise and sensitive creatures, they should have been informed of the death of their master. No one had done so, and the bees have died. Surely this must be the cause. So it is handed down from one to another, no one taking pains to study into the real cause of the death of the bees. These thoughts have been suggested by looking over a yard where the owner died last fall; and I said to myself many times as I looked them over, "I guess no one informed these bees of their master's death." It was in early May. I was told there were 128 colonies last fall, but I found only 100 alive. Some 50 more were nearly gone. There were, indeed, only a few really good colonies. Some had starved. Some I found with feeders still on the hives; some with leaky covers; some without packing. A great gap had been left in a fence put up for a windbreak, so the north wind had a fair sweep thru the yard. Surely it was a sorry day for that yard of bees when their master died, and they had to pass the winter with so little care.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

THE BEXAR CO. ASSOCIATION PICNIC.

A most interesting event was that of the annual beekeepers' field meet and picnic at the apiary of Mr. E. G. LeSturgeon, about seven miles south of San Antonio, on June 18. The gathering was quite large, and consisted of representative beekeepers from Bexar and adjoining counties. Refreshments were amply supplied, and there was "buzzing" of beekeepers during the entire day. The value of such coming together can not be estimated in dollars and cents.

The afternoon was profitably devoted to a program of timely discussions by some of the prominent beekeepers. The old veteran beekeeper, M. M. Faust, of Floresville, discussed the foul-brood situation and inspection work, and touched also on the market conditions existing at the present time. The writer followed with a plea for co-operation and organization of the beekeepers in order to prevent the disastrous losses thru low honey prices brought about by improper handling of our honey crops. In this he was joined by B. I. Solomon and E. G. LeSturgeon in vigorous remarks in the same direction.

The outcome of the above-mentioned meeting was a motion by the writer that a meeting of the honey-producers of Texas be called at an early date by a properly authorized committee to be selected, and that an effort be made to organize along the same lines as those of the Colorado honey-producers and other like organizations that have been successful in marketing the products of its members. A call for such a meeting was issued July 1, signed by E. G. LeSturgeon, secretary of the Bexar Co. Beekeepers' Association; M. M. Faust, of Floresville, for Wilson Co.; Louis H. Scholl, of New Braunfels, for Comal Co.; Louis Biediger, of LaCoste, for Medina Co.; Henry Brenner, Seguin, for Guadalupe Co.; W. A. Winters, Jourdanon, for Ataseosa Co. This was the beginning of the move for organization.

THE TEXAS HONEY-PRODUCERS' ASSOCIATION.

A new record was established in Texas beekeeping when the greatest gathering of most of the foremost beekeepers assembled in the Chamber of Commerce Hall, San Antonio, July 15, in response to the call above mentioned. Over fifteen thousand colonies

were represented by the owners present, among them being more than a dozen with 500 colonies or more, and running up to over 1600 colonies as the highest number of any one beekeeper.

After much timely and valuable discussion on the question for which the meeting was called, the writer's motion to organize and adopt the Colorado Honey-producers' Association plan and rules, with such changes as may be necessary, and to appoint a board of seven directors to perfect the organization, was duly carried.

The officers and directors are as follows: President, Louis H. Scholl, New Braunfels; Vice-president, W. J. Stahman, Clint; Secretary, E. G. LeSturgeon, San Antonio. A manager and a treasurer are to be selected later.

A capital stock of \$25,000 in \$10 shares, with a limit of one hundred shares to any individual or group of individuals, was decided upon. Over \$5000 of this stock was subscribed for before the close of the meeting, and it is hoped that the rest will also soon be taken care of.

There are to be a good many benefits for the members of this organization aside from the effort to obtain better prices and a better market for the beekeepers' products. Co-operative buying and selling of supplies and other needs of the beekeeper are to be taken care of. The dissemination of information on crop conditions, market prices, market conditions, etc., are all to be looked after, and the protection of the members in a number of directions is to be another important item.

A BIG FIELD FOR THIS ASSOCIATION.

There is much to do for this new organization. With an effort in the direction of putting on the market thru its organization a superior and more uniform pack of honey, graded according to the rules set down by the association, one step toward a better market and better prices will have been obtained. The next most important effort is that of regulating, as far as this is possible for the association to do so, the prices of honey, instead of letting this go on rampant as has been the case almost every year. With a hearty co-operation of the beekeepers this association can do much in this direction, and the beekeepers as a whole may enjoy the benefits therefrom. I am looking for better times for the Texas beekeeper, if the beekeepers will help make them so.

E. G. Baldwin

FLORIDA SUNSHINE

DeLand, Fla.

Continued from July 15th issue.

"Are there many beemen about DeLand? I used to think there was not much chance for an apiarist anywhere in the high pine-lands; but conditions may have changed."

More all the time, or would be, did not an occasional bad year like the present, for orange honey, keep over-enthusiastic beginners or recruits from the business. Our only source of good table honey here is, however, that from the citrus fruits (orange, grapefruit, etc.).

"Do you have trouble with dragon-flies? We do, and also from skunks at times."

About every other year, on an average, the dragon-flies "gobble up" half our virgins on their wedding-tours! This year, happy to say, they have been conspicuous by their absence. As a result, our virgin queens have mated beautifully, and with almost no loss. I wish I knew the cause and remedy. I am still hoping that the U. S. Department, under the direction of Dr. Phillips, may be able to get at some method of exterminating the pests. "Jimmy Skunk" does not bother us here at all, nor anywhere else where I have ever run an apiary.

"In spite of all the pests we have, I average about 120 lbs. per colony, in fair years, and as high as 150 lbs. in good years. One year I extracted 10,680 lbs. of honey from 88 colonies (121 lbs. per colony). The best I ever did was to get 183 lbs. per colony from 20 colonies extra strong in one season."

Your average is good for any part of the state. Especially does it seem to me that your average of 121 lbs. per colony, which you say was from saw palmetto, is a remarkably fine showing. I should say that this can not be duplicated from that source oftener than once in a dozen years. Do you? Your record of 183 lbs. per colony, while not bad (indeed, very fine), is not anywhere near the state record for a rousing yield. A record of 400 lbs. per colony has been made on the East Coast. Mr. W. S. Hart, of Hawks Park, secured 41,000 lbs. of fine honey from 116 colonies, spring count, being an average, you will see, of 353 lbs. per colony for the season for the entire yard (extracted honey). But that was "before the freeze" in 1894-'5 (will A. I. R. note this, see p. 335, April 15?).

The June bloom of orange-trees in the state this year was a marvel. It was never

before so profuse. Tho it did not last as long, nor yield generally as much as the same bloom would have done in March, some report as much as 60 lbs. per hive from this source in June. Mr. Harry Hewitt, of Apopka, Fla., seems to have won the prize for big yields from it. We congratulate him, especially as his early crop was a failure.

OUR BEES HAVE GOOD WINGS AND STINGS.

"Brother Baldwin, were it my privilege to assign you a task I would give you the problem of introducing a bee into your state that would fly more than 1¼ miles for nectar," p. 429. Friend Chadwick, did I think for one minute that we have not already such a bee with us, I would take the first train for California and secure some of the good Sunset stock of the State of the Golden Gate, with which to improve our flying qualities. The orange-trees, for example, near us, bloom at varying periods. I have traced my flying bees directly and unmistakably by their route thru the air, straight from the yard to groves 2 and 2½ miles away, many times. I have done this with honey coming in at profitable rate too; and I have known them to go two or more miles to the mangrove islands, and gather successfully and profitably. Moreover, there is no saw palmetto within a radius shorter than two miles from my home yard; and yet my bees gather considerable palmetto honey. So you see, friend C., I do not accept the premise you assume. I am wondering if possibly you do not confuse the initials of my name with those of a good friend of mine, Mr. F. M. Baldwin, of Sanford, Fla. His remark in a previous number of GLEANINGS seems to have suggested your reply. I am sure his conclusions would not hold for the state as a whole, however true he may have found it on special occasions. No, our bees, our "Cracker bees," can fly as far and sting as hard as any in the Union.

SHALL WE DESTROY THE BEE-MARTINS?

No matter how well "prepared" a teacher may be, now and then will come a query that seems at first somewhat of a "poser." Such was our experience lately. A good friend of our fraternity, and a successful real-estate man as well, Mr. S. H. East, of Clearwater, Fla., sent us the following:

What information can you give me about bee-martins or kingbirds, as enemies of bees?

The pretty little fellows, with white breast, gray back, and red or purple under the gray top-knot—such are very numerous around here, and pick up a lot of my nice bees. Shooting is too slow, and rather expensive. If it can be established that they take only drones, I won't mind, as I have plenty of drones and to spare. I find the crew chockful of bees, but have not been able to determine whether they are drones or worker bees.

When I had read this I stopped and scratched my head; then I did it some more. I had had experience with almost everything that flies about the apiary; but this was more avicultural than apicultural—more biological than beeological. Tho the pretty bee-martins are housed by my neighbors, and fly often about our home place, I had, personally, never seen them haunting the beeyard, nor had they ever impressed me as enemies of the bees. In fact, I had always had a lingering impression somewhere in the back of my head, from my boyhood days, that they were really friends, not enemies. However, not wishing to hazard a guess I wrote at once to Washington, and also to the State Department at Harrisburg, Pa. The replies that came promptly were so illuminating that it seems most pertinent to the time and place and circumstances to quote them at some length.

Professor Surface, Economic Zoologist of Pennsylvania, and well known to all bee-men, himself an apiarist of considerable note, and a careful and accurate scientist, says that the bee-martins are kingbirds that are flycatchers. Examination of hundreds of stomachs of these birds has shown that they but rarely eat worker bees; that they eat more drones than workers; that out of hundreds of stomachs examined, only four or five were found that actually contained the remains of worker bees. He adds that they *do* feed altogether on insect food, among which are some of the worst pests of the cultivated plants and trees, and even eat larger insects like robber flies, the latter being enemies of the bees. As the robber flies eat honeybees (including workers and queens), the martins perform a real service to bee-men.

We also wrote to Dr. Phillips, of Washington, who referred our letter to the Bureau of Biological Survey; and the chief of that department, Mr. H. W. Henshaw, replied most fully and courteously as follows:

We have examined 665 stomachs of the common kingbird (bee-martin). Honeybees were found in 22; the total number of bees was 61, of which 51 were drones. The above percentage of drones is so large that we

think the harm done by eating the comparatively small number of workers is fully compensated by their destruction of the drones, most of which are superfluous. It is believed, therefore, that the destruction of the kingbird, on account of its bee-eating propensities would be a mistake, unless possibly an occasional individual should develop an abnormal appetite for bees. In such cases shooting would be the only remedy.

In addition to its other useful habits it should not be forgotten that the kingbird has a strong animosity against crows and hawks, and never hesitates to drive them from any locality it considers its own. This habit is well known, and the kingbird (martin) is, therefore, an asset on the farm it inhabits.

The above reply is so enlightening, so full, accurate, and detailed, that it leaves nothing to be said. Note that the figures show, in other words, that, say, 661 martins (which would be more than any one locality would be likely to have), would consume, all told, but *ten* worker bees at a single feeding-period; that is, 66 martins would consume but one worker on an average, at one feeding-period. Even if we were to assume that the martins fed ten times a day on bees, the 66 birds would eat but ten workers a day; and 66 martins would make a pretty good-sized aviary of these birds for any premises. The added information, that they eat robber-flies, is very hopeful.

Some time ago we asked whether the United States authorities could not give us some methods for destroying the robber and dragon flies. May not a way out lie along the lines here suggested? Four or five years ago our own apiary was badly pestered by the dragon-flies, or mosquito-hawks. So bad were they usually that queen-rearing operations were sadly hindered, often almost prevented altogether. About two out of every three mating virgins would be destroyed. About that time our neighbor, who loves birds and trees and flowers, set up many martin-houses on his place. These pretty little feathered friends are flying in ever-increasing numbers about our yard, tho not particularly near the bees. For the past three years we have had very little trouble with the robber-flies. We wonder if the two facts are coincidental and consequential, or merely accidental. We shall be interested in making more careful observations, and wish that our Florida friends especially (for the inquiry came first from Florida) would watch and note likewise. The crow and hawk chasing propensities may be of special interest to the combined apiarist and poultryman.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

It is with sincere regret that I read in Wesley Foster's note the sad misfortune to Mr. D. C. Polhemus. All of one's extracting combs for 2000 colonies of bees is "some loss," and would put the discouraging crimp in the career of most of us. The great loss of wax and labor involved is in itself considerable; but to have one's combs destroyed when the honey season is just at hand is equal to losing a honey crop besides. It was my good fortune to meet Mr. Polhemus and his wife, who spent the night with myself and family last season. He is one of the few very successful beekeepers, and has on his own initiative created a market for his honey that is of very great value to his future. When he has insufficient honey of his own production to supply his trade he goes into the market to get a supply.

BE CAREFUL BEFORE YOU SELECT A BREEDER.

In recent articles there has appeared a suggestion that tested queens were good enough for breeding purposes. It seems to me that in this there might be a pitfall to some beekeepers. I would warn all to refrain from breeding very extensively from a queen that has not had at least a summer's tryout in the honey season. A tested queen might prove to be the equal of any; but there is too much chance in requeening an entire apiary from a single queen of this kind, that she would not prove equal. For requeening an entire apiary, or perhaps several of them, a guaranteed queen from a reliable breeder should be used, and no other kind. A queen-breeder who has kept close record on a queen for a year is able to give you value for your money, and you run very little risk by paying a fancy price for such a queen. The greatest risk is in not being able to keep her laying a sufficient length of time to complete requeening operations before she is superseded, especially after traveling a long distance thru the mails.

DANGEROUS LEGISLATION.

There seems to be a feeling, tho I hope to a very great extent, that no honey from a diseased apiary should be allowed to be placed on the market. Wesley Foster, June 1, is the first to voice that opinion, and there are several in our own state who think the same. It is the belief of the writer that the

amount of good obtained would not be commensurate with the vast amount of harm that would result. If it were a matter of vast importance I might take another view of the situation, but I am of the opinion that there can but little harm come from the sale of honey from diseased apiaries, inasmuch as it is not injurious to the human race when eaten. But such a thought enacted into law might become a vicious matter in the hands of some men, even those who fostered the movement. In the first place we have entirely too many laws on bee-disease control as it is, and the entire lack of the proper kind of laws. In other words, we have a multitude of county, state, and district laws whose enforcement is done largely according to the individual fancy of the interpreter. What we need is a national law that will define the rights of the shipper so definitely that there can be no doubt of its meaning, or the rules laid down in its provisions, this law to supersede all others, and be *the* law of the future. Such a law would place us all on the same level; and if we had bees, queens, or honey to ship we could go at it in an intelligent manner, and with the thought we knew what we were about. With a law such as Mr. Foster recommends there would be a great hardship worked on the producer, for disease might be discovered at the close of the season, and that a man's apiary contained disease, while previous to that time there had been no trace of it visible; yet on the face of the fact his honey would have to be destroyed. The editor, on page 425, shows where such a law might work a hardship even on Mr. Foster's own state. I think it would be another case of whose ox was gored as to the individual leaning toward the law, and it is very probable that there would be a change of sentiment in some cases. But I am not ready to believe with Mr. Foster that such a law is nearer than we think. I am firmly of the opinion that such a law will never be passed unless "gumshoed" to final passage. Neither can I believe that Mr. Foster is anything but sincere in his views on the question; but I am as yet not ready to follow his idea. There is too great an economic waste in sight. [Our views are already given on page 425. We might add that a national law would be effective only on interstate business. It could have no jurisdiction within any one state. We would have to have state foul-brood laws as well.—Ed.]

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

VALUE OF DRONES.

"I am a beginner in beekeeping, but have read quite a little about apiculture. I note that you and other writers propose to allow each colony only a meager quantity of drone comb so that a greater amount of honey may be stored thru the gathering of a maximum number of workers being reared in all-worker comb except two or three inches square left to comfort the bees along the drone line. Now are you not mistaken here? I cannot believe that nature makes a mistake in providing drones. Are not these drones of value aside from their use for the fertilization of queens?"

Modern beekeeping has taken the bees out of their primitive state, where they were in isolated places, rarely more than one colony in any locality; and with colonies several miles apart there had to be enough drones in each colony to make it an almost absolute certainty that the young queen of this colony would surely find one in the few minutes to one-fourth hour that she was out in the air; otherwise she would be more liable to become the prey of some king-bird or other enemy which might abound in the place where the colony was located. Upon her life the very existence of the colony depends, as more often than otherwise there is no other means left for the continuance of reproduction in the colony. All beekeepers of any experience know what little chance there is for a colony whose queen is lost in her mating-flight, if a queen-cell or young brood is not given by the attentive apiarist.

Under our modern and more successful management these primitive conditions are changed. The colonies being massed or congregated together in large number, it is quite evident that the drones of a few colonies will serve the same purpose that they would have served where one-fourth of the comb covered by one colony was of the drone size of cell. It is, therefore, reasonable to suppose that it is useless to rear such a number of drones in each of the colonies congregated together in an apiary of from 20 to 200 colonies.

I have made several careful experiments by way of massing three or four Langstroth frames quite well filled with drone brood from different colonies, set apart as drone-rearers, in order that these drones might be kept for mating with queens after other inferior drones had been killed off at the end of the honey-flow, and have always

found that the drones from these three or four frames would consume about all of the honey brought in during the late honey-flow, while colonies of the same strength with only an inch or two of drone brood would store a surplus of from 50 to 100 lbs.

Our questioner thinks we are mistaken, but he gives us no proof save that he believes that nature makes no mistake. In answering his question in regard to drones being of value aside from the fertilization of queens, I will ask, "How can they be?" They do not work; they fill themselves with honey from the combs every time they fly from the hive; they are never seen out on the clover or any other bloom, and their rearing decreases the number of workers reared. Are not these facts sufficient to incite any beekeeper to prevent their production in numbers limited only by nature? It seems hardly necessary to theorize on the profit, and the approximate amount saved by their suppression. In a square inch of comb, approximately 55 workers may be reared, while the same space will furnish room for about 36 drones, figuring both sides of the comb. Thus in a square foot of comb where 5000 drones could be reared, we may rear approximately 8000 workers. Would it be unreasonable to say that the same amount of food will rear either brood, since it occupies the same space? And when they have emerged, we have a small swarm of workers instead of a heap of useless, bothersome, voracious feeders that do nothing but loaf, but are sure to come home to eat. After they are reared, to get rid of them drone-traps must be provided. And these are a nuisance to the worker bees and their keeper. Better not rear them at all. If we have taken pains to make sure of a sufficient number in one or two of our best drone-breeding colonies, why go upon some imaginary idea to permit their production in every colony? Try your best to get rid of the drone comb, and you will still find more inferior drones than you wish.

I am sure that every beginner will do well if he removes the largest patches of drone comb in all his hives, replacing the same with worker comb, except in such colonies as are set apart as breeders, as mentioned before. Of late it has seemed to me that the advantage of removing the drone combs and replacing them with worker comb, or foundation, is sufficiently apparent to make the matter a question of very serious consideration among practical beekeepers.

GENERAL CORRESPONDENCE

IS THE ISLE OF WIGHT DISEASE NEW?

BY C. E. BARTHOLOMEW,
Associate Professor of Apiculture, Iowa State College

The beekeeper need not become panic stricken when a new(?) bee disease has been discovered. Most new diseases are simply a new name for something we have always had with us, and the so-called Isle of Wight disease is one of these. This disease has been confused by beekeepers with a great many other common ailments of the honeybee, as the great variety of symptoms demonstrates. This is due to a great extent to our meager knowledge of actual causes.

There are at least two and possibly more diseases distinguishable among the many symptoms ascribed to Isle of Wight disease. Bees suffering from paralysis and those suffering from dysentery are affected by two distinct diseases, both of which may be present at the same time in the same colony, but not necessarily so. There is present, in all bees examined that had died of malignant dysentery, a protozoan parasite that is not nosema, but is a near relative of it. This parasite in all cases was present in large numbers, and infests the digestive tract. In bees dying from the apparent effect of this parasite the alimentary tract was almost destroyed. In fact, it was simply rotten. The nosema is occasionally present in the spore stage in these cases, but it is extremely rare. In bees suffering from paralysis the nosema spores are common, and I have found a protozoan present in the muscles of the honeybee; but whether this is a stage of nosema, which I am inclined to believe it is, or some other parasite, I am not prepared to state. The present status of our knowledge of the life-histories of these parasites is very meager, and I can only predict that it will be a long time and require considerable study before the end is gained.

I feel safe in making the statement that malignant dysentery and paralysis are two distinct diseases, and that the malignant dysentery is caused by a protozoan parasite that is not *Nosema apis*. I call this malignant dysentery to distinguish it from the dysentery caused by long confinement and a heavy consumption of stores, and which is not necessarily fatal if the bees have an opportunity for flight.

The mortality from this dysentery is higher in the spring than any other season of the year, and a great deal of spring dwindling is due to it and not to the quality of the stores or many other of the attributed causes. This disease is at its worst at the beginning of brood-rearing in the spring. If the colony survives the rearing of the first brood and the appearance of the new nectar the disease is checked and may not be again apparent until the following spring. When prolonged periods of wet weather reduce the nectar flow and confine the bees to the hive the disease may make its reappearance to such an extent that the beekeeper may notice it. One reason why this parasite is apparently more virulent in the spring is that the longer life of the wintering bees gives a longer developing period for the parasite, while in the summer the sick bees die in the field while the developing brood make good the losses.

One of the principal symptoms of this disease is the brown liquid dropping, together with a heavy mortality. When examined under a high-power microscope these droppings will be seen to contain myriads of spores of a protozoan parasite.

There is nothing to add to the methods of treatment for this disease but to caution the beekeeper against leaving the daubed frames and honey for the young healthy bees to clean up, and thus become infected with the parasite. Remove all daubed frames. These may be washed and returned if not too much soiled, but do not leave it for the bees to do. All traces of droppings should be washed from the inside and outside of the hive as well as from the frames. Thin sugar syrup or thinned honey fed in outside feeders seems to have some influence in reducing the mortality.

Ames, Iowa.

[The writer of this article is Associate Professor of Apiculture at the Iowa State College located at Ames, Ia. He is, therefore, probably in possession of a complete equipment for making investigations.—Ed.]

NOSEMA VS. ISLE OF WIGHT DISEASE

BY GEO. W. BULLAMORE, F. R. M. S.

Dysentery may occur in normal bees as the result of conditions, or it may occur under normal conditions when the bee has a deranged digestive system. If the bees winter on good food, only a small proportion of the stocks affected with Isle of Wight will show dysentery. The prominence given to this symptom by Zander probably arose from the fact that his observations were first made when heavy losses were occurring in cold wet years. A sickly bee on the unripe or dark honey-dew stores that have to serve at such times would be very much subject to this trouble. Varieties of yeasts occur in dysentery, but I do not think there is one special kind responsible, tho all the cases in one apiary may show large numbers of the same kind. Yeasts, and molds which also cause fermentation, are certain to be present in honey-dews, for instance.

Both Swiss and German observers agree that nosema has no particular symptom except the death of the bees in large numbers. This is our view of Isle of Wight disease.

I would advise caution, therefore, as to harmlessness of nosema. In this country a small percentage of people die of pneumonia. The pneumonia germ is reported to be present in 60 per cent of the population. There are districts in India where the malarial parasite is present in the blood of 100 per cent of the native school children, yet a slight infection would bowl over a European. I have read of a village where all the inhabitants were carriers of the typhoid bacillus. It was the visitor who suffered from the effects of typhoid germs. As to nosema and Isle of Wight disease. I am personally committed to the statement that the Isle of Wight disease is associated with an intracellular parasite *believed to be* the young form of nosema. I have often picked up crawling bees in disease districts and found this young form in the stomach-walls. The life-history of a pathogenic protozoan such as nosema is necessarily conjecture, as we cannot watch the growth and development. We merely find the different stages and piece them together. When any

work of Rennie and Anderson is published I may send you an article on nosema and Isle of Wight disease. There is nothing fresh in what they are saying, apparently—no new facts.

Too much attention is given to nosema spores, I think. The poisons will be excreted by growing stages and not by such a resting form. A bee that gets thru the early stages may well appear normal, altho spore-laden. The suggestion has occurred to me that the difference between endemic and epidemic nosema may be in the arising under certain conditions of an infective *young* form. A few bees could pass them from the "blood" to the salivary glands and infect large numbers with the stomach trouble. When disease developed the blood-infected bees would have disappeared, and proof would be impossible. This suggestion is only one possibility, but I feel sure that I could dodge a lot of trouble if I could dodge nosema.

Albury, Herts, England.

[Altho wintering colonies on unripe honey or honey-dew may be, and often is, the cause of dysenteric trouble, this disorder, we are credibly informed, is more often than not present in cases of Isle of Wight disease when no question of unwholesome stores arises.

The gut content of the bee is normally alkaline; but with nosema infection it becomes acid, and this acid medium is a congenial breeding-ground for years; and these yeasts which are frequently present in enormous numbers are responsible for the dysentery. A more correct term for this disorder would, we think, be diarrhea, as the active agent does not cause any disintegration of the tissues of the gut.

There appears, however, to be at least one true dysentery of bees. Prof. C. E. Bartholomew, of the Iowa State College, has discovered in the faeces of dysenteric bees numerous sporocysts of a protozoan parasite whose life-history he has not yet fully worked out. The tissues of the gut of the infected bee are destroyed by this organism.—Ed.]

BEE PARALYSIS

BY MAJOR SHALLARD

The first we knew here of bee paralysis was what we called Californian trembling disease. The bees got on the ground and could not fly, and their wings trem-

bled. It did not do any particular amount of harm, and we treated it by dashing a half-cup of salt water across the combs. This was about 25 years ago; and some

little time later its character changed, and the bees fell out of the hives and crawled about the ground with swollen bodies. It weakened the hives somewhat, but did not do any serious damage. The following season it attacked the bees on the Hunter River, 60 miles north of Sydney, and acted much the same as the Isle of Wight disease in England. The bees swelled up and tumbled out in heaps until there was a bucket of bees under some hives. It wiped Mr. Mich. Seobie's apiary of 150 hives right out all but 15; but there was a sequel to this, as the next season he bred up from the 15 to 150 again, and took 9 tons of honey. What price that, for good beekeeping!

Now it has assumed another form, or, rather, it has two forms. The bees will hop about the ground in one case, but they suddenly curl up and die in the other. In the former they are a little swollen—not much; but in the latter they are not swollen at all. I had been sitting under a tree having my lunch, when a bee laden with pollen fell on to the paper I was reading. It curled right up as tho it had the cramps, and died almost instantly. I have seen them do the same thing on the road many times, and have wondered if this was not partly the cause of the disappearing disease which we get here sometimes.

You, Mr. Editor, say that the bees get some sort of fungus, possibly with the pollen. Perhaps you are right, and that would account for the fact that one apiary will get it while another two miles away will be quite free. As I mentioned once before in GLEANINGS, I know of places here where

the bees get paralysis every year at certain seasons, while other apiaries only three miles away are healthy.

At the present moment I have one apiary pretty badly affected, while another not two miles away has not a trace. At the same time there is a fair flow of honey at the latter, and plenty of good pollen; whereas at the former there is hardly any honey-flow and hardly any pollen.

I have known this disease for many years, but it is so contradictory that I do not profess to know much about it. We do not pay very much attention to it anyway, as it is seldom that all the hives are affected, altho they once used to be; and if one hive persists in the symptoms the queen is either changed, or sometimes moving to another apiary will effect a cure. As you say, our bees have become largely immune to it.

Glenbrook, N. S. W., Australia.

[The writer of the foregoing is one of the best-known beekeepers in Australia. The reader who goes over these three articles will be able to make his own comparisons and determine whether he has any of the troubles among his own bees.

By referring to an editorial elsewhere on this subject, it would appear that bee paralysis and Isle of Wight disease are not one and the same disease altho some of the symptoms are similar. The ordinary bee paralysis of the northern states is not serious, and usually does not affect more than one or two colonies. But there has been a peculiar kind of malady that struck apiaries in the Mississippi Valley and the Northwest, and particularly in Oregon that killed a good many bees.—Ed.]

MANY CONDITIONS CONTROL THE DISTANCE BEES FLY

BY J. E. CRANE

P. C. Chadwick, p. 149, Feb. 15, reports that bees in southern California will go from five to seven miles for nectar and do very good business at storing honey, while Mr. Baldwin, of southern Florida, has told us that his bees would not go over a mile for nectar. Both are reliable men. The editor says the topography of the country has much to do with it—bees will fly further in a hilly country than in a level one; also the scent of nectar may be carried by the wind. All of this is true; but they have wind enough in Florida to carry the perfume of flowers a long distance. Doubtless it makes a difference whether the wind is blowing from the source of nectar toward the apiary or in the opposite direction.

Thirty or forty years ago we thought we knew just how far bees would fly. I drew circles around my yards on local maps to show just the territory a yard would cover. We know more about the subject now. Not only does the topography of a section of country and the direction of wind affect the flight of bees, but several other conditions have a bearing. I will first mention climate. The climate of California is dry and bracing; that of Florida is damp and hot. One tends to industry, the other to inactivity. Said a Californian to me in Florida a few years ago, "What kind of climate is this? In California we could walk six or seven miles and just enjoy it; but here in Florida if you walk two miles you are all in."

This explains it exactly. Doubtless bees feel the effect of climate and the indisposition to work as keenly as man; and why should they exert themselves to go a long distance when they have enough in their hives? We little realize how much muscular energy is required to carry a bee thru the air, especially when loaded, until we watch them drop at the entrance of the hive exhausted and panting for breath. It stands to reason, therefore, that bees will not go nearly as far in the climate of Florida as in a different climate, even if other conditions were the same.

Another condition affecting the flight of bees, especially here in the North, is the temperature of the air. I have been surprised to learn within the last few years the distance bees will fly in cool weather as compared with the distance they will fly in warm weather. A few years ago the weather was quite cool during fruit and dandelion bloom, and, as a result, the bees of almost every large apiary were in a starving condition before clover bloomed, while those in the small yards, with half a dozen colonies, had filled their hives and were swarming. This is easily explained. While there were flowers enough in the small area over which bees could fly for a few colonies, there were not enough for a large number. Had the weather been warm enough so bees could have flown as far as they do in July, I believe there would have been but little difference in the condition of large and small apiaries.

Another proof of the short distance bees will fly in cool weather is the barren fruit-trees or cranberry-bogs some distance from where there are bees. This is not so notice-

able when the weather is warm; but if cool we may learn the fact to our sorrow.

Another factor governing the distance bees fly is the strain or race. A friend was telling not long ago how, when he first Italianized his bees, he went two and a half miles from home to a piece of alsike clover to see if any of his Italian bees went that far. To his surprise he found them in great abundance. He said that another beekeeper living only one mile from the field of clover had black bees, yet he found fourteen times as many of his Italian bees to the same number of colonies, by actual count, as he did of the black bees, altho his Italian bees were two and a half times as far away. He said, further, his bees had no trouble in getting basswood honey when the trees were two to five miles from home. An inspector is not infrequently surprised at the stories told by old bee-hunters of the distance they have lined bees.

Altho there may be no way to prove it, it seems probable that bees do not fly nearly as far in cloudy weather as when the sun is shining, other things being the same. The same is doubtless true of showery weather. Bees do not like to be caught out when it rains; and yet if nectar is abundant they will work freely a short distance, even in the rain, if it is warm.

Thus we see there are many things that control the flight of bees in their search for nectar—the topography of the country, direction of the wind, climate, strain of bees, temperature, weather conditions, and it may be other conditions we have not yet come to recognize. How much the years, as they go by, are adding to our knowledge!

Middlebury, Vt.

HOW CAN I PREVENT SO MANY DRONES?

BY CHARLES E. DUSTMAN

There are three ways by which the number of drones may be restricted. They may be trapped, they may be destroyed before emerging from the cells, or only worker comb may be permitted in the brood-nest, excepting, of course, a few drone-cells which will be scattered thru the hive despite the efforts of the apiarist.

Some have argued that the apiarist is but little hurt by the production of many drones. In this they are much mistaken. It costs much to produce drones, and much to maintain them. To determine the cost of producing drones we must consider the amount of space they occupy, the amount of stores they consume in development, and

the amount of time they receive from attendant bees.

Sealed worker-brood combs are one inch thick; drone-brood combs are $1\frac{1}{4}$ inches thick. In the matter of thickness of comb the square foot of drone brood occupies 25 per cent more space. Worker brood occupies the combs but 21 days, whereas drone-brood occupies it 24 days, or $14\frac{2}{7}$ per cent longer; 125 per cent of space occupied $14\frac{2}{7}$ per cent longer is equal to $142\frac{6}{7}$ per cent of space occupied for the same length of time. This does not take into account the damage done by crowding the adjoining worker comb.

As to the amount of stores required to

produce a square foot of drone brood, it may be considered that it requires the same amount, bulk for bulk, as does worker brood; and that being 25 per cent larger in bulk they will require 25 per cent more stores. But this is not all, for worker larvæ feed for but six days, whereas drone brood feeds for $6\frac{1}{2}$ days, or $8\frac{1}{3}$ per cent longer. If a square foot of drone larvæ consumes 25 per cent more stores for $8\frac{1}{3}$ per cent longer time it consumes $35\frac{5}{12}$ per cent more stores.

The time required from the attendant bees to produce this square foot of drone brood probably corresponds exactly with the amount of stores consumed, which is $35\frac{5}{12}$ per cent more than is required to produce a square foot of worker brood.

To sum it up, it requires $42\frac{6}{7}$ per cent more space, $35\frac{5}{12}$ per cent more stores, and $35\frac{5}{12}$ per cent more time of attendant bees to produce a square foot of drone brood than it costs to produce the same amount of worker brood.

We believe that all drones other than those produced for necessary breeding purposes are entirely worthless. Our square foot of drone brood has yielded us 2304 worthless drones. This same amount of space and time and stores given to the production of worker brood would have produced 3120 workers, even if the space occupied were only $35\frac{5}{12}$ per cent more.

It may be argued that the presence of drones gives the colony a better working spirit; but we cannot believe that this is true until competent observers give it their support.

It is sometimes argued that drones are helpful in producing heat; but this argument will never carry any weight unless it can be shown that, when denied drone comb and provided with worker comb instead, they will refuse to produce an equal bulk of workers.

It is also sometimes argued that man cannot improve on nature, and that bees should be allowed to follow their inclinations in the matter of drone production, for they surely know what is good for them better than we do. This argument is inexecutable. It is strange indeed that a man

will constantly improve his stock and crops by selection and breeding, his fruit by budding, grafting, and pruning, and dispose of his surplus rams and cockerels, and then argue that it is best not to restrict the number of drones because "Nature herself provided them in large numbers, and nature surely knows best." If it is established that it is well to restrict the number of drones, then it only remains to determine the best method of accomplishing this.

We said they may be trapped, destroyed in the cells, or eliminated by supplying only worker comb. Restricting drones by trapping is a makeshift, and is unwise. Trapping saves nothing in the cost of production. It saves only the cost of maintenance. Indeed, it does not save even so much as that, for traps hinder greatly, especially if the colony be populous and the day hot.

Restricting by destroying the brood is probably worse; for after brood is sealed it requires no stores and little attention. But should it be destroyed the bees will promptly fill the cells with other thousands of hungry mouths, and consume another requisition of valuable stores.

Drone brood is capped in $9\frac{1}{2}$ days from the time the egg is laid. It emerges from the cells in 24 days. Now, just for argument's sake, let us say the apiarist who practices restricting by uncapping uncaps his drone brood every ten days. Then, allowing two days for the recleaning of the cells, he has put the bees to the expense of feeding twice as much stores, for they would have to carry two generations of brood entirely thru the food-consuming period, and in addition it would require the services of many more nurse bees than if one generation were allowed to occupy the cells the full 24 days.

We grant a very small portion of drone comb or cells here and there, for bees seem so determined to have a little that it is possible it is best to humor them to this extent. But beyond this we claim that the only method of restriction worthy of practice is the practice of removing from the brood-nest all drone comb, and replacing it with worker comb or foundation.

Des Moines, Iowa.

THE BITTER HONEY FROM BITTERWEED

BY J. L. LEATH

My apiary is located in the suburbs of the city on a hill gradually sloping east and southeast. The early sun warms the hives, and the bees begin to stir early, and I believe they build up better in the spring.

People pass my apiary every day; but it is seldom that a bee tries to sting. Stock come around, and wagons are driven near them, but they seem not to care.

After trying in my yard several breeds

J. L. Leath's apiary located in the outskirts of Corinth, Mississippi.

of bees I have decided on the three-banded Italians. My experience is that the three-banded have more good and fewer bad qualities than any others I have tried. I keep bees for pleasure and profit. I have worked bees for about 25 years, and I enjoy the work very much.

In the accompanying illustration can be seen small hives that hold four regular Langstroth frames. These I use in mating young queens. This is not a first-class honey location, but a good place to rear queens. Our honey-flow is a long-drawn-out one, beginning early in spring, and continu-

ing more or less until autumn. Bees seldom store a large surplus here. The largest from any one source is probably from bitterweed. I have seen them fill their supers and brood-chambers full of this bitter honey, and they mix it with the new honey the next spring, not consuming it all during the winter.

Our main sources of honey are fruit bloom, white clover (yielding for a short time); sweet clover, bitterweed, and aster. We have plenty of natural pollen-producing flowers almost all the season. My best yield this season from one colony was 120 pounds of fine extracted honey.

Corinth, Miss.

MY METHOD OF QUEEN-CELL PRODUCTION

Preparing the Cell-builders

BY W. H. CRAWFORD

Select a strong colony of bees in an eight-frame two-story hive, in a perfectly normal condition, and at a time when the weather is good and the flowers are yielding nectar, so as to encourage and stimulate the bees to such a degree as to produce perfect conditions as nearly as possible. See that the lower story contains eight full combs of

brood with a normal amount of honey and pollen. After making sure that the queen is in the lower story, put a queen-excluder between it and the upper story, and at the same time remove all combs from the upper story.

Three hours before starting cells, take seven combs of brood in all stages of de-

velopment from several different strong colonies, with adhering bees, being sure not to get a queen with them, and put them in the upper story, spacing three combs on each side of the hive normally, putting the seventh one in the center of the space left. This will give just the right space on each side of the center comb for a frame of prepared queen-cells. In less than an hour these spaces will be full of clustered bees, and hence an ideal condition will have been brought about as well as an ideal place for the reception of embryo queen-cells.

The mixing together of bees from different colonies, together with the fact that the brood in the seven combs put above a honey-board is decreasing every moment, produces the superseding impulse upon the bees in that part of the hive, and therefore gives the finishing touch to a perfect condition for the development of as good queen-cells as bees can produce. In my estimation a colony prepared as here described is near perfection. At times I have had 100 per cent of the cells given to such colonies accepted, abundantly fed, and completed; but, as a general rule, when twenty cells are given, about ninety per cent of them are completed. Where more than twenty cells are given at a time a less per cent are accepted; and where less than twenty are given, a greater per cent will be accepted and completed.

These cell-building colonies can be kept in the same ideal condition all thru the season by removing the cells three days after they are given to them; at the same time giving a fresh lot of prepared cells. Two full combs of brood with adhering bees should be given to the upper story once a week, removing the full combs of honey as fast as filled, so that no crowded condition will be noticed by the bees. In putting in empty combs, care should be taken never to put a fresh extracted comb, wet with honey, into the upper story of cell-building colonies; for fresh feed of any kind given in the super of such colonies means destruction to many unsealed cells; and all open cells are neglected for a time sufficient to damage them, while the bees are rushing about in an excited manner, taking care of the newly found sweet.

Every third day the cells are removed from cell-building colony No. 1, the jelly in one of them being used in preparing 20 new cells which are given in the place of the ones removed. If the bees of No. 1 are allowed to finish cells the superseding impulse wanes to some degree every time they do so, and hence the ideal condition is lost; but if they are not allowed to finish any

cells at all, it is an easy matter to keep the superseding disposition up to the maximum degree all thru the season.

By this method seventeen cells are secured from one colony of bees every three days without the loss of a pound of honey from any part of the apiary, and such cells are as good as can be produced by any known plan.

The frames of cells, with adhering bees, should be carefully taken out of cell-building colony No. 1, and placed in colony No. 2, where they are finished. Colony No. 2 is prepared the same as No. 1, except it has only three combs of brood in the upper story in all stages, the remaining four combs being partly filled with honey. It is a simple mathematical problem to find the number of cell-building colonies needed to supply the amount of cells required.

HOW THE CELLS ARE LOCATED.

The best device for holding queen-cells is like a division-board, $\frac{1}{2}$ inch thick by $3\frac{1}{2}$ wide. The bottom edge is dipped several times in melted beeswax so as to form a thick film of wax on it. The cell cups are molded on a cell-stick as per the Doolittle plan, and are fastened to wooden cell-blocks by pressing the base of the cell against one end of the block when taken from the melting wax the last time in forming it, then the cell and the block together are dipped into the melted wax again, thus securely fastening the cell to the block, and forming a film of wax all over the block. Then once more the end of the block is dipped in the wax so as to make a still thicker film of wax on it, making the cell and block ready for use.

The wooden cell-blocks are made of white pine or redwood, $\frac{1}{2}$ inch thick by $\frac{3}{4}$ inch long. There is no need of a cavity in them for the cells.

GRAFTING THE CELLS.

After the cells have been provided with royal jelly, transfer the larvæ 24 hours old with a tiny wooden brush made by chewing the point of a tooth-pick a little. With this kind of transferring-needle quite a bit of jelly can be dipped up with the little larvæ if they have been as abundantly fed as they should be. (I would not breed from a queen whose bees do not float the tiny larvæ in jelly.)

Next press the waxed end of the cell-blocks into the wax on the edge of the cell-board, giving them a little turn with the thumb and fore finger at the time, so as to fasten them securely there. Twenty cells can be put on one cell-board; but it is better to use two cell-boards, putting ten one inch apart centrally on each board, then quickly

put them in the spaces made ready to receive them in cell-building colony No. 1. This puts the cells near the center of the hive, and along the center of the combs as they should be.

The board described above is perfection in the way of a queen-cell frame, having no objectionable features whatever. Last summer I discovered the plan of waxing the edge of the cell-boards and cell-blocks as a means of fastening them together, making a cheaper and more satisfactory fastening

than any I have ever used. There is no danger whatever of cells coming loose if ordinary care is taken in putting them on, especially if the board is allowed to lie in the sun for five minutes just before. A cell-frame of this kind eliminates the objectionable features of having comb built in it, or having bees cluster in it in a way that makes it awkward for the queen-breeder to handle the cells and frame to the best advantage.

Reswell, N. M.

WHITE-CLOVER POLLEN

BY JOHN H. LOVELL

FORM OF THE POLLEN GRAINS.

The pollen grains, when examined under a high magnifying power, are shown to be oblong, cylindrical, rounded at each end, with three longitudinal slits or grooves on the sides, and the bands or spaces between the slits finely roughened with many shallow pits or depressions. A knowledge of the form of the pollen of white clover is very essential in order that it may be recognized with certainty when taken from the pollen-baskets of bees or from the hives; otherwise expressions of opinion become largely if not wholly guesswork. The color of the pollen in the anthers is yellow.

THE COLLECTION OF WHITE-CLOVER POLLEN BY BEES.

There are five petals. The upper petal, called the standard, is much the largest; the two lower partly cohere to form a sac called from its form a carina, or keel; the two lateral petals, called the alæ or wings, are attached to the keel, and act as levers to depress it. The stamens and pistil are completely enclosed in the keel, and ordinarily are not visible. A bee cannot collect pollen from white clover as it does from a rose, because there is none in sight, and it is not directly accessible. Bees never visit the flowers for the purpose of gathering pollen only, and in all my observations I have never seen a bee trying to obtain the pollen.

There are ten anthers, each of which produces a small amount of pollen; but it is yellow, not brown, as stated by Dr. Miller. The filaments (stems of the stamens) unite to form a tube, at the bottom of which the nectar is secreted. The superior stamen is, however, free, leaving two small openings at the base of the staminal tube thru which a bee may insert its tongue to obtain the nectar. It is manifest at a glance that the individual florets of a white-clover flower-

cluster are far too small to hold a honeybee. The bee clings with its legs to several flowers, and only its head rests on the flower from which it is sucking nectar. When a bee pushes its head beneath the standard, the keel and wings are forced downward, the anthers and stigma emerge, and, if the former have opened, a little pollen is deposited on the under or inner side of the head. In a bee before me the whole under side of its head is covered with a layer of moist pollen. If a pointed leadpencil is thrust into a mature flower, when it is withdrawn a little mass of pollen will be found on the under side. As soon as the bee moves to another flower, the elastic petals cause the anthers to return again within the keel. The collection of pollen is, therefore, an incidental result over which the bee has no control. While it is visiting white-clover flowers, more or less pollen is necessarily rubbed on the under side of the head; but a part of it is again rubbed off on the stigmas of the flowers subsequently visited, effecting cross-pollination, for the stigma stands slightly in advance of the anthers. A part of this pollen may be also transferred to the pollen-baskets, where it appears as little brown balls varying in size from a shot to an almost inappreciable amount. On many bees at work on white clover I could see no trace of pollen in the pollen-baskets, neither could I see any pollen on the thighs of many bees coming into the hive.

Several of these little brown balls were removed from bees captured on the flowers of white clover; the mass was comminuted, and portions of it examined with a high magnifying power. The form and structure of the grains, as described above, showed at once that it was white-clover pollen, altho it was slightly modified by the moisture. The little balls of pollen appear brown instead of yellow, the color of the pollen in the

anthers, because they are composed of a moist compact mass of grains which have been slowly collected and manipulated by the bees' legs.

WHITE-CLOVER POLLEN IN THE HIVES.

The white-clover honey-flow is now at its full height here, and the bees are so busy that I can stand by the side of the hive entrance and watch the incoming and outgoing bees without being attacked. The season has been a very wet one, and never before within memory have the white-clover blossoms been so abundant in the fields and along the roadsides. Here and there masses of white and red clover are mingled with purple vetch, and vie with the flower-gardens in attractiveness. On many of the home-coming bees I can see no pollen, while others bear little brown wet balls, evidently composed of white-clover pollen.

Three hives were opened, and the frames examined for pollen. In none of them was there a large quantity of pollen; indeed, with every desire to be perfectly fair I should say that they contained a small amount of pollen. From two of the frames of one of these hives I took samples of brown pollen which apparently might be from white clover. To my surprise the compound microscope showed neither of the

samples to consist of white-clover pollen, for the grains were round or globular, with a roughened surface. After the pollen has been packed in the frames, no matter what its source, it seems very generally to have a dark-brown appearance.

Compared with its value as a honey-plant, white clover is of little importance for pollen. The pollen cannot be gathered directly, and occurs in small quantities in individual flowers. Much that is rubbed off on the under side of a bee's head is again deposited on the stigmas of flowers visited later. In most localities, I believe that bees will be found to collect a comparatively small amount. But sometimes great results may come from small causes, as when great cliffs are sculptured by grains of sand blown against them thru the ages. Where white clover is very abundant, and its bloom whitens great areas, as has been pictured several times in GLEANINGS, and the flow lasts for a long time, perhaps the total amount of pollen brought in may be large; but it is exceedingly small compared with the quantity of nectar gathered. Even in these cases the pollen should be examined under the microscope before a conclusion is drawn.

Waldoboro, Me.

THE PAST SEASON IN NEW ZEALAND

BY E. G. WARD

The reader should remember that the seasons in New Zealand are just the opposite from ours—their summer coming during our winter.—Ed.

The season of 1915—1916 in New Zealand was one of the most remarkable on record. Reports from the North Island indicate that the output has been rather below the average. The spring was cold, wet, and boisterous; and to keep the bees alive, feeding had to be resorted to as late as the middle of November in some districts.

The southernmost districts of the South Island, on the contrary, enjoyed one of the finest seasons on record for all agricultural pursuits. The beekeepers in most cases had splendid returns, and a late flow from cats-car and thistles obviated any necessity of feeding for winter stores.

In Canterbury and North Otago (the central districts of the Dominion) the season was the worst ever experienced. The season of 1914—1915 was bad enough; but the one just ended was still worse. Many colonies died during the summer on account of the drouth. One man had only 60 left out of 300. Many artesian wells which had never been known to fail previously went dry, and cattle gave only about half their

usual quantity of milk. There was a severe frost on the morning of Nov. 22, which cut down clover just as it began to yield, and another on Dec. 30. Dec. 15, was the hottest day in eight years, and the following day nearly as bad. Very little extracting was done; and if feeding was neglected there will be a big percentage of empty hives next spring.

The rainfall for the last three years has been diminishing, and was only about half the normal for the year 1915.

Three successive dry winters brought matters to a climax, as the following figures for Christchurch (Canterbury Province) during recent years will show:

Year	Inches	Year	Inches
1902	28.780	1909	32.282
1903	18.998	1910	25.181
1904	33.351	1911	29.253
1905	28.440	1912	27.294
1906	29.496	1913	27.384
1907	19.508	1914	20.380
1908	25.417	1915	15.694

The rainfall during the last 6 months of 1915 was 6.015 inches. For

1911	15.633	1914	7.225
1912	12.697	1915	6.915
1913	15.505		

In contrast to the above, and to show that we have rain in some parts of New Zealand, the following figures for the town of Hokitika (on the west coast) may be of interest.

In 1915 rain fell on 220 days, totaling 134.05 inches. This is not unusual, as the following figures will show.

The fall in 1908 was 110.48 inches.

1909	121.06	1913	101.18
1910	132.69	1914	112.32
1911	104.89	1915	134.95
1912	115.62		

The heaviest rainfall on record for Hokitika was in 1878, when 154.44 inches was recorded; the lightest was in 1869, when there was *only* 88.21.

I am not aware that any bees are kept there; but if so, I should imagine they should never leave their umbrellas at home. Christchurch, N. Z., May 9, 1916.

REMOVING A COLONY FROM AN AUSTRALIAN GUM-TREE

BY E. B. MACPHERSON.

Out in the "bush" one lovely day I found bees going in and out of a gum-tree. The owner dared me to get the bees and combs into a hive. I did not like the idea of cutting down such a fine old tree, so I borrowed a ladder that was just about long enough to enable me to reach the bees.

With a small ax I cut a hole where the bees were going in and out large enough for me to dig out the combs of brood. By the time I had the hole cut the bees were frightened enough to desert the brood and honey, hanging in a swarm above the combs between some rotten wood inside the tree.

I drew out the brood-combs one by one and let them fall into the tall grass and ferns below which broke the fall nicely. When all the combs were out I went down the ladder, fixed them into shallow frames, tying them in with strings to keep them in position. I thought I could get the bees out by carrying them down in handfuls, but could not get the queen in that way, and it was rather slow work anyhow, as most of them would keep flying back before I could get up again for another handful.

I had no smoker with me so I took a piece of old rotten wood from the hollow of the tree, made a fire on the ground in order to light the rotten wood, then carried it up where the bees were. They soon found they could not live with so much smoke, so they came out in a swarm and settled in the ferns below. I moved the hive over to them and every bee went in. The colony is doing well now.

Port Fairy, Vic., Aus.

[Nothing like succeeding under adverse circumstances! How many beekeepers would tackle a proposition like this, working on the "tip top" of a ladder and without a smoker? Our friend is not one to give up at the first obstacle that presents itself.—Ed.]

I tried putting the transferred combs in the hollow, thinking the bees would settle on them, but the plan did not work.

Whole valleys in eastern Tennessee and in North Carolina were submerged in the flood which destroyed thousands of colonies of bees.

TERRIBLE FLOOD IN SOUTHEASTERN UNITED STATES

BY L. E. WEBB

The terrific flood which has passed over North Carolina and eastern Tennessee has dealt a great blow to the bee industry. Every stream in western North Carolina was swollen to a width of forty to seventy-five feet, sweeping the valleys bare of houses, barns, crops, bees—everything.

Coming as it did at the beginning of the finest sourwood honey-flow in many years the flood cut off all chance of a late surplus from this source. The prospects were fine for three to five supers per colony when the crop was rained out and the bee business in the fertile valleys swept from existence.

The bees belonging to Farm Demonstrator Perkins, of Burke County, were drowned. The hives remained on their stands altho

covered with water. There was no way to save them, as Mr. Perkins' people were marooned in the second floor of their home for two days, unable to get to the hills. Mr. Perkins is an enthusiastic beeman as well as farm demonstrator. He has been in close touch with the government bee experts, and was giving the farmers some valuable points.

My apiary is situated in town far above the flooded area. The loss of the sourwood crop is serious, altho most colonies had made from one to two supers from the first bloom. I feel thankful for a strong apiary in a district where the business has suffered such great loss. Thousands of colonies have been swept away.

Morganton, N. C., July 21.

HEAVY LOSSES FROM THE FLOOD IN FLORIDA

BY J. J. WILDER

For thirty days it has rained almost continuously. Today, July 25, the clouds are broken a little, and the sun shines once more.

The great flood which came down the streams, spreading out wide over the country, sweeping down everything in its path,

has done much damage to beekeepers, and to all who happened to be in its path. They were safe from all previous floods; but this one, being many feet higher than the former record, swept hundreds of colonies of bees on with it as well as all the equipment. This was especially true along the great

Apalachicola River and its tributaries. This region is the heart of the great tupelo-gum belt from which thousands of barrels of this fine honey are shipped each season. Some beekeepers sustained a total loss of both bees and equipment, while many suffered partial losses. All told, thousands of dollars' damage have been done to the industry from which we can perhaps never fully recover.

I have not yet learned the names of all beekeepers who were heavy losers. Messrs. Tucker, Freeman, Lanier, Edwards, Aldermann, and Humes are reported among those

who lost heavily. I shall make a further report later on.

I lost only one apiary which I supposed was several feet above the high-water mark. We could not reach it in time to save it; but when the water goes down we hope to recover a part of the equipment, especially the supers and hives. However, as all of the combs were full of brood and honey this will be a complete loss.

One very fortunate feature is that most of the honey had been shipped out before the flood came. Otherwise the loss would have been much heavier.

Cordele, Ga.

SOME MISHAPS AND BLUNDERS OF LAST SEASON

BY J. L. BYER

Fire is a good servant, but a bad master. This proverb is familiar to all, but never so fully realized as when the time comes that we have actual experience with this dread element. Our apiaries are not pretty to look at, and in many ways our management is rather rough and slipshod, I am afraid, as compared with some of our very careful men; but one thing I have always been careful of is to warn all working in the yards, and to try to show by example as well, the necessity of being very careful to take no chances so far as danger from fire is concerned.

Up to September, 1915, we never had the slightest accident with smokers in any way, and in no other way did we have any experiences with fire where it was not wanted. Working at the home yard in September my son and I were going rapidly thru some 90 colonies taking out filled or partially filled combs of buckwheat honey. The season had been so poor that no filled supers were in evidence. We started in the morning in the northwest corner of the yard, and along toward noon we saw that, by stopping extracting and both taking in combs, all hives could be cleared before dinner, and then Edwin could extract the rest in the afternoon while I went to another apiary to do some necessary work. We finished in the southwest corner of the apiary, and left the yard exactly at 12 o'clock, going to the house for dinner, a walk of about 40 rods. Edwin left our place promptly at 1, and went up to the apiary, intending to finish the extracting. About the time he got there our telephone rang furiously; and on answering the same I was told to come at once as the beeyard was on fire. The bees are on our old homestead, while we now live a short distance from the old place. Needless

to say, I covered the distance from home to the apiary in record time: but I found on arrival that Edwin and the farmer on the place had isolated the fire to those hives burning when they arrived there after dinner. My! what a fire eight large hives filled with combs, bees, and honey do make! In some way that will never be explained, a spark from the smoker, we suppose, had ignited shavings or something in one of the packed hives, and the fire had, no doubt, been about ready to go nicely when we left the yard. The eight hives were alongside of one another in the southwest corner of the yard where we finished taking off the honey before dinner, and that explains how we left the yard without noticing the trouble; but it does not explain how we happened to do the mischief. Both of us had used the smoker by turns, so neither one could blame the other. That was one fortunate factor in the situation. It was a sorry sight indeed to see the bees of the eight powerful colonies going up in smoke; but I was glad that the fire was in the south corner of the yard instead of the north, as a strong north wind was blowing at the time. The colonies were nearly all heavy enough for winter, as they were of the Quinby dimensions. In addition they had most of the super combs on, as this particular lot of colonies had very little buckwheat honey in supers, and consequently the combs were not taken off.

Naturally we both felt like reproaching ourselves for carelessness in some way; but as we had taken all precautions, and used the smoker as at other times, we did not see how the accident could have been avoided. For fuel we were using chips from a wood-yard, our favorite variety for steady work. Years ago I used to put a handful of green grass on top of fuel when refilling; but of

late we have not done so because of the trouble caused by the juices from the grass gumming things up so. Possibly after this experience we may go back to the old practice. While the fire had the effect of making me doubly careful during the rest of the season in handling the smoker, it also had the disagreeable effect of causing me to worry when leaving an outyard after doing work there. No matter what pains I had taken, when leaving the thought would come to my mind, "What if a fire should start here where there is no one near the place?" If it did I guess they would simply have to burn; for after seeing how fire goes so rapidly thru hives, I am convinced that if a fire was started and let go it would clean out an entire apiary, even if hives were quite a long way apart. The only thing to do, no doubt, is to take all due precautions; and, in the absence of any system of insurance for bees that I know of, just trust to luck and stop worrying.

DON'T PUT YOUR NOSE INTO OTHER PEOPLE'S BUSINESS.

The apiary at Altona is situated in an orchard, a rail fence separating the yard from the rest of the ground, occupied by apple-trees. The bees at this place are wintered in rough cases, some two in a case and others singly. When packing them early in November I left one colony at one side of the yard, calculating to carry it about 20 feet to another place to go in with a colony alone on a stand that had a two-hive case. About the latter end of the month I went out to the yard to do this work after being away from there for two weeks or more. I might say that the farmer on whose place the bees are is very careful; but being busy he had not been in the beeyard for some time. Arriving there and going into the yard my first thought was that there had been an earthquake in the vicinity. About half a dozen of the cases for two hives were shoved off the stands, and three of the single-hive cases were actually turned upside down. The single hive left to be moved was the worst sufferer. It had a loose bottom and loose frames, and it was turned upside down, and the combs jammed together more or less, the bottom being off the hive and the bees exposed to the weather, which was below freezing at the time, and had been so for three or four days. First of all I righted the cases that were turned upside down, and then went for the smoker to do the best I could with the wreck of the colony in the single hive. The case was all ready, and I turned the hive aright, hastily arranging the combs as best I could, during which operation the bees

flew out more or less. I noticed that many were crushed. The hive was then placed in the packing-case with the expectation that they would die anyway; but I thought I would give them a chance to end up in a half-decent way. Jan. 25 I was at the yard and they appeared all right, much to my surprise; but I thought the queen might have been killed. The packed cases when righted appeared to be little the worse, in so far as the bees were concerned. The clusters were quiet, and the combs had not been loosened at all—score one for narrow top-bars in a locality where propolis is abundant.

Now as to the cause of all this trouble. Investigation showed that a long-snouted old sow had broken a rail and got into the apiary. The pigs had free access to the other half of the orchard to pick up fallen apples after picking had been done. Some apples had rolled under the packing-cases; and in order to get at them she had put her nose under and given the hives a hoist. That explains the damage but does not help matters very much. In this case, again, it was just another thing that *might have been* avoided, but under ordinary circumstances is likely to happen once in a while in running out-apiaries.

"THEY" SAID SO—AND THEY WERE RIGHT.

Years ago I read that boiled honey would kill bees if given them for winter stores. Repeatedly I have told others this same thing because some one had told me; but I never had any actual experience in the matter. Last September when starting to feed bees at home yard I came across about 40 pounds of honey I had taken from cappings the winter before. In the spring I had diluted some of this with water and boiled it as a precaution before feeding a few needy colonies in May. I never fed stuff that was better for brood-rearing than this boiled honey, no doubt with a lot of pollen in it. Examining the colonies so as to find the amount of feeding to do, I came across a Danzenbaker colony that had been run for extracted honey; and when supers were off the colony was almost destitute of honey. Now, here was a good chance surely to find out *for sure* whether boiled honey would kill bees if given them to winter on. In a foolhardy moment I placed a large Miller feeder on this hive and gave the bees all they would take of this boiled mixture. About Christmas I was in the yard and noticed about a pint of dead bees dragged out in front of this hive while not another colony of the 80 was in a like condition. I raked them away and listened, and there were live bees in the hive yet; but I was

beginning to think that the text-books were all right. Jan. 25 was quite mild, and a few bees were flying at most of the hives; but I noticed the boiled-honey colony was very quiet, with no bees dead or alive around the entrance. A tap on the hive brought no response, and so, sure enough, they were gone. Taking off the packing I found all the bees of this strong colony were dead, and lying all over the bottom of the hive. It did not look like an ordinary case of dysentery, but the bees' bodies were distended a great deal, and the cappings

had been opened all over the combs just as tho the poor things were trying to get better food than was available. I do not know how long they had been dead, but it looked as tho this strong colony without a flight had not been able to live more than three months at the most on the only diet available. Yes, I am now fully convinced that boiled honey will kill bees in the winter. If *you* do not believe it, try for yourself, and don't risk more than one colony in the experiment.

Markham, Ont., Can.

AS GLIMPSED THRU THE CAMERA

Some Experiments with Portable Extracting Outfits

BY H. H. ROOT

In former years we have nearly always extracted all of our honey at the home yard in a convenient extracting-room, hauling in the combs from our six or seven yards around Medina. This year, however, our extracting-room was being used for other purposes; and while we had another place that we could have used we decided to assemble a portable outfit that we could haul from yard to yard. At most of the yards we have small buildings in which to put the outfit; but at one of the yards, a new one, there was no building. As honey was coming in rapidly, however, we decided to ex-

tract right out of doors in an orchard, knowing that the bees would not bother very much.

Extracting out of doors is ordinarily bad practice, even during a honey-flow, for in most localities the weather cannot be relied upon absolutely, and a sudden shower is not particularly good for an extracting-outfit. Furthermore, conditions of the weather or atmosphere may change enough to stop the honey-flow, and then it does not take long for the bees to discover what has been going on right under their noses.

With a portable outfit, especially a power

The platform with extractor, engine, tank, wheelbarrow, and the whole outfit, in fact, loaded on the truck.

A few minutes later. Platform slid off on the ground, staked down, engine bolted in place and all ready to extract.

outfit, much time is usually lost in bolting the apparatus down to the floor. It takes time to line up belts and make everything secure so that it runs just right. If one uses a screened wagon the outfit, of course, is left on the wagon all the time, and no time is lost; but if the outfit is put inside of buildings and moved from one yard to another it takes a good deal of expensive time to get it set up ready for work.

Our truck body is just 44 inches wide. We built a stout floor, or platform, just 43 inches wide, long enough to hold a six-frame power extractor with engine and pump. Everything was marked so that it took only about fifteen minutes after reaching the yard to get the platform inside the building and the outfit set up. The pump, of course, does not need to be removed ordinarily, altho it can be quickly unbolted from its base if necessary. It is a little inconvenient to have to step up five inches on to this platform; but when one becomes accustomed to it, it is really no handicap.

This year, for the first time, we used a hose to convey the honey from the pump to the tank. Heretofore we have always used a galvanized pipe. A hose is a little more convenient for a portable outfit, for it may be quickly disconnected and coiled up inside the extractor so that there is no drip nor lost time in draining out pipes. If the honey is to be elevated only four or five feet, a hose of small diameter may be used; but it is much better, in order to avoid friction, to use a hose the full diameter of the

Large hose carrying the honey from the pump to the tank. A hose is all right, but costs too much.

exhaust port of the pump. Even with the $\frac{3}{4}$ -inch pump the exhaust port is for a one-inch pipe, and a hose large enough to slip over a one-inch pipe is pretty expensive—so expensive, in fact, that it seems to me that a galvanized pipe is more practical. The pipe, moreover, will last forever, while the hose, unless very carefully handled, will deteriorate rapidly.

This year, for the first time, we tried uncapping into a wax-press, intending to press the honey out of the cappings when the basket was full, then set that one away to be melted up later, an empty basket meanwhile being put in the press.

Uncapping into a wax-press. We made the mistake of not laying a cloth on the cappings under the plunger when we applied the pressure, and consequently the plunger stuck fast.

A strong colony with three to five supers is "some colony." It is bad practice to confine the bees merely to the brood-chamber when the supers are taken off. Empty combs should be provided at once, and if the supers are freed from bees by means of a bee-escape, a super of empty combs should be placed under the escape unless the honey-flow is entirely over.

The plan works very well for one uncapper; but we found that it is absolutely necessary to have the cappings in a sack or else to put a piece of cheese-cloth or other soft material under the plunger of the press, otherwise it is impossible to remove the

plunger after the pressure is applied. The cappings are forced into the perforations by the pressure, most effectually locking plunger, cappings, and perforated basket together in one solid mass.

NURSE BEES AS THE CAUSE OF SWARMING

BY WILLIAM BEUCUS

I was surprised indeed to read in Mr. Chalou Fowls' article, July 15, 1915, the following words: "A natural swarm is made up of bees old enough to fly; but a shaken swarm consists of bees of all ages—nurse bees, cell-builders, all sorts." In this locality, bees of all ages join the swarm, excepting only those weak downy things that have not been out of their cells more than a few minutes, or, at the most, a few hours. And even these may be seen in considerable numbers crawling about in the grass. The only reason they did not join the swarm was because they could not fly. The nurse bees and cell-builders can fly, and they join the swarm in large numbers. What is the function or what are the functions of the clouds of young bees which fly at the entrances and fill the air during the brightest hours of sunshiny days? The functions of those bees are nursing, cell-building, comb-building, and evaporation of honey. These bees do not go to the fields; but when a swarm issues they join in the exodus. If the presence of too many nurse bees in proportion to the amount of unsealed brood is the cause of cell-building, queen-cells should invariably appear shortly after a prime swarm is hived.

The theory that living things lower than man are merely automata is still entertained by the majority of human beings, altho it should long ago have been discarded. It seems to be assumed by many beekeepers that bees do not deliberately build queen-cells, but that they build them only because there is in the stomachs of nurse bees an accumulation of larval food. According to this theory, bees are only machines. They do not consciously determine to build queen-cells, but merely proceed to do so mechanically. This seems to be the view held by Mr. Fowls. To me, this seems entirely wrong.

All higher forms of life, including bees, associate ideas—they think. There is no difference in kind between the mind of a Shakespeare and that of a newsboy—it is only a difference, and there is no difference in kind between the mind of man and that of a bee—it is still one of degree. How

could it be otherwise? In all living things, life is made up of internal changes which occur in answer to external changes. That these internal changes may be properly adjusted to the ever varying conditions outside of the body, it is necessary that the internal changes be in some way directed. That direction is merely an act of mind—a deliberate act. The mind of a man moves in a large circle, and directs the adjustment to numerous involved conditions. The mind of a bee moves in a small circle, and directs the adjustment to less numerous and less involved conditions.

It is quite remarkable to me that even the most careless observer can go thru a single season without noticing many proofs that bees are guided by intelligence, and are not merely the creatures of instinct—automatism. Only yesterday I observed a colony the bees of which were working but were not carrying in pollen, while the colony two inches to the left was carrying in immense loads. I immediately concluded that the colony first mentioned was queenless and broodless, and that the bees were not carrying in pollen because they were aware that it was not needed. An examination revealed the queenless and broodless condition expected.*

If the building of queen-cells and absconding, spoken of by Mr. Fowls, were due to the presence, in the nurse bees, of an oversupply of larval food, how could we ever manage to get rid of foul brood—particularly when shaking twice? In this case every bee goes with the swarm. We should naturally expect, from the immense overdose of larval food present, a large batch of queen-cells started, and then desertion.

Here is what happens in this locality when the shaken-swarm plan is practiced: If shaken on to starters, almost certain absconding; if shaken on to full sheets, very much less absconding; if shaken on to a set of clean, sweet-smelling worker combs, no absconding whatever. If absconding, in either artificial or natural swarming, is due

* Queenless and broodless bees *do* bring in pollen, however, and sometimes the combs are even "pollen-clogged."—Ed.

to the presence of too much larval food in the stomachs of nurse bees, there would necessarily have to be desertion with the accompanying building of queen-cells, no matter if the swarm were hived or shaken on to starters, full sheets, or full combs. The statement that too much larval food in nurse bees is the cause of queen-cell construction, and therefore of absconding or swarming, is not a full truth but an adumbration of the truth. It is a minor truth forming part of a major truth. This major truth is that, whenever there is either swarming or that which some prefer to distinguish as absconding, there is a restriction of function. In shaking or hiving a swarm on to starters, the functions of fielders of nurse bees and queen are all restricted. In shaking on to full sheets, the restriction of function is relatively short. In shaking on to full combs, the restriction is too brief to be a serious obstruction to the immediate performance of the work of life.

Since coming to the conclusion that restriction of function is the cause of swarming, I have got into the habit of asking myself, after treating colonies, "Have I removed every obstacle to the performance of function? Is there anything which stands in the way of raising brood and storing

honey?" At first I thought that merely giving a full set of combs was all that was necessary. Here are some of the minor conditions which, later, were observed as occasional causes in the restriction of functions: A new comb which had been partly drawn out in a top story the year before, and then, in the fall, had been more or less discolored by deposits of propolis; a new comb with very deep cells; moldy combs; extracting-combs which had been uncapped with the knife the year before. Some queens will refuse to lay in combs like the above, and some bees will refuse to prepare them properly. When a comb is uncapped, the mouths of the cells are hexagonal; but the mouths of cells ready for the queen are round. Several cases have come to my notice where the queens refused to lay in such combs, and where the workers refused to remodel the mouths of the cells. In all of the above cases, the effect was the same as tho dummies had been inserted. There was a restriction of egg-laying and consequent swarming.

Failing to observe these occasional minor causes, it is not at all hard to convince oneself that giving plenty of room will fail to prevent swarming.

Cadott, Wis.

STRAIGHT COMBS WITHOUT FOUNDATION

BY H. H. KOLLOSTER

I indorse Mr. E. E. Colien's article on page 279, April 1, in regard to home-made hives. It is about time for some one to defend the principle of home-made hives. It is a common thing for our best beemen to advise against home-made hives; and the average uninformed beekeeper, unable to buy factory-made hives, stays in the old rut and keeps his bees in an old box, thinking that there is something mysterious about a modern hive. This is a mistake. Factory-made hives are improperly made for all except the professional beekeeper. I can use them if I can afford to buy foundation; but if I cannot, then they are a nuisance, unless all the frames are filled with drawn comb.

I make my own hives. If I have no foundation, and a swarm is in the trees, I just take my home-made hive, fill it with empty frames, and put my swarm into it and let the bees go to work. If I don't see them again for two or three weeks I know that I have straight movable combs. I do not say that they are perfect, for it takes a good beeman with lots of experience to get good perfect combs; but in my home-

made hives and frames the combs are straight and the comb is built in the center of the frame. This cannot be done with the factory hives, for they are made so that foundation must be used.

The construction of my frame is an old idea. A $\frac{7}{8}$ -square bar is used, set into the hive, corner down. The ends are cut out on the bottom side to the center of the bar, and the side pieces are nailed on to the shoulder thus formed. The ends of the bar rest in the rabbet in the usual manner. I use $\frac{7}{8}$ square, but I plane down the two sides and top, as that size is a little too thick; but this size is kept in stock at the lumber yards, therefore is handier to get.

Foundation may be used, and the frames

should always be wired. If I use foundation, I lay it on the wires and press the edge of the foundation fast to the bar so that it centers at the corner, then run a hot soldering-iron over it. So fastened, the sheet never comes loose. If I have no foundation I just fill a hive with empty frames and put in the bees. Spacing is the main point to watch in that case; but should they run off the track I straighten them out a bit and the bees do the rest. Bees always

fasten their comb to the corner of a bar, no matter whether the bar is with the flat surface down or with the corner down.

Thirty years ago I found this bar in use in Ezra Catlett's apiary at Goleta, Cal. Later I found all the other apiaries thereabout used the same kind of frame, so I concluded that all frames were made that way until I saw the factory-made frame. I then discovered why foundation is not only necessary but indispensable.

Palatka, Fla.

REQUEENING AFTER TREATING BEE DISEASES

BY JOHN L. BYARD

My yard being one of the first in Massachusetts to be condemned and quarantined for American foul brood, together with all others in the town of Southboro, it gave me a chance to become early familiar with the disease. After treating my yard I assisted in treating those of my neighbors.

Before inspection in July I had requeened several of my colonies in June. My yard was quarantined, promptly treated, and then I requeened the rest of the colonies the last of August. Those colonies requeened in August far outstripped the others, wintered in perfect condition, and gave a good crop the following season. Those requeened in June before treatment barely pulled thru the winter, and in two colonies the following season I found slight evidence of American foul brood.

In comparison, those colonies in the town of Southboro, near my yard, but which were treated in the usual way without requeening the following year in nearly all instances showed disease. I cannot say that at that time I considered requeening as an essential part of the process of treatment; but with years of experience, both as a beekeeper and as an inspector I am now aware of its importance in combatting American foul brood. I am not prepared to say that the queen transmits the disease; but it is reasonable to presume in egg-laying she has thrust

her abdomen into thousands of cells containing the scales of foul brood. It is beyond me to say that in so doing she is able to transfer the disease organisms upon her abdomen. Yet there are far more significant meanings to the procedure.

First, the presence of infection at once condemns, in my mind, the worth of the queen heading that colony, especially if the disease seems to have taken a firm grip.

Second, from experience, as is shown above, the shaking treatment does not appear to promote the efficiency of the queen. On the contrary, be it the abrupt stoppage of egg-laying, the rough handling in the shaking process, or the confinement, or whatnot, nearly all queens appear to be impaired, lose their prolificness, become "slow to build up," following the shaking treatment.

Third, on general principles new vigor may be induced in a colony by introducing a strong young queen.

Fourth, while there may be some uncertainty as to the transmissibility of the organisms of American foul brood, either in the egg or in the depositing of the egg, the facts of experience show that reoccurrence of this disease, after a most painstaking method of treatment as usually recommended, is accompanied by the old queen from the formerly diseased colony.

SWARM PREVENTION IN COMB-HONEY APIARIES

BY C. F. BENDER

I have run two outyards for comb honey for eight years, and expect to continue. In April the bees which have been wintered at home in the cellar are returned to the outyards. The main reason for returning them so early is to catch the honey from dande-

lion and fruit bloom, which helps to build up the colonies for the clover flow. Another reason is that the hives are less populous at this time, so there is less danger of smothering bees in moving.

The only difficulty in running out-apiaries

for comb honey is the prevention of swarming. All queens are clipped at the beginning of the season. When the flow from clover begins, we go thru all colonies every ten days, destroying queen-cells wherever they are started. A record is kept on the hive-cover, and when cells are started the second time in any hive they are destroyed and the queen removed also. Ten days later the queen-cells are destroyed again and a young queen is given in a candied cage.

I have never succeeded in entirely preventing swarms; but by careful work they may be reduced to about two per cent. As I do not always do my work carefully, about five per cent swarm and get away. A part of the loss is caused by taking chances, when the few swarms saved would not pay for the labor of going thru every hive. A part of it also comes from the natural contrariness of some bees. Some colonies will supersede their queen and swarm earlier than I expected, tho I aim to prevent this by having young queens in all the hives at the outyards. Some colonies may swarm at the end of the flow, but the loss is then small, and is, perhaps, balanced by the young queen, which is reared free of charge.

Twice I have had a colony swarm without a sign of queen, queen-cell, or brood in the hive, as far as the closest search could discover. They had been held back, when they were determined to swarm, by removing the queen, killing all queen-cells nine days later, and again killing cells on the fourteenth day. They swarmed promptly when clipped queens were given them, sulked for a week after the queens were taken away, then

swarmed without queens. My guess is that they had laying workers, tho no brood of any kind was found in the hive. Both swarms hung in cluster until they died from exposure, without either leaving or returning to the hive. Such cases are very rare.

Ninety-five per cent of the colonies may be kept from swarming by the method outlined above. The queens given should always be clipped before caging. Rarely a colony will sulk under this treatment, cluster out, and refuse to work. In such cases I usually shake them on combs or full sheets, giving a queen at the same time.

In the matter of swarming, there is a difference in seasons that is not accounted for by the difference in the honey-flow. In 1913 I got a heavy crop with little labor. Not one colony in ten even started cells. Last year, with a smaller yield, the bees swarmed from dandelion until frost, even coming out in the rain. Taking seasons as they come, 150 colonies will keep one man busy if all are run for comb honey on the non-swarming plan.

In running outyards after this method, several palliatives may be used that will save much labor. Large entrances should be given, and plenty of super room. Ten-frame hives swarm a little less than eight-frame, but are not so handy for moving. Young queens reared the previous fall will prevent much of the swarming. Dr. Miller tells us that queens of the present season's rearing will not swarm for him. They sometimes swarm here on a fall flow, but not usually.

Newman, Ill.

POSSIBILITIES ALONG THE ST. JOHN'S RIVER, FLORIDA

BY F. M. BALDWIN

Drawn by that tie that so strongly binds the members of our fraternity, I went yesterday, in response to Mr. C. H. Clute's repeated invitations, to Sanford, Fla. I found the flora and conditions so attractive that I cannot resist the desire to tell of what I saw.

Early bloom fills the hives with bees and brood. The first week in March finds them ready for orange, wild cherry, oak, and elder. Before the citrus bloom can close, gallberry, to judge by the indications, will be yielding nectar, and then will come saw palmetto overlapping that flow. There are many acres of all the above within reach of the yard we examined.

Mexican clover, ditney, bay, cabbage

palmetto, and linn are also on every side. Some of these should give a summer flow, even tho the most of them fail. Any two or even one of them would be profitable. From the river dock we could see large stretches of low lands that will be later filled with smartweed and wild sunflower. The variety of goldenrod that is abundant in the Manatee country is much in evidence. In the swamps that are near at hand is a different variety, a much better yielder of nectar. From it the Rev. Mr. Blaisdale used to get a very heavy crop of fall honey in the Apopka Swamp. The latitude and physical conditions are the same at Sanford. One can see no reason why there should be a difference in output.

Much has been written along the line of any place being good enough for bees—the roof of a store building in a city or a back yard in a town. There is much on that side of it; but is it not more desirable to find the finest locations, and get all we can out of them? If there is in one's section a place that can be reached without too much cost where the returns ought to be better, let's be hunting it up. Why not? Florida has a lot of poor bee pasture, and some that is good. Then we have a little that is extra good. Is that not the case in other states also? Why not recognize it, and take advantage of it? At any rate, that is why I am writing about the things I saw yesterday. I hope I'll at least set some one to thinking.

The problem at Sanford is the same that it is in any field. Not all the best flora can be reached from any one spot. Can one better conditions by trying to reach different points at different stages of the honey-flow? I could conceive a place where there would be a big flow from white clover, but little fruit bloom upon which to build up and get ready for it. In that case would it be possible to find a location near by that would combine fruit bloom and clover? I got a fine yield of white honey of the very best quality from clover in western Illinois in 1886. A dry spell in July put an end to it. But it was followed by a fine crop of golden honey from Spanish needle in Au-

gust. Many who were not far away went out of business for that year when the dry spell struck them in July. If they had been on the job they would have been making provisions to share in the August flow. Last summer I moved my bees from Palmetto to Terra Ceia Island. I wanted the flow from black mangrove, and got it. The move much more than paid for itself. If the bees had stayed at their spring location I would have lost this.

The fine flora of the St. John's basin is not all accessible from any one location. Mr. Clute has bought a boat with which to practice migratory beekeeping, but he does not expect to have to move more than a few miles at any one time. For instance, the yard that we examined yesterday is not near willow from which usually a super can be gathered in January and February. The idea is to move to the willow early in the season, build up, and gather surplus. As soon as the oranges begin to show, take the yard and its denizens to a good grove section. If gallberry and saw palmetto are plentiful in that neighborhood, let the hives alone until smartweed and wild sunflower make it clear that another move is in order. This may not pay. It may cost more than it comes to. But it now looks good to me, and I am glad Mr. Clute is about to try it out.

Wildwood, Fla.

INTRODUCING LAYING QUEENS IN A QUEEN-CELL

BY KENNETH HAWKINS

Make the colony queenless toward evening, preferably giving the bees a little time to know they are without a queen. Make an artificial queen-cell as in "Scientific Queen-rearing," by Doolittle, but make it half an inch longer than an ordinary queen, with quite heavy side walls. After dipping the last time, cut off the point with a sharp knife and dip once more, leaving a thin point. Place the queen in this head first, and pinch the cell tightly shut behind her, and staple on a frame in the center of the cluster of the colony previously made queenless. Close the hive and leave it alone for 24 hours. Queens laying before being put into the cell will continue that night. Mated queens from the mails and virgins will invariably be successfully introduced. It has been suggested that the queen might suffocate before getting out. Some of my losses not otherwise explainable might have been due to that. I advise always pricking

a few holes in the side walls of the cell with a pin.

Successful introduction of queens depends not at all on odor, but entirely on the attitude of the queen toward the bees, and not *vice versa*. That explains the Simmons fasting method, and probably the Miller smoke method, which frightens both bees and queen alike; and only when they recover simultaneously does the latter method work. I have not experimented enough to know my real percentage of failure.

Plainfield, Ill.

[Plans for introducing queens are legion. We shall have to give our correspondent credit, however, for having proposed a method that is at least unique. At first we feared that the queen might suffocate or starve before being released by the bees, but the pin-holes doubtless will overcome the latter danger.—ED.]

Heads of Grain from Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

Uncle Andy Sweetclover says these loafers that hang on the outside of the hive when honey is comin' in remind him of a colony he once bought from a stranger. Smoke wouldn't budge them. They seemed to like it. Come to find out, the bees had come from Pittsburg.

THE HUMMING OF BEES.

BY GRACE ALLEN

When the white cherry bloom with its breath
of perfume

Made fairyland here in the tree,
How the bees all would come and hover and
hum

In riotous ecstasy!
And then when I heard, I was stirred—was
stirred

By the mood that eternally seems,
In blossoming trees that are haunted by bees,
To open the doors of dreams,
The bonnie bright doors of dreams.

But now it has died, the tree of my pride—
Its worn boughs are ugly and dead;
The spring, too, has gone and the midsum-
mer dawn,

Half-clouded, hangs hot overhead.
But the cherry-trees die and Aprils drift by,
And shadows come blurring the gleams,
Yet forever to me shall the hum of a bee
Swing open the doors of dreams,
The bonnie bright doors of dreams.

What in the World was She Doing?

A few days ago, while looking thru a nucleus I happened to be just in time to see the queen push the cap of the cell open and look out for about a second, when she went back again. I lifted the cap of the cell, and she came out. I watched her closely to see what she would do, and was greatly surprised to see her put her abdomen into a worker cell as far as it would go, and keep it there for a few seconds, just as a laying queen would do. When she came out I looked closely into the cell, but could see no sign of anything. Next day I looked at that hive again; and after looking over the combs several times without seeing the queen I was about to close the hive when I saw the tip of a bee's abdomen sticking out of a worker-cell. But there was something unusual about it, so I touched it with my finger; and, after a great struggle, out came the queen. But she did not stay out long, for she just walked a few inches away and crawled into another cell in which she stayed until I got tired of waiting (about 15 minutes). I again touched her, and again she laboriously backed out, but only to go into another cell. As she seemed determined to stay there, I let her stop. I might say that there was absolutely no honey in any of those cells, being cells from which bees had just hatched. And they were deep cells, too, as only about $\frac{1}{8}$ of an inch of the queen's abdomen was protruding. Do you think that she was sleeping? and what do you think she was doing the day before?

CAPEWEED HONEY, BUT NOT CAPEWEED POLLEN.

After reading *Stray Straws* for Oct. 15 I thought the following, regarding bees visiting the same kind of flowers on the same trip would be of interest. This season, fully half of the bees working on capeweed, which yields light-yellow pollen in large quantities, had a full load of bright-red pollen. The bees, which were getting honey from the capeweed, were, in most cases, well covered in the yellow pollen. Evidently the red pollen was of a better quality, as very few bees had loads of the yellow pollen.

Douglas D. Brearley.

Subiaco, West Australia, Dec. 10.

[Dr. Miller replies:]

This is interesting, and helps answer a question that has puzzled me no little, and no doubt has puzzled others. When one is looking for a queen it sometimes happens that she cannot be found, no matter how carefully one looks over the combs, even for the second time. When that happens, experienced beekeepers well know that she is not likely to be found, no matter how many times one looks over the combs, and the wise thing is to close the hive until an hour or

more later, or the next day, when, most likely, she will be found very readily.

The puzzle has been to know where the queen was that she could not be found. Of course, if the bees were unduly stirred up and running, she might be on the side or bottom of the hive; but in many cases where the bees have remained in perfect quietude the queen has remained invisible. The only guess I could make was that she was hidden; but where? Sometimes she is hidden under the bees, the queen being close to the comb; but a light touch of the fingers upon any such mass of bees easily discovers whether she is there or not.

The only guess left then was that she was hidden in a cell; but it was only a guess, and I never had any proof that it was the right guess. Mr. Brearly now furnishes what seems to be quite satisfactory proof. To be sure, this was a virgin queen, but why should not a laying queen act the same way?

What was that queen doing in the cell? She might possibly be merely hiding because frightened; but a queen as young as she was is not easily frightened, and is generally very easily found, altho when a few days older she is more shy than a laying queen. It is more likely she was resting, and, in the case of the longer stay, very possibly sleeping. A queen sleeps as well as other folks, doesn't she? She remained in the cell 15 minutes. It would be interesting to know how much longer she would have remained if she had not been disturbed.

What was she doing the day before, when she went thru the motions of laying, but of course without laying? I don't know; possibly, as happens in other cases with the very young, going thru motions that can mean nothing, but pre-glimpsing what they will do later on.

Mr. Brearly's observations with regard to pollen is a bit puzzling. Bees were working on capeweed, and half of them were carrying loads of pollen obtained from some other flower. We are not told anything about the number of bees working on capeweed, nor whether it was yielding honey largely. If there was something of a dearth, then it was not so strange that the bees should get honey from one source and pollen from another on the same trip. If a considerable proportion of the bees were working on capeweed, and that plant was yielding well, then it was a remarkable thing that they should get pollen from another source.

Marengo, Ill. C. C. Miller.

Can a Bee Candy be Made that will be Suitable both for a Moist and a Dry Climate?

I am situated on a promontory 84 feet above the Atlantic where the humidity at times is excessive; and, tho an amateur in bee culture, I think I have discovered something that may interest you.

Last fall I put away in an expensive and well-considered apiary 11 stands of bees; and as three of them did not appear to have such

abundance of honey needed to carry them thru the long and severe winter here as recommended in the books, I purchased a number of pies of "bee candy" and placed one in each of the three lightest hives, setting each pie on one end of the frames in each hive.

In the spring it was found that only these three hives had perished; and on opening them it was found that most of the combs in the middle of the frames were crushed and apparently melted, and all the bees dead, and I could not understand it.

Today is an exceedingly humid day, and I find that the pies of "bee candy" left over have melted into very thin syrup, and dissolved the pie-crust, so that the liquid, almost as thin as water, has all run out, so I am satisfied that that is what killed my bees.

Would it not be possible to make a candy that will not dissolve in the extremest humidity by testing it during manufacture? Gloucester, Mass. Anson Mills.

[The conditions referred to so far as humidity is concerned are rather extraordinary. It would be very difficult to make a bee candy that would stand this kind of condition, and yet one which would not be too hard and dry in an ordinary climate. It is difficult to make a candy that would be moist in a hot dry climate and not be too soft for your conditions. In fact, we may say it is impossible to meet both conditions in one candy.]

We doubt very much, whether, with the amount of moisture that you have, any candy could be made that would hold its consistency unless the ordinary bee-cage candy is used, and even that should be put in a metal or porcelain dish, right side up, and not upside down. Our belief is that you had better rely upon sugar syrup made thick or combs of sealed stores.—Ed.]

Clipping the Queen's Wing without Picking Her Up.

With some, clipping queens seems to be a job that causes some nervousness. I have a plan which I have never seen described. I find the queen, and, with the comb flat upon my knees, I take a small pair of spring tweezers, such as jewelers use, and catch her by one wing, and pull just hard enough to hold her without lifting her off from the comb, and with a pair of scissors in my right hand I snip off the wing which I am holding. By this method one doesn't get nervous, or at least I don't, because it isn't necessary to handle the queen, and she doesn't get scented from one's fingers. I have clipped about 75 queens this summer, and haven't lost one, which is pretty fair for a beginner.

SHE FAINTED AWAY.

I had a curious time with one queen, however. Just as I cut her wing off she fell over on her side, just as tho she had fainted, and lay there quivering. The worker bees rushed up to her and began to nose her over.

I thought to myself, "There is my first dead queen." She lay there for about a minute, then I took my tweezers and gave her a poke, and she immediately got up on her feet and began running around over the comb as if nothing had happened. I went into the hive about a week after, and she was laying all right. This seems to indicate that cutting a wing off does give the queen more or less of a shock. I have always thought that it does.

PLACE END-SPACING STAPLES LOW.

In lifting a frame out of the hive one has to be very careful that it doesn't bump against the end of the hive, and in so doing crush some of the bees. I have hurt a good many that way, and it made me feel bad to see the poor little fellows crawling around all humped up as tho they were in great pain; so, instead of putting the spacing-staples just below the top-bar, I put them clear to the bottom of the frame. With it down there one can take out a frame without hurting a bee, and not have to use any precaution either. Of course if one wished he could put in four staples—two above and two below.

Wallowa, Ore.

B. R. Curtiss.

[We doubt whether it is a shock to the queen to have her wing clipped. So many of them go on their way, unconcernedly as tho nothing had happened that it seems hardly possible that any queen could feel any shock. Queens are sensitive, "highly strung" creatures. On two occasions we have known queens to double up in that peculiar way merely because they were picked up. It seems to be the result of fright. A number have referred to it as "cramps."]

No less a beekeeper than W. L. Coggs shall advocates placing the end-spacing staple low on the end-bar.—Ed.]

Boosting the Cell-builders.

On page 613, July 15, the editor says, "Make colony queenless for six days before giving freshly grafted cells." Suppose the following is given a trial.

As soon as the "cell-starting" colony refuses to do as good work as may be expected with freshly grafted cells, make another colony queenless and broodless, giving all brood to the colony that has been used as a cell-starter. Shake about half the bees from this colony, No. 1, in front of the hive; then shake the queen and bees from No. 2 from all frames in front of same hive. You can then shake the rest of the bees from No. 2 in front of the same hive, and allow the queen from colony No. 2 and bees from colony No. 1 to go into the hive together. The fact that the bees that have been queenless for some time find a hive of brood when they expected nothing but frames of honey causes them to take most kindly to the changed conditions. I have never lost a queen this way, even with fertile workers in the hive.

I usually make this change about every

ten days, and about the sixth day I shake a few frames of bees, about three to a colony starting cells. In this way the colonies are not run down.

Some days ago I had one of these queenless and broodless colonies start 102 cells in one day. A colony that has been without a queen and brood for about three hours will do better work than one that has been queenless for six days. At any rate, give it a trial.

Spring Hill, Tenn.

Ben G. Davis.

An Apparatus to Destroy Drones.

I am sending you a drawing which represents a drone-trap. This will serve to prevent swarming, provided the wings of the queen have been clipped.

No. 1 is a perforated zinc sheet, allowing the workers to pass thru, but not the drones, which are thus obliged to pass up to the pyramid, and on thru the tube 3 and to the tank 4, which latter contains kerosene. Inasmuch as the passage from No. 3 to the tank is made of perforated zinc, the workers have time to escape, and the queen, whose wings have been clipped, cannot pass up thru pyramid 2. The walls of the latter should be of glass on the inside and tin on the outside, to avoid the light, while escape No. 3 should be of sheet zinc, perforated.

Timote, Argentina. Francisco Peroy.

When is a Select Queen Not a Select Queen?

I am interested in Arthur Williams' article on page 548, July 1. I wish the readers of Gleanings would express themselves in regard to the advertising of untested queens.

Untested queens should be sold as untested, and there should not be two grades of untested. One of the poorest-looking untested queens I ever received proved to be one of the best. Did some one say the selection was for color only? The advertisements do not say what they are selected for.

Queen-breeders can grade tested queens; but what do they know about the untested?

I shall favor those listing one grade of untested queens altho, of course, some of the best breeders list two grades of untested.

Antioch, Cal., July 5. Geo. W. Moore.

[Whether there is any merit in extra size, it is a fact that most beekeepers favor large queens. Why should not a large fine-appearing untested queen be marked "select"?

We agree that there is far too much ambiguity in the so-called grades of queens. The term "golden," for instance, may mean a bright-yellow three-banded bee, or it may mean a leather-colored four or five banded bee. Can there not be greater standardization? We should be glad to hear from our readers.—Ed.]

How to Disinfect Supers that have been over Hives Containing Foul Brood.

Please let me know the best thing to do in the matter of about eleven supers which I placed over some hives containing foul brood, and which I removed a short time afterward. Could I dip these supers in salicylic acid or hot water and use them again? or would it be better to burn them up?

Claude W. Wilson.

Pardstown, Ky.

[The eleven supers which have been placed over hives containing foul brood may or may not have the germs of disease; but it is always wise to err on the safe side, and so we would recommend scorching them out with a common painter's torch. All that is necessary is to blacken the inside of the supers.

Painting the insides with salicylic acid, or putting them in boiling water, may or may not be effective—probably not; but it is a great deal safer and better to use the actual flame itself. If you have no painter's torch you can place a little straw in each super, ignite it, and stir it around so that the flame will reach all sides of the super. Then dash on a little water to quench the flame.—Ed.]

Queens Whose Eggs Fail to Hatch.

I had a young queen this spring that commenced laying when 12 days old. I was busy with other work, and did not look in that hive again for more than ten days, and at that time there were still eggs, no larvæ nor young bees. I thought then that perhaps I was mistaken at first about the eggs, so I waited three more days and still eggs and no larvæ. So I waited three more days, and looked thru all the literature I had, but could not find anything like it. I asked men who had kept bees for twenty years, and they said they never heard of a thing like it, and she was as big and fine looking a queen as any one ever saw. Now, can you tell me why that queen's eggs did not hatch?

Glasgow, Ky.

Joel O. Garman.

[There is, perhaps, one queen in ten thousand whose eggs will fail to hatch. We have had one or two in all our experience,

and we have a number of reports of them, but they are by no means common. The only thing to be done with a queen of that kind is to kill her and replace her with another queen. Why these queens fail to lay we do not know unless there was something wrong with their development in the first place. There is nothing particularly unusual about the queen laying when twelve days old.—Ed.]

How to Mark Sections and Cases to Comply with the Federal Law.

I take the liberty to address you in regard to the net-weight law on honey. In the season of 1915 I marked each box as the law requires, and then I marked the actual net weight on each case, not including the weight of wood and carton. This made $2\frac{1}{4}$ lbs. less weight on each case than I had usually given. I sent to a firm that had done a satisfactory business for me for 20 years. I fully described the net-weight law, and told the firm how I had weighed it, etc. They evidently sold the honey by the pound instead of the case, charging the usual price per pound, which left $2\frac{1}{4}$ lbs. short on each case. A neighbor of mine marked his sections the same as I, but put the weight on the cases as usual—that is, wood and cartons in.

It seems to me the weight on the cases should be the net weight of the honey; but that belief made me lose over one hundred dollars on my sales last year. Which is customary, and which is right?

Shoreham, Vt.

R. H. Holmes.

[The question of just what is necessary to comply properly with the provisions of the net-weight law is still a matter of uncertainty to a good many beekeepers, and there are many who, in complying with the requirements of the law as understood by them, feel that they have been placed at some disadvantage like yourself, having neighbors shipping to some market which pays no attention to the requirements of the law. Yet ignorance or carelessness will not exempt a person from the penalty. Our advice has been to meet the requirements as nearly as possible. In states not having the net-weight law, it is not necessary to stamp honey in any way unless it is intended for interstate shipments; and under these conditions honey sold in the local market is exempt from the requirements of the law in regard to marking; but when sent out of the state, then it comes under the provision of the net-weight law, and a beekeeper selling his honey locally has no assurance of the honey being sold within the limits of his own state.

We pack the honey in cases containing sections of uniform weight, marking the sections with the minimum weight as "Net weight not less than 12 oz." The same stamp or mark should appear on the outside of the case. When the law went into effect, and honey was sold by net weight, the price

advanced 1 ct. per lb. to cover the weight of the section lost by the beekeeper, so really he is getting the same price as before. We do not believe it has been customary for beekeepers as a rule to sell their honey by weight, including the weight of carton and section, as we infer you had been previous to the enactment of the net-weight law; so in reality you will lose only 1½ lbs. per case.

So long as the law stands, there is only one way left open, and that is to comply with its requirements, regardless of what others may do.—Ed.]

Bees Drifting into the Wrong Hive.

I have my bees arranged in two rows at right angles to each other in my backyard, a space of about 60 feet square, one row facing the south and the other facing the west. The hive nearest the angle facing the west, I have noticed for the past month, shows at all times a lot of dead and dying bees in front, with fighting bees on the entrance-board. This seems to go on when the yard is brisk with honey-gathering. The colony has a good queen, and is full of brood in healthy condition. The hive is now light in bees, and has gathered but little increase in honey.

My solution of the matter was that the location of the hive was such that bees from other hives entered it by mistake, until this hive has really worn itself out trying to drive out the innocent invaders. I have now moved it away, and today it seems quiet, but so weak in bees that all but few seem busy inside attending to the brood, with just a few coming and going.

Youngstown, O. Dr. C. E. Blanchard.

[Very often a colony will ball a queen for no apparent reason, and the only thing to do is to cage the queen and let them try it over again.

Your solution of the trouble of the one colony nearest to the angle is correct. The bees made a mistake; and, during the height of the honey-flow, the alien bees were not welcome, and, of course, were killed one after another. The probabilities are that the bees in the angle hive drifted to the other colonies, resulting in a constant decrease in the strength of the hives. You did the right thing in moving the hive to another location.—Ed.]

Polk County (Iowa) Field Meeting.

The Polk County Beekeepers' Association held its third annual field meet at Union Park, Des Moines, on Friday, July 28.

The attendance was not large, partly because it was intensely hot, and partly because the meeting had not been sufficiently advertised. All present joined heartily in the picnic spirit and dinner and were pleased and profited by the program.

Good talks were given by A. L. Clinite, of the Des Moines School Board; by Hamlin B. Miller, of Marshalltown, and by Editor Jarnagan, of the Iowa Farmer. A splendid

reading was given by Miss Crow, of the Des Moines schools, and folk dances by children. J. W. Schlenker, of Ankeny, gave demonstrations in handling bees.

Following the program a business session was held and officers elected for the coming year. Dr. C. L. Wright, of Des Moines, is the new president. The doctor is a live one, and great things are expected for next year's meeting.

Charles E. Dustman.

A 7—30 Increase and a Ton of Honey.

We had a very late and cold spring here. The main honey-flow from white clover started June 25, and we got our first new swarm June 28. To date (July 27) this swarm has produced 84 finished sections.

There has been a letup of a few days in the honey-flow, but it has started big again today, and the yard once more is a perfect roar.

We started a year ago last spring with seven colonies. We now have thirty. We got 800 pounds of good honey last year, and we expect a ton this year.

We live on the river, and there is much timber here (basswood), and acres of waste land. Our principal honey-plants are white clover, alsike, basswood, goldenrod, hearts-ease, and buckwheat. My wife is also learning the business.

We started all of our new swarms this year on full sheets of wired foundation. We also use full sheets in sections. We find that it pays us big to do this. We do all of our hauling with a "tin flea" (Ford). We went to a neighboring city, 80 miles away, the other day with a load of honey, and got there for breakfast, sold our honey, and were back for dinner.

I must close and go to the woods and find the source of this honey-flow. I think it is basswood.

Osage, Ia.

G. D. Nelson.

But the Queen Comes from a Worker Egg.

When Mr. Doolittle, p. 474, June 15, will remember that the female bees or queens, mothers of the worker bee, are not the product of a special egg, but the product of a worker larva, made fertile by the special work of the nurse bees, then he will understand how this worker larva made fertile "can transmit to a greater or less degree its habits, faculties, peculiarities, and desires to its progeny of worker bees."

Luis R. Casablanca.

Bayamón, Porto Rico.

A Correction.

In my article, page 611, July 15, I noticed that I made it say five frames in each brood-chamber. It should be nine frames, both the full depth and shallow brood-chambers.

Stanton, N. J.

L. K. Cole.

[We find that the mistake is ours. The original copy read nine frames.—Ed.]

Safe after Nine Years?

I have about 25 boxes which can be used to house bees. They had foul brood about nine years ago. Is this foul brood still in them? How can it be stamped out?

Watertown, Wis. Cornelius Trachte.

[There are two types of foul brood, called the American and European. We assume from what you say your experience was with American foul brood as this formerly was called merely foul brood.

In case of American foul brood it would not be best to attempt to use the combs again. However, we do not suppose this is what you have in mind. The hives are all right to use, but even tho it has been nine years we should take the precaution of scorching out the inner walls with burning straw or a gasoline blow-torch. This would take but little time and it is worth something to be on the safe side. Safety first! Do not char the wood deeply, simply scorch well, and they will be safe.—Ed.]

And Swarm They Did.

I have just been having an epidemic of swarming the like of which I have never seen at this season. All during the month of June there was just flow enough to keep the colonies breeding up. I did everything a man could do to prevent swarming, but swarm they would and swarm they did. And such swarms I never saw before.

Recently, after a swarm had issued I went thru the old colony for queen-cells. I found and cut out 48. One comb had 20 cells on it, two bunches in the middle of five each.

TWO QUEENS IN ONE CELL.

Later we found one cell with two well-developed queens in it in different stages of development. One would have hatched in a day or two, the other in about a week. This cell was a little larger than usual—wider at the base. There was no wax partition between the two queens—only a tin film or skin. The cell was built on the lower edge of the comb.

S. A. Fuller.

Helena, Ark., July 8.

Does the Law Prevent Moving Bees?

I have 12 colonies of bees out on the farm, and am working here on the railroad. I should like to move the bees here in town. Is there any law in Indiana to prohibit it?

Huntington, Ind.

Carl Christ.

[There will be no difficulty about moving the bees provided they are at least a mile and a half from the new location where you propose placing them. If you do not sell the bees to any one else there will be no law against your doing this; but if you propose selling them you probably would have to have them inspected by some authorized inspector before such sale could be made. In that case write to State Inspector of Apiaries, Indianapolis.—Ed.]

Good for Sore Eyes.

It's a novel sight, and very gratifying, too, to see bees active on red clover as they are here now. This is owing, no doubt, to the effect of the terrific heat and drouth of the last two weeks of July that so pinched and dwarfed the bloom that the bees can reach the nectar so abundantly contained in red clover. Abundant rains within the last two days have broken the severe drouth, and with more moisture in prospect it looks as if white clover and alsike would soon revive with the usual return of nectar to the late bloom.

Manawa, Wis.

E. E. Colien.

[We assume that the red clover referred to here is the second crop. The second growth is usually somewhat dwarfed, so to speak, and the corolla tubes likewise are a little shorter.—Ed.]

Cabinet Scraper for Propolis.

In the issue of April 1, 1916, C. Mitchell relates some experiences with various utensils for scraping frames, etc. Permit me to recommend an article intended specially for scraping, and that is the old-time cabinet-scraper—simply a piece of flat sheet steel about 3 x 5 inches in dimensions, and varying in thickness somewhat. It costs ten cents, or probably now fifteen, at any well-stocked hardware store. The cabinet-scraper is sharpened by setting it in a vise and then drawfiling the edges with a single-cut file. Any mechanic will explain drawfiling. It is a very effective tool for many purposes.

Hoboken, N. J.

B. Keep.

O You Yellow-jackets!

In the evening, when the bees come in heavily loaded, I have observed yellow-jackets pouncing down on them as they alight at the entrance, bite them in two at the thorax, and fly off with the abdomen, which contains the honey-sac, while the front part of the bee, the head and thorax, containing the legs and wings, run around on the front of the hive. I have sometimes seen them go in.

I have been unsuccessful in catching these yellow-jackets, and do not know what to do to get rid of them. I am located in the hills, and the brush is full of jackets.

A Subscriber.

Then They Don't have a Chance.

I think I have found a condition wherein the smoke method of introducing queens will not work. It is when the bees are in a cell-building mood—for instance, when they are trying to supersede their queen or when swarming from any cause. With me they will build cells and reject the new queen if they have anything to build them over. I take away all unsealed brood and the old queen and wait twenty-four hours and then introduce.

Grosvenordale, Ct.

Ernest Ryant.

OUR HOMES

Editor

Without me ye can do nothing.—JOHN 15:5.

Behold, I stand at the door and knock; if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me.—REV. 3:20.

A friend of many years has just sent me the tract below. Read it, and see what you think of it.

CONVERSATIONS WITH CHRIST.

If I were asked what is the thing which the devil, the world, and the flesh try hardest to prevent Christians from getting, I should reply, "Conversations with Christ." I say this from my own experience, and from observations of all the Christians I have ever known. A quiet, unhurried speaking to Jesus alone and hearing his replies—this is what every Christian needs every day, and what many get only once a month—or more seldom still—or never.

WHEN DID YOU LAST SO TALK WITH CHRIST?

Stop and answer this question to yourself before you read on.

It is so easy to go to services and listen to prayers and to join in them. It is so easy to sing or pray to him with others, or to think we are doing so because we feel refreshed and helped by it. But what if it should turn out that it was a mistake of ours to imagine that we were actually conversing personally with him at those times; and that we were really talking and singing for other people and ourselves to hear? I tremble for people who pray only in churches or at prayer-meetings, or with other Christians present.

Communion services are very blessed helps and means of grace, but they are not necessarily conversations with Christ; nor is preaching or teaching or working for him. You may be a most religious person—busy all day about God's matters; you may give time and money and thought to him, and yet you may never converse with him. And the danger is, if you do not converse alone with him each day, you will certainly get on the wrong road and get thoroly wrong altogether, and that when you and he meet you will see all your work crumble away, and yourself naked—suddenly waked up to the fact that you and your Savior are strangers to each other. It will be a horrible surprise to you that nothing should remain of all the work on which you spent your life, the solemn words, "Without me ye can do nothing," having been forgotten by you.

He meant that you should have talked to him continually about everything you did, and everything you cared about, and should have been always conscious of his sympathy and oversight and working. But instead of that you talked only to men and women, and made shift with their sympathy, advice, and help. He meant you to ask his counsel about that money trouble. He would have arranged it all; but you only asked your lawyer, and it turned out badly. He meant you to tell him your anxieties about your son, and he would have ended them; but you only consulted your friend, and matters grew worse. He meant you to ask him for light about that doctrine which you could not understand; but you went to books to get it explained, and you became more uncertain than before. He would have satisfied you. He meant you to confess to him that secret sin, and he would have forgiven you and cleansed you; but you confessed it to your clergyman or minister, and it torments you to this hour. He meant you to commit to him that painful illness, and he would have been your physician and healed you; but you trusted your family doctor only, and got no relief. He meant you to ask him how much

money you were to give away; but you settled that yourself, and settled it wrong. He would have been your counsellor about the profession you chose, the situation you accepted, the servant you engaged, the books you read, the friendships you formed; but you chose other counsellors, or did after your own choosing, and all has been failure.

An hour of conversation with him each day will make all the difference.

May the Holy Spirit strike the scales from your eyes now, and may you arise from your enchantment, and take Christ *now* for your personal friend and counsellor!

One there is above all others;

Oh, how he loves!

His is love beyond a brother's—

Oh, how he loves!

With his precious blood he bought us,

In the wilderness he sought us,

To his fold he safely brought us;

Oh, how he loves!

Best of blessings he'll provide us,

Naught but good shall e'er betide us,

Safe to glory he will guide us,

Oh, how he loves!

And will not we take such an almighty lover, Savior, and friend, *wholly* as our counsellor and guide while here below—his own chosen ones, soon to be with him and like him in the glory above?

This little tract has startled me. I have read it several times, and the more I read it the more I am impressed with its truth. In reply to the question which is printed in small capitals, "When did you last so talk with Christ?" the answer to this question will make this Home paper. Those of you who have read Our Homes for years past will remember that I have several times—perhaps not very lately—spoken about getting off by myself where I can pray aloud. When greatly discouraged in years past I have sometimes gone off in a field of tall growing corn; and I like to pray when walking along.

In answer to the above, the last time I so prayed was when I paid a visit to the old cabin in the woods, July 13. I reached Traverse City about six in the evening; but I felt as if I must spend the night out in the country up near that old cabin, instead of in a city hotel.

As we approached Traverse City the baggageman on the train said it would cost me \$5.00 to send me up near the old Bingham dock on Grand Traverse Bay by automobile. When I suggested that I was equal to the task of walking eight miles instead of investing so much money, he insisted it was *eighteen* miles, and then came down to \$2.50; but when I agreed to pay so much a mile for all over eight miles, he came down to \$2.00, and finally agreed on \$1.50.

I stopped with the nearest neighbor; but before I went to sleep I pushed my way thru the dense undergrowth and explored

all around the cabin, and next morning I was back there again bright and early. It was interesting to see how my various fruits had stood the years of neglect. A Yellow Transparent apple-tree had made an enormous growth, and was just bending with beautiful apples soon to be ripe. There were also some beautiful sour cherries; but cherries are so plentiful in that region that no one seems to care for the cherries out in the woods. Two mulberry-trees were so laden with luscious fruit, just beginning to ripen, that their willowy limbs lay resting on the ground in the deep grass.* My currant-bushes also had stood neglect pretty well; and three Paragon chestnut-trees gave promise of quite a crop of nuts.

It was going to be a busy day with me, and so I had to bid adieu to the old cottage. In leaving I happened to glance my eye back of the house where Mrs. Root and I planted a variety of roses. Back there in the wilderness were roses, almost a wagon-load of them, many of them as large as saucers, "wasting their sweetness on the desert air." As I thought of the pleasant hours we passed there years ago, and as I looked thru the windows of the deserted old cabin and saw still on the walls the photographs of the children, and the other pictures Mrs. Root had fixed up so tastefully in that old wildwood home, it brought back so many memories that I almost felt like crying because I knew I should probably never go back there again to live. Mrs. Root thinks that, at our age, one home in Florida and one in Ohio are enough for us.

As I had planned walking many miles before night, I reluctantly started off. Soon I was in that old lumber road up thru the hills under the dense shade of the maples and other trees. The beauty of the morning scene, and the inspiration of the fresh air away up toward the top of the hill, prompted me to break forth out loud in praise of God. I prayed for many things, and especially that my influence during the busy day that lay before me might be blessed. As I came out of the woods I have now a distinct recollection of a feeling that my prayer was going to be answered.

I have before mentioned that my good old mother used to say something like this: She would tell me what she wanted, and what she expected of me; and then she would end by saying, "Amos, I have been praying over it, and I have had the assurance that my prayer will be answered."

Dear friends, do not think me visionary when I say that I too felt I had "assurance"

* In that same "deep grass" were great luscious strawberries, the remnants of our strawberry patch of years ago.

that the "talk" with the dear Savior as I went up that shady path thru the woods would be answered.* Two years ago I told you of Mrs. Boone, who led the prayer-meeting there in that Bingham church while her baby lay on a pillow on the floor "cooing" to himself. Well, when I got to the top of the hill I found this same Mrs. Boone; and as she smilingly expressed her pleasure at seeing me once more, she pointed thru a window where there were *two* beautiful children instead of one. Mr. Boone was cultivating potatoes on the hillside where he had just made a clearing. I wish the readers of GLEANINGS could have seen him get his horse and cultivator thru the snags and roots, and dark, rich, loamy soil. While we were talking, a bright young boy eyed me curiously. I had not seen him for so many years that I did not know him; but we soon made friends. At the time of my last visit, his mother, Mrs. Wilson, was an invalid; but I found her then looking well and strong, and at work in the garden.

My next call was at the home of her mother-in-law, Mrs. Wilson, who has been superintendent of that Bingham Sunday-school ever since it was started, about fourteen years ago, or almost that. Very soon after I got there she said something like this:

"O Mr. Root! you ought to have got around to the Endeavor prayer-meeting last night. Jimmie Hilbert led the meeting."

* In going from our cabin in the woods to our little church over between the hills we were obliged to climb over one of the tallest hills in that region; and from the summit of this hill there is a magnificent view of Grand Traverse Bay on the east and of Carp Lake on the west. For years past, when going over this hill I have been in the habit of singing "Beulah Land"—that is, if I were not too much out of breath, as we often are when climbing that hill; and it just now occurs to me that the second verse of Beulah Land fits in wonderfully with the sentiment of the tract in this Home paper. Here it is:

The Savior comes and walks with me,
And sweet communion here have we;
He gently leads me with his hand,
For this is heaven's border-land.

CHORUS:

O Beulah land, sweet Beulah land!
As on thy highest mount I stand,
I look away across the sea
Where mansions are prepared for me,
And view the shining glory shore
My heav'n, my home for evermore.

Notice particularly the words "sweet communion," and see how beautifully it comes in, as one stands still on the summit, and pulls in great lungfuls of the air in the Grand Traverse region. Why, it is almost worth a trip to northern Michigan to stand on that great hill and sing with all your might,

As on the highest mount I stand
And look away across the sea.

It may require some stretch of faith to add—

Where mansions are prepared for me;

but to stretch your faith and your lungs also is good for one, both spiritually and physically; and I truly believe it is our privilege even in this world to get a faint glimpse now and then of that "shining shore."

"*Jimmie Hilbert* led the prayer-meeting, did you say?"

She smilingly assured me that it was Jimmie himself. Let me explain a little. Years ago, when I found friend Hilbert up among the hills, there was quite a family of Hilberts. The two youngest, Jimmie and Gladys, were not only the life of the household, but sometimes they kept the household pretty busy in getting them out of the scrapes they got into. There was but little difference in their ages; but they were always off together somewhere. One afternoon Jimmie got lost; and as he was only three or four years old there was quite a stir in the neighborhood until toward night they found him away over the hills curled up in a fence-corner on the grass, sound asleep. He had evidently wandered away, got tired of trying to find his way home, and concluded to "rest up" while the neighbors hunted for him. Jimmie was always inclined to be a little wild and reckless, but still he loved the wildwood and the farm. A few years ago his father got into the "moving-picture business," and he went around from town to town, taking his family with him. But Jimmie got tired, and wanted to go back home. It may not be true; but one of the neighbors said Jimmie got so homesick to get back among the woods and hills that he said that if he had got to stay in the picture business all his life he would kill himself and have it done with.

As Jimmie grew from boyhood to manhood I felt anxious for his future, and had several talks with him. Two years ago his father got a motor truck to carry his fruits and garden stuff to market, and Jimmie soon learned to run that truck with wonderful skill, and seemed to enjoy it. When good Mrs. Wilson told me that wild Jimmie had actually *led the prayer-meeting* I felt that part of my prayer as I walked thru the woods had been answered already. Gladys, that used to be only a baby, full of mischief, was now a bright grown-up woman, or approaching womanhood. She reminded me so much of her sister Alice that I could hardly keep the tears back. When I expressed my pleasure to hear that Jimmie not only attended prayer-meeting, but had led the meeting, she said, "Why, Mr. Root, I too have led the prayer-meeting." I should not have been so much surprised to learn that Gladys led the meeting, because the girls and women folks more naturally gravitate toward prayer-meeting and all religious gatherings; and may God be praised that it is so.

After dinner, Jimmie took a load of cher-

ry-pickers up to the cherry-orchard, and I went along. I told his father I wanted to see the cherry-trees. Yes, that was true; but I also wanted to have a good talk with Jimmie all by himself. Good Mrs. Wilson said that, while they were members of the Endeavor Society, and led the prayer-meeting, neither Jimmie nor Gladys had as yet united with the church. I had got something of a promise from Gladys, and I wanted some sort of pledge from Jimmie. When I told him how glad I should be to know that he was a member of that little Bingham church he finally said something like this:

"Mr. Root, I am not ready to promise you, just now, that I will unite with the Bingham church; but this I will promise: I will say that, whatever happens, I will *stick to God.*"

He gave me his hand on it, and I felt that such a boyish promise as that perhaps meant more, before God as a witness, than a promise to unite with any particular sect or body of Christians. I think of it again and again, and feel glad and happy. "I promise, whatever happens, to stick to God." Dear reader, do you know of any better pledge given by a boy just merging from boyhood into manhood?

By appointment I met at the Hilbert home Mrs. Erna Rorabacher, an older married daughter of the Hilbert family. "Erna," as we always called her, was a little older than Alice. She now lives in Wisconsin. Some time ago I sent her one of my little tracts, "How to be Happy when People Abuse You." I think she wrote to tell me she had just united with the church at Green Bay, Wis.; and when she showed the tract to her pastor he preached a sermon with that tract as a text, and Erna stood at the church door after the services and gave each worshipper one of the tracts. She said to me, "Mr. Root, you will never know, in *this* world, how much good those tracts have done."*

* Friend Hilbert is still a beekeeper; and as I stood before the door my eye caught a glimpse of toward a hundred hives tiered up, most of them two stories high, some three stories, and a few, if I remember correctly, even four stories. When I asked friend Hilbert if we were to understand those four stories were full of honey, he got his smoker and took out comb after comb filled and sealed with beautiful white honey. To see if I could detect the source I took my knife and cut out a mouthful from one of the great white slabs; and I think I never tasted any more luscious honey. It was probably a mixture of clover and wild red raspberry; and, by the way, according to my notion there is no better honey in the world than the raspberry honey of northern Michigan. Friend Hilbert's plan is to leave the honey all on the hive, and do his extracting after the season is over or nearly so. In this way it is most perfectly ripened, and superior, of course, to the unripened, and the job can all be finished up at once. With the present price of sugar, these great heavy slabs of honey are the

Then she added that there was a woman in Traverse City who was so anxious to see me that she almost cried when she learned, two years ago, that I had been in Traverse City and she did not know it; and she sent a special request to have me call. Her reason for wanting to see me is one I have heard so many times that it is almost laughable. She said that, in years gone by, in her early childhood her father kept bees, read GLEANINGS, and thought there was nobody in the world like Mr. Root; and her good husband placed his Buick automobile at my disposal while I waited for the night train. As I was interested in the summer cottages he took me past the beautiful summer homes in the edge of the woods around both points of Grand Traverse Bay. Cottages are scattered all along the shores of the bay. The water is as clear as crystal, and the white sandy bottom makes an ideal place for summer outings. Women and children in light airy clothing go there to pass the hot months.

After a refreshing sleep, even on the cars, I awoke in Detroit, a stranger, as I supposed, in a strange land. Our Homes for August 1st has told you of my finding my good friends the Flowers, and how they took me in their automobile not only to the great Ford establishment but all around the city. Surely I can say with the Psalmist, "Goodness and mercy shall follow me all the days of my life, and I will dwell in the house of the Lord for ever."

Now, with this long wandering-away from this subject of that little tract, let us get back. Was not what I have been telling you an answer to that prayer in the woods, that the dear Savior would bless and guide my footsteps during the two following days?

This talking with Christ as described in the tract is to be where nobody can hear or know anything about it. At such times I do not even want to think of how it would strike the people or what others might say. It is all between you and your unseen Lord and Master. A hypocrite or an unbeliever never prays when he is alone. It would be stupid, and sheer folly. I am ashamed to say that of late years I have not gone off by myself and "talked with Christ," as I did years ago, and I firmly believe I have suffered in consequence. It is mostly when disturbed, and something worries me, that

simplest way of feeding a needy colony. Certainly it is the *simplest*, and may be, all things considered, the *cheapest*. Years ago I decided that a pound of honey in the comb, well ripened and sealed up, was worth a good deal more than a pound of sugar in preparing bees for winter—perhaps twice as much. I should like to know what Dr. Miller thinks about the comparative cost of this manner of feeding.

I feel like going away by myself where I can pray out loud; and such praying almost invariably bears fruit.

After the above was in type I came across the following in the *Sunday School Times*. I give it because it is so much in line with our tract at the head of this Home paper. I think I will put a head on it—

"TALKING WITH GOD."

Recently a lady I know had this experience: She had collected a debt due her, and had put aside the Lord's tenth. She was about to apportion it out to home and foreign missions, when suddenly the question came, "Have you asked God about the disposition of that which belongs to him?" She fell upon her knees and waited a while. Suddenly there came to her mind a person she had not seen in years; in fact, it had been about twenty years since they had been in touch with each other. This person, the daughter of an old minister, left with very limited means, served the Master by putting a baby organ in an old buggy and driving out in the country to play at the meetings of an denomination. The order came, "Send ten dollars to that lady." It was done, and the return mail brought a letter saying, "I was sitting on my little porch when your letter came, and I had just said to my heavenly Father, 'Lord, you know I've promised to go to a meeting, and I want to go and help; but you know I haven't a dollar, and my old buggy can't be mended for less than ten. If you want me to go, please send me the money.' Was it not a case of 'Before ye call, I will answer'?"

TRUE AND FALSE PATRIOTISM.

The following, which I clip and abbreviate from a tract sent me, is, as I understand, by Frederick Lynch, in *Christian Work and Evangelist*. I have given place to it because, almost for the first time, it has come to me that what is called patriotism, or a love for one's country, may be not only a mistake but an instigation of the Devil. Those who claim to be followers of the Lord and Savior Jesus Christ should love all countries as well as their own; and I begin to think that the command "Thou shalt love thy neighbor as thyself" might fittingly—at least at the present time—read, "Thou shalt love other nations as thou dost love thine own nation." When humanity gets up to this view of patriotism, worldwide peace will come. As I take it, Frederick Lynch has been himself a witness of the horrors of the battlefield.

Women are rushing from besieged and burning cities with little babies in their arms, and cold, hungry, tired boys and girls, hardly old enough to walk, trying to keep up. Poverty stares millions in the face—poverty not only during the war, but during long years to come. Thousands of women are to be widows, millions of little children are to be left fatherless. Natural affections are already blotted out, and their place being taken by strange, cruel lusts and passions. The virtue of women will be a free commodity for all soldiers. Drunkenness has already spread thruout these lands in a bad orgy.

The thousands of men we saw howling in all the cities of Europe not men any longer. They had become beasts. The beast could even be seen in their eyes. They howled for only three things—drink, women, and the blood of their brothers. Perhaps there has got to be a wholly new presentation of Christianity before these things can be stopped. Perhaps we have really got to teach what Christ himself taught, namely, that love of all Christians for each other, all men of good will for one another, must transcend race, nationality, and every other bond. We have never dared preach this. He even went further, and said it must transcend *family ties*.

There are exceptions, but in most of us the beast lies just below the surface, and nothing but a regeneration which shall sweep thru men's souls as a wind from heaven can make them clean.

LOVE'S OF ONE'S COUNTRY BEING RIGHT

This whole miserable business has arisen out of a perverted patriotism, a race consciousness raised to the power of madness. It was a Servian "patriot," a devotee of "greater Serbia," who threw a bomb that stirred Austria to revenge. All thru Europe there is this patriotism which makes a god of one's country, and declares there is no other god, which puts love of country above love of one's country *being right*.

"I AM TRYING TO BE A CHRISTIAN WITH ALL MY MIGHT."

On pages 502, 503, June 15, I made mention of E. Whitcomb, of Friend, Nebraska. It would seem that for some reason or other he has not been getting GLEANINGS of late; but I will take pains to see that he gets it from this time on. With this explanation I think our readers will be much interested in the letter below. It is characteristic of Friend Whitcomb:

Brother E. K. Root:—I have been thinking of you quite frequently of late, and wondering if your father, A. I. Root, is yet living; and if so, how he is getting along. When I first started out to be a Christian I was greatly aided by his kindly advice and real helps. I am trying to be a Christian yet with all my might, and am running the newspaper and "monkeying" with the bees in order to help pay expenses. When last we met I think it was down at Dr. Gandy's, investigating his catnip honey. What a sly old mink he was, to be sure! We were able to secure quite a lot of catnip honey ourselves last year, and Mrs. Whitcomb thought the flavor was grand.

Along last winter I noticed an account of your failure in attempting to put a live bee in your mouth without being stung. Mr. Kretchmer once attempted to demonstrate that to me at Chicago, and I pulled the sting from his tongue. In making that illustration a drone is much safer, and it has the same effect with the boys. I am thoroly convinced that the bee is "no respecter of persons." I am in possession of 25 colonies of bees. They stored quite a lot of white-clover honey during June, and swarmed "to beat the band." One could find a swarm hanging on a tree or a bush almost any time.

One swarm alighted on the top of a maple-tree about 30 feet above the ground. This was out of the reach of a swarm-catcher, and I am rather too old to climb any more, so I fixed the hive on the ground and shot the limb off with a 10-gauge shotgun. They came down all right, and were placed in the hive. The weather is very dry now, and the bee business is all shot to pieces with hardly a bloom in sight. Really we are up against it with

the corn crop unless it rains within a very few days. Really God is very good, and I believe he will send the rain in his own good time. Mrs. Whitcomb's health is very poor; but I have not felt so well in ten years as I have this summer. With 100 in the shade almost every day, yet I am standing the hot weather finely. My son James is down on the Rio Grande with the 4th Nebraska National Guard waiting and watching for President Wilson. He has a wife and three children here in Friend, but is too proud to ask for his discharge under the order of the Secretary of War.

Friend, Neb., July 28.

E. WHITCOMB.

THE GOSPEL TRACT MISSION.

For some years I have been more or less acquainted with S. E. Roth, of Woodburn, Oregon, who sends out gospel tracts, etc., free of charge. I clip the following from one of his tracts:

Gospel tracts, leaflets, calendars, and blotters free as the Lord provides the means to print and mail them.

GOSPEL TRACT MISSION,

Rt. 3, Woodburn, Oregon.

The letter below will explain more fully his lifework; and after you read it I hope you may be prompted to send for some of his tracts, not forgetting a few stamps, or something more than stamps, if you feel like it. My opinion is that whatever you may send will be "treasure laid up in heaven," if not exactly here on earth.

Brother A. I. Root:—

Greeting in Jesus' name

I just thought if I told you what we, in great weakness and awkwardness, have been trying to do along the line of distributing the gospel in tract form and otherwise, you would make mention of it in GLEANINGS and cause many of God's dear children to pray for us and assist us otherwise.

God has mercifully allowed us in the past eleven years to distribute from several hundred to 10,000 Gospel Tract Calendars annually, also many thousand (possibly millions) of pages of tracts, leaflets, etc., free of charge.

Last year we sent out about 9000 of those calendars, distributed about 50 copies of the Bible and many testaments, gospels, tracts, etc. Now, we do not want to boast, but thought that, if some of God's faithful children who read GLEANINGS knew what our Gospel Tract Mission stands for, and knew that we are just now in need of your most earnest prayers, it would possibly result in much good both to our humble establishment and to others who are interested in distributing literature. Now remember, dear brother, we are *not* a rich concern—have all of life's necessities, such as what we eat and wear; but above that we have far from a thousand dollars' worth of property in this world's goods; are somewhat in debt, and need funds for printing next year's calendars and sending out Bibles, tracts, etc., for which there is a great demand among the poor in various countries. I have sent out literature to United States, Hawaii, Philippines, and even some to Australia, New Zealand, Africa, etc. Oh the joy and satisfaction to be allowed to help a little in proclaiming Jesus' love! It is beyond our ability to express it.

Now our humble request is this: that you mention in GLEANINGS that we wish the prayers of all of God's children that we may be enabled to continue—in spite of hard times—to send out the gos-

pel free as heretofore; or, if it please God, more so than ever.

I would like to mention that I am interested in poultry, and have an incubator standing not more than twelve feet from me here in my little printing-shop, and the chicks are hatching right now. They peep and make quite a fuss. I also have a few stands of bees; have an observatory hive standing

in the rear end of my printing-shop, and am much pleased in watching the busy little creatures doing what God created them for. I wish mankind were as busy trying to fulfill their purpose of creation.

I am glad to hear from you at any time. Many thanks for your kindness in extending our subscription gratuitously for another year.

Woodburn, Ore., July 23.

S. E. ROTH.

TEMPERANCE

OUR CHURCHES, OR THE LIQUOR PARTY— WHICH SHALL RULE?

From a column article in the Youngstown Telegram I clip the opening and closing paragraphs as below:

THE EAST SIDE CLEAN-UP.

The East Side has banished the saloons. Because the work has been carried on without noise or blare of trumpets, the significance of this action is probably not understood by the city at large. It is one of the most advanced steps ever taken by the people of a section of Youngstown to improve their own neighborhood, and, incidentally, to benefit all Youngstown.

In the clean-up movement the pastors and members of the Immaculate Conception, Grace Methodist Episcopal, Second United Presbyterian, and Himrod Avenue Baptist churches, the St. James' Episcopal chapel and Emma Street mission participated. There were non-church goers as well who gave assistance; but by general consent the honor of being the commanding general in this great movement belongs to Rev. J. R. Kenny, pastor of the Immaculate Conception church. It was Father Kenny who first raised the protest against objectionable saloon conditions and undertook the leadership of what would have been looked upon twenty-four hours before as a forlorn hope. It was his summons to East Siders to "clean off their own doorsteps" that awakened them to a realization that they were submitting to an unnecessary handicap to the progress of the East Side. The fact that ninety-two per cent of the men of voting age in his own congregation signed the ouster petitions, and pastors and members of other congregations willingly took up his rallying cry emphasizes the progressiveness.

The above demonstrates most emphatically what has long been said, that if the churches of any average town or community, or even the large cities, would work together, the saloons would have to go. My impression is that East Side, Youngstown, had been for years past under the dominion of the liquor party that had trampled every law under foot, and by action, if not by word, said to the good people of East Side, "Help yourselves if you can;" and the above tells how they could and *did* "help themselves."

Later.—The clipping below from *The American Issue* tells what happens when the churches pull together.

WHY THE DRYS WON; AND WHY TWO BIG CITIES KNOCKED OUT THE SALOONS.

What was the big factor in the voting dry of Duluth, Minn., a city of 100,000 population? Why did the nearby city of Superior, Wis., with 40,000 population, vote dry?

Well, the drys in both places had good organizations, and the churches pulled together for the overthrow of their greatest enemy, but that was not all. The heads of the great iron mines and steel works near these cities threw their influence on the side of the drys, and thousands of their employees enthusiastically boosted the dry cause. When capital and labor unite with the church they form an invincible combination.

Farming Business gives us a little more information in regard to the outcome of making a city dry.

One proof that prohibition will keep the jail free of drunks is found in a news report from Superior, Wis. On Saturday, July 1, the town went dry; on Saturday, July 8, the city jail was empty in spite of the fact that it is a town with close to 50,000 population. It is the first day "in the memory of the oldest veteran policeman" that the jail was empty.

This is but the common experience of communities which have changed from wet to dry. There is a big reduction in jail and court expenses, and this means a corresponding increase in the economic welfare of the community.

PROHIBITION AND ITS "DEPLORABLE" RESULTS.

Very likely our readers have seen statements in the papers to the effect that prohibition in Des Moines, Iowa, had been "disastrous," etc. For their authority they quoted a Congregational minister. Of course the statement was marked "advertisement," but many people may not have noticed it. Well, as Dr. Kirbye was for several years pastor of our own church here in Medina, I sent him the clipping and wrote him as follows:

DR. J. EDWARD KIRBYE, PLYMOUTH CHURCH, DES MOINES, IOWA.

My good friend Dr. Kirbye:—The enclosed explains itself. I presume likely you have seen the thing many times already, and have probably made some reply to it. Could you kindly send me something in print, or briefly otherwise, telling me how you came to furnish "ammunition" to the liquor people in the way that they have put it? I am sure there is some explanation, as is usually the case in the "facts" they present. Of course it is a paid advertisement. If it will save you time and trouble, you might reply briefly on the enclosed postal.

A. I. ROOT.

Very promptly came the following, penciled on a postal card:

It is a lie of the liquor interests. I said that the new chief of police was not enforcing law as well as the former, and more drunkenness was the result. I am the sworn enemy of the American sa-

loon, and have been fighting it in Des Moines as when in Medina. Prohibition is a success in Des Moines, when we have decent officials to enforce the law. They misrepresent me.

Frankfort, Mich., Aug. 4. J. E. KIRBYE.

The above is only a sample of the way these liquor stories turn out when they are traced down. There is a pretty big moral prominently brought out in the above—the folly of having a chief of police *in sympathy* with the wets after you have voted for prohibition.

SALOONS HELP BUSINESS.

The liquor people urge, as you may know, that saloons help the business of a town; and we shall have to admit, I suppose, that some kinds of business are helped by saloons; and one of these lines of business is the jail business. See the following, which I clip from the *American Issue* in regard to two counties in Ohio:

Belmont County is wet and Hancock County is dry. An item in one of the Belmont County papers last week says there were 70 persons in the county jail. The same week Hancock County papers reported the jail in that county empty. Saloons boost jail business.

PROHIBITION DOES NOT PROHIBIT(?)

Some good friend has mailed us the clipping below, but he does not tell us what paper he took it from.

\$12,000 IN GOOD WHISKY COMES TO BAD END ON DUMP.

Denver's city dump at Thirty-first and Platte streets enjoyed a spree yesterday.

Last night it was "saturated." Whisky worth \$12,000, good whisky, and bad and indifferent, was poured into the ground.

The whisky came from five railroad depots. It

had all been consigned to G. D. Phillips, who until Monday had a "store" at 1704 Sixteenth Street. Phillips was fined \$150 in the county court Monday for violating the prohibition law, and the whisky "poured" at the dump tea party yesterday was his goods. The spilling was directed by police and sheriffs

It occurs to me that, after a few doses of medicine like the above, the guilty one will "sit up and take notice" that prohibition *does* prohibit.

NO PLACE FOR BOOZE IN THE GREAT FACTORIES OF OUR LAND.

The following, from the Methodist Temperance Board, explains itself:

THIS POSTER WAS TAKEN FROM THE SHOPS OF THE GIER PRESSED STEEL CO., LANSING, MICHIGAN.

Covered with machine grease, and mutilated by the tacks which held it to the wall, the original is in the office of the Board of Temperance of the Methodist Episcopal Church.

YOU CAN'T DRINK AND MAKE GOOD.
MODERN BUSINESS SETS PACE TOO FAST FOR DRINKING MAN'S MIND TO KEEP UP—HE IS NOT IN THE RUNNING.

Science Proves by Delicate Instruments of Precision that He Thinks, Sees, Hears, and Acts More Slowly than the Man Who Doesn't Drink.

Nothing will destroy the usefulness of a strong brain as quickly as alcohol. It is just as disastrous to man's delicate mental machinery as a handful of sand to the mechanism of a watch.

Bright business ideas, ambition, energy, and execution fade under the influence of alcohol like a dream, to be replaced by air castles, "large talk," laziness, sluggishness, and neglect.

HEALTH NOTES

SAVING THE BABIES; "GOD'S KINGDOM COMING."

Just now the whole wide world is, if I am correct, giving more attention toward protecting and saving the babies than ever before. Infantile paralysis is (*perhaps* providentially) directing attention to the matter; and our best and ablest physicians as well as our professors and scientific men are giving it their best attention. Will they succeed in combating this terrible scourge? I take courage when I think how quickly the foot and mouth disease among our domestic animals was stamped out when our nation realized the damage the disease was likely to do. The way in which it had got started before our stockmen knew what the trouble was made it seem almost incredible that it should be so soon headed off. Well,

now, here is something of terrible significance that I copy from the *Ohio Messenger*:

Women have voted in New Zealand for twenty years. The lowest death rate for babies in the world is in New Zealand.

Women vote in Norway, Australia, Sweden, Denmark, and Finland. The next lowest death rates are in these countries.

What would become of this world of ours if it were not for the mothers? and has the world ever given them credit for what they have done and for what they are doing? Now, I am impressed in reading the above of two things. First, that the babies of this world are of infinitely more importance than all the domestic animals on the face of the earth; but I am afraid that even our United States of America have not in times past given them the thought and care that

they have given the cows, pigs, and chickens. The second thing that impresses me is that the mothers of the world have a better *right* to vote, and help in making laws, than any man who was ever born. May God bless the present movement to care for the babies, and also the wave of reform toward keeping temptation out of the way of the little ones when they get to be boys and girls.

"Suffer the little children to come unto me, and forbid them not, for of *such* is the kingdom of heaven."

HOW TO AVOID CONSUMPTION.

The medical adviser of the *Plain Dealer* recently gave a lot of such excellent advice, not only to those having a tendency toward consumption but to everybody else, that I take great pleasure in quoting from it as follows:

But even if your rooms be sunny, don't stay in them all the time. Get out of doors as much as you can. Outdoor work is vastly better than indoor work, especially if one's lungs are weak. On cold rainy days take special pains to keep the feet dry.

Breathe with deep long full breaths, so as to carry the fresh air to every corner of your lungs. Do this every day for several minutes in the morning, and at night with the windows open or while out of doors. Breathe thru the nostrils and not thru the mouth.

Next to fresh air good food is most important for the person who is liable to contract consumption. Spend your money for simple food—milk and eggs, good fresh meat, cereals, vegetables, bread and butter, and fruit.

Don't gorge yourself at every meal—that is likely to do you more harm than good. But eat heartily. Between meals drink milk if it agrees with you.

Live a regular life—get plenty of rest and sleep at regular periods as well as eating regularly.

A daily sponge or tub bath is good when followed by a brisk rub, preferably upon rising.

Above all, keep your courage up. Courage is one of the most important things in preventing or curing consumption. Remember consumptives can be helped and many are cured.

Among other things to be avoided if you would sidestep consumption are dirty shops and stores, overcrowded living and sleeping rooms, dirty saloons and dance halls, dusty kinds of business, and dusty, dirty air. All these things are bad for weak lungs.

Self-indulgence and intemperance are also very bad for the person trying to keep out of the clutches of consumption. Vice weakens the strong, kills the weak.

Then there is the evil of patent medicine. Even the patent medicines which claim to cure consumption are bad for weak lungs, because they contain a large amount of alcohol.

DR. WILEY IN REGARD TO DRUGS AND DRINKS.

We clip the following from the *Vindicator*. See if you cannot say amen to it—especially the closing paragraph.

ALCOHOL EVIL AND DRUG EVIL.

The *Chicago American* (a Hearst paper) quotes Dr. H. W. Wiley, at one time the great Chief Chemist of the Department of Agriculture, as having said in a recent lecture in Chicago that 60 per cent of

the young men who apply for enlistment in the United States army are rejected as physically unfit, and attributing that state of affairs to the use of "habit-forming drinks and drugs." The *American* says:

"Apart from the humanitarian reasons that have all along inspired opposition to injurious drinks and drugs, a new and powerful argument for social efficiency is having its effect.

"It was here that Dr. Wiley's lecture became most forcible.

"The American people can't afford to build and maintain jails, asylums, and poorhouses to take care of millions of human wrecks and their progeny ruined by drugs and drinks.

"They can't afford to have a poisoned heredity injected into the veins of the commonwealth.

"They can't afford to have a large per cent or any per cent of their young men so disabled that they can be of no service to their country, either in peace or war.

"This country, as a matter of incalculable self-interest, must defend itself against enemies which are all the more dangerous because they fly no banners and beat no drums. It must protect the birth, education, and development of every child born under the Stars and Stripes!"

RESUSCITATING DROWNED PEOPLE.

I clip the following from the *Florida Grower*:

Boy Scouts at Boynton proved the worth of their training by rescuing a seven-year-old boy who had fallen into a hole over his head. They plunged in and dragged him to the shore, and then were compelled to use artificial respiration for nearly thirty minutes before he recovered.

There are two points in the above that interest me. The first is, that the Boy Scouts are being taught what to do, and how to manage a drowning person. Secondly, this boy was brought to life after nearly thirty minutes of efforts with artificial respiration. It would be a most sad and serious thing if the friends should become discouraged and give up when there is still a possibility of resuscitation. I regret that they did not tell how long the boy was under water, for it is exceedingly important to know *how long* after submerging there is a possibility of recovery.

"HOW TO KEEP WELL AND LIVE LONG."

The *Christian Herald* gives us an excellent picture of Mrs. Louisa K. Theirs, who is now 102 years old; and the picture they give represents her as quite a good-looking old lady. We clip the following in regard to her:

Mrs. Theirs, when asked for a greeting to the *Christian Herald* readers, said:

"Let me say that I congratulate you on having lived to this day of wonders. If we have only 'picked up pebbles, while the ocean of truth lay all unknown before us,' still wonders have been brought to light.

"If you want to live long and enjoy life, make yourself useful to your fellowmen and cut your food down to the smallest possible quantity. In regard to myself, I can only say that God has been very good to me in giving me health, a long life, many friends, and blessings too numerous to mention."

HIGH-PRESSURE GARDENING

GROWING FIELD CORN IN FLORIDA.

I hold in my hand an ear of corn that is about the handsomest, all things considered, to me, of any ear of corn I ever got hold of. On page 627, July 15, I made mention of three or four ears on the stalk of corn in my Florida garden. I wrote Wesley, when it was hard enough to ship, to send me an ear by mail, and here it is. The seed was procured of the Kilgore Seed Co., Plant City, Fla. Here is what their catalog says about it:

CUBAN OR HAVANA YELLOW FLINT.

This corn will make under all kinds of adverse weather conditions. Small ears, small grain, and one of the hardest of all flint corn, and one that withstands weevils better than any other variety.

The corn is a deep yellow. The kernels are perfectly smooth, as hard as flint, and as shiny as if they had been varnished. It looks somewhat like our old-fashioned Yankee corn, but the kernels go rather deeper. If I understand it correctly, it is so extremely hard and flinty that the weevils cannot easily bite into it. The corn was planted after digging a very nice crop of potatoes. If we gave it any fertilizer at all, it was only a very little. The ground had been, for several seasons before, a part of our poultry-yard, and that probably explains why there are three and even four ears on a stalk. You will recall that Professor Rolf advised me to plant corn and Velvet beans after digging my potatoes. The Velvet beans were inoculated so they might gather nitrogen and benefit the ground. Now, the fact that I have succeeded in getting a fine crop of beautiful corn from the little piece of ground that had been a poultry-yard, or a part of one, does not amount to much. From a late issue of the *Manatee River Journal* I clip the following from a description of

A "500-ACRE CORN-FIELD."

Five hundred acres of corn in Manatee County, in one field, under one fence, and belonging to one firm, is the record up to date, so far as we have been able to learn.

We have seen many fields of from ten to forty acres, and have information that there are some containing seventy-five acres, and one or two of a hundred and fifty; but for a South Florida county to have one field with five hundred acres of good corn in it is somewhat of a revelation.

In much of this corn a fine stand of Velvet beans will be seen, the bean-runners very often covering the stalk so as to hide it entirely, and the ground a perfect mass of vines. The value of beans as a stock food is well known, and is also highly recommended as a cover crop.

At the estimated yield of forty-five bushels to the acre (and, mind you, that was a much lower estimate than that made by experienced corn-men from northern states, the crop would run twenty-two

thousand five hundred bushels; and at the price of ninety cents per bushel would bring to the owners the sum of \$20,250. In addition to this income, in a county where "they" say we can't raise corn, Scally & Knight will turn several hundred head of cattle on the fodder and grass to fatten for the market.

There is no mention in the above of the variety of corn used for this great corn-field. It may be the same as the corn I have just been talking about, the Cuban, or it may not. It is true that corn has been grown more or less in Florida for years past; but until just recently nobody seems to have discovered any such possibility as mentioned above; and I would warn people in the North, who think they can go down to Florida and raise corn like the above, and get such yields, that these are probably the exception, not to be secured except by an expert under the most favorable circumstances. When we can grow not only our own hay but our own corn down in Florida, without sending up to Ohio and away out west for it, we certainly are forging ahead.

Below is Wesley's report of my garden up to Aug. 3:

I am sending the ear of corn. It will not be ready to "house" before the first of September or last of August. The pieplants died during the month of June, as it was so hot. The Velvet beans have covered the whole place. We are having plenty of rain now. I keep the ditches all open so that the water doesn't stand on the place at all. The sweet potatoes are doing nicely. I keep all of the big weeds out of the Velvet beans.

Manatee, Fla., Aug. 3. WESLEY WELCH.

I am sorry to know our pieplants have died; but I was told when I planted them that they would not be likely to stand the summer, and that I would have to replace with new plants every fall. It seems clear that the Velvet bean interferes but little or none at all with the corn, but I was assured all around that such was the case. One reason Wesley speaks of the big weeds is because I found big weeds towering away up above my head the year before, right where that beautiful corn is now maturing.

POISON IVY; A REMEDY.

Mr. A. I. Root:—I notice under head of Health Notes, March 1, remedies for poison ivy, etc. I have accidentally learned that salty meat grease is a sure cure for poison ivy. Applied three times a day for two or three days, it always cures.

Montgomery, Ala., Mar. 6.

J. M. CUTTS.

Thanks, my good friend; but do not poison-ivy troubles usually "let up" in "two or three days," even if nothing is done but to let it alone?

Better Queens and Bees for Less Money

20 years of select breeding gives us bees and queens of highest quality---Queens for Honey production---Queens of unusual vitality---Queens that successfully resist European foul brood

Our select colonies for breeding purposes, larvæ, and select drones are those of the highest standard, the choice of over 1000 hustling honey-producing colonies of pure Italian bees. These select colonies are located at such a distance from all other bees as to assure pure mating, and thus effective use of our select drones. The larva we use in grafting is as small as can be seen and handled, having just come out of the egg. These are placed in cells, which in turn are placed and nourished in strong ten-frame colonies, which, when honey is not coming in sufficiently, are heavily stimulated by feeding. Thus we get large well nourished cells, which in turn produce large, long-lived, and hardy queens that give workers unexcelled for honey production. We use no baby nuclei. All our queens are hatched and reared in strong three and five frame full-depth hives. Thus natural conditions are preserved, and the best queens produced.

Price List of Our Three-banded and Golden Italian Queens. Ready by Return Mail.

Untested.....50 cts. each or \$45.00 per 100	Tested.....\$1.00 each or \$ 90.00 per 100
Select Untested..65 cts. each or \$60.00 per 100	Select Untested..\$1.25 each or \$115.00 per 100

All queens are warranted purely mated. Wings clipped free of charge.

Price List of Our Swarms of Bees for Fall Increase.

1-lb. swarms with select queens..... \$1.75	2-lb. swarms with select queens..... \$2.50
3-lb. swarms with select queens..... 3.50	5-lb. swarms with select queens..... 5.00

TENNESSEE-BRED QUEENS! My three-band strain that has given such universal satisfaction for over 40 years. Orders filled promptly or money returned by first mail. 1000 nuclei in use. Tested, in June, \$1.75; untested, \$1.00; in July, \$1.50 and 75 cts. Postal brings circular.
JOHN M. DAVIS, Spring Hill, Tenn

QUEENS.—From a strain of Italians, wintered for thirty years in the foothills of the Adirondack Mountains out of doors. Hardy, gentle, industrious, and fine resisters of disease. \$1.00 each, or \$9.00 per dozen; also nuclei and full colonies.
CHARLES STEWART, box 42, Johnstown, N. Y.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, beautiful and gentle. Mated, \$1.00; 6, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SONS, Wilcox St., Binghamton, N. Y.

BY RETURN MAIL.—Young tested queens, \$1.00; \$12.00 per dozen; untested, 75 cts.; \$7.00 per doz. We breed the three-band Italians only, and we breed for the best. We have never had a case of foul brood in our apiary, and we guarantee every queen sent out by us. J. W. K. SHAW & Co., Loreauville, La.

QUEENS.—Improved three-banded Italians, bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.
H. C. CLEMONS, Rt. 3, Williamstown, Ky.

NOTICE TO HONEY-PRODUCERS.—We will send by return mail three-banded Italian queens at 50 cts. each. Lots of 25 or more, 45 cts. each. A choice lot of select tested at \$1.00 each; 25 or more, 75 cts. each. No disease. Safe arrival guaranteed.
MARCHANT BROS., Union Springs, Ala.

FOR SALE.—One hundred colonies of bees in fine shape, free from all disease, and fine location; equipped for comb honey. Started in spring with sixty colonies, and have taken off 5000 lbs. white-clover honey; have increased 100. Reason for selling, I want to change to California.
J. H. HALL, 1828 Cypress, Kansas City, Mo.

Famous Howe's, Root's, Moore's, Davis' select strain of honey-gatherers, disease-resisting. None letter for all purposes. Untested, one, 75 cts.; doz., \$7.50. Select untested, one, \$1.00; doz., \$9.00; ½ doz., \$5.00; tested, \$1.25; doz., \$10; select tested, one, \$1.50; ½ doz., \$8.00; extra select, \$2.00. Bees by the pound, \$2.50 with queen. Honey crop short. Will have plenty of bees in June.
H. B. MURRAY, Liberty, N. C.

PURE ITALIAN QUEENS.—Golden or three-banded by return mail. All queens are warranted purely mated. They are large and long lived. They have proven themselves highly disease-resistant in many localities. One select untested, \$1.00; 6, \$4.25; 12, \$8.00; 100, \$60.00. Tested, \$1.25. Bees by the pound, nuclei, colonies. Safe arrival and satisfaction guaranteed. Circular free.
 J. E. WING, 155 Schiele Ave., San Jose, Cal.

The bargain of the season—listen: *The Beekeepers' Review* to new subscribers is \$1.00 per year. Ten three-banded Italian untested queens at 50 cts. each would be \$5.00. *The Review* for the last four months of this year would be 33 cts., total \$6.33. Send us \$5.00 for the *Review* 16 months, beginning with the September number, and receive 10 untested queens, mailed you direct from our breeder in Mississippi. To get this exceptional bargain, address all orders to *The Beekeepers' Review*, Northstar, Mich.

BEEES FOR SALE.—120 colonies Italian bees, located in one of finest honey belts in the U. S., in the heart of the great Salt River Valley, under famous Roosevelt Dam, six miles from Mesa, Arizona; entirely surrounded by miles of alfalfa. Equipped with fine queens, ten-frame Langstroth hives, combs of full-sheet foundation, queen-excluders, supers, and all latest improvements; honey-house, extractor, and accessories included free. A snap at \$6.00 per colony—less than total original cost, not considering location and bees. An excellent chance to locate and expand in a great up-to-date farming country with a remarkable future. I am permanently located in Chicago, and must sell at once. Only those who mean business write at once for interview or further particulars.
 J. EARL PETERSON,
 S. A. E. House, Evanston, Ill.

HELP WANTED

WANTED.—Young man to work with bees and poultry; some experience required. Must be temperate and willing to work. Steady employment if satisfactory.
 E. L. LANE, Trumansburg, N. Y.

Special Notices by A. I. Root

GOOD BOOKS AT A BARGAIN.

In our issue for June 15 I gave you a list of books that had got to be somewhat out of date. Quite a lot of them have been sold, but there are a good many of them left yet. We cannot very well reduce the prices any further on most of them, because quite a few at the low price I gave (five and ten cents) only a little more than cover the postage. I find that what is left of "The New Agriculture," a \$2.00 book, most of them are more or less damaged by having the covers get wet by an accident. The reading-matter is just as good, however; but in view of the damaged covers we make the price from now on 50 cents, postage paid.

DR. BIGELOW ELECTED SCOUT NATURALIST.

The managers of the Boy Scouts of America have elected Dr. Edward F. Bigelow, of Sound Beach, Ct., "Scout Naturalist." He will guide the great and growing organization of boys in their nature studies, answer questions, and conduct a department entitled "On Nature's Trail" in *Boys' Life*, the official monthly publication of the Boy Scouts. Their magazine has already attained a circulation of more than 100,000.

Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER.** By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE.** By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES.** Our new complete catalog, mailed free to any address on request.

QUEENS AT 50c

These queens are guaranteed to be as good as money can buy. They are bred by the same and with the care as the high-priced ones. They are bred from imported mothers, the best in the world, and will produce bees that are the best for honey-gathering, gentleness, and not inclined to swarm.

TRADE NOTES

SECOND-HAND HONEY-CANS.

Those in need of cans for extracted honey will do well to consider the choice second-hand cans which we have to offer. We save only the best, and repair any boxes which need repair. The cans are free from rust inside, and rarely have any trace of rust outside. They are really good enough for choice honey. The price is \$4.00 for 10 cases of 2 cans each; \$8.50 for 25 cases, or \$30 for 100 cases. We have a supply at Philadelphia; also in New York, at same price.

CARTON AND LABEL ORDERS.

Notwithstanding the two advances in prices of cartons and labels the demand is phenomenal, and we are somewhat behind on orders. In order to take more prompt care of orders for goods in this line we are installing a new automatic self-feeding printing-press with a capacity of 3600 impressions per hour. With this to help out we hope to catch up, and also take care of future orders more promptly.

SHIPPING CASES AT BARGAIN PRICES.

We call attention to a list of shipping-cases offered at bargain prices and prompt shipment. The list is found on the first inside cover page of this issue. We have the following to add to this list, all in stock at Chicago, Ill. We also list some bargains in glass honey-packages no longer listed in our catalog.

- 5 crates, 50 each, 12-lb. cases for $1\frac{1}{4} \times 1\frac{3}{8}$ sections, \$4.00 per crate.
- 35 crates, 10 each, 12-lb. cases for $1\frac{1}{4} \times 1\frac{3}{8}$ sections, 85 cts. per crate.
- 3 crates, 50 each, 10-lb. cases for $1\frac{1}{4} \times 1\frac{3}{8}$ sections, \$4.50 per crate.
- 7 crates, 10 each, 16-lb. cases for $1\frac{1}{4} \times 1\frac{3}{8}$ sections, 90 cts. per crate.
- 7 crates, 10 each, 12-lb. cases for $1\frac{1}{4} \times 1\frac{1}{2}$ sections, 85 cts. per crate.
- 1 crate, 50 each, 12-lb. cases for $1 \times 5 \times 1\frac{3}{8}$ sections, \$4.00 per crate.
- 12 crates, 50 each, 15-lb. cases for $1 \times 5 \times 1\frac{3}{8}$ sections, \$4.00 per crate.
- 9 crates, 10 each, 15-lb. cases for $1 \times 5 \times 1\frac{3}{8}$ sections, 85 cts. per crate.
- 4 crates, 10 each, 12-lb. Safety cases for $1\frac{1}{4} \times 1\frac{3}{8}$ sections, with cartons at \$1.20 per crate.
- 5 cases 2 doz. No. 25 jars, porcelain top, at \$1.00 per case.
- 7 cases, 2 doz. 1-lb. Hershiser square jars, nickel top, at \$1.30 per case.
- 1 case, 12 doz. 1-lb. Hershiser square jars, nickel top, at \$7.00 per case.
- 8 cases, 2 doz. $\frac{1}{4}$ -lb. Hershiser square jars, nickel top, at 80c per case.
- 2 cases, 12 doz. $\frac{1}{4}$ -lb. Hershiser square jars, nickel top at \$4.50 per case.
- 1 case, 12 doz. $\frac{1}{2}$ -lb. round Hershiser jars, nickel top at \$5.00 per case.
- 15-oz. Octagon jars with screw cap in crates $3\frac{1}{2}$ gross offered at \$4.25 per gross.
- 3 2-3 gross of $\frac{1}{2}$ -lb. square jars with cork at \$3.75 per gross.
- $\frac{1}{2}$ gross of 1-lb. square jars with cork at \$4.75 per gross.
- 90 3-gallon cans at 25c each.
- 12 5-gallon round wood jacketed cans at 50c each.

GLASS HONEY-PACKAGES ADVANCED.

Increased cost of materials affects glassware to such an extent that we are obliged to announce higher prices on the various glass packages listed in our catalog. The taper-panel jars are advanced 10 cts. a case, making the new price for $\frac{1}{2}$ -lb., 90 cts. per case; 6 cases, \$5.10; 1-lb., \$1.10 per case; \$6.30 for 6 cases. The round Federal and Tiptop jars are also advanced 10 cts. per case, making the new prices as follows: Federal jar, \$1.20 per case of 2 doz.; 6 cases, \$6.90 15-oz. round jar, 95 cts. per case of 2 doz.; 6 cases \$5.40. 16-oz. round jar, \$1.00 per case of 2 doz.; 6 cases, \$5.70. $\frac{1}{2}$ -lb. Tiptop jar, \$1.10 per case or \$5.50 per crate of 1 gross. 1-lb. Tiptop jar, \$1.20 per case or \$6.00 per crate of 1 gross.

$\frac{1}{2}$ -oz. tumbler, \$1.00 per case of 4 doz.; \$7.50 per bbl. of 40 doz.

TIN HONEY-PACKAGES.

New quotations received on tin cans and pails are very much in advance of former prices. We are fortunate in having a supply of 5-gallon cans, bought before the advance, so we can continue for some time yet furnishing these cans at the present list price. We are obliged to name higher prices on the friction-top cans and pails for shipment direct from Chicago or Baltimore as follows: 2-lb. can, 500 to crate, \$16.00 per crate; 90 cts. per case of 24. $2\frac{1}{2}$ -lb. can, 462 to crate, \$17.00 per crate; \$1.05 per case of 24. 3-lb. can, 420 to crate, \$18.00 per crate; \$1.20 per case of 24. 5-lb. pail, 200 to crate, \$13.00 per crate; \$1.00 per case of 12. 5-lb. pail, 50 to crate, \$3.75 per crate. 10-lb. pail, 100 to crate, \$10.50 per crate; 80 cts. per case of 6. 10-lb. pail, 50 to crate; \$5.50 per crate.

REGULAR AND SAFETY SHIPPING CASES.

Because of the great increase in the cost of paper in all forms we find it necessary to advance prices of the regular 24-lb. shipping-case \$1.00 per 100, and of the safety cases, including safety cartons, \$4.00 per 100. In 100 24-lb. cases there are 2400 safety cartons. The price of these cartons is advanced \$1.50 per 1000, which makes the increase for cartons alone \$3.60 per 100 cases. There is, besides, the drip paper and corrugated pads, which are now costing considerably more. These pads cannot well be dispensed with. In fact, where cartons of some kind are not used, there should be divisions in the case to protect the comb honey properly for safe shipment.

THE A. I. KOOT Co., Medina, Ohio.

AN ANNOUNCEMENT.

It has been the dream of beekeepers for many years to have honey so widely and thoroughly advertised that it would become an article of common everyday household use. This dream is now crystallizing into substantial form. The United Honey Producers is arranging to have the food value of honey and domestic use taught in the schools of the United States. Obviously there is no quicker way to popularize it than to educate our future housekeepers to use it in the best manner.

The school officials have been asked if they would assist in this, and in almost every instance they have agreed to do so if suitable bulletins are supplied to the schools by the beekeepers. The United Honey Producers is arranging to do this, and will print them in quantities to supply all the schools.

This is a grand opportunity; and, as the editor of the *Western Honeybee* declares, "A grand idea, and no one interested in the production of honey can afford not to endorse it."

We will take it for granted that you do endorse it; but we want you to say so. Write to your vice-president or to the secretary, and tell him so. It is planned to have one or more beekeepers in each county, and more when possible, to represent the United Honey Producers, and be ready when called on to give simple demonstrations before the pupils, to supplement the instruction, and for other necessary work in connection with the United Honey Producers.

This is a matter of general importance, as well as personal advantage to the county members, as it will bring liberal compensation to them in the way of prestige as representatives of the National organization. For the present these positions will be filled by volunteers. Later they will be elective or be appointed.

The United Honey Producers will specialize on this policy, and concentrate its efforts in pushing it to a successful culmination. When its present plans are successfully realized, it will take up some other things that are needed and carry them out. The discipline and organization that this campaign will bring will make possible other things.

Detailed information can be obtained by writing to your vice-president or to the secretary.

Redkey, Ind.

GEO. W. WILLIAMS, Sec.

SPRAY THE EASIEST WAY BY USING Myers Cog-gear Spray-pumps

It pays to protect the orchard and garden by careful and thorough spraying. USE MYERS SPRAY-PUMPS and you can do the work easily and effectively. The Patented Cog-Gear Head on Myers Pumps causes them to operate easily, even when working against high pressure. These pumps can also be used for painting, whitewashing, and disinfecting.

Write for catalog showing Bucket and Barrel Sprayers, Power Spray Outfits, and all kinds of spraying accessories. We have a copy for you.

Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in our yards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

June and July		August and later	
Select Tested Queens	1 for \$1.75; 12 for \$19.25	1 for 55 cts.; 12 for \$ 6.00	
Tested Queens	1 for \$1.05; 12 for \$12.00	1 for \$1.00; 12 for \$10.75	
Untested Queens	1 for 60 cts.; 12 for \$ 7.00	1 for \$1.65; 12 for \$18.00	
Very best queens for breeding,	\$3.00.	1 lb. bees in package, \$1.25; 2 lbs. in package, \$2.00.	

Add price of queen. If any of our untested queens should prove to be mismated we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

W. D. ACHORD, FITZPATRICK, ALABAMA

EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

Special Bargains in Shipping-cases

With the bountiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

- | | |
|--|--|
| 8 crates of 50 each, 9½-inch, 2-row, at \$4.00 per crate. | 8 crates of 10 each, 15¼-inch, 2-row, for 15 sections, at 95 cts. per crate. |
| 19 crates of 50 each, 10-inch, 2-row, at \$4.00 per crate. | 14 crates of 50 each, 11¾-inch, 2-row, for 12 sections, at \$4.00 per crate. |
| 15 crates of 50 each, 6¾-in. 3-row, at \$4.00 per crate. | 6 crates of 10 each, 12-lb. safety cases with cartons at \$1.20 per crate. |
| 56 crates of 50 each, 12-lb. cases, at \$4.00 per crate. | 3 crates of 10 each, 8-inch, 3-row, for 12 sections; at 85 cts. per crate. |
| All of the above have either 2 or 3 inch glass, and take 12 sections 4¼x4¼x1½ plain. | 2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate. |

There are also for the same size section, packed 10 in a crate:

- 10 crates of 10 each, 9½-in. 2-row at 85 cts. per crate.
- 4 crates of 10 each, 6¾-inch, 2-row, at 85 cts. per crate.
- 4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.

For the 4¼x1¾ beeway section we have:

- 5 crates of 50 each, 15¼-inch 2-row, for 15 sections, at \$4.50 per crate.

For 24 sections, 4¼x1½ plain:

- 1 crate of 25 each, 9½-inch, 4-row, at \$4.00 per crate.
- 2 crates of 10 each, 9½-inch, 4-row, at \$1.75 per crate.
- 3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.

For 12 sections 4x5x1¾:

- 26 crates of 50 each, 3-row cases, at \$4.00 per crate.
- 1 crate of 50 each, 3-row, for 15 sections, at \$4.00 per crate.

ADDITIONAL SHIPPING-CASES AT BRANCH OFFICES.

At Washington, D. C.

HONEY GRADING RULES

GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

BREEDERS.—The cream selected from our entire stock of outyards; nothing better. These breeders, \$5.00 each.

Can furnish bees on Danzenbaker and L. or Hoffman frames.

Above price on bees by pound, nuclei, and colonies does not include queen. You are to select such queen as you wish with the bees, and add the price.

Queens from now on are mailed promptly by return mail.

Free circular and testimonials.

H. G. Quirin-the-Queen-breeder
Bellevue, Ohio

Golden and Three-band Italian Queens . . . 45c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested, one, 45 cts.; 12, \$5.00; 100, \$40.00; tested queens, 75 cts. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. The Italian strain of bees have proven themselves able to resist foul brood to a greater degree than any other strain, and they are, therefore, the strain to buy if you have foul brood in your locality.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.

Marengo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested 60 cts.; 12 for \$6.00. Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00. Will replace inferior queens.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

The Stover Apiaries
Mayhew, Miss.

WARDELL STRAIN OF ITALIANS

Descendents from the Famous Root \$200 Queen

I was head queen breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

Untested	during June, \$1.50; in July, August, and September, \$1.00
Select Untested	1.75 " " " 1.25
Tested	2.50 " " " 2.00
Select Tested	3.50 " " " 3.00

"THE WHOLE WIDE WORLD FOR JESUS."

Tell Mr. Root that I am with him on the saloons. Our township is dry. I should like to see the United States go dry, and not allow any whisky to enter its boundary.
Sparksville, Ind., June 12. **EVERT HELLER.**

KIND WORD FROM A B C AND X Y Z SCHOLAR.

My bees are doing fine. I bought 20 colonies in April and divided them. I now have 35 and they are as lively a bunch as you ever saw. I never had bees before, nor even saw the inside of a hive with bees in it, but that "X Y Z" book "got me by" all right so far. I really believe I have it almost committed to memory.
Wauseon, O., May 27. **DR. A. P. BETTS.**

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

CLEVELAND.—There is a little old honey still in market at \$2.50 to \$3.25 per case, according to quality and condition. New honey, fancy grade, is selling slowly at \$4.00. Demand is light for all grades.
C. CHANDLER'S SONS.
Cleveland, Aug. 24.

ALBANY.—Weather here has been so hot during the past ten days there has been no demand for honey, and but very little offered. A few local producers have appeared in city public market with white comb honey, selling it in a retail way at 15 cts. a comb. No established prices yet. White honey is a good crop. Buckwheat also is promising at present.
CHARLES MACCULLOCH.
Albany, Aug. 25.

DENVER.—We are selling new crop comb honey in the local market at the following prices: Fancy, per case of 24 sections, \$3.11; No. 1, \$2.97; and No. 2, \$2.85; white extracted, 8½ to 8¾ cts. per lb.; light amber, 8 to 8¼ cts. per lb., and amber 7 to 8 cts. per lb. We pay 26 cts. per lb. in cash and 28 cts. per lb. in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, Aug. 26. FRANK RAUCHFUSS, Mgr.

KANSAS CITY.—On account of the extremely dry weather the honey-flow has stopped; but there is still quite a surplus of new comb honey on the market. Strictly No. 1 white comb honey, 24-section cases, is selling at \$3.00 to \$3.25 per case; No. 1 amber comb honey at \$2.85, and No. 2 amber comb honey at \$2.70. Strictly fancy white extracted honey is selling at 8 to 8½, with a good demand. The demand for comb honey is still only fairly good.

C. C. CLEMENS PRODUCE CO.
Kansas City, Aug. 15.

PHOENIX.—The bulk of our alfalfa and light-amber honey has been moved at 5½ to 5¾ cts. per lb., on board cars, with a dollar rate to common eastern points. Mesquite was a very light crop, but of excellent quality and would have sold readily at \$6.50 F. O. B. had there been a carload at any given point. Some 10 cars of light amber have been sold up to date at from 5½ to 5¾. Beeswax brings 26 to 27 cents here. At present the indications are favorable for a good fall crop.

WM. LOSSING.
Phoenix, Aug. 23.

CHICAGO.—The new honey from the harvest of 1916 is appearing on the market. No sales have been reported. Comb is being held at 13 cts. per lb. for the best grade. Owing to the warm weather that has prevailed during the past four weeks, that would have a tendency to prevent any activity, so that at this time it is difficult to diagnose the conditions, especially as to what the price is going to be this coming month. Yet indications are that there is not going to be much, if any, advance over that which has prevailed for the product of 1915, a goodly quantity of which is yet unmarketed. Extracted also remains quiet at from 7 to 8; white and ambers, from 5 to 7. Beeswax is steady at from 28 to 30, according to color and cleanliness.

MRS. ONA FOLIART.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

WHY IS THIS TRUE? BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who "has been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis Sections in a season, and has not found one section in the whole lot that was not perfect. Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.

G. B. Lewis Company, Watertown, Wisconsin

Catalog on request giving nearest distributor.

DO YOU WANT Your Bee Supplies Shipped Promptly?

NO. 17

EDITORIAL

THE beekeepers of Iowa are requested to write to Frank C. Pellett, Atlantic, Ia., or to the A. I. Root Co., Des Moines, for a copy of the inspector's report for 1915.

FIELD meets are getting to be quite the fashion nowadays. In former days there were no meetings of beekeepers except during the winter; and now it is quite the fashion to have summer meetings also. It is well.

The Alexander-House-Miller Plan for Curing European Foul Brood Indorsed

MR. R. F. HOLTERMANN, in this issue, page 801, introduces a letter from P. W. Stahlman, of West Berne, N. Y., that details a long and varied experience with European foul brood. This letter serves to confirm the findings of E. W. Alexander, S. D. House, and Dr. C. C. Miller on the nature and treatment of this disease.

The Bee King of Honolulu

WE are glad to make the acquaintance of Mr. Oswald St. John Gilbert, one of the most extensive honey-producers in the world, the "bee king" of Honolulu, and manager of the Sandwich Islands Honey Co. See page 795. Our readers will take pleasure in learning something about this producer. It was with no little pride that we noted that he made his start with the A B C and X Y Z of Bee Culture as his sole guide.

Importance of Marking the Net Weight on Honey Packages in some States

WE have stated in these columns that while it was not absolutely necessary to mark the net weight on honey-packages, provided the goods are not to be shipped out of the state, and provided, of course,

there was no net-weight law within the state, some states have laws based on the federal law, and some beekeepers are going to run a great risk unless they mark all their sections with the minimum net weight. See what Frank C. Pellett, state bee inspector of Iowa, says:

It would seem that your editorials on the net-weight law are plain enough. However, several Iowa beekeepers have been misled into believing that they do not have to mark the net weight on packages sold at home, but only on those shipped out of the state. You will confer a favor upon your Iowa readers by calling their attention to the fact that the Iowa law is copied after the federal law, and that it is necessary to mark every section of honey as well as every package of the extracted honey with the net weight, even tho it is sold to the next-door neighbor. I understand that similar laws have been enacted in several other states.

Many Iowa beekeepers are laying themselves liable to prosecution because of their neglect to comply with the law in this respect. The fact that laws are not similar in all states has led to much confusion.

FRANK C. PELLETT.

Atlantic, Iowa.

As no one knows whether his honey will be shipped out of the state, he should mark the net weight on the packages, whether there is a law in his own state or not. It is the only safe thing to do.

Queen-bees in Danger of being Excluded from the Mails

ACCORDING to newspaper reports, Congressman Frank E. Doremus, of Detroit, has introduced a bill into the House of Representatives excluding liquor, poisonous animals, insects, and reptiles from the mails. The bill as drawn would exclude queen-bees and the dozen or so of attendants. There was probably no intention on the part of the author of the bill to ruin a large industry and seriously handicap honey-producers desirous of improving or renewing their stock. While there is but little likelihood that such a bill will pass at this session of Congress, all queen-breeders should write at once to their congressmen, requesting that the bill be modified so far

as it relates to the mailing of queens. A great majority of beekeepers would welcome the exclusion of liquor from the mails.

Competitive Civil-service Examination for Apicultural Assistants on Sept. 20

THE United States Civil Service Commission announces an open competitive examination for apicultural assistants for men only, on Sept. 20. The salaries will be \$1400 and \$1600 a year. Those interested should write to the United States Civil Service Commissioner, Washington, D. C., for particulars. These apicultural assistants are desired in connection with the extension work about to be undertaken in the South. Competitors will be examined on the following subjects:

<i>Subjects.</i>	<i>Credits.</i>
1. Practical questions	40
2. Thesis, to be delivered to the examiner on the day of the examination.....	20
3. Education and experience	40
TOTAL	100

Two years of experience with at least 100 colonies, or two years' experience in apicultural inspection, or two years' experience in teaching bee culture, are pre-requisites for the consideration of this subject.

Honey-crop Conditions and Prices

THERE is not much new to add to what we have already given on page 710 of our issue for Aug. 15. The drouth has continued, altho it was broken by some heavy rains that seemed to be quite general according to the U. S. weather maps. This drouth, however, was severe enough to check the clovers—alsike and white. Had the rains continued, the crop of clover honey would have smashed all records. As it is, it will greatly exceed last year; but the very drouth that checked the alsike and white has stimulated the second growth of red clover. When the weather is dry enough, the corolla tubes are short enough to enable the honeybee to get the nectar. In localities where red clover is grown largely, the shortage in white clover will be made up slightly of red-clover honey. There has been almost no basswood honey this year.

The reports from the West are still very meager. The few reports show the yield in the West has not been as heavy as in the East. There has been a large amount of honey, both comb and extracted, left over from last year in many of the warehouses of the commission merchants. Whether this will make up for the shortage in alfalfa

we are unable to say. Prices on mountain sage and orange honey are firm in California. On Eastern clover the prices will be easier than last year. Comb honey in general, where it is selling at all, is selling for less than last year's prices; for be it remembered there was an enormous production of comb honey in 1915, thousands of pounds of which were carried over into this year. We warned producers not to run so much to comb honey this year. It is easier and safer to carry over extracted than comb.

Early in the season the market took a regular toboggan slide; but as soon as the drouth came on in the East, and as soon as a knowledge of the shorter crop in the West became general, the market began to recover and find itself. It is apparent, however, that Eastern honey, both comb and extracted, will be lower than last year, while mountain sage, orange, and the lighter grades of alfalfa will possibly bring as good prices as last year. But Western producers should be careful not to unload too much of their honey in the East, as the markets there are well supplied with the local production. Local consumption should be encouraged as much as possible. The Eastern markets will not stand heavy Western shipments altho they will take orange and sage, all that can be furnished.

Dr. H. A. Surface; a Faithful Public Servant

FOR the last fourteen years Dr. H. A. Surface has been the efficient and energetic Economic Zoologist of Pennsylvania, with headquarters at Harrisburg. He graduated from the Ohio State University, did a large amount of post-graduate work, and then taught botany, chemistry, and other natural sciences. He finally accepted a position with the State College of Pennsylvania; later resigned and accepted the position above mentioned.

Dr. Surface, a thoroughly trained man, has been one of the most untiring workers whom it has ever been our pleasure to meet. He is a zoologist—one of the best in the country—a fruit-grower as well as beekeeper.

Here is a sample of his practical efficiency. A few years ago he bought a piece of old worn-out land near Harrisburg which everybody said was good for nothing. He saw its great possibilities in fruit-growing, and began setting out fruit-trees. After two and a half years of his skillful management the trees were yielding a basketful of peaches each, and now he is getting fruit

off the farm—immense quantities of it. The land is now worth many times its cost.

Dr. Surface, on account of his active campaign against certain commercial insecticides that are worse than useless, and because of his insistence that only fit men serve in his department, has stirred up a lot of opposition. But during this time he has also been winning the friendship of thousands of fruit-growers in his state. However, politics has apparently been having its influence. Surface is not a pliant tool. His men must be efficient and not mere vote-getters. And now this man who has done so much for the farmers and fruit-growers in Pennsylvania has been dismissed without charges being preferred and without a hearing being given him. He earnestly pleaded for a hearing, but it was denied him.

The numerous Pennsylvania newspaper clippings that have been received at this office, dealing with the dismissal of Dr. Surface, indicate that the administration has apparently made a mistake that will react.

Another man, and a good one, will soon take Dr. Surface's place, in the person of Prof. Sanders, of Wisconsin; but apparently Sanders will have nothing to say concerning the selection of his field men; and if he runs up against the politicians, as Dr. Surface has had the courage to do, he will be severely hampered.

Similar removals of officials have been made in other states. When a nursery inspector or entomologist becomes familiar with the conditions in his own state, a new man, altho equally capable, will be very seriously handicapped before he can get the run of affairs.

We hear nothing but good of Prof. Sanders. Indeed, Dr. Surface speaks of him in the highest terms. We wish him every success.

In the meantime, Dr. Surface is considering several tentative offers, but he will probably take a much-needed rest before he takes up with any of them.

The Field Meet in Tennessee

IN this issue, in her regular department, Mrs. Grace Allen graphically describes some incidents connected with the meet held at her home. She did not tell the readers how royally she entertained her guests, nor about her charming personality. She is just what her writings would signify. She bubbles over with enthusiasm, and the beekeepers who were fortunate enough to meet at her home will long remember the day.

Mrs. Allen did not tell of her little apiary in the back yard; of its neat appear-

ance, of the gentle strain of Italians—how, during the whole day, not one of the bees stung a single person except, later in the day, when Mr. J. A. Buchanan was illustrating one of his stunts in introducing. Crowds mingled freely among the hives; in fact, they ate their luncheon right in the midst of the flight of the bees going to and from the entrances.

The speakers consisted of Dr. E. F. Phillips, of the Bureau of Entomology; Frank C. Pellett, of Atlantic, Iowa, who is writing for the *American Bee Journal*; Mr. J. S. Ward, foul-brood inspector of Tennessee, and who acted as presiding officer; Mr. Ben G. Davis and his father, John M., both of them extensive queen-breeders; Hon. H. K. Bryson, Commissioner of Agriculture; Mrs. Grace Allen; and E. R. Root.

The following day Dr. Phillips, Mr. Pellett, Mr. Ward, Mr. Buchanan, Mr. Drane, and Mr. Root went to Hollow Rock apiary where they were the guests of Mr. N. E. Smith. The crowd was not very large; but we spent a delightful afternoon there after which we went to Memphis. The field meet at this point was held on the fair-ground, where the persons already mentioned gave short addresses.

Mr. W. E. Drane entertained the crowd with an automobile ride around Memphis, winding up with a couple of mammoth watermelons at his home. This part of the "program" was a special success.

There are wonderful possibilities in keeping bees in Tennessee. It has a mild climate and the honey flora is varied and abundant.

Diagnosing Colonies Without Removing the Frames

MR. M. M. CUNNINGHAM, in his article in this issue, page 804, incidentally tells how he determines the condition of his colonies by merely lifting up the back end of the hive from the bottom-board, and looking up under the frames. Some years ago, it will be remembered by our older readers, the editor told how he managed to go thru one of our outyards one season with very little manipulation of the frames. The condition of each colony was determined by the flight of bees at the entrance and by tilting up the brood-chambers or supers and looking up under. We not only kept down swarming but produced a fine crop of honey. The visits to the yard were made on the bicycle, and only about half an hour or an hour was consumed at a time. These external examinations enabled us to determine about all we desired to know.

The flying at the entrance of any colony indicated whether they needed more room. If "hefting" at the back end of the hive confirmed the entrance diagnosis, super room was added in the form of a half-depth extracting-super. If the colony showed that it was not doing much, the brood-nest was opened up and the frames examined. A failing or missing queen was noted, and the colony was put in condition to build up.

The number of flying bees going into an entrance of a beehive will determine pretty accurately whether a colony needs more room. If there are only a few bees the colony may be weak. If there are only one or two bees at the entrance the colony needs an internal examination. One comb will often show the cause and suggest the remedy. Of course, one must not be confused by the playspells of bees.

If bee disease is found an examination of every comb is essential.

There were scarcely half a dozen colonies out of an apiary of some 80 odd whose brood-nests had been examined the entire season, and yet we believe no yard since has ever received any better care.

The ordinary beginner will not be able to make these external examinations; but as he grows in experience he will be able to determine a good deal by the flight of the bees at the entrances, and by hefting, as already described.

The late James Heddon placed a great deal of emphasis on the possibility of determining the condition of his shallow-brood-chamber colonies without handling frames. He urged that it was not necessary to handle frames to any great extent; that most of the work could be done by looking up between the combs; and to a great extent he was right.

We venture to say that some of the most extensive honey-producers today depend largely on these external examinations in order to save time. Mr. Cunningham is the only one to make any specific mention of it for some time.

The Eating Quality of Comb Honey Built from Starters or Full Sheets

IN this issue, one of our correspondents, Mr. Friedman Greiner, page 793, while preferring to use full sheets of foundation in sections from a money-making point of view, yet indorsing the sentiment of the late W. Z. Hutchinson, thinks he would prefer for his own eating combs naturally built without foundation.

Some years ago we conducted some quite

extensive experiments under the direction of Mr. E. B. Weed, of Weed foundation fame. We proved conclusively, or thought we did at the time, that comb honey built from a very narrow starter would actually have more wax to the cubic inch of honey than the same article built from a *full sheet* of thin-super foundation. This was not a mere guess, for it was tested out by Mr. Weed by actual weighing. As a general thing bees will build drone or store comb, when sections are being built on the hive, if they do not have full sheets of foundation in the sections.

Mr. Weed also discovered that even when bees built all worker comb, without foundation and with, the difference between the two was so slight that it could not be detected in eating. There are times, however, when one comb will be softer and more pliable than another; and if one should happen to get hold of a naturally built comb and bite into it he would conclude that it was certainly softer than combs that at other times were built from full sheets of foundation.

This would be an interesting experiment to try out on some field day. Sections should be prepared in advance, built without foundation and with full sheets. In the former case it would be permissible to use a very narrow starter in order to get the bees started right. If both these sets of sections when filled were exposed to the same temperature for a few hours before being eaten, we venture the prediction that the committee, after eating one and then the other, would not be able to tell one section from another.

The results of exhaustive experiments, some years ago, and which have been given in several editions of the A B C and X Y Z of Bee Culture, have convinced us that it is not only good business policy to use full sheets, but that the consumer is actually favored, because worker combs built from thin sheets of foundation have less midrib and less wax than the ordinary drone comb without foundation.

We suggest that, if Mr. Greiner will take a piece of naturally built *drone* comb and a piece of worker comb built from a full sheet of thin foundation, and fill both with plaster of Paris, he will find that, on hardening, the cross-sections will show more wax to the naked eye in the former than in the worker comb built from thin super foundation. We have in our office today plaster-cast samples of both. In some of the old editions of the A B C and X Y Z of Bee Culture appear actual photos in half-tones showing these casts.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

M. H. HUNT writes: "On page 427, GLEANINGS, June 1, you say it is unfortunate that raising the brood to stop swarming cannot be worked with comb honey. I have done it for 20 years with comb honey, using a ventilated bee-escape board on top of the sections. The ventilation allows the heat to pass up, and the brood hatches and passes down."

"It is no use," says a British authority, "trying to prevent drone-rearing by cutting out drone brood, as the bees will only build drone comb again." It is true, the bees will again build drone comb, but is there not still some use in it? For if drone comb be cut out at least once every three weeks, no drones will ever come to maturity, and we save all they would eat. Of course, the better thing is to plug the holes with worker comb or worker foundation.

WESLEY FOSTER, you say, p. 652, you don't like honey in your hot drink. I don't like it as well as sugar, either, at least most honey. But just to please me I wish you'd use honey anyhow. I'd like to have you live longer. Pick around and try to find some honey less objectionable to your taste. Some honey I can't endure in hot drink. For a time I bought Colorado alfalfa, as having mildest flavor; but the last I got was too strong, and white-clover honey is now my staple.

I WANTED eggs and larvæ in soft new comb, for queen-cells, from No. 67. July 17 I gave it an empty frame, not a starter of any kind in it. July 25 I found worker and drone comb built in it, some honey, and a good many worker-cells just started, but not a larva nor an egg in the frame. I left it so, at the same time giving an old black brood-comb, containing no brood of any kind. Aug. 2 I found the new comb as before, plenty of cells that looked as if they might be inviting to the queen, and not a larva or egg in the frame, while the black comb was well occupied with eggs and larvæ. Now, some of you people—nice, respectable people—people that I like, please reconcile the foregoing with the statement that your queens show a preference for new comb while my queens, other things being equal, always prefer old comb.

DECIDEDLY interesting is J. E. Hand's analysis of the swarming problem, p. 599. There seems no little to support his view, that diminished fertility causes the building

of cells, cells cause swarming, an open cell does not cause swarming because "an open cell is not an element of antagonism," and a closed cell causes swarming because "a capped queen-cell is an element of antagonism to a vigorous queen." But some troublesome questions arise. If a sealed cell is necessary to cause swarming, how is it that I've known many cases in which cells were persistently destroyed and the bees swarmed without waiting for cells to be sealed, in some cases swarming with only eggs in queen-cells? And if diminished fertility on the part of the queen is a necessary factor in swarming, how is it that I have known colonies to swarm with a vigorous queen not a month old, said queen being introduced while the swarming fever was on? The important thing, however, is the practice resulting from the theory, and in that Mr. Hand is solid: Requeen "before the zenith of fertility merges into broodiness." Yet it must be confessed there are objections to carrying out that practice in all cases.

PROF. BALDWIN, as I was reading what you say, p. 525, about introducing a queen by daubing her with honey, I said, "But don't you know that's more than 50 years old, and long ago laid aside?" Then as I read on about "half a teacupful of honey" it began to look as if you had something different from the old formula, which was merely to daub the queen with honey taken from her new home. Now suppose you tell us minutely just what you do, for success and failure often depend on apparent trifles. [The honey method of introducing was dropped years ago because it was noticed that, after the queen was laying, she looked as if she had been thru a period of smothering. Her body would look sleek, and she would look for all the world like some bees that had been nearly smothered to death. The general consensus of opinion at the time was that, while this plan was sometimes successful, it often and generally resulted in injury to the queen. The fact that such queen might die at a time when she could least be spared, during mid-winter or early spring, and that the colony would then be hopelessly queenless, made it unadvisable at the time to recommend the method. Prof. Baldwin, however, is usually careful, and he doubtless has eliminated the objectionable feature. If the queens introduced as he recommends look fresh and not as if they had been greased up, it is probably all right.—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

The very loveliest thing in all GLEANINGS is on page 619, July 15. No, I'm not going to tell, it's so worth your while to look.

* * *

The magnificent swarm that pours out so splendidly in the bright noon of May or June is one thing; and the little ornery, pesky (yes, I am choosing my words with the daintiest deliberation), measly swarm, no bigger than your fist that slips out at five o'clock some August evening is quite another. The first one is worthy a chapter in Maeterlinck; the other—well, one chooses one's words—and wishes one needn't!

* * *

Those June rains caused the clover to hold on a little longer than usual, and the bees had made a fair start in the supers again after extracting, when now along comes a flow (?) of honey-dew which is being stored generously in both brood-chambers and supers. It is interesting to notice how early the bees start out after it in the morning. It is all very well for wintering on, down here, but we don't want any left over in the supers.

* * *

I am greatly interested in Mr. Arthur C. Miller's article, "The Cost of Honey Production," page 591, July 15. This is something that undoubtedly most beemen are not sufficiently accurate about. Mr. Miller's article seems to me very thoughtful and concise in its presentation of estimates that are practical and definite. As to the accuracy of the figures—who speaks first? We are keeping our own accounts very carefully; but, being mere backlotterers, they are no especial value in such a case. Some day we shall be able to pass more intelligent judgment on that annual per-colony expenditure of \$2.75. At the present writing, it impresses me favorably—that is, when no time is spent except for work actually necessary, which is, of course, what Mr. Miller refers to. He was not attempting to estimate either the time or the value of the time some of us backlotterers spend per colony per year!

* * *

THE NASHVILLE MEETING.

It is certainly a delightful experience to meet people whom we have long known by name and have admired greatly. On August 9 it was the great privilege of the beekeepers about Nashville to meet Mr. E. R. Root,

Dr. Phillips, and Mr. Frank Pellett—a privilege we appreciated greatly, for we did thoroly enjoy our distinguished guests. May they come again and often—Tennessee and Tennessee beekeepers will always welcome them. My personal pleasure in these new acquaintances was particularly keen, and, in the case of Mr. Root, it seemed a bit like meeting a member of the family I'd not chanced to be thrown with before. It is nice to come to know the editor, especially when he turns out to be just what the letters from his office (even those he doesn't write himself) would suggest—a pleasant, friendly, courteous gentleman.

We did have a good time that day. "if I do say it myself as shouldn't." At any rate, the hostess did, even tho the weather did force her to pack her forty or more guests rather closely on the narrow porch all the morning, and even tho the prosy market-wagon did stop in front of her gate and announce itself with a shrill whistle right in the middle of a speech ("Nothing today," she called. "Gitap!" the driver exclaimed, when he saw the crowd); even tho, when called on unexpectedly for a talk, her embarrassed wits went scattering till not even one poor little wit would come back to help her thru her stammering; even tho the lunch, lazily ordered out from town, didn't come, and didn't and didn't (fortunately, it finally did); and even tho the nearly serious climax of the comic came the next day, when one section of the porch rail, graced all Wednesday morning by several prominent beekeepers, swayed out into space when she sat on it, and with a sort of last-straw-on-the-camel's-back air gave way utterly, depositing her none too gently in an ignominious and almost unconscious heap among the vines at the foot of the porch, and then, promptly banging down on top of her, so that the firemen came rushing dramatically across from the other side of the street to lift off the debris and help her into the house in their best rescue manner. But "for a' that," she did enjoy her guests greatly, from the least amateur, whoever he may have been, to the most important gentleman who sat on the porch rail; and she hopes that if ever any one of them comes this way again he will call up the telephone by the front window and say, "I'm coming out." He may be sure of a hearty welcome, a sandwich, and a cup of tea, or a cracker and a bit of honey, and plenty of talk about bees. Won't you all come back?

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Mr. Editor, in your footnote, page 585, July 15, you say that if Dr. Miller is right, "does it not argue that it is an advantage to produce both comb and extracted honey in the same yard?" I am not sure as to producing comb honey in an extracting-yard, but I am sure that it pays to use extracting-combs in connection with the production of comb honey.

SIMILARITY OF THE TWO DISEASES.

Inspector M. J. Meeker, of San Bernardino County, informs me that American foul brood seems to be more of an aggressor than the European variety (black brood) this season, with the two converging apparently in some instances. The American caused the "big scare" among beekeepers a few years ago, but now in this section the other kind seems to be more dreaded. He advises the adding of sealed brood in abundance to check the latter, caging the queen when necessary. He always encourages Italian stock. Mr. Meeker is emphatic as to Italianizing to cure the disease.

In a recent conversation with Mr. George W. Dixon, of Beaumont, he mentioned the similarity of the American and European types, but his description of the converging lines caused me to believe that the American form is mistaken for the European before it has reached the ropy, coffee-colored state of the last stages. Mr. Dixon did not claim that European foul brood is often sealed, but that the larvæ of sealed cells at first do not appear as being infected with American; but later there could be no doubt about the matter. It is a well-known fact that, even with American, the brood when it first succumbs to the disease has not reached the stage where it is but a ropy mass in the bottom of the cell, but is nothing more nor less than a dead larva. Later it degenerates into a mass of ropy filth in the bottom of the cells. This may in a way explain something of the converging lines, which are in reality only mistaken symptoms. Of course there may be cases where the germs of the two diseases are vieing with each other for the victim.

POISONING SKUNKS.

Skunks having begun their annual onslaught upon my Treemont yard I decided

to give them their usual feast of strychnine, which, as a rule, puts such a check to their operations that the bees are relieved at once. As I have before mentioned, I use small chunks of fresh beef in which the poison is well hidden. This is necessary, as it is not eaten readily if left on the surface so it may be tasted. All undevoured pieces should be taken up the following morning if there are domestic animals that might get hold of it.

But I started to relate a little experience. On the evening of July 22 my twelve-year-old son Ralph and I made preparations for a journey to the ranch for the express purpose of putting out some poison. It was quite late when we arrived, but we prepared the poison, lighted a lamp, and started to distribute the dope. We soon discovered that the bees were on the war-path at any noise that chanced to pass the hive, having been made so by being irritated so much by skunks. We were obliged to abandon the light; but as it was not yet extremely dark we continued to distribute the poisoned meat. We had traveled not more than a third the distance of the length of the yard when to my horror I found I was standing face to face with a large skunk. Well, as a rule I am not much of a coward; but I shall have to admit that these skunks have got me "bluffed" from the start. There I stood gasping for breath in a manner that left no doubt about my emotions; but I made no move, neither did the intruder. I was afraid I might draw forth some of its abundance of perfume, but I finally got up courage enough to pick up a rock to throw at it. My moving seemed to give it a spell of fear, and it dodged under the honey-house. It is safe to say that I left it undisturbed. When we reached the upper end of the yard we ran on to the second one; but it did not tarry long, to my great delight. Before we got back to the bunkhouse we saw the third one. We retired for the night, and such a night as it was! I had some difficulty in getting to sleep, and it was near midnight when I finally lost myself; but it was not many minutes before I found myself again. About that time it seemed that all of the skunks in the country were giving me a smell of their perfumery, and sleep for the rest of the night was out of the question. Poison causes such distress in some cases that the odor is released, while in others it acts so quickly the result is the reverse.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

ONTARIO HAS A FINE CROP OF HONEY.

I should not be surprised if the crop of clover honey would turn out to be one of the largest ever produced in the Province. As to the quality, a better honey has never been produced—color, body, and flavor being considered, and that is claiming quite a lot, as this province has produced some good honey in past years. Never has there been a better opportunity to popularize further the use of good extracted honey than the present time, for along with the keenest demand ever known for our product we have the finest of honey to supply the consumers. Why such a demand? Simply because of the high price of sugar and the greatest shortage in the fruit crop of all kinds, nearly, that we have had for many years. In my Notes for Aug. 1 I stated that much depended on whether the public looked upon honey as merely a luxury or as a food in determining the matter of prices; and judging by the way our telephone rings so frequently, callers asking to be supplied with from 60 to 200 pounds each, the fact seems evident that they consider honey a real necessity, and there need be no worry about the present good crop not being disposed of at fair prices. In our own case, at least, we are already to the point when we are considering refusing local orders in order to supply a number of customers in the West who annually expect to be supplied. "It is an ill wind that blows nobody good;" and while we are sorry the fruit-growers have such a poor crop, still we should rejoice that we happen to have a good crop of honey to help take the place of their product for this year.

While the crop has been good indeed, present indications for our own locality, at least, would make it appear that quite likely next year's crop is included in the present one, as the prolonged drouth is playing havoc with the clover. Buckwheat will be almost if not quite a total failure from the same cause, so considerable feeding will be in order later on. However, the brood-nests are the heaviest I have ever known at the close of a good flow; so, after all, the sugar-bill may not be excessive.

WHAT SHALL THE PRICE BE?

August 14, and as yet no report has come to beekeepers as to prices recommended for the season. This is no criticism of the

committee who have this work in charge, as the season was late, and doubtless it has been impossible to get the statistics necessary to form a reliable estimate of the crop at an earlier date. At the same time, a delayed report has its disadvantages in some ways, as many have chances to sell early in the season and have to use their own judgment as to what price to ask. In our own case, three-quarters of the crop was sold while still on the hives. What should we do in a case of this kind—wait for the report, or sell when the buyer was asking for the crop? Quite a problem to decide, surely; and when one has the chance of a good sale, taking tons at once, the temptation is strong to make a deal. However, the report coming later, helps to steady the market, and assists those who have not already sold their crop, this class no doubt being in the majority among the beekeepers.

STAY BY THE JOB.

If there is anything to be made in any business, the man who stays with the job is the one who will win out in the end. The truth of the foregoing was forcibly brought to my mind a few days ago when motoring home from the north yard, 90 miles away. Stopping for a few minutes to call on a friend I asked him what kind of crop a beekeeper had who lived just a short distance away. Imagine my surprise to learn that the beekeeper sold out all his bees last spring. Asking the reason why, I was told that, following the big crop of 1913, the two poor years of 1914 and '15 had discouraged him, and he had decided to sell. If he had held on to the bees this year in that same locality, he could have successfully weathered two more years of failure—a thing that is not likely to occur, for that matter.

Frequently I have remarked that if the virtue of patience is more necessary to any one class of people than to others, beekeepers are the needy ones, and the illustration just given once more proves this to be correct. Beekeeping is not a "get-rich quick" game, and the men who take up the calling expecting anything like that will surely be disappointed and disgusted in the end, while on the other hand the one who is adapted to the business, has lots of patience and "sticktoitiveness" to help tide over the poor seasons that are sure to come, stands at least as much chance at making a comfortable living, and perhaps a bit more, as those engaged in any other rural pursuit.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster. Boulder, Colorado

CARBOLIZED CLOTHS.

J. A. Green's article on freeing bees from supers is very interesting. My experience with using carbolized cloths is rather limited, but I look at it this way: During the honey-flow the bees may be smoked out as rapidly as they can be run out with the carbolized cloths. At the end of the season, when the weather is cool, the escapes will do the work far more satisfactorily. In fact, it is practically impossible to remove bees with carbolized cloths when the weather is cool. Bee-escapes have worked well with me, and it does not take more than twelve hours when not to exceed three supers are piled up on an escape. I am going to try carbolized cloths again, following pointers learned from Mr. Green's article.

* * *

THE CROP AND MARKET.

The honey crop is pretty well accounted for in the Rocky Mountain region now; and while the bees are still gathering (Aug. 12), little is being done in the supers except finishing. The total crop for the West will not be large—nothing like 1913, but probably near last season's crop. It is better in places than last season's crop and poorer in others. The drought in July cut the crop in Colorado fully fifty per cent, and the cool spring in Idaho made things turn out unsatisfactorily there. One and a half cases of comb honey per colony is about the average yield in some districts, and much less than that in parts of Idaho. Probably a few small areas will show higher averages. The demand for comb honey has not been brisk, as the white-clover crop has supplied the early market. The local demand for extracted honey has been good; and with a little more work the home market will absorb a large part of our crop.

* * *

GRADING COMB HONEY.

It is easy to grade comb honey so that it will comply with almost any grading rules if a few simple rules are followed. 1. Pack all sections of like color, weight, and finish together. Recognize that general poor appearance will consign a section to the cull class, even tho there may be little said in the grading rules applicable to that special

case. In packing, the lower grades require more cases to receive the various colors and weights than the higher grades. Three cases will generally accommodate the No. 2 grade; two cases for the No. 1 and two cases for the fancy grade. Learn to decide in a second or two just where each section of honey goes as you pick it up. It will soon become necessary to weigh but very few sections of honey unless you are stamping the exact weight on each section.

In polishing comb-honey sections a steel putty-knife, a piece of glass, or sharp-edged piece of steel will do the work necessary without the dust injuring the surface of the comb the way the polishing-machines do it. The manner of producing the honey is quite an item also.

* * *

SUPERING AND DESUPERING.

Early in the season the beekeeper is concerned with getting the bees into the supers; later he concerns himself with the problem of how to super; still later he is perplexed to know how to desuper his colonies. If spring work has been done properly, and the season is favorable, it is easy to get the bees into the supers if you have eight-frame hives. Here in Colorado it is far easier to secure a crop of comb honey from an eight-frame than from a ten-frame colony. Colonies may be forced to super work by lifting the body from the bottom-board an inch or by the use of bait combs.

In supering, it is rare that a season is so favorable that lifting supers and placing empties beneath is advisable. This season, all (or practically all) supers have been placed on top, and even at that there are some ten and eleven ounce sections. Full top starters and bottom starters are used too. Comb honey is removed when supers are four-fifths finished, and the unfinished sections are returned.

At the wane of the flow the bees are crowded down to what they can finish. When the hives are "skinned" of supers two combs are removed from each, and empty drawn combs are inserted in the brood-nest to induce more brooding for winter bees of youth and vigor. We have more trouble here with too much honey in the hive than too little; but we save combs for use in feeding too. One way that is a good one is to have shallow extracting-combs to put on when the season wanes. These may be left on the hives all winter.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

TWO SIDES.

A correspondent writes: "Would not the beekeepers be better off without so many useless middlemen who style themselves 'dealers'? Are they not living without effort off of the real producers of honey? They add nothing to the real wealth of society. They merely transfer things from the place of production to the place of demand."

There is an old story about two men who stood on the opposite sides of a signboard which read on one side so many miles to A, and on the other side so many miles to B. The first man read from his side, and the other disputed him in no good-natured terms, reading from his side to prove the first wrong. This resulted in their leaving the sign and pounding each other till both were exhausted. On getting breath they returned to the sign, but happened to exchange places at the sign. This resulted in a good-natured shaking of hands, with the exclamation, "What fools we have been!"

Is our questioner sure that to "transfer things from the place of production to the place of demand" plays no important part for the beekeeper? What is production, any way? and who are the producers of wealth? Take honey for an illustration. When does production begin, and where does it end? Are the bees the producers, or is the man who manipulates the bees the chief and only factor in the production of honey? When is production completed, or when does the act of production cease and that of consumption begin? Evidently, production ceases when the honey is in the hands of the consumer, and not before. If this be true, and it seems to be so, then every man who aids in bringing honey in a suitable form to the consumer should be considered a producer.

Not only this, but the man who helps create a desire for our honey is a factor in its production—very little less so than the man who owns and manipulates the bees. Wealth is whatever satisfies human desires; and if no one desired honey, then it would have no value; and the placing it on the market would not be real production, or, to say the least, would be useless production. Production, then, in the broadest sense of the word, means gathering into a suitable form for use, and placing before those who have a desire for that special article the product in such a form as will

satisfy the desire. But this, if I see correctly, is not all, for there must first be created a desire for any article before there can be any benefit derived from placing it before the one who is expected to consume it. The one who creates a desire adds as much real value to an article as the bees or the man who manipulates them, where that article is honey. Whoever checks this natural movement of trade, or forms a combination with his fellowmen to restrain or control it, is a traitor to society. All legitimate trade is production. A combination or trust to produce a monopoly is robbery.

The question then is, Does the dealer or middleman check the natural movement of trade in honey? Does he form a trust or monopoly to hold up the legitimate desire for our product? Is he not rather of value because he brings our goods to the point of consumption at a less cost than could be done by the beekeeper or the consumer? Have not the dealers in the past been prime movers in creating a desire for the honey the beekeepers have produced? If so, the dealer cannot be considered a useless idler by any means. The real idler is the man who has no trade at all—the man who thinks society owes him a living and is all out of joint because he does not get it. On the other hand, the man or woman who has created any new desire in any part of the world for our products from the bees is as much a producer as the man who brought the alfalfa and alsike clover into the parts of the United States where they were not known 50 and 75 years ago, to the nearly doubling of our honey crop in very much of the territory of our country.

Another thing that none of our beekeepers seem to have thought of. Suppose we could do away with all of these "useless middlemen," so that they could not get any commission on the handling of our honey. What then? What occupation must they take up in order to become producers? Must they all go to keeping bees? If they did, what would be the consequences to the beekeepers of the United States? If every drummer would quit the road, every dealer cease to buy and sell, every so-called "worthless middleman" stop his trade and barter, and all in one mass begin investigating the wonders of the hive, and become "producers," according to the ideas of most of those who proclaim on this subject, where would be found a market for the products of their labor and ours?

GENERAL CORRESPONDENCE

CURES AND IMMUNITY OF THE ISLE OF WIGHT DISEASE

BY GEO. W. BULLAMORE

"Labor in vain and lost cash" is the usual result of attempts to cure bee diseases by means of drugs; nor do I think we are justified in hoping for any other result. The physician has attained some success in the treatment of human ailments; but the drugs administered are usually for the alleviation of the more distressing symptoms. Careful nursing and dieting then bring about the cure. In a few diseases, drugs, such as certain compounds of arsenic, have a direct effect on the cause; but for successfully stamping out an epidemic it is necessary to resort to methods for the prevention of contagion.

The sudden death in winter of a large number of stocks which were packed down in the autumn in apparently good condition after producing surplus is a symptom of the Isle of Wight disease which does not offer opportunities for treatment. At certain times, however, bees are to be seen crawling with the bowel heavily laden with pollen residues. Attempts are often made to treat this manifestation of disease by means of aperient medicines administered in sugar syrup. Sometimes success is claimed; but we know very little about the action of drugs on insects, and it is not unlikely that the result would have been the same had the drug been omitted from the syrup. A natural honey-flow may also bring about the cessation of crawling. When syrup or dilute honey is being administered to the bees, excess of liquid is often passed off thru the intestines. When nectar is being gathered, some of the water finds its way to the bowel. The resultant flushing relieves the system of toxins (poisons produced by disease germs) which cause the symptom, but the disease itself remains.

All the reported cures of Isle of Wight disease appear to be records of the disappearance of this crawling symptom, and to have been brought about either by feeding with syrup or dilute honey, or by means of a sudden stoppage of brood-rearing. The giving of sulphate of iron in the food, sprinkling the combs with sulphur and other fungicides, and painting the inside of the hive with creosote, are operations known to destroy brood, and have been suggested as cures. When brood-rearing ceases suddenly, the vital drain of gland secretion from the workers is arrested; and, in addition, the excess moisture from the

food will now pass to the bowel. Crawling due to weakness and parasitic intoxication will then cease in a few days. For some such reason an apparently immune stock in an attacked apiary often proves to be queenless.

Attempts have been made to find a strain of bees that would resist Isle of Wight disease in much the same manner as the Italian race resists European foul brood. It is no test of resistance in this latter case if we merely change the queen of a foul-broody stock without allowing a period of queenlessness. Neither do we give the new race a fair trial when we requeen a stock showing the crawling symptom of Isle of Wight disease. In both cases the bees are swamped with disease from the commencement of the experiment. When Italian bees have had a fair chance I think that there is some evidence that they are the last to be affected, and that they more often recover temporarily. This suggests some slight degree of resistance rather than actual immunity; and to make the distinction clear a few lines on the nature of epidemic disease may be of use.

The breaking-up of organic matter into simpler compounds in nature is brought about by the agency of fungi, among which we include minute organisms known as bacteria. Many of the bacteria have resting forms, known as spores, which tide them over periods of adversity. Others depend for their continued existence on a continuity of food supply.

While life is present, the organic matter can resist the attacks of the majority of these bacteria (it possesses immunity), but certain forms have power to overcome the resistance of the living host, and a condition of parasitism results. Should the bacterial growth prove harmless, or should it handicap the host but slightly, the relationship is one of tolerance. But the growth often results in the production of poisons known as toxins, and these produce disease and death in a susceptible host. In much the same manner minute animal parasites may produce disease.

Diseases were originally much more local than they are at the present day. The result was, therefore, that the constant attack on a limited number of hosts meant the extinction of the hosts, and, in consequence, of the disease for lack of material. Other-

wise it resulted in the weeding-out of susceptible strains and the survival of those possessing tolerance or immunity. Owing to variation in this tolerance and immunity, disease might show from time to time, and in such a district the disease would be said to be *endemic*. Owing to migrations or to commerce some of these tolerant individuals reach other localities where the disease is unknown. In such a favorable field the germ is able to attack large numbers of individuals with low powers of resistance, and the result is an *epidemic*.

Now we can understand what has been happening in the bee world. Commerce and the increase of beekeeping, so that districts are now linked up by living bridges over which the disease can cross, give advantages to disease that it never before possessed. We do not know when Isle of Wight disease first issued from its endemic center, and it is quite likely that it has found a home permanently in more than one district. It is not much in evidence in dry hot summers, but will cause heavy losses during the winter. In a dry warm country where there is no wintering problem such a disease might attract no attention. In the struggle for existence, however, the more resistant bees would be favored. Unfortunately when such bees are brought to northern latitudes the winters are likely to prove fatal when the parasite is present.

The survival of certain apiaries on the Isle of Wight for several years after the other bees were dead does not appear to have been due to immunity, but, rather, to the fact that the disease did not reach them. Such apiaries disappeared quickly enough when attacked. On the same lines it is possible that the success of the Dutch bees was due to their freedom from harmful parasites when imported. They gave good results, but, like other kinds, were liable to contract disease after a time. When a district has been cleared, bees from Holland are very useful for restocking purposes; and as it is possible to obtain colonies of them the grafting of healthy queens on to moribund or doubtful stocks of native bees is avoided. Fecundity is one of their assets.

So far as I can interpret the facts, attempts at drug cures and the requeening of dying stocks can be dismissed as of no avail. The destruction of stocks showing crawling symptoms, too, has little or no effect on the spread, because the disease travels by means of the flying bees before such symptoms are manifested. To be of use the destruction of the stock in question should be accompanied by the destruction of all stocks within a radius of several miles. As this is scarcely practicable, it is advisable to avoid attempts at keeping up a dwindling apiary, but to wait till the district has been cleared of bees, and then make a fresh start with a healthy strain of bees. My preference in this direction would be for a strain of yellows with a record for longevity similar to that given by Doolittle on page 10 of GLEANINGS for this year. We can feel pretty sure that longevity and health are associated, and I always feel suspicious that the short-lived bee may be suffering from some chronic trouble which robs it of a few days of the best period of its life from the honey-producers' standpoint.

As to using the combs again, we know that infection may precede the first symptoms of disease by at least six months. We know that then the disease may disappear to terminate fatally six or nine months afterward. If we do not notice the first batch of crawling bees we may think that these bees have remained healthy for over twelve months. When bees are put on to old combs, and death takes place a year or two afterward, it may be due to reinfection; but there is an element of uncertainty about it. It is far safer to store the combs for a time at least, and reject some of the heavier, dirty, breeding-combs which afford the maximum protection to disease germs. The precaution may be unnecessary; but some of the evidence suggests ground infection, and it is, therefore, supposable that a germ may sometimes reach the combs.

A minute animal parasite, *Nosema apis*, is thought to be the cause; but diseases of this type are the most baffling with which the pathologist has to deal, and afford ample opportunity for controversy.

Albury, Herts, England.

THE HONEY-MONEY MAKERS

BY ROSE WILLIAMS.

To my way of thinking there is nothing more attractive and at the same time so remunerative as bee culture; and for the life of me I cannot understand why more people don't take it up professionally. Every

little country place should have a few colonies of bees, and big places would profit by having a full-fledged apiary.

My place is situated about three miles from a thriving city; and while I hold a

Miss Williams' apiary, Nashville, Tenn., consisting of ten colonies increased from one in three years.

position in town I enjoy my bees as a side line. I think I must have been born under the honey star, for I've always had great admiration for bees. As a child I enjoyed them on our neighbors' adjoining farm, and I grew up with the intention of having bees of my own. The fact is, when I was quite young I planted the orchard which the hives now beautify for a future beeyard; and when I finally reached that long-looked-for period I started my apiary. Under the

most imposing peach-tree I placed the first hive of bees, which I bought from a friend, and then waited for results.

I remember how excited I was when I had to deal with my first swarm; and for the inexperienced apiarist there is nothing to compare with that sensational thrill that simply envelopes one with the startling realization of the novel duty devolving upon him in hiving his first swarm. I think I can safely say that to a *real* beekeeper (I

use the word *real*, meaning thereby one who actually loves the study and work of bee culture) there is nothing more inspiring than swarming bees. Coming at a season when one is usually busiest about his place it often happens that a swarm will issue from the hive at a most inopportune time, thus testing his patience; still, when he sees the hurrying and scurrying of his pets as in a mob they scramble out of the hive, and hears the joyous note of their madly whirring

The hiving-board is to a hive what a porch is to a house.

The first swarm after the limb was cut from the tree.

wings as they fly swiftly about before settling in a cluster on some convenient bush or low-hanging limb, he cannot help being convinced that the occasion is a festive one for the bees, in which he is glad to join and do his part.

It seems fundamentally to be the case that swarming is caused by an overcrowded condition of the hive. In May and June, after the honey-flow is well established and the hive is full of bees, the honey-combs laden with honey and the new brood soon to hatch, the bees decide that it would be advantageous for part of the colony to leave their present home and seek new quarters; so queen-cells are built, and pro-

vision thus made to supply a new queen, for the old queen always leaves with the swarm. It is not known what determines some of the bees, usually about two-thirds of the colony, to leave while the others remain to care for and hatch the brood. But so well organized are their methods that in this as well as in all other economical questions, their procedure is based upon wonderful foresight.

In the first place the bees realize that their existence depends upon their having a queen, for the queen lays all the eggs (in the working season she lays as many as three thousand eggs a day) from which the bees are hatched. There are three kinds of bees to a hive—the great majority, known as “worker” bees, being the honey-gatherers; the queen which is ruler of the busy tribe, and a limited proportion of drones. The drones are of masculine gender, the “workers” being females. Eggs for workers and drones are unlike; but one of the queer things is that the same egg that produces a worker-bee will, if fed and nurtured in a certain way, produce a queen. Therefore the workers may decide for themselves when they wish to hatch one or more queens. With admiration I gazed upon a queen-cell, shaped somewhat like a peanut hull, and hanging down from the side of the comb. This is made by the workers to accommodate the queen’s wonderfully slender, tapering body. I also noticed drone-

Removable combs make it possible to examine the colony at any time.

cells, which are similar in shape but larger than the worker-cells.

I had examined the colony only the day before, and had seen that the queen-cells were almost ready to hatch; still I felt a thrill anyway when some one near the beeyard yelled, "Come quick! your bees are swarming!" Hurriedly adjusting my veil and gloves (for I had not then sufficient self-confidence to risk handling them without some sort of protection) I ran to the scene of action. The air seemed filled with bees darting in every direction, making the morning beautiful to me by the sunlight glints flashing from their rapidly whirring wings. They were all about me, whirling and humming, apparently with no thought of settling into the cluster I so anxiously waited for them to form. Being a novice I might have been terrified, in spite of my armor, to be in the center of such a madly rushing mass of bees had I not known that; far from being hostile, they were in the happiest frame of mind possible. I knew their honey-sacs were laden with honey in preparation for their unknown journey in quest of a new abiding-place, for they always leave their old home with true holiday spirit.

After ten or fifteen minutes of patient watching I was glad to note that they had begun to form a cluster on a peach-tree limb near by. I waited till the cluster was completed and the bees quiet. Then with black Bill's assistance I carefully cut the limb, and with cautious step carried the entire cluster to the new hive which I had previously set in a shady place. The new hive was fitted with frames of wax foundation, which, I find, saves the bees some work besides insuring straight comb, as the cells are built with mathematical precision on each side of the foundation. After reach-

60,000 bees on the march into their new home.

ing the hive safely I quickly drew up a hiving-board to the entrance, and, with a quick jerk, shook the bees upon it in front of their new home. With a soft brush I lost no time in starting the main body of the confused mass of bees toward the hive. They readily entered, for the stately queen graciously led the way. Had the queen for any reason not gone into the hive, no amount of persuasion could have caused the other bees to remain inside; instead, upon discovering her absence they would have soon returned to the parent hive, probably to swarm again within the next few days under the leadership of one of the newly hatched queens.

After the first or "primary" swarm in the spring there may be one or more swarms, known as "secondary" swarms, within a week or ten days as the young

greens hatch. These swarms are never as large nor as enthusiastic as the first one to issue, and their number depends on the subsequent strength of the colony.

The hive that I use is an ordinary modern eight-frame hive. The removable frames make it possible to examine the condition of the colony at any time. A top compartment, or "super," containing twenty-four sections in each of which is a small piece of wax foundation for a "starter," is placed upon the hive when the bees are ready to store surplus honey. These sections, each holding about a pound of honey, are easily

removed, and are ready for immediate use or sale.

I began with one hive, but within three years had increased the number to ten, which is quite enough to handle unless one makes a regular business of it.

So to the man who has room enough under a fruit-tree for a hive of bees, I say from personal experience, put one there—you will be repaid many times for your trouble, for in this day of unfaithful servants you will find a very remunerative helper and willing, conscientious workers in our friends the bees.

Nashville, Tenn.

A BANKER WHO COUNTS HIS HONEY

BY J. J. MOYERS

The photograph shows one of my eight apiaries, this one numbering fourteen colonies. On May 31 I extracted from these fourteen colonies 130 gallons of honey, leaving untouched the entire lower bodies and all the frames that contained brood in the upper supers. This honey I retailed for \$1.25 per gallon. From the cappings of this yard I extracted 9 lbs. of beeswax at 27 cents per pound, making a total income of \$164.96. My expenses were three men at \$2.00 per day, taking half a day, \$3.00; containers, \$8.40, this giving me a net profit of \$153.56.

These figures are only from the first

extracting, and I feel sure I shall be able to extract twice more before the flow is over, as the white clover (which is our principal crop) is just now at its best. I am confident that by the 25th of this month (June) my bees will be just as rich.

There is no question but that this is a great surplus for the wonderful little bees; but after noticing the white clover in the foreground of this picture, and knowing that there are hundreds of acres surrounding it, makes my statement more plausible. We are also in the center of the crimson-clover belt.

I have never seen the honey-flow better.

One of eight apiaries owned by a banker, J. J. Moyers, Fayetteville, Tenn.

It seems as if they might have a running fountain.

In 1914 and 1915 the crop was almost a complete failure in this section, causing a loss of about half of all colonies in this section, due to starvation.

After banking hours are over my spare hours are spent with the bees. For profit

and pleasure I find there is nothing better. My two observation hives, as shown in GLEANINGS, June 15, 1914, I keep at my home. They are my greatest pets. Even my baby loves them. Every beekeeper should have one or more observation hives. Ten times the worth of mine would not buy them.

Fayetteville, Tenn.

WHAT I DO ON MY ROUNDS OF THE OUTYARDS

BY MILTON C. BERRY

Twenty-five years ago I joined the beekeepers' fraternity by annexing to my small lot of boyhood possessions two old gums of black bees bought from a neighbor who kept a few bees in the old-style way. After having carefully closed up the hives with old sacks, very securely fastening all the little fellows inside, I moved them to my home near by. Gradually I acquired necessary tools such as a smoker, and later, after purchasing some dovetailed hives, I added a hive-tool, my father's old screw-driver. After this the two hives were carefully guarded. Swarms came, and the two old gums—the nucleus of a future large business—began their increase.

During the day, when not busy with the bees, I was thinking of them, and, when asleep, I remembered them in my dreams. I looked forward to the future when my two old gums of blacks should become a thousand or more beautiful Italians in up-to-date, modern hives. Well do I remember my mother saying fondly, "My boy, you certainly must have a bee in your bonnet." The mother is gone now, but my boyhood dreams have come true for I now have over a thousand colonies of virtually pure three-banded Italians.

These thousand colonies, forming nine separate yards, are located within a radius of twenty miles around my home town, Hayneville, Alabama. Eight of them I term "out" yards, and what I wish to tell my brother beekeepers is how I manage these yards so as to enable me to make from one to two solid cars of honey annually, and at the same time to ship thousands of pounds of bees.

In each of these yards I have from fifty to two hundred colonies of bees, depending upon how many each location or territory will support. I learn the right number by observation and also by test, placing a few colonies in a given location, and gradually increasing until I find just how many such territory will support. It is quite possible to have a territory which will support a

double number just during the main sweet-clover honey-flow, but one has always to figure on the spring and fall when there is a slow flow from other sources, and not a great quantity at that. If the locations were given all of the colonies which they would at times support, then during the spring and summer one would be compelled to feed large quantities of sugar syrup. Therefore I deem it expedient to locate at these different yards only as many colonies as can be supported the year around with a small cost of feeding. At all of these yards which I am running for honey production there are good houses equipped with extractors, smokers, hive-tools, etc. In fact, on arrival at one of these yards all that I have to do is to unlock the house, light the smoker, and get busy.

THE SPRING MANAGEMENT.

Either the last of February or the first of March I begin my first round, as we call it, going to each yard, examining all hives, and thus determining as to stores. If any seem to be light, and thus short of honey I take from those which have an abundance and some to spare, and give to their less fortunate relatives. In fact, the main object of this first round is to equalize stores, or feed the colonies short of stores. The next round is made about two weeks later. This time, if the weather is warm, and it usually is by March 15, I remove covers, scrape tops of frames, and, with a file bent to form a hook, I remove all burr-combs between the frames. This tool is made very easily from any old worn-out file by bending the handle so as to form a hook, which can be run down between the frames very nicely, and then drawn from front to back. The hook not only removes the burr combs, but also holds the wax so that it can be removed and placed in a box, and thus saved. By saving these small particles of wax at the end of the second round I often have from seventy-five to one hundred pounds of wax when these scrapings are rendered.

While on this round I not only clean up all hives as well as covers if they need scraping, but I note the condition of all colonies as to brood and also the condition of all queens. If any seem to be failing I mark the hives to be requeened on the next round. Entrance tins are now removed. These are what we call mouse-guards and are two inches high and six inches long, having three small sawtooth holes in them just large enough to allow two bees to squeeze in together. In the fall these are slipped in behind the regular entrance cleats, made of common plastering laths, with entrance cut about one-half inch high by four inches long. These tins keep mice from going into hives during cold winter nights and gnawing the combs containing pollen. Thus I am able to save many beautiful combs from being virtually ruined by the inroads of the well-known field mouse.

My next round comes about the first of April. This time I requeen all colonies having poor queens, and give queens to any that may have had no queen the round before. I again equalize stores.

About the middle of April I make my fourth spring round; remove cleats on all strong colonies; draw brood from the colonies that appear to be about ready to swarm, and give to weak colonies, or else elevate brood to the upper story above the queen-excluders in exchange for empty combs.

About one week later I make another trip around, and if I find any bees still inclined to swarm I elevate the brood again, and if this does not have the desired effect, and I find some queen-cells started, I elevate the hives a little at the front, and sometimes crack the covers about one-half inch to the

side. By this practice, and always seeing that all hives have plenty of room for both brood-rearing and honey-production, I seldom lose any swarms.

MANAGEMENT DURING THE HONEY-FLOW.

The main honey-flow from sweet clover is now close at hand, and my colonies are running over with bees ready for the harvest. If the clover sees fit to yield a bounteous flow in return for my labor, you may well know how I feel. I work, I almost slave, to keep ahead of the bees, elevating the full supers and placing those that have either empty combs or those partly full always just above the queen-excluder and next to the brood-chamber. At the same time I am busy extracting combs that are full and capped over. Thus I get my large crops. On the other hand, if the clover does not yield the nectar—again you may know how I feel—another long year to wait for another opportunity. So if I am blessed with a good crop of honey, I gather it; if not, I take my medicine with a smile, altho, perhaps, it may be a sickly one.

Incidentally I wish to mention that while making my rounds all colonies that show unusually good qualities for honey production and gentleness of disposition I mark and later move to my queen-yard. To all colonies having old queens I give new young mothers, and all which have not yielded returns as I believe they should I also requeen, thus preparing for the coming year.

About the last of October I make my last round, putting on entrance cleats and mouse-tins, carefully scraping covers, and seeing that they fit closely to keep out the cold winter winds.

Hayneville, Ala.

HONEY AND HONEY PRODUCTION

BY HOMER MATHEWSON

Half of my life I spent in New York, producing clover, basswood, and buckwheat honey. Since then I have visited many of the great honey-producing sections in Florida, Texas, Colorado, California, Nevada, and Utah.

There is a great contrast between New York and the tupelo region of Florida, the mesquite and horsemint of Texas, the alfalfa of Colorado, and the orange and sage of California. The alfalfa of Nevada is water-white, while that of Imperial Valley is light amber. Why the difference? Simply the heat, and perhaps a little owing to the water.

The outlook in Utah seems better than in

Colorado, where in many localities, at least, it would seem that the honey crops are diminishing, owing to the land being used for diversified crops.

The marketing methods in most places are very poor, not over a tenth of the crop being sold at home. The home market should be increased.

Speaking of disease, the successful men of today have learned how to cope with disease, and they have very little fear. There may be a few cases of bee paralysis, but far more of beekeepers' paralysis. Much is written of the eight and nine hour day. Sometimes it needs 16 hours for success.

The picture [cover illustration.—Ed.]

A city apiary that developed from a couple of swarms. The straw around the hives was for protection in the spring. Photographed by HOMER MATHEWSON.

shows one of the many apiaries in the San Fernando Valley, Southern California. This yard is located near Chatsworth, and is one of nine outyards owned by the California Honey Co. This apiary produces only sage honey, very little orange being within reach. A fire-brake has been plowed around the yard, but even with this protection I am informed that there was some damage done by fire the year following my visit.

These apiaries are placed where there is sage enough to make a profitable yield, the one necessary asset being water, which must be near. At a water-hole on a hot July day there may be a bushel of bees getting water at one time. An amateur might think it was a large swarm. There may be a fair crop from sage every year, yet the sage will yield only three or four large crops in ten years.

Same city yard in July. Photographed by HOMER MATHEWSON.

The city apiary moved into the country for the buckwheat flow. Photographed by HOMER MATHEWSON.

EMIGRATES TO SUCCESS.

The last picture shows one of the large apiaries of Mr. Geo. B. Larinan, of Pasadena, Cal., a native of the Middle West. Mr. Larinan went to California a few years ago, settling in the San Joaquin Valley, where he commenced the keeping of bees commercially. After spending a year or more here, Mr. Larinan went to Pasadena. Mov-

ing his bees and buying more, he was able to establish two large apiaries of about 400 colonies each. These are located at Duarte, Los Angeles Co., among the orange-orchards, the bees having access to thousands of acres.

The fact that all the orange-orchards are irrigated makes possible a crop every year, altho it sometimes varies in quantity.

George B. Larinan's apiary near Pasadena, Cal., hauled by auto truck to the sage regions near Newhall, Cal., where the picture was taken. Photographed by HOMER MATHEWSON.

After the flow from the orange is over, the bees are carried by motor to the vicinity of Newhall, where they are loaded in the early evening, and in the morning they are flying among the sage 30 miles away. By moving this apiary Mr. Larinan is able to

secure a crop of honey much greater than he would if he had left the bees in the orange location. The motor truck is a great boon to the nerry beekeeper who wants the honey.

Lexington, Ky.

ARE BEES GUIDED BY SCENT OR BY SIGHT?

BY B. BLACKBOURNE

The editor has stated that the flight of bees is dependent on the distance they can see pasturage. I should like to suggest that scent plays an important part in helping the bees to find extensive areas of honey-producing plants. I have frequently noticed that on a windy day the perfume from certain flowers is carried for a considerable distance, and I am inclined to think that bees will follow up the "trail," so to speak, against the wind.

A year or two ago I came across a case which pointed to the above conclusion. My apiary is situated in an orchard bounded on its north side by a high hedge and a thick row of plum-trees. Beyond this the fields stretch away up hill, and three-quarters of a mile to the north-west are many acres of sainfoin upon which my bees were working. On this particular day an east wind was blowing; and as I was returning from the fields I noticed a steady stream of bees proceeding against the wind along the north side of the hedge. Being curious as to where they were going, I followed them up and found that they were working on about an acre of white clover situated at the end of the hedge about a quarter of a mile from my apiary. Now, this white clover was mixed with some other clovers and rye grass, and the actual flower-heads were mostly short and not at all thick. That is to say, they did not present a mass of white that could be seen from a distance. The bees were blacks, and must

have come from an apiary situated a mile to the west of my own. I could see that none of my bees were working on the clover, for mine were Italians and hybrids.

Now, why were not these blacks working on the sainfoin, which was much nearer to them—less than half the distance of the clover? I concluded that the scent from the clover had been carried down by the wind, while that from the sainfoin had been carried to the north of their hives. Why, then, were not my bees attracted? Either because, in order to get out of the orchard to reach the fields, they were obliged to rise high in the air to clear the hedge and trees, or else because they had previously been

working on the sainfoin for some days, tho if this latter is the reason why did not the blacks also work on it?

The whole question is an exceedingly interesting one, and also important for those engaged in commercial beekeeping; as one of the principal aids to success is in the study of one's locality.

Ramsgate, England.

DRIFTING SWARMS FROM BOX HIVES

BY F. GREINER

The practice of making forced swarms by driving or drumming them out of their habitation into a box or hive placed on top is a very old one. When the straw skep was in fashion this manner of increase was

practiced to a great extent in European countries and is now. The follower of modern methods, however, scorns the idea of making forced swarms by this simple and effective method, and still it may be

practiced to advantage even by him. In some cases it seems to be the best way. I would not want to recommend the method to the up-to-date beekeeper who uses hives of the Langstroth pattern, has every comb a perfect one, easily movable, etc. He probably will make brushed or shaken swarms if such a procedure should become necessary. But when using such hives as the Heddon or Hand sectional hives, particularly when they have been occupied for a number of years by the bees, the method of driving and drumming out the swarm will prove to be as simple and successful as any other. I frequently resort to it in the management of my sectional hives.

It is not a bad practice to place the empty hive on top of the hive which is to be treated two or three days in advance, or perhaps even a week, if it is in the out-yards. In the latter instance it is better to place an excluder between the occupied hive and the empty one. I have the hive which is to receive the swarm filled with comb foundation preferably, or comb. Then before I make the drive this excluder is removed. Drumming and pounding on the hive for 10 or 12 minutes sends the majority of the bees with their queen into the hive above. A little smoke given at the same time facilitates the work. I close the entrance during the operation, opening it for only a moment when applying smoke now and then. After the drive is made, the upper hive with the bees is lifted off carefully and placed on a bottom-board, when it is given the same place the mother hive had occupied. The super is given at once, perhaps two of them, according to circumstances.

The mother hive may be given a new location and a queen run in at this time. Or, if desired, a queen-cell may be substituted. If increase is not wanted, the old hive is moved back; and after three weeks' time a second drive is made, the bees added to the new colony, all the time plenty of room being provided for storing honey in the supers. The plan is practically the same as transferring according to the improved method.

The brood-chambers, now free from bees and brood, are tiered up on colonies not in the best working order. More or less honey will be stored in them, and they may come very handy in supplying winter stores to the colonies that have given the most section honey and are often lacking enough stores to carry them thru the winter safely.

WHY I NOW USE FULL SHEETS OF FOUNDATION IN SECTIONS.

Our lamented friend Hutchinson express-

ed his idea of comb foundation in section honey thus: "I would rather pay five cents more per section of honey for my own use if the comb was all built by the bees with no foundation used." This was exactly my idea, and I have produced honey, tons of it, for years, using only small foundation starters in my sections. How much more money I might have made had I used full sheets all the time would be interesting to know, but will remain a matter of speculation. I am satisfied that my bank account would have made a better showing.

What is the reason for my change of practice? In the first place, my efforts to produce a better grade of honey from the consumer's standpoint were not appreciated. My honey did not bring a better price—rather the opposite. There was a reason for buyers preferring honey built on foundation. It not only looked better, was usually built out better, and fastened to the wood more securely, but it carried much better when transported by vehicle or railroad. This last is a very important point in favor of the more inferior article.

This fact was vividly brought to my mind when I bought about 200 sections of honey from a farmer beekeeper this fall—honey which had no foundation in it except very small starters. It was fine honey; the sections were not very neat, well filled out, and well attached. I scraped it, erated it in cellular shipping-cases, and carried it home in the auto over pretty fair country roads. When I arrived home and examined the honey I found one-fifth of the combs broken out. I have carried practically all of my honey from the outyards home in the auto for two seasons, and have not broken any at all. The foundation that the boxes were filled with made all the difference. I did not feel so very bad over the mishap, for we could and did use this honey on our own table, and also sold a good part of the unbroken lot to special friends who, we knew, would appreciate a good thing. It is my aim to produce a little comb honey every year without the use of foundation. We like it very much better for our own use.

It is very difficult to arrive at definite facts as to how much more honey a colony will produce when full sheets of foundation are given over the colony given starters only. I have reason to think it is somewhere between 20 and 25 per cent. I am satisfied that it is a good investment to fill every section with foundation—extra-light section foundation—no other should be used. The cost is half a cent per section, or thereabout. If on an average we obtain 50 lbs. of comb honey per hive, the cost of

the foundation would be 25 cents; and if ten pounds of this honey is owing to the use of the foundation in full sheets, the 25 cents represent the cost of the ten pounds

gained to us. Because it is profitable to use comb foundation in sections is the second reason why I have changed my practice.

Naples, N. Y.

OSWALD ST. JOHN GILBERT, A "BEE KING"

BY LESLIE BURR

Who is the most extensive honey-producer today? How many can answer?

My acquaintance with extensive honey-producers dates from the year 1900—the

year I attended the convention of the National Beekeepers' Association at Chicago, and there met many of the extensive beekeepers of the United States. Prior to that time I had never met any person who had more than a hundred or so colonies of bees, so it was with a feeling of awe that I took my seat at the convention among men who were large honey-producers, estimating their crops each season as so many tons or earloads. Particularly do I remember W. L. Coggshall. He sat next to me during one of the sessions, and later we talked over some of the subjects that had been under discussion. Coggshall at that time was in the lime-light as the foremost practical honey-producer on a large scale. When I met him I had a feeling that I had met one of the super-men — a man who was able to see further and go further than the ordinary mortal. Since that time I have met most of the extensive honey-producers of the United States and Cuba, but never one that gave me the feeling that my first meeting with Coggshall caused until I met Oswald

St. John Gilbert, of Honolulu, Hawaiian Islands, manager of the Sandwich Islands Honey Company.

Gilbert, even tho he is known in the

Oswald St. John Gilbert, of Honolulu, manager of the Sandwich Islands Honey Co.

Reading the record of a prize queen.

Hawaiian Islands as the "Honey King," is, like most truly great men, modest. He has always made it a rule to avoid publicity, and so for that reason his name is practically unknown to beekeepers outside of the islands.

At the present time Mr. Gilbert has on the island of Oahu about one hundred apiaries. As to number of colonies in each apiary, they will probably average up with those of the extensive beekeepers of New York and Colorado—perhaps 100 to 125.

Another thing that will, perhaps, be a surprise to those that think a hundred colonies of bees sufficient to occupy one man's attention, is that the bees are but one of several business ventures in which Oswald St. John Gilbert and his brother, Lee St. John Gilbert, are jointly interested.

I spent one entire day with Mr. Gilbert visiting a few of his many apiaries, and it was one of the most pleasant days of my life. He is a prince of good fellows, and one whose good nature always remains on top, even tho the roads are rough. He is of English parentage, born in Australia;

and so while he is not an American he is the nearest thing to one. His entry into the ranks of the honey-producers was one of those matters that just naturally happen. The particular event that was responsible occurred one Sunday morning in 1893 when the trade winds blew a stray swarm of bees into the dooryard of the Gilbert home. Lee St. John Gilbert, Oswald's brother, decided that he would hive the swarm; but these particular bees had no desire to be hived, and it was not until the operation of hiving them had been repeated six times that the bees made up their minds that they had in fact been hived, and decided to remain. Both of the Gilberts at that time were innocent of any knowledge pertaining to bees or bee culture; but after the trouble they had taken to hive this particular swarm they were determined to see what could be done with the bees. With a copy of the A B C of Bee Culture as their sole guide, and their lone swarm of bees as a foundation, the Gilbert brothers built up the greatest chain of apiaries, and the best system of apiary

Mr. Gilbert considers the gluebush a great forage-plant for stock.

management, that is to be found. Part of this system of management is the feature that puts an end to the rival beekeepers in the territory they occupy. This has been accomplished by purchasing the absolute and exclusive right to place bees in the territory they desired to make use of. On the island of Oahu they have complete control of all the island except in and about the city of Honolulu. Honolulu being a city, and having thousands of small property-holders, it would be impossible to control that territory. (In the event that any person may think of coming to Honolulu I will state that at this time the Japanese at the present time have the Honolulu territory overstocked, there being about twice as many colonies as good management would dictate.

The Hawaiian Islands, while but small patches of soil in the center of the Pacific Ocean, are the home of wealth and big business. Big corporations are the rule. In this land of big plantations, honey production was at first looked upon with amusement. To use Gilbert's own language, "For the first seven years we were the joke of Honolulu. That there could be money in honey production was beyond the wildest conception of the average islander." But such was not the prevailing opinion after the first few years had passed, and today one of the richest bankers in Honolulu is interested in honey production, and owns a large chain of apiaries on one of the islands.

Honolulu, H. I.

Nine-year-old algeroba-tree.

THREE BEE-TREES HAVING TOP VENTILATION

BY W. H. CRAWFORD

On page 1019, Dec. 15, 1915, the editor says: "For it seems to be a fundamental principle that hive entrances for colonies in winter quarters should be at the bottom, primarily to hold the warmer stratum of air that naturally rises to the top, and is confined because it cannot escape." This reminds me of three bee-trees I found in middle Texas in the spring of 1892. The first one was a Spanish oak that had been broken off six feet above the ground, having a hollow ten inches in diameter from the top to the ground. The bees entered at the top, and began to build their nest two feet below, and continued the combs to the bottom, using the opening at the top of the stump as their entrance.

The second one was a post-oak tree about the size of the first one. It had been broken off four feet from the ground, leaving a stump with a hollow four feet long and

ten inches in diameter. The bees entered at the top, and occupied the entire space.

The third was a live-oak that had been broken off twenty feet from the ground, with a hollow twenty feet long, and averaging nine inches in diameter. The bees entered this tree at the top as in the first and second, and began their nest two feet below, and had built nice straight combs seven feet long. The combs showed that the bees had occupied this place for three seasons at least. Notwithstanding this tree had an opening at the ground four inches in diameter, and one at the top six inches in diameter, thereby allowing a current of air to pass up thru the tree, and also allowing rain and snow to fall directly upon the bees, nevertheless they were a prosperous colony when I found them.

I cut this tree off below the combs, and hauled it to my apiary of twelve colonies,

and stood it up by another tree, allowing it to remain there until the colony swarmed, which it did two weeks later, on May 1. Soon after this I transferred the combs and bees from this hollow log into an eight-frame hive, filling five frames with brood and three frames with combs nearly full of honey.

The bees in all three of the trees described were healthy and prospering. No. 1 and No. 2 had large openings at the top, but none at the bottom, but No. 3, having a large opening at the bottom and one at the top—entire top of hive off winter and summer—makes me wonder how a colony of bees could prosper in such a place, for it rains, snows, sleets, and freezes in that locality. I have seen it as cold as fifteen degrees below zero there, and *often* as cold as ten degrees above.

I have sometimes seen bees winter well in hives with long cracks near the cluster, and come out booming strong colonies in the spring.

So I am forced to conclude that bees have a far greater capacity for adjusting themselves to their environments than we usually think.

Last August a fine swarm clustered on a limb of a cottonwood-tree, twenty feet from the ground; and the scouts, failing to find a place that suited them better, at least failing to convince the swarm of the fact, they

agreed to make that limb their permanent abode. "Let come what may, we will do the best we can," they said, and so they did. When I took them down, Sept. 15, they had three combs of brood, 6x10 inches wide, and other small pieces besides. The wind had blown upon them, and some rain had fallen while they were there, and robbers had passed that way; but they had conquered them all, and were hastily preparing to make a stand against the attacks of the approaching winter when I took them down. They seemed glad and thankful when I put them in a hive and gave them combs of brood and honey, besides what they had, fixing them up snugly for the cold wintry days drawing closer all the time.

Not a bee offered to sting me during all the manipulations in locating them in their new home; and I was equally kind to them, not killing more than a dozen, perhaps, in the whole transaction. They were well-marked three-banded Italians; and by the way they acted I am compelled to believe they are a colony of *very* intelligent little folks.

Lest my purpose in writing this article should be wrongly interpreted by some, I will add that I perfectly agree with the editor of GLEANINGS in his views as set forth in the statement quoted at the beginning of this paper.

Roswell, N. M.

TWO-POUND SECTIONS INSIDE STANDARD FRAMES

BY W. F. COX

I am enclosing a sketch of an experiment I made this year with standard Hoffman frames and special sections of such a size that four will just fit inside. I find that my bees like them much better than the regular sections. As is well known, bees much prefer working in the frames to that of sections, and will store a much greater amount of honey. I think it is largely due to the fact that they like to work in large units.

The advantages of this plan are partly due to the deeper section and partly to the wire-screen separators thru which they pass. The screens also permit them to cluster closely when cool days come.

One can use these frames of sections for feeding very nicely, and there is no real objection that I can see to using them for brood-frames in a pinch. The average person cares but little whether his section is one or two pound.

Danville, Va.

[The two-pound section is not new. In fact, the first sections that could properly be called sections were about two pounds in weight when filled. They were rather thicker in proportion than yours, however, and of course the details of construction were different. We do not know that we have ever seen exactly the same idea. The nearest to it is the small mating-hive frame, three of which fit into a Hoffman frame for the purpose of getting the combs drawn out and filled with brood. No effort was made, of course, in this idea to secure comb honey.

There is one feature that we should be a little afraid of, and that is the greater fragility of such combs. It seems to us that they would require such careful handling that shipping them any great distance, or possibly even a short distance, would be almost out of the question. We know that it is very difficult indeed to ship full-size combs of honey—so difficult that it is al-

most never attempted. We have found that it is difficult to ship even shallow frames of honey. This two - pound section, less than four inches wide, and nearly twice as high as the ordinary section, and also thinner proportionately, would break rather easily, we are afraid.

Of course, not having had any actual experience with the idea in question we may be mistaken. We realize that it is not always a good plan to raise objections without having actual experience. However, we mentioned our fears to our correspondent, and his reply follows.—ED.]

The points raised are to be considered; but is it not a fact that the comb in shallow frames and standard frames break from the top-bar because of the great distance from the end supports? and isn't it true that the sides of these two-pound sections, being less than four inches apart, support the comb about as well as the sections of greater width

and less depth? I am a constructing engineer, and my line of work leads me to the theory of these points, which I have reasoned out as above. Therefore I believe you will find that an eight-inch section will ship all right.

Danville, Va., July 6.

WHAT'S THE NEED OF FOUNDATION, ANYWAY?

Short Cuts Sometimes Necessary

BY E. J. LADD

Verily necessity is the mother of invention. Time, the present; place, the mountain, miles and miles from nowhere; scene, a mountain apiary; scenery, a hillside up and up the mountain, and, as far as the eye can reach, acres and acres of fireweed, elkweed, or willowhart; in the foreground, 100 colonies, each 2, 3, 4, or 5 supers high; a rough cabin for the beekeeper (a beginner), who, nearly bereft of his senses thru lack of necessary supplies (a fair example of lack of preparedness), made the scribe welcome, and unburdened himself to a willing listener. Somewhat thus ran his story.

The bees had been carried to the present location over trails — no roads; blankets, tools, and a grub stake, and a few bee-supplies entirely inadequate were also packed in, and the season opened, and the flow was on.

Supers were filled rapidly, and others substituted, till, presto! all foundation for starters was exhausted; my host was in a quandary. Supers were filled with empty sections, placed on hives, and then trouble commenced, for the bees had the supering habit, and in a few days combs were started in all directions, mostly across from separator to separator. This was the situation, when on the scene arrived yours truly. After some cogitating we took stock, and found some wax, toothpicks, a cover to a lard-pail; then a small bed of coals made going easy. As soon as sufficient wax was melted, toothpicks were dropped in, and then one was placed straight in the center of the top of each section. They stuck well, and the process was rapid. Supers were filled and placed on hives.

On examination the next day we found

the bees had accepted the "starters," and that trouble was over. My stay was of sufficient duration to see some fancy finished sections, straight and smooth, sealed, and fastened to the edges. What more could any one ask? This stunt worked

successfully, and the mountain beekeeper was feeling better; but, listen! If any of you Easterners get some sections of mountain honey with a toothpick, kindly admit that it didn't hurt the sample. Blame it on to me.

Portland, Oregon.

TWENTY FOR A START

BY MORLEY PETTIT

The first summer course in beekeeping was held at the Ontario Agricultural College, June 12 to 16, 1916. There were about 20 in attendance, which was a good number considering the busy season and

Vice-president of the Ontario Beekeepers' Association; Morley Pettit, Provincial Apiarist, and Geo. F. Kingsmill, Assistant to the Provincial Apiarist.

The work was concluded to supplement

Members of the first summer course in beekeeping at the Ontario Agricultural College.

the fact that backward weather had put all farmers behind with their work.

The speakers included Mr. Frank C. Pellett, State Apiarist of Iowa; Mr. F. W. L. Sladen, of the Central Experimental Farm, Ottawa; Mr. James Armstrong,

the winter course, applying in the apiary the things learned in the classroom. Members of the class were expected to supply themselves with veils and smokers, and were given apiary practice.

Guelph, Can.

HONEY METHOD OF INTRODUCING — A NEW WRINKLE

BY ROY D. TAIT

I have noticed Mr. Baldwin's reference to introducing queens daubed with honey. I have a way that has never failed me, nor has it failed any one I have induced to

try the method. It is simple, quick, and absolutely sure.

After dequeening I hold the caged queen in my left hand, pry out the little nails

that hold the screen on the cage, and at the same time hold down the screen with my left thumb. With a small spoon in my right hand I scrape out of one of the combs a spoonful of the bees' own warm honey. I let the queen crawl out of the cage and daub her as she comes out with the warm honey, bits of wax and all, and let her roll down between the frames, put on cover and the job is done.

I introduce the new queen immediately

after the old queen is removed. It makes no difference whether the new queen is a virgin or a laying queen, nor does it make any difference whether the colony has cells or not. She is always accepted.

The new queen is thoroly daubed with their own honey; and after they get her nicely cleaned off I suppose she has the same odor. Anyway she is always accepted.

I have just introduced twenty-six queens without a miss.

Hornbrook, Cal.

THE ADVICE OF JOB'S FRIENDS

BY R. F. HOLTERMANN

When we look at the medical profession, and the diversity of remedies they prescribe, it does not seem out of place to lose all faith in them. When we look at our apian doctors there appears to be a similar condition. Since my article appeared, asking for the advice of those who have cured European foul brood much has been said in GLEANINGS upon the subject, and the experience given differs widely. To this conclusion, however, I have come, that the diversity of opinions and experiences advanced only go to prove that this disease is a fit subject for investigation by Dr. Phillips, of Washington. I have no doubt that, with the financial help he has, and the natural ability he possesses as an investigator, he is in position to solve the problems involved, and leave the apicultural world the richer for his investigations. The work he has done in connection with the wintering of bees has proven this.

Let me make an apology for saying anything which would justify any flippant remarks about Job. We are so much given to imitation that the name Job is used in a way it should not be. Few of us (I am not) are worthy to be compared to this man, and his life teaches us that God in wisdom allowed certain things, many things, to come into his life to make him understand himself better and know God better. The climax is reached in that passage, "I have heard of thee by the hearing of the ear; but now mine eye seeth thee. Wherefore I abhor myself."

In the articles already referred to, and out of which I am to find such consolation and edification, we find a very great difference. We have on the one hand almost nothing done; then the removal of the queen, and, in the case of George H. Rea, page 273, the shaking of the combs. Mr. Rea says, "If the infection is general in the apiary, which is probable in an out-

break of European foul brood, all colonies are shaken in order to run no risk on those that do not show it," etc. This view rather agrees with what I think ought to be done to deal with the disease in anything like a scientific way. My opinion still is that all diseased brood should be removed from the bees to prevent their contact with the germs in clearing the dead larvæ from the cells.

However, I have received some valuable and kindly advice from beekeepers not at all agreeing with Mr. Rea and myself; and there is such a great saving from shaking and melting combs that I shall likely follow that plan if the disease shows up in many colonies. If only a few show disease I shall continue to remove all diseased brood from the hives.

As to Italianizing, that had already been done, aiming at getting disease-resisting strains, as, for some years, owing to the prevalence of the disease, I have been expecting to have to battle with it sooner or later. I still consider the conflict in which I am engaged quite as serious as I expected. It is no child's play with seven apiaries of more than 700 colonies, and the disease found in almost every apiary.

Among the communications received is one from P. W. Stahlman, West Berne, N. Y. As Mr. Stahlman writes in a very catchy way, driving his points home, I shall be pardoned for using his own words. The letter, dated Feb. 8, 1916, is as follows:

I am not writing for any bee journal; but when I read your article I could not help feeling that I might assist you materially in your work with the disease; and what I am giving to you I give free-handed, as I have always considered your writings well worth reading, as they come direct from the shoulder, and from an experienced beekeeper. Mr. Crane tells you the shiftless beekeepers may well regard this disease as a serious matter if not an actual calamity. I say amen to that.

In the February issue of *Gleanings*, Timberline Riggs gives a cure, but says in substance he does not claim that it will hold good in all cases and in all localities, and I say that also is true. And so it goes. From time to time men of experience will tell you things which do not agree, and yet in one way or another all may be good sense.

But when you once get thru the mill, and the grist is ground [A painful operation, I think.—R. F. H.] you can rest assured that your own experience will be your best doctor [Thanks. I think it will be, in my own estimation, at least.—R. F. H.] I have been in this locality ever since Frank Boomhower was our first inspector; and to say that I have seen the disease in all its forms and ravages is putting it mildly.

THE TREATMENT ATTEMPTED.

We bought up all the old box-hive bees we could get, at a low figure, and drummed the bees out into modern hives, and in so doing we helped to a great extent to clean up the disease, for the brood in these same box hives was generally in a diseased condition, and, with the old black bees, a favorable pasturing-ground for European foul brood.

I have been thru this disease thru thick and thin, night and day. I was here when the disease was in its youth in New York, and I am here yet. I have seen and handled it from a light case to complete rottenness; and for my part I can say that I do not care to go over the ground again—at least not on as extensive a scale as I have done. In our treatment we shook and we drummed the bees. We fumigated with formalin, and we fumigated with brimstone. We bathed the combs in a strong solution of salt water. We put the bees on starters as well as on full sheets of foundation. We doubled up colonies, and we tiered them up as many as four bodies high to get strength. At that time our inspectors were new in the work of the treatment of European foul brood, and all or nearly all recommended shaking as the only means of eradication. We washed our hands and tools in carbolic-acid water. We made all new hives, etc., because we were told that anything that was infected must be cleaned up, and fire was the remedy, even to the burning of bees in some cases.

WHAT HELPED.

Not until we began to tier up to get strength did we begin to see that there might be some way out besides melting up all combs, getting rid of all the honey, making comb foundation or buying it, which was a great expense and muss.

We today know by experience and proven facts that even our authorities may be wrong in some things, and this method of cure was one of them. I am speaking from experience, not theory; and I will say the field has been well covered; and where the disease is not just making its appearance it would be wisdom to follow the advice of those who have fought the battle well before

present experiences were available, the benefit of which I will now offer you. This advice has been given you before, but perhaps I can say it in a different way so that it may soak in better; and the same is my very best advice that experience has taught me and many others in this vicinity ever since the disease struck us fairly in the face.

THE CURE.

1. Be prepared for the disease, and before you enter into the actual battle by having your colonies hit by the disease, by getting good young Italian queens in your apiary. In such a case you will not be hit so hard. Get these queens from a reliable man in a locality where the bees survived the disease. Know that he is honest in furnishing you with his best immune stock (a hard matter). You could get a breeding queen of such, and do the trick yourself—breed the queens, but better if you can do the former. When the disease appears, do not let it get bad before you attend to it, but either shake or change combs of brood to the upper story, and keep the queen below on clean combs, and have the colony strong in bees, and this will save you combs and honey; and once you get all Italianized you will not have much to contend with more than to see that young and prolific queens are in all colonies. Then the work is more than half done.

Of course you will occasionally find a mild case after either treatment, when action should be taken at once.

Here is a good thing in connection with the treatment: Do not have a lot of weak colonies around. Avoid all things that arouse the apiary; do not work with the bees out of curiosity, but attend strictly to the treatment in one way or another as given heretofore.

Every fall, if any colonies are affected, take them up, especially the weaker ones. This is a great advantage.

We have had no disease to speak of for three or four years; but once in a while a very light case appears, the origin of which we do not know; but it is there nevertheless. Such a case we treat at once, and with that it generally ends.

BEEES MUST GATHER DURING TREATMENT.

Of course it is conceded that bees need to be getting honey when treating them for the disease, otherwise they must be fed.

The object of this is not to cure the disease but to help the colony prosper again. And let me say right here you cannot treat the colony and get as much honey as tho they could go on without being shaken. [Just what I felt sure of.—R. F. H.] But something must be done, and your very best weapons are:

1. Good young immune Italian queens.
2. Strong colonies.
3. Mean business when you attempt to stamp out the disease. [I suppose a man who expects his wife to get up and light the fire and get breakfast while he would be resting in bed would not do for the above.—R. F. H.]

Do not imagine you can clean up everything at one stroke, nor absolutely even in one year. It will crop out occasionally. I nearly always kill the queen of a colony that tolerates the disease, and replace her. I have bought small lots of bees near me to keep the disease from being harbored there. I do not believe that bees must rob the infected honey to get the disease, as it can surely be cured and still retain the combs. This is sufficient proof. Also shaking on starters or foundation does not always cure. [I know that from experience.—R. F. H.] Oh, no! Do not think that. I treat both ways. Again, by dequeening we shall have our combs yet. Any one can see them in the breeding season, full of as nice brood as ever was. I say again, therefore, do not burn good comb.

I will not say do not shake at all, but why should we when it is not necessary?

Mr. Reuben V. Cox, Sloanville, N. Y., also kindly wrote the following:

I am only a small beekeeper compared with you, or only about a quarter your size, having 200 colonies; nor have I stamped out the disease; but I own the yard into which European foul brood was first introduced into New York by nuclei brought from the South, probably in 1890. I bought the apiary in 1908. I have had perhaps 24 or 25 cases, and none in the past four years, so I am one from whom you wish to hear. There are other apiaries around here that have gone thru the same. For instance, I worked for E. W. Alexander, seven miles from here, when he had only a few cases. I am told he has had more in the past few years. I think the disease, like most others, varies in severity; and I think Dr. C. C. Miller's bees must have had a very mild form to be able to cure it in about a ten days' gap in brood-rearing.

E. W. Alexander, you will notice, recommends 25 full days to be sure that every cell of brood, worker and drone, is hatched. He told me he had lost, from first to last, over

1000 colonies; yet, shortly after 1900, he secured from 25 to 35 tons of honey from his own apiary of 600 colonies. On the other hand, one D. Kimbel, only about two and a half miles west of here, kept and still keeps about 100 colonies, part of which are in box hives. So you can see none of the usual treatment could be given in his case. Yet I know the disease has been on his ground. Here we have sometimes three honey-flows—a light one in June from clover; sometimes a good one in July from basswood, and usually a good one in August from buckwheat. I can cure severe cases by the Alexander treatment in any of these flows. Mild cases will sometimes cure themselves; but I find it hard to winter such cases; and generally the first of the buckwheat flow I kill the queen, and, to prevent robbing, a few days before that flow closes, sulphur the bees, extract the honey, melt the combs, and burn the frames and scorch out the hives. I find that the money from the honey and wax about pays for the new colony I buy in the spring. Some might object to selling honey from the diseased bees; but I consider it no worse than selling it after the Alexander treatment, as in either case the bees polish the cells. European foul brood seems to decrease in severity as the bees become used to it in any locality.

If the bees can clean out diseased brood, and put the cell in a condition not to transmit the disease to the next larva, they must secrete a disinfectant. If a cell is so cleaned before storing, either honey or the queen laying in it, then it must be a safe method to remove the laying queen until all cells have been cleaned by the bees. The success of the Alexander method would sustain the above. I am looking forward with interest and some anxiety to the developments which will take place among our own bees, and, if able, will give the result of my experience.

Brantford, Ont., Canada.

OVER ONE HUNDRED GATHER AT CHICAGO TO LEARN FOUL-BROOD AND SWARM CONTROL

BY KENNETH HAWKINS

Over 100 beekeepers of Indiana, Illinois, and Wisconsin gathered at 3000 North Cicero Avenue, Chicago, on Saturday, July 15, for the first annual field meet of the Chicago-Northwestern Beekeepers' Association, where they listened to prominent beekeepers of Illinois and Indiana. N. E. France, president of the association, was not able to be present.

A feature of the day was the picnic luncheon in charge of Secretary John C. Bull and President E. S. Miller. Following

dinner the events of the day occurred in the following order, with Mr. Miller's system of swarm control featuring: Inspector A. L. Kildow's methods of handling foul brood. A. Stanley, of Chicago, told how he reared queens, as did Kenneth Hawkins, of Plainfield, Ill., who also gave his plan of queen introduction by his new queen-cell method.

An excellent demonstration with live bees was given by Mrs. Coppin, who, without a veil, gave some beginners several thrills when she opened one of Mr. Bruner's

strongest colonies, found the queen, and passed the frames out thru the crowd.

Mr. Miller's method of swarm control, which was the feature of the afternoon talks, is as follows: When it is determined that a colony is about to begin swarming preparations, one frame of brood with the queen is removed from the hive and placed in an empty one. This latter is set on the old stand, and the rest of the room filled out with empty combs or full sheets of foundation. The frames of brood and honey, with the space of the one frame removed,

filled with a comb or foundation, is raised over the hive containing the queen above a super, which latter is also above an excluder. Altho this method requires a great deal of careful manipulation on the part of the beekeeper, Mr. Miller has followed it for some time, and handles all his colonies in this manner, and has controlled swarming in the past few years to a negligible minimum. It is also used at his outyards as well as in the home apiary. I believe Mr. Miller handles his bees without help.

Plainfield, Ill.

SWARM PREVENTION IN OUT-APIARIES RUN FOR COMB HONEY

The Importance of Requeening in the Fall

BY M. N. CUNNINGHAM

For the past five years I have kept from one hundred to one hundred and fifty colonies in outyards from four to nine miles from home. I have a very small percentage of swarms—perhaps not over 5 per cent.

I begin in the fall by replacing any old or failing queens. Old queens are one of the greatest causes of swarming while young queens are very little inclined to swarm. My plan is to visit each yard about once a week after the colonies start brood-rearing in the spring. As some begin to get strong in young bees I equalize by taking combs of hatching brood from the strong to the weak.

We usually have sufficient honey coming in by April 15 to cause swarming. About this time the bees show their crowded condition by hanging out at the entrance. I proceed to ventilate such colonies by raising the hive from the bottom-board, in the rear only—with a wedge-shaped entrance block or a small stone or stick—from one-fourth to one and one-half inches according to the weather and the strength of the colony. This makes it possible for the bees to live in the hive and proceed with their work instead of having to stop work and cluster outside to keep their combs from melting down. Is it any wonder bees swarm under such conditions? With means of ventilation they can go on with their labor, and the hive can be kept full of brood in comfort while the honey goes into the super. As the weaker colonies begin to cluster and get strong I raise them at the back also.

From now on I examine only by walking behind the hives and tipping them up from behind, blowing a few puffs of smoke between the bottoms of the frames and noting the conditions as to room, brood-cell emps,

and queen-cell. All of this can be easily done after a little experience.

If the hive is crowded with brood and the main flow has not yet started, I build up my weak colonies with sealed brood, probably only one frame from a hive, replacing with an empty frame or comb foundation, so both colonies are benefited. If a hive is very strong or shows cell emps containing eggs or larvæ, I take more brood and give more room and plenty of ventilation. In case of a colony containing cells sealed or nearly so, practically the only cure is to take all brood away and give empty space, but if one is a little careful this need not happen often.

As soon as our main mesquite flow starts I give one super, and when this is half filled I put another on top, not underneath, so the bees finish what they start before going above and are not discouraged by having the first super so far from the brood.

The first few days of the main flow is my rush time. The colonies that start work in the supers seldom cause trouble, but a few start cells and want to swarm, and those few get nearly all their brood taken away so that by the time the new combs are filled they have forgotten they want to swarm.

I make nearly all my increase later from nuclei and build them up on dark honey in the fall.

After the main flow is started I look the colonies over by lifting the hives from the rear as before about once a week or perhaps two weeks and add supers as needed. This is done merely to save a few swarms from colonies whose queens are failing and might swarm. To these I usually introduce a virgin or ripe cell. These examinations are quickly and easily done—so easily that I know the condition of a colony by the time

a man opening a hive would have the cover off.

There are two objections to this way of procedure, but they are so unimportant that I do not consider them. First, the bees

build burr comb below the frames, but it is necessary only to take a hive-tool and scrape it off to handle the frames. Bees also jump out of the back of the hive and sting the shins. A puff of smoke cures that. Carlsbad, N. M.

WHY SUGAR-FED HONEY IS NEVER FOUND ON THE MARKET

BY WM. COX

Last spring Mrs. Allen asked how many pounds of syrup are required to make a certain number of pounds of sealed stores. Dr. Miller answered that 5/7 of a pound of sugar is about equivalent to a pound of honey, or in substance that she would get a pound of syrup stored for each pound of thick syrup fed. Several years ago I asked Dr. Miller about the same question, and in his answer he thought the number of pounds I would get stored would about equal the number of pounds of sugar fed. I suppose he has forgotten more about bees and honey than I ever knew, but both his estimates are certainly too high.

In writing about having sugar syrup stored in the comb to sell for honey, E. W. Alexander said: "Aside from any consideration of fraud or the pure-food law, there is no money in it." Dr. Phillips says, "Of course this has been tried; but there is nothing in it, financially or otherwise."

If I can buy sugar for 5 cents a pound, and get it stored in the comb and sell it for 15 cents a pound, it looks to me, aside from any consideration of fraud or violation of the pure-food law, like a pretty good investment.

When I asked Dr. Miller that question I was trying to post myself so I would know how to talk to a lot of people who think nearly all the honey offered for sale is made from sugar.

I sold a man a pail of honey. He said it all went to sugar. He did not openly accuse me of fraud, but it was pretty evident he thought the honey was made from sugar. Neither he nor his relatives who had bought of me ever bought any more.

A lady came to my place to get 20 pounds of honey for herself and 10 pounds for a

friend. She said, "We don't want to buy it at the store, for that is this sugar-fed honey." I told her what the United States Department of Agriculture had to say about sugar-fed honey, and that the Department has a beeyard a few miles out from Washington, in charge of bee experts who are gathering information for the benefit of farmers and others who keep bees. I told her that from a little experience I had in feeding up weak colonies I thought we should have to feed on an average about three pounds of sugar for every one-pound section we could get the bees to fill, and the price of a pound of honey would not pay for the sugar. I may be a little off, but I guess I am about as near the mark as Dr. Miller.

I also told the lady that the honey in the store was pure bee honey, but my honey had been left on the hive for the bees to ripen, and it was probably a better grade of honey than she could get at the store. I told her a lot of other things. If there comes a time I cannot sell all the honey I can produce, I intend to write some things for the local paper.

Oakland, Ill.

[There is certainly a danger that un-informed persons finding that a beekeeper buys large quantities of sugar to feed his bees might jump to the conclusion that honey, especially honey that has granulated, is made from sugar syrup. Producers cannot be too careful in matters of this kind. There is need of constant education. The truth never hurts. Explain that honey produced from sugar is a possibility, but not a paying proposition, and consequently there is none on the market.—Ed.]

NOW WHO'S RIGHT ?

BY M. T. PRITCHARD

In compliance with Dr. Miller's request, page 521, July 1, I submit the following report:

A frame of eggs nearly ready to hatch

was taken from one of our breeding-queen colonies, and a small patch of the eggs carefully removed from near the center of the frame. It was then returned to the colony.

and a close watch kept to ascertain when the queen found these empty cells and laid in them.

The queen laid in these cells between 8:30 and 9:30 A. M., Aug. 3. Two of the eggs were hatched at 7 A. M., Aug. 6; the rest within an hour.

These larvæ were grafted into queen-cells at 10 A. M., Aug. 7, and the last cell was sealed at 10 A. M., Aug. 11. I failed to find when the first cell was sealed; but cells grafted at the same time, but with smaller larvæ, were not sealed at this time. From this I concluded that they had been sealed only two or three hours. These larvæ, which were about 26 hours old, were larger than we use ordinarily.

The first virgin emerged from her cell at 6 A. M., Aug. 18, and the last one 4½ hours later.

Medina, O.

[Sometimes a little dog unconcernedly bites a temporarily peaceful big dog. . . . To make a short story shorter, after some other big dog joins in the fight, the little dog wiggles out and sits by the side of the road watching the fun.

Without intending any disrespect to the other parties concerned, I claim the honor of being the little dog that started this scrap between Dr. Miller and Mr. Pritchard (the two big dogs), and I am now sitting by, watching the fun.

From my point of view it appears that Mr. Pritchard has a little the best of his opponent. I have admitted that my original statement, page 403, May 15, is probably extreme in that six to eight days between the hatching of the egg and the sealing of the cell is surely beyond the average length of time. But I still believe that Dr. Miller's estimate, "never more than five days," is also extreme in the other direction.

Take Mr. Pritchard's figures: In spite of the hot weather, the time between the hatching of the eggs and the sealing of the cells was about an even five days, or possibly a little more; and the total elapsed time from the laying of the eggs to the emerging of the queens was just about fifteen days. What would these figures have been under less favorable circumstances, cool weather, weaker colony, etc.? Sic 'em, Dr. Miller!—H. H. Roor.]

THE SEASON IN SOUTH FLORIDA

BY A. E. AULT

The usual time for orange and grapefruit to bloom in south Florida is from Feb. 25 to April 1. Last season, probably owing to cold and dry weather, there was scarcely any surplus orange honey, tho the bloom continued a month later than usual. Saw palmetto, which blooms in April and May, gave good returns in a few favored locations, but as a rule the crop was short.

The conditions that seemed unfavorable for the secretion of nectar from orange and palmetto proved favorable for seagrape, black mangrove, and cabbage palmetto. Black mangrove began in June, and continued till about Aug. 1. The seagrape and black mangrove grow only along the coast. Toward the last of May seagrape began to yield, and continued thru June. The honey from this plant is of fine quality. A peculiar feature of it is that, as the light reflects from the honey, it shows a decidedly green color.

My best average this season was produced at a small apiary of 26 colonies located at Cortez, a fishing town near the point of a narrow peninsula. There is not much fruit bloom in reach of the bees, nor is it a first-class location for saw palmetto. But to offset this the bees have access to a vast

range of seagrape and black mangrove; and, altho they cross the water to outlying islands to secure the greater part of this honey they never fail to "deliver the goods;" and I have secured from this apiary as much as 200 lbs. average. My record of honey taken from this apiary for the season is as follows: May 31, saw palmetto, 400 lbs.; June 12, seagrape, 680 lbs.; June 28, black mangrove, 1060 lbs.; July 14, black mangrove, 1300 lbs.

At the out-apiaries I use a 10x14-foot tent with 4-ft. sides. I use no ridge-pole, but, instead, have a long overrope. At the end of each gable two knots are tied in the rope 1½ inches apart. The tent is supported on two poles 8 ft. long, having a slot at one end which fits between the knots at the gable of the tent. In practice we use the tent-poles outside the tent, as they are more convenient to set up and take down. The tent-pins are left in the ground from one visit to another so that the tent can be set up in a very few minutes. With a large screened window on opposite sides, the room is light and airy. A small hole at the point of each gable serves as a bee-escape.

THE EQUIPMENT.

I use an automatic two-frame extractor.

Two discarded supers, well-braced, act as a stand for the extractor at the end of the tent where two posts are firmly set, to which the extractor is braced. A small barrel is used for the cappings. An old Novice extractor with the basket removed makes a good strainer can. A double thickness of cheese-cloth is put over the top, and over this a fine wire screen. From this the honey is drawn into the cans.

I always use a strong light wheelbarrow when collecting honey from the hives. This is wheeled in and out of the tent thru the loose flap at the end. Two light carrying-boxes each of the capacity of a ten-frame super are used on the wheelbarrow, kept covered with a heavy robber-cloth. Boxes used for the square 60-lb. honey-cans make a good carrying-box. I put two together, removing the inner side, and nail a good handhole at each end, with also a cleat across each end inside for the combs to rest on. Such a box is strong, light, and just the right size.

On July 14 with such an outfit as I have described, my 18-year-old boy and I drove seven miles to the Cortez apiary, and by 9 A. M. had the tent set up. By 2 P. M. we had extracted 1300 lbs. of the finest mangrove honey, and had it ready to load on the wagon. In the mean time we had our dinner, cut the weeds and grass about the apiary, made an increase of two colonies, and waited on several parties who came to buy honey.

Aug. 9 I visited this apiary again and found many of the supers full and others partly full of white mangrove honey. I estimated the amount then in the supers at about 800 lbs. If I take 500 lbs. of this as surplus it will make an average of a little over 150 lbs. per colony.

MY WAY OF MAKING INCREASE.

I have also increased from 26 to 37 colonies. This was done by a method which I

have practiced for years. It tends to prevent swarming, and has given good results. In reviewing the bees, when they first show a disposition to swarm, as I find a colony that is congested with bees and brood, and is, perhaps, starting cells, I select one, two, or more frames of sealed and emerging brood with adhering bees, and place them in an empty hive. I generally throw a handful of grass or leaves against the entrance. When another in similar condition is found I again remove one, two, or more frames of brood as before, and add them to the others placed in the empty hive. This practice is continued until the brood-chamber is full. Besides the bees that adhere to the combs I occasionally shake the bees from one or more frames into the colony I am building up. Bees so united do not fight. Care should be taken that these built-up colonies have a good supply of honey. When the brood-chamber is full of brood and bees a super is often added and filled with frames of brood and honey.

"Pulled queens," that is, queens just emerging from the cell, are readily accepted by these built-up colonies. Lacking such queens, a cell may be given, and they are very rarely torn down. Such built-up colonies can even be found without a cell, as when the work is well done they will build good cells of their own. Of course all such colonies should be inspected in due time to make sure that they have queens.

When formed early in the season I often secure some of my best yields of surplus honey from these "built-up" colonies. By this method we keep all colonies strong, and have no weak nuclei to nurse.

The bees along the coast have given the best results this season; but while they were busy storing seagrape and mangrove honey the inland apiaries were showing a steady gain from cabbage palmetto.

Bradentown, Fla., Aug. 13.

SOME OF THE HONEY-PLANTS OF PARAGUAY

BY J. BROWN

Tucked away in the heart of South America is the little-known republic of Paraguay; in the heart of Paraguay is Villaria, a town of some 15,000 inhabitants, a little less than three miles to the east of which lies my present home. As I look toward the rising sun from my open-air bed-chamber my eye passes over my apiary of some fifty colonies, and pauses a moment on the gentle slope behind, thick with waving palm and orange-trees. Beyond this declivity stretches for two leagues a level

grassy plain, which I am unable to see from my position. Then comes my horizon, a 2000-foot wall of forest-clad rock, running north and south, called the Sierra de Ibituru. Place yourself in imagination on the summit of this, and try to picture the leagues upon leagues of crowded primeval forest that stretches northward and eastward, inhabited by strange and unknown animals, and tribes of human beings but little above them. But two days' journey on horseback, from where I write these lines,

and the traveler is in the Stone Age. Since the coming of the Spaniards, a tribe has lived there against whom has been and still is the hand of every man. Some say they are a tall race, others a dwarfish one, and the men are bearded. Their arms consist of a stone roughly shaped into the form of an ax-head. This stone is inserted in a split sapling of the right size. So rapid is the growth of wood that in a short time the head is firmly imbedded, so that when cut down the ax is provided with a handle that will not come off.

Now, these people are very fond of honey, and are, consequently, great bee-hunters. Without a stitch of clothing, and armed with their stone hatchet, they climb the bee-tree and hew their way into the coveted stores. Sometimes the native Paraguayan hears the tapping, comes up with his gun, and shoots the poor Indian dead, giving as a reason that the skins of this particular tribe are very good for making bags for carrying Paraguayan tea (*yerba maté*).

The native bees of Paraguay are many, and of the stingless variety. Some of them make up for want of a sting by furious biting and frantic buzzing on every part of the body on which they settle, snipping off every hair on the hands and face by the roots as if they considered themselves animated depilatories. They gather only a small quantity of honey; but this is much esteemed by the natives as a remedy.

About a quarter of a century ago Italian bees were first brought to the country. At various other times Carniolans and Caucasians have been introduced, and the bee commonly met with is a hybrid of the three varieties. Some are very gentle; but those that show any trace of yellow are very much the reverse. Besides my own, there is only one other apiary in the country run on modern scientific lines.

Our principal source of nectar is the forest-trees, chief of which are the many varieties of laurel. The lapacho (*Tecoma curialis* and *T. varia* of the family of the *Bignoniaceae*) yields a very strong aromatic honey, which, from description, seems to be something akin to that of basswood. The palo blanco (*Exostemma* of the family of the *Rubiaceae*) yields a large amount of beautiful white honey. I had a large surplus last year from *sangre de drago* (*Croton succirubrus*), a widely distributed tree-shrub which produces a red resin yielding the dye known as dragon's blood. This honey was almost as dark as molasses, and very bitter when first extracted. After standing in the tanks for about ten days the bitterness went away and it became very

sweet. I had no difficulty in disposing of it. Orange and banana are also good yielders.

Our honey-flow begins about August, and lasts till the end of October. About January the banana begins to yield, and there is a fall flow from various flowers till the end of April. Only extracted honey is produced here, and the honey is put up in second-hand kerosene-tins, as a rule. I tried barrels one year, but they were not a success. Kerosene-tins are cheap, and, when well washed with soda, and exposed for a week or so to the tropical sun, there is no danger of contamination. I use factory-made Hoffman frames, but the hives I made myself, some out of rosewood (*Macherycaenum Sp.*), and others out of "female" mahogany (*Cedrela braziliensis*). The latter is far and away the best material, being light and durable. Rosewood hives sound very luxurious; but their weight in handling soon humbles one's pride.

DRONE-CELLS ON ONE SIDE OF COMB.

Some time ago Dr. Miller mentioned having received a specimen of such, and wanted to know if any one else had seen this. On going thru my extracting-combs I found no fewer than five with a patch of drone-cells on one side, all the other cells being worker. Four were small patches of about one to two square inches; but one was about four. As these combs had been stored away I am unable to say whether they all came from the same hive or not.

WHICH MILE IS WHICH?

In GLEANINGS for April 1, 1915, J. A. Heberle discusses this question with reference to observations made in Germany. About two miles seems to be the limit there, and Mr. Heberle quotes Mr. Goeken as saying that if American bees can fly six to eight miles it would be well to introduce such into Germany. There is evidently some confusion here. When an American writer speaks of a "mile" he means the English mile. German writers naturally mean a German mile. Now, the German geographical mile is more than four and a half times longer than the English mile, and therefore the bees fly the same distance.

Villarica, Paraguay.

Sure, It's Love at First Sight.

The honey method of introducing queens, page 525, July 1, is a good and sure way. I have introduced several with the best of success. The bees lick them dry, and then fall in love at first sight. And it is permanent too.

J. P. Lockwood.

Owen Sound, Ont., Can.

Heads of Grain From Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

"Where, where did the bee sting you?" said little Avelala's mother, who was trying to stop her daughter's tears. "Why, the bee stunged me, right, right d-d-down by the Presbyterian church!"

The Beekeeper's Faith.

BY GRACE ALLEN

Dismayed by the visionless faeces
 Of town, he came back to his bees.
 "Could they know but your rapture of humming
 And quiet of shadowy trees!
 But a dawn shall yet break when all people
 Shall answer an ultimate need
 By divineness of dream that forever
 Begets a serenity of deed.
 Then men shall be all noble-minded,
 Their petty, mean gods put away;
 Then women, full-grown and large-natured,
 Shall justify faiths of today;
 Then cities shall fall out of fashion,
 While cut in the cool of the trees
 With their books and their thoughts living
 gently,
 More men shall be keepers of bees."

Don't Let the Bees Clean up Cappings; Press the Honey Out.

As to the advice to let the bees clean up the cappings, I should like to repeat Punch's advice to those about to marry—"Don't."

Any cleaning-up by bees is always dangerous.

Everybody thinks his own plan the best. This is mine. I have an uncapping-can wide enough to hold the Langstroth frame, and six feet long. At one time I ran the cappings thru the solar extractor, but I burned the honey. Now I put the cappings in the wax-press and press out all the honey, and it is as good as any. I have a German wax-press, and use a jack for pressure with an iron rod one inch thick and three feet long as a lever. As I could not make a box strong enough to stand this pressure I got my blacksmith to make a band out of an old wagon-tire and fit it around the box about one inch from the bottom of the box! This makes the box so strong I can have a couple of half-inch holes above the band to let the honey run out freely. I leave the cappings as long as possible in the press. The cakes when taken out of the press are laid aside until we have time to melt them. There is no honey in them worth bothering about, as I have found by putting some of them thru the solar.

To turn these cakes into wax I fill up an ordinary wash-boiler with as many cakes well broken up as the boiler will hold, then cover with water and bring to a boil to make sure the wax is all melted. I leave it in the boiler until cool, and all the wax will be on top. The last cake I had weighed 27 lbs. All my wax finally goes thru one of the D. A. Jones steam wax-extractors.

How Long Does it Take to Become an Expert Beekeeper? A Bunch of Questions.

Five or six years ago a beekeeper told me it would take ten years to learn the business. At that time I thought he was crazy. I have studied books on bees for the last year; have read the A B C of Bee Culture some three or four times, and many other books. Last spring I bought four hives of bees, and now I feel very much "at sea." I now have 13 colonies, counting the nuclei.

1. I found a comb a few days ago with dead brood. Some are of a slimy mass, and some have the shape of the nymph. It does not rope, and is white. Do the larvae ever die from natural causes? or is it European foul brood?

2. In making nuclei about May 10, how would it do to put two frames of bees and brood with queen-cell on each side of a screen division-board in a ten-frame Buckeye hive, and have one entrance at the southwest corner and the other at the northeast corner? At the time of division give each side one frame of sealed brood and one frame of honey on the outside; then in ten or twelve days give each another frame of sealed brood. If anything happened to the queen on either side, remove the division-

board and make it one hive. If both queens mated and went to laying, shove the hive 15 inches to the south and give entrance at the northwest corner. Put another hive at the north side and lift out the frames in the north side of the old hive, placing the same in the new, and giving an entrance at the southeast corner. If this plan is good, would not a screen be better than a wood division-board on account of the heat passing thru better?

Would it not be better, when one wishes to give a queen in a nucleus more room, to give a frame of hatching brood instead of empty comb?

3. Has any one ever practiced changing queens in strong colonies to prevent them from becoming exhausted—say switch the queens back and forth between a strong colony and a nucleus?

4. Could one take a strong colony of two stories and constantly rob it of sealed brood and give empty combs in the center of the lower story to take the place of the frames of brood? Would there be any advantage in this? Would it induce the queen to lay more?

Moline, Ill.

Louis O. Stone.

[The average person ought to get a fair knowledge of beekeeping inside of two or three years. This does not mean that he will know all that can be known, or that he will be competent to run a thousand colonies; but two or three years' experience ought to qualify him to operate a single yard or a few colonies in the back yard. Some people would need a hundred years to learn the business, and then they would get it only imperfectly. Ten years ought to qualify any person to get the business thoroughly, so that if he has it in him he can operate a series of outyards comprising a total number of colonies of 500 or 1000.

1. This may be a case of European foul brood or sac brood. If it does not spread, or if it disappears of itself, it is probably nothing worse than sac brood. Yes, larvæ often die of natural causes. Sometimes they are chilled or overheated. Sometimes they are starved because of a lack of sufficient nurse bees.

2. The general plan here outlined would work, altho we would recommend a solid division-board of thin wood. However, the wire screen will answer very well.

The possibilities are that, if the queen on one side of the hive dies, the bees of this one side will desert and go over to the other side. We find this to be true in the case of baby nuclei that are on the same principle. For this reason alone we would advise the use of solid division-boards.

One can give a frame of hatching brood providing the weather is not too cool. This will be preferable to giving an empty comb; in fact, there is no better way of strengthening a nucleus than to give it a comb of hatching brood.

3. We are not sure that any one has tried

this plan; but we see no reason why it would not work. The one drawback is that some queens would be lost in introducing from one colony to another. A better way would be to leave the queens in their hives and have other young queens take their place when they wear out. A queen that lays continuously during the entire season will not do good work if she is shipped south and then put at the job of egg-laying again. Seemingly she has to have a rest of at least six months before she will do good work the next season.

4. The plan could be carried into effect, but we hardly see what advantage would be gained. Sometimes it would stimulate the queen to laying more eggs; but a two-story colony would give a queen, if she is worth anything, all she could do.—Ed.]

Whose Bees Are They?

Has a man a right to have bees on another man's premises without the owner's consent even tho he claim them as swarms from his own apiary? Can he defy the owner with impunity?

Quakertown, Pa.

A. H. Shank.

[When a swarm of bees leaves the premises of a beekeeper, that swarm is his property so long as he can keep his eyes on them and follow them to a point where they cluster again; but under the common law he can not invade another man's premises to recover the bees unless he obtains his consent.

In your case if the other party claims the bees as his, it is up to you to prove that you did not lose sight of them at any time, from the time they left your hive until they arrived at his premises. If you can not prove this to the satisfaction of the court, and if the other party refuses to let you come upon his premises, you can not very well recover your property which is morally yours. No, you can not enter upon the other man's premises without rendering yourself liable for trespass.—Ed.]

How to Mark the Net Weight.

I think I have noticed boxes of honey stamped something like this: "This box contains approximately 1 lb. of honey. Will you inform me whether there is now any legal requirement making it necessary to stamp boxes in any way?"

Lyons, N. Y.

W. S. Gavitt.

[The wording, "This box contains approximately 1 lb. of honey," is not in accordance with the national pure-food law, nor any state law with which we are acquainted. If the federal inspectors were to get hold of a package of this sort they would probably seize it and hold the packer responsible. The net-weight law requires that the exact net weight exclusive of the package shall be marked somewhere upon the label or container. This weight under a pound should be stated in ounces; if more than a pound, in pounds and ounces.

In the case of sections the wording should be, "Not less than — ounces." The ordinary section honey-boxes now in use will run all the way from 10 to 14 ounces minimum net weight. The average of them will run about 12½ ounces. The usual rule is to sort the sections into various weights, each weight in excess of some minimum net weight. It is not practicable to mark upon every box the exact net weight, and therefore the sections are graded according to weight. All in excess of a certain minimum are put in one class; those in excess of another in another class and so on. After they are put in classes by themselves they are marked with the appropriate rubber stamp.

Whether there is a net-weight law in operation within the state, it is always advisable to mark all packages of food with their net weight or minimum net weight as the case may be.—Ed.]

Annual Field Day of the Worcester County Beekeepers' Association and Eastern Massachusetts Society of Beekeepers.

This year, at the invitation of the Worcester County Beekeepers' Association, the Eastern Massachusetts Society met with the Worcester County Association at the home of Mr. W. E. Parker, West Boylston, on Saturday, Aug. 5. From 11 to 5 the air hummed with the sound of bees—not the insects themselves entirely, but with discussion and genial talk about them. The day was rather overcast, but pleasant, and there was a good gathering. All enjoyed the kindly hospitality of the host. Dinner was on the basket-lunch plan, after which came the speaking.

The special guest of honor, Mr. C. P. Dadant, of Hamilton, Illinois, editor of the American Bee Journal, spoke delightfully and instructively on prevention of swarming. He was followed by Arthur C. Miller, Providence, R. I., on "What to Do Now." Mr. Allen Latham, Norwich, Ct., and Dr. Burton N. Gates, Amherst, Mass., followed. Dr. Gates spoke particularly of the symptoms of bee paralysis which has appeared lately in different parts of the country. Later he demonstrated the proper method of opening and inspecting a hive, with valuable practical advice. Mr. W. E. Winter, of Ross Bros. Co., Worcester, had a good display of Falconer's supplies, while Mr. Jepson had sent some of Root's supplies from Boston.

Josephine Morse, Sec.

South Lancaster, Mass.

Easy Enough to Clean Out the Grooves.

Dr. C. C. Miller says, page 521, July 1, that the wedge and saw-kerfs in brood-frames are fine the first time when used, but the second time they are no good. Last spring I had about 50 old frames that I had cut the combs out of on account of foul brood. I just boiled them in lye and water; and as fast as I took them out of the water

I took out the wedge and took a little stick and cleaned out the saw-kerfs. When I was ready to put in foundation they worked as nicely as when new.

E. G. Baldwin, page 524, July 1, says that he would like to have others report who have tried the honey method of introducing. I have tried it on five queens, and have not lost any. It works finely. One colony I tried it on had been queenless so long that they had nothing but a little drone brood that was ready to hatch.

Lake Cicott, Ind.

T. C. Johnson.

They Didn't Need Any Queen.

I have a swarm that filled every frame with brood, and produced a rousing colony and filled one super of honey. When I took the honey off I examined the brood-chamber. They had no brood. They had been queenless for a month. They started no queen-cells and have no laying workers, and have filled combs with honey and bee-bread. There is no place for a queen to lay. Now, will they accept a queen? I gave them a frame of young brood and punched a hole in it to provide a place to start cells, but they refused to do so.

Rardin, Ill., July 19.

W. F. Shafer.

[It is a little unusual for a colony to produce so much honey when the bees have no queen. They gather pollen and some honey, but it is not common that they produce as much as a super of surplus honey, as you say.

We would suggest that you live a comb of young unsealed brood and see whether the bees will start queen-cells. If they will, then it will be all right to destroy the cells started and introduce a queen in the regular way. The fact that the bees refused to start cells from the comb of brood you gave them rather indicates that they would not accept the queen, altho we cannot be sure.—Ed.]

Honey at the Missouri State Fair.

We had the best exhibits last year of any previous year. We shall have more space this year for a finer and larger exhibit than ever. I have induced the fair board to increase their premiums, and shall try to get them to increase more in the future. I make an exhibit of both comb and extracted honey, also bees.

R. G. Robertson,

Marshall, Mo., July 22.

[See complete premium list on page 824.—Ed.]

Why Those Workers were Dwarfed.

I have just noticed the reference, p. 616, July 15, to a freak worker bee. This is no freak to me, for it is very usual where there is European foul brood. The dwarfed workers are due to climatic conditions and lack of stores for the nurse bees to feed them properly during the first few days of their larval state. This lack of attention of the nurse bees causes the larva to be starved.

Chico, Cal.

OUR HOMES

Editor

My son, let thy heart keep my commandments; for length of days, and long life, and peace, shall they add to thee.—PROV. 3:1, 2.

Know ye not that your body is the temple of the Holy Ghost which is in you?—I. COR. 6:19.

He paweth in the valley, he rejoiceth in his strength.—JOB 39:19, 21.

Some time ago I told you about the enjoyment I was getting from my little second-hand electric automobile. It was called the Stanhope when it was brought out years ago; but when it was discovered that gasoline, especially when the price was away down, was so much cheaper than the electric current, the electric gradually fell into disuse except by the very wealthy. Another thing, our friend Ford put a cheap machine on the market that not only rivals the electric, but rivals a horse and buggy. Over a million of them are now blessing the people of the world. Well, when I bought this little electric the batteries were about used up and needed renewing; and it cost nearly a hundred dollars to have the whole outfit made good. As soon as I got it my old craze for electricity revived, and I commenced studying storage batteries, reading everything I could find on the subject, consulting the manufacturers of electric vehicles, and even going so far as to employ an expert to pull the whole thing to pieces and explain everything to me. Altho it took him two or three days, I stood by him almost every minute. I questioned a good deal about how many miles one could get on a fair road with one charge of the battery. By the way, after one has used up the charge it takes ten or twelve hours to get a full charge again. Well, the makers of the machine informed me that if I got 25 miles out of that rig on fair roads I could consider myself lucky. They said the majority of them on the streets of Cleveland usually went below that. You see I was anxious to know how long a trip I could make to surrounding towns or visiting beekeepers and other friends.

There are many curious things about storage batteries, and, like the poultry business, beekeeping, and almost everything else, the one who *succeeds* is the one who gives the work the most intense and intelligent thought and study. For instance, if you wish to preserve the life of your batteries, you should run them clear down; then when you store them you should store them clear up full. When you have got them stored clear up full on full voltage current, you want to cut the current down a half or less and make it run up again.

Furthermore, when your batteries get exhausted like a tired horse in climbing a long steep hill, you must let them rest. When a charge is needed again, and you are a mile or more from home, you can "get there" by giving the battery frequent rests. On one occasion I found myself half a mile from home, and the machine would not go another inch, even when I was out by its side and led it as one would lead a horse. As I was in a great hurry I left the machine by the side of the road and went home on foot. Going back a couple of hours later, it went home full speed like a young colt. It simply needed *resting*. Well, shortly after the cells had been renewed I got 26 and then 27 miles; then as I learned the different tricks about it I got 30 miles, then 35; and I cannot tell you how intensely I enjoyed the fun of seeing my machine day by day break its record. Where hills are very steep I get out and push the machine to the top of the hill, or carry along a newspaper, and read, when the battery gets tired. I soon found out that muddy roads or a big hill is a bugbear, and I planned to go around them and look out about getting on clay roads during a storm.

In order to get the best results—that is, the most miles, I find it important to make the vehicle as light as possible by removing every article not absolutely required. Leaving off the heavy laprobe that is required only in cold weather made quite a difference. I also omitted my overcoat, and this helped, and walking uphill as I told you. I think that in a former issue I told you about making a trip to Elyria, and afterward getting miles enough to make *fully 40 miles*; and I can hardly tell you the enjoyment and enthusiasm that I experienced in making the last few miles, getting it clear up to 40.

As the batteries grow older their strength is reduced. It was two years ago that I succeeded in getting 40 miles. Just now about 25 miles is the best I can do. Since I have had a Ford car for long distances, the little electric has been used for only short distances about town, or say four or five miles out of town. Our youngest daughter, Mrs. Boyden, has been appointed "deaconess" in our church, and she is expected to do a great deal of visiting. Well, this little electric hits the business to a dot. You can start it easier than you can start a horse. You can stop anywhere—no cranking, nor anything like it. In fact, if you want to move ahead only ten feet you can

just touch the lever and go the ten feet. It just now occurs to me that I omitted one other trick, and it is something that will apply to gasoline machines as well. When you have learned by practice how far the machine will go by its own momentum after you have cut off the current or gasoline you will make quite a saving by making it stop of itself at about the right point, without using the brake. The same thing applies to turning corners. When you come to a place where you are about to turn, cut off the current or the gasoline, and the machine will turn the corner by its own momentum. The differential machinery that is needed in all classes of vehicles to enable us to turn corners is an expensive apparatus. When it gets out of repair it is hard to get at, and an expensive job to make good. But if you stop the current or the gasoline so the power that is pushing is cut off when you turn corners this complicated machinery is relieved—there is no wear and tear on it. If you consult the daily papers you will find again and again where machines "turn turtle" and kill one or more of the occupants, besides maiming for life several others, all just because the driver turned a corner at too high a speed. Had he cut off the driving power before he reached the corner this could not have happened.

Perhaps you begin to wonder by this time what our text has to do with running automobiles. Well, I am just getting ready, friends, to talk about something besides automobiles. I have already mentioned, page 558, July 1, what the insurance doctor told me about so living that I shall be not only alive, but in good repair, as long as possible. The experience I had a few weeks ago suggested to me that I was, in a good many respects, very much like that little second-hand electric Stanhope with its storage battery and ingenious machinery to store up power with which to run. I succeeded in making the storage battery accomplish almost twice what it would do without that careful management and study. The machine and the batteries made not only 30 miles but clear up to 40 miles. My body and brain have passed the three-score-and-ten landmark, and the question begins to arise, "How much *more* is it going to make?" You know I have written several times about my forgetfulness—forgetting to take my mail to the postoffice down in my Florida home, etc. Well, I told the good doctor about my forgetting. He laughed as he said something like this:

"Mr. Root, you should consider that your memory is a part of the machine, and it is *wearing out*. You must rest it. You must

not drive it too hard, and you must not expect too much of it. From what you say, I think it is a wonder that you *do* remember things in your past busy life as well as you do."

Just a word right here in regard to helping the memory. Like everybody else (or at least I suppose so) I have places for my separate tools—hammer, wrench, screwdriver, coldehiscels, etc. Now, I have lately decided that I had better not leave my things in *different* places. For instance, just this morning I wanted my little cultivator wrench. I had used it only an hour before, but it was not in its accustomed place, and I spent quite a little time looking for it. Finally I sat down and said, "Why, what *could* I have done with that wrench that I used just a little time ago?"

After a little brown study I said:

"Oh, yes! I decided that the best place for it would be to hang it on a nail where it would be in plain sight where I was cultivating."

Then I looked up at the nail, and there it was, sure enough. I had decided hanging it on a nail would be a better place than the one where I had been accustomed to keep it; but the fact of making that decision and of hanging up the wrench had entirely gone from me, and so I concluded that for the rest of my life I had better be careful about putting things in a *new* place. I told you I had discovered the tired-out batteries would work again with considerable vim if they were "rested" for an hour or two. Well, it is just so with this old body of mine. After I feel that I cannot go any further here in the office, read the letters, or go out into the garden to run the cultivator, a little sleep will fix me all right again. The younger friends all around me take their sleep just once in 24 hours. I do not know at what time they go to bed; but a good many times I *do* find them asleep after the factory whistle has blown in the morning. (I don't know what time they went to bed). Babies, you know, take short naps, and I begin to think that old people could as well do the same thing probably. I like to be about early, say shortly after daybreak. I delight in seeing the sun rise. Before it is up very far I want my breakfast. This good doctor said my heart would not hold out for long sieges just as it did when I was younger; and he said the heart, in order to do this work, needs a good supply of oxygen. A dusty atmosphere or a confined atmosphere, he said, is a clog on the heart. He asked me if I ever panted for breath. I told him I often did when cranking my automobile. He said the exercise was all right, and just

what I needed if it were not too severe, and that better air, and the pure air of the country, is very much better for one who is anxious to retain his powers of mind and body as long as possible.*

In regard to food, nature will indicate what is best for you if you will enter into her way. By the way, the Cleveland *Plain Dealer* is now printing some talks on health every day from a very competent and able physician. I greatly value these health talks, and I rejoice to hear this good doctor say again and again that stimulants and intoxicants are all to be avoided. He answers more or less in every issue of the daily, and every little while some one asks him if a little beer or whisky would not be a help for this, that, and the other. But his reply is *no* every time. May God be praised that the physicians of the present day are getting to be a unit in regard to alcohol as a medicine.

By the way, our good friend R. F. Holtermann, of Brantford, Canada, made us a call yesterday, July 5. We were talking about preserving health clear up into old age. He said something like this: "Some good authority has said that a man should exercise enough to take a good sweat twice a day;" and then he added, "As a matter of course we do not want to overdo the thing." He said his test was if, when he got up the next morning, he felt bright and well as a result of the exercise of the day before, that exercise did not do him any harm. That has been my experience. Many times lately when I feared the use of the cultivator might show itself, next day, to my surprise, I would get up feeling unusually well, and all ready for some more of the same kind of medicine.

Now, friends, in summing up is it not very likely that we can have greater "length of days, long life, and peace," as we have it in our text, if we study these bodies of ours exactly as I studied that electric automobile which I made do double the work they told me at the factory where it was made I would be likely to get out of it? But it came about because it was my delight to study it and master its mechanism from beginning to end. I went over books on electricity, and questioned experts, and studied God's laws in regard to the wonderful current which does our bidding in so many ways.

Our text also intimates that "length of days and long life" are the result of keep-

* I have just discovered that riding in an automobile, say early in the morning, against a good stiff breeze, tones and braces me up a thousand times better than any dope or stimulant ever invented. Just take in long breaths, as much as you can hold, and get an extra supply of God-given oxygen.

ing God's commandments. A study of the Bible will, I am sure, be a great help to long life. Then we can make it a lifelong earnest study to understand better the mechanism of these bodies. We can find out by careful intelligent experiment what helps and what hurts. When I discovered that headache powders gave instant relief, not only to headache but to toothache and earache, I was delighted; but when I found out shortly after that those same powders interrupted the digestion and "made mischief" with the machinery in other ways, I decided "no more dope for this child." It must have been toward thirty years ago that toward night I felt a queer breaking-down which I could not understand. I remember one evening just before our teachers' meeting I said to myself, "What in the world *is* the matter?" and I managed to get along in a dazed sort of way until bedtime. In the morning I was all right, and pretty soon I discovered that a *little sleep*, say twenty or thirty minutes, was a cure for this giving-out, if I may so express myself, when I have been doing an unusual lot of brain-work. My brain or nerves were in just the fix that the storage battery was. A halt was necessary in order for the various chemicals to assemble, as it were. Now, I do not know just exactly *how* sleep enables nature to readjust and make good certain things in order to make up for those that are worn out. After careful cutting and trying I discovered that physical exercise and taking a sweat are almost as necessary as sleep; and by carefully noting the effect of different kinds of food I was able to decide what foods are best for me, or the quantity of food that would enable me to do the most work. Upton Sinclair, as you remember, discovered he could get great benefit by fasting; and thousands besides myself have found out that over-eating is one of the great sources of mischief. Do not have too many different kinds of food at a meal; and beware of tempting dishes that are invented, it sometimes seems to me, for almost the sole purpose of persuading us to eat more than we need. Let us remember that these wonderful bodies of ours that hold out sometimes close to a hundred years are or should be "the temple of the Holy Ghost;" and let us remember the promise that if we study and keep God's commandments we are likely to have "length of days and long life." And, finally, if you will excuse the abruptness of my third and last text, even old men like myself, if we live right, may feel like that beautiful God-given domestic animal which "paweth in the valley and rejoiceth in his strength."

I spoke about the importance of storing

the storage battery clear up full and then letting it run clear down. It is better for the battery, and it will give longer service, than if a little more current should be added, especially when it is only part way run down. Now, I think this will also apply to these bodies of ours. At least for myself it is better to do a thoro day's work—of course not overdoing, but to avoid sitting around in a lazy way. After doing a fair day's work with both mind and body, I am then ready for a good sleep, and then ready for another day's work. If my regular hours of sleep are broken on it impairs the machine. This comes right in line with the injunction to "wear out, instead of rust out." If possible, find some kind of work that you enjoy—better still, some that you *thoroly* enjoy. But I would recommend keeping busy, even if you do not always enjoy it. I would especially urge all old people to study how to help themselves, and take care of themselves as much as possible, and avoid *in every possible way* being a burden on the younger ones. I am *thoroly* convinced that "length of days, and long life and peace," depend very much on what I have been saying.

THE AMERICAN CIVIC REFORM UNION.

The superintendent of the above institution writes me as follows:

My dear Mr. Root:—What do you think of my brand-new lecture circular? I know you can say "amen" to "Why I am a Reformer." Cleveland, O., Aug. 8. A. S. GREGG.

The first page of the circular referred to reads as follows:

WHY I AM A REFORMER.

Because innocent and helpless little children cry for food and clothing while brewers, saloon-keepers, and corrupt politicians wax rich on money stolen from the breadwinners.

Because of the broken-hearted wives, mothers, sisters, and sweethearts whose loved ones have been robbed of strength, health, and all that makes a man noble.

Because Mr. Indifferent Voter is so busy making a living or striving to get rich that he doesn't care a hang who is elected to office unless the election happens to hit his pocketbook.

Because evil men in high places corrupt the people, and control government for private gain.

Because ignorant goodness and a "pork-barrel" state of mind breed a "pork-barrel congress."

Because fiends in human form "sit in the lurking-places of the villages," and often in the palaces of the city, and plot destruction of innocent young girls.

Because our jails, asylums, and poorhouses are overflowing with the uncanny victims of vice, drink, and degeneracy.

Because many men are so rotten with the results of vice and drink that they could not defend the country in case of attack by a foreign foe.

Because I want to help destroy the works of the Devil and establish justice, purity, and sobriety on earth.

My program.—A relentless attack on evil conditions by means of lectures, sermons, books, newspaper articles, legislation, and investigations; and the development of a righteous public opinion that will elect honest and capable men to public office and keep them there.—*Rev. Albert Sidney Gregg*, Lecturer and Promoter of Civic Reforms, Superintendent of the American Civic Reform Union, 501 Caxton Building, Cleveland, O.

If I am correct, friend Gregg stands ready to respond and take charge of any case of white slavery, cruelty to children, or anything along that line. Address him as above and he will have the matter looked into. And I want to say to my good friend Gregg that I not only give a hearty "amen," but, as you see, I have got it in print also.

SOME OF THE ADVANTAGES OF FLORIDA.

We take pleasure in clipping from an article in the *Florida Grower* the following, written by W. A. McRae, Commissioner of Agriculture. Our readers can rest assured the statements, coming from such a source, are unbiased:

The *centers* of continents are subjected to greater intensity of storms and variations of heat and cold than along sea-coasts. Kansas is the center of more uncertainty in weather than any other part of the Union. More dangerous storms occur in the central section of the Mississippi Valley than elsewhere in our country.

Florida is freer from dangerous winds than any other part of the South Atlantic or Gulf regions. Severe storm centers originating in the West Indies or Carribean Sea pass across the Gulf and strike as a rule the coast adjacent to the mouth of the Mississippi and pass up that valley to the Ohio Valley and Lake region, and thence to the east, or else subside on the way. Florida has heavy rainfalls; but most of its rivers are tidal and seldom overflow their banks regardless of the quantity of water flowing into them from downpour.

Florida is more fortunate in having a purer atmosphere than any other of the States, it being duly swept by mild and constant winds from the seas on each side—modifying the heat of summer and the cold of winter—with air free from impurities, which is not possible in the interior region of the country, where it is liable to contamination from the land. Florida, too, is fortunate in having a larger supply of good fresh water in surface lakes and rivers and underground than any other State, not to speak of its unrivaled sea-coast—the longest in the Union.

Florida, therefore, has an ample supply of a remedy that's good for what ails you, no matter what it is, and it costs nothing. It is good externally and internally. Applied externally, with a bit of soap, it has magic effect on the skin—a refreshing experience always—and yet few understand that equal magic comes by its frequent internal use. We eat when hungry, and most people drink when thirsty. But thirst does not come until the tissues are waiting, and a United States public-health bulletin recently announced: "Taking in just enough water to satisfy thirst means living on a stagnant level with never a flood to wash out the old and stir the new." About 70 per cent of the human body is water. Have a drink; and the more you drink, the better. *Water's about all you can get now in most Florida towns, and hasten the day when it will apply to every nook and corner of the State.* Water is the world's one best drink. Have another!

And there's our good air to breathe. To breathe well helps one keep well. To live longer and better, the doctors say, make it a habit to take breathing exercises. Experts declare that the average man ordinarily uses about one-tenth of his lung space. Is it any wonder that diseases of the throat and lungs are so easily contracted? Florida air is safe to breathe. It comes in clean and pure from the seas.

It is estimated that the atmosphere—the vital part extending not more than six miles from the surface—carries annually from the sea to the land to flow back again to the sea no less than 130 millions of tons of water. The average annual rainfall of the United States is about 33 inches, while that of Florida is 53 inches.

Florida can in all truthfulness boast of its good

air, water, and healthfulness. Air and water are the prime essentials of life; and with plenty of the best of both, there is no reason why our state should not become one of the greatest in the Union—if there is any advantage in having the essentials of life.

I want to give a hearty amen to the sentence above which I have taken the liberty to put in italics. When we get good men into high offices that are not afraid to come out before the world and make such statements as that, we are certainly making progress toward the coming of God's kingdom.

HIGH-PRESSURE GARDENING

THE DUST MULCH IN TIME OF DROUTH.

On page 557, GLEANINGS for July 1, I spoke of the Barker cultivator for making a dust mulch, etc. Well, I so much enjoyed running the Barker cultivator that Mrs. Root remonstrated. She said I was cultivating the garden over and over, when there was not a weed to be seen. Well, it is true I did run the little cultivator when it seemed there was no particular need of it. One reason was that I was getting so much benefit from having a good sweat every forenoon or afternoon. By the way, toward seventy years ago I once heard my grandfather, Jesse Hart, say that he aimed to keep his garden in such condition that no one could find in it a tobacco-boxful of weeds by going all over the enclosure inside of the picket fence. I suppose this was at a time when my grandfather was almost too old to do much but make garden. Well, when I got my garden in such fine condition I thought about the tobacco-box story; and altho I do not have any "tobacco-box," and never had one, I think my garden must have been pretty nearly equal to my grandfather's. I distinctly remember the luscious melons (they did not have "cantaloups" in those days) that he used to get out of that garden and divide up among his children. Well, now, for the point of this garden story.

When the great drouth came on about the first of July there was a soft dust mulch, perhaps an inch deep or more, all thru my garden stuff; and altho we had five weeks of it right here in Medina without anything to call a summer shower, our garden scarcely seemed to mind it. We could not use the sprinkling system I have mentioned, because a flood destroyed the dam of our Medina waterworks, and the water board had cautioned everybody in our town to be careful about wasting water.

This dust mulch stood for four or five weeks without a sufficient sprinkle of rain to form any crust. Great cracks opened up in many places in our clay soil in consequence of the drouth; but our corn, beans, and everything that got a good start before the drouth did not seem to suffer at all. Some things that were planted late that had not got their roots far down were hurt by the drouth. I have before said something about preparing a dust mulch to overcome or offset the results of a drouth; but I never realized before what is possible in this direction. You can easily test it by experiment. Clay ground will never get dry and hard when there is a mulch of soft fine earth on the surface. I suppose other tools will form this dust mulch the same as the Barker cultivator; but I never saw any implement that would pulverize a clay soil and spread it over the surface so evenly as does the Barker cultivator.

MULCHING THE ORCHARD WITH SWEET CLOVER.

For years I have witnessed the contrast between a block of trees at our Ohio Experiment Station which were mulched, and another block of trees adjoining that had the best of cultivation. The mulched trees were far ahead; but I do not know that they ever tried mulching with sweet clover. So far as I know their mulch consisted of grass and weeds that were cut between the trees. The mulch extended out as far as the limbs reached, and it was kept heavy enough to keep down all weeds. The following from the *Ohio Farmer*, it occurs to me, is an excellent suggestion. One who has tried plowing and cultivating an orchard, and has also tried mulehing, can realize what *cultivation* costs.

SWEET CLOVER IN THE ORCHARD.

I was interested in the attitude that Prof. W. F. Massey took in the April 29th issue of *The Ohio*

Farmer in regard to growing sweet clover in an orchard. I have made a careful study of this legume, and in my opinion no other cover crop can compare with it. Last spring I seeded an acre of my orchard to sweet clover which I mowed as soon as the crowns for this year's growth had formed, which was about Sept. 15.

The growth from this acre was sufficient to mulch every tree in the acre one foot deep and five feet in diameter. This year I will get two or three cuttings, each of which will be equal to the one made last fall. If this be used for mulch, which in course of time will decay, forming humus and in the mean time holding the moisture, I cannot see how it will rob the trees of moisture.

There is no doubt that the sweet clover will draw somewhat on the soil moisture, but compare it to the average grass that we find growing in orchards, which is usually a mixture of timothy and bluegrass. It has to rain a day and a night to soak this leathery covering, while with sweet clover the water finds easy access into the soil.

Furthermore, the large roots of the clover in decaying and opening not only the surface soil but also the subsoil, greatly increase the power of the soil to assimilate and hold large quantities of moisture. I will admit that to plow under a crop of crimson clover each year is good; but other things must be considered. It is a whole lot easier to say plow than to go into an orchard and do it. It is impossible to plow an orchard without injuring some trees, either with the plow or the horses' barking the trees. In the next place you cannot avoid ridges and dead furrows which, if your orchard is planted on a hill, will result in disastrous washes and gutters.

Here are the advantages of growing sweet clover in the orchard: 1. It makes sufficient growth to mulch the trees heavily, thereby retaining moisture. 2. It is a legume, therefore enriches the soil instead

of making it poorer. 3. By allowing the last crop to seed, it never requires re-seeding. 4. By not cutting the last crop until it has ripened its seed, then in raking this up and mulching with it, all danger of fire running over the orchard and destroying it is entirely overcome, which is one of the greatest if not the greatest disadvantage of the mulch system.—FRED SATTLER, Tuscarawas Co., O.

SACHALINE, "EUREKA CLOVER."

Some eight or ten years ago, I am sorry to say, our journal gave quite a favorable report of sachaline as a new forage plant. In 1908 I gave notice that it had never made a growth to amount to much unless planted in exceedingly rich ground. I regretted that I had ever boomed the stuff; and the worst part of it was that no kind of stock seemed to care enough for it to eat it. We have just received the following:

EUREKA CLOVER.

Under the name "Eureka" clover there is now being advertised a forage plant for which enormous yields of green fodder are asserted. The plant in question is sachaline (*Polygonum sachalinense*), introduced into the United States in 1883, and much exploited in 1893 and for a few years thereafter.

Washington, D. C.

It seems that the business of booming some old and well-known plant under a new name is not altogether done away with.

Together with the above clipping came a couple of pages regarding sachaline, first and last.

TEMPERANCE

"THOU CHILD OF THE DEVIL; THOU ENEMY OF ALL RIGHTEOUSNESS; WILT THOU NOT CEASE TO PERVERT THE RIGHT WAYS OF THE LORD?"

The above sounds a little rough, does it not, dear friends? But if Paul were alive and on earth now I believe he would say just that thing to the liquor people and their business. I was reminded of the above by the following, which I clip from the *American Issue*:

BOYS AND GIRLS OF MORE VALUE THAN NATION'S MATERIAL RESOURCES.

The Van Wert (Ohio) *Republican* hits the nail on the head, from an economic viewpoint, in discussing the liquor question. We quote from that paper:

"Life-insurance experts figure that each young man and woman of good habits and sound physique is an asset to the nation, as a producer or conservator of wealth, to the extent of \$8000. There are in the United States 50,000,000 children and young people under 25 years of age. At \$8000 apiece they are an asset of \$400,000,000,000. In mere dollars and cents the youth of our nation are worth more than our coal, our iron, our silver, our gold; more than the cattle on a thousand hills; more than grain from a million fields. And the legalized liquor-traffic is the ruthless destroyer of youth. It begins the work of destruction before birth: handicaps boys

and girls physically and morally, and renders tens of thousands not only unable to produce or conserve their quota of \$8000, but makes of them dependents and undesirables, an economic loss to the nation and a menace to its stability.

"BOOZE" SHOPS IN THE DISTRICT OF COLUMBIA.

Have we not as a people and as a nation progressed almost far enough toward God's kingdom to declare most vehemently that it is a burning shame and a disgrace to our nation that these hotbeds of all vice and iniquity should longer remain right close to the capitol of our great nation? See the following, which I clip from the *American Issue*:

It is thought that the District of Columbia dry bill will pass the Senate at the short session, if not during this summer. Senator Vardaman, of Mississippi, in his speech in the Senate the other day said:

"If the question of saloons or no saloons for the District of Columbia should ever be put squarely to the American Senate, I have no doubt about the saloon hearing its death-knell in so far as action in this body is concerned. The American people demand it, and the interests of humanity call for such legislation. The open saloon is an evil without a mitigating incident, and I submit that the great capital

of the greatest nation on earth should not be marred by such social cancers and festering sores. It is not in keeping with the highest order of Christian civilization.

IT PAYS TO BE DRY AND "DECENT."

When I was fourteen years old I attended high school in Wellsville, Ohio, one winter. It was during this winter that I made my first experiments in electricity, and at the same time I succeeded in exploding a mixture of air and gas by means of an electric spark. Little did I think at that time my cheap, rude, boyish apparatus was going to be the forerunner of the automobile that is now, I might almost say, turning the world upside down. For the above reason I was interested in the clipping below, which I take from the *American Issue*:

NO SALOONS, LESS CRIME; JAILER MORGAN TELLS OF CHANGE IN CHARLESTON, W. VA.; IT PAYS TO BE DRY; IF YOU DOUBT IT, ASK THE CITY OF WELLSVILLE.

There is little wonder that Lisbon, Columbiana Co., voted dry recently. The voters had only to look across the county to the city of Wellsville to see the benefits of a saloonless town. In fact, they had the benefits right at home, but quite often do not appreciate them as much as when seen from a distance.

Wellsville, a dry city of 8000 population, has nearly \$60,000 on deposit in the Postal Savings Bank. Besides this amount, she has \$30,000 of postal-savings deposits invested in United States bonds.

In the same county is the wet city of East Liverpool with a population over three times as large as that of dry Wellsville, and yet the deposits in her Postal Savings Bank amount to only \$16,000.

Furthermore, in two years in dry Wellsville the city has reduced the bonded indebtedness by \$50,000, and this year will pay off \$30,000 more of its indebtedness. The past two years dry Wellsville has spent \$140,000 in building new churches; \$95,000 has been spent on a new high-school building, and \$15,000 on a public-library building.

The above tells why in a pecuniary sense it pays to be dry; and the next clipping from the same paper shows how it pays to be dry and *decent*.

BAD BUSINESS; INSURANCE COMPANY DOES NOT WANT SALOONKEEPERS FOR PATRONS.

An agent of one of the big New York life-insurance companies took the application of a saloon-keeper for an endowment policy. The company rejected the application. The agent wrote to the home office and registered a kick because the application was not accepted. In reply the company wrote the agent in part as follows:

"So far as we are concerned we do not believe risks of this class will contribute to a satisfactory mortality in the first place, and in the second place we do not care to write our business among that class in the community. We think it would do the company harm rather than good, even if it got a few hundred thousand dollars of seemingly good business on the endowment plan every year, if the holders of these policies were saloonkeepers. We do not want the name of being a saloonkeepers' company and of taking the grade of risks which are refused by the leading and conservatively managed companies of the country.

"Life-insurance companies are engaged in encouraging thrift, protecting homes, and in promoting the welfare of the individual, the community, and the state. Saloonkeepers—all of them—are engaged in discouraging thrift, destroying homes, and in injuring the individual, the community, and the state. There is nothing in common between us, and we do not even care for business relations with them."

I am glad to know that now even insurance companies do not care to take money that is gotten by selling "booze."

THE ANTI-CIGARETTE LEAGUE OF AMERICA.

This is located at 1119 Woman's Temple, Chicago. There are something like forty or fifty different officers, including an advisory council. This is headed by P. P. Claxton, U. S. Commissioner of Education, as Honorary President. By the way, is it not remarkably appropriate and fitting that the *Commissioner of Education for the United States* should be president of this much-needed organization? In the advisory council we notice the names of Judge Ben B. Lindsey, of Colorado; Thomas A. Edison, Wilbur F. Crafts, J. H. Kellogg, M. D.; Ira Landrith, of Tennessee; Daniel A. Poling, of Ohio, and a host of good men and women of our nation. Last, but not least, as the *superintendent and founder*, is the name of Luey Page Gaston—just a little woman, but a "live wire," and no mistake. By the way, among the other things that I have to thank God for is the fact that I have so many good strong friends who are standing away up in the crusade for the betterment of humanity. I am going to let you get a glimpse of a letter just received from Miss Gaston:

Dear Mr. Root:—I am very glad indeed to know that you keep up your fight on tobacco. The story of your practical work ought to be passed along, and I may find a way to publish it. We have such an abundance of good material, only waiting the financial ability to get it to the world.

Hoping that we may some time have the opportunity of meeting again, I am

Yours for clean living,

Chicago, Ill., Aug. 11. LUCY PAGE GASTON.

P. S.—I wish you were 20 years younger. My dear mother is in her 84th year, and is as bright as ever. L. P. G.

When I came to the postscript I had to have a big laugh; and I am still wondering just *why* she wishes I were "twenty years younger." Please notice just above her signature, "Yours for clean living." Well, now, this clean living is the explanation for her mother being as bright as ever, even up to her 84th year; and I think, also, it is the "clean living" that has enabled me to feel so bright and well this 15th day of August, 1916.

Why Not Declare War?

against weak colonies, old queens, and diseases by buying and requeening with my young, vigorous, three-banded Italians. They are bred for honey and gentleness. 50 CENTS each; \$45.00 per 100. This is a first-class queen at a cheap price. Guaranteed to be as good as money can buy; to give perfect satisfaction, and reach you in first-class condition.

N. Forehand . . . Fort Deposit, Ala.

Prices Reduced for . . . Rest of Season

For resisting foul brood no bee can be found that will excel ours. Requeen now while you can get them cheap.

Pure mating; no disease; safe arrival guaranteed. CURD WALKER, Queen-breeder Jellico, Tenn.

PURE ITALIAN QUEENS.—Golden or three-banded by return mail. All queens are warranted purely mated. They are large and long lived. They have proven themselves highly disease-resistant in many localities. One select untested, \$1.00; 6, \$4.25; 12, \$8.00; 100, \$60.00. Tested, \$1.25. Bees by the pound, nuclei, colonies. Safe arrival and satisfaction I guarantee. Circular free. J. E. WING, 155 Schiele Ave., San Jose, Cal.

Special Notices by A. I. Root

GOOD BOOKS FOR A SMALL AMOUNT OF MONEY.

Some thirty years ago we sold hundreds of copies of Pilgrim's Progress. The edition we had contained 384 pages, with illustrations all thru. The book is nicely bound, and makes a beautiful present. But because it was published so long ago we offer it now for only 50 cents; by mail, 60. My impression is that it was originally a \$2.00 book. We have only seven copies left.

Pilgrim's Progress was first published about 260 years ago, and has been translated into more languages than any other volume, the Bible alone excepted; and probably no other book (the Bible again excepted) has done more to keep alive the true spirit of Christianity than this wonderful allegory. The variety of characters Bunyan introduces with such vividness surpasses that in any other volume of human production. No person can be said to have read the Bible without having read this ever interesting volume; and one who has not read it is certainly greatly lacking in a knowledge of English literature.

HONEY AT THE BIG FAIRS

MISSOURI STATE FAIR.

QUEENS

Our July, August, and September SPECIAL PRICE on untested leather-colored queens--- a bargain never offered to the American beekeeper before.

Prices on	1 to	10 queens,	50 cts. each
"	11 to	25 queens,	45 cts. each
"	26 to	100 queens,	40 cts. each
"	101 to	1000 queens,	38 cts. each

Safe delivery. If not satisfied, return queens and get your money back. The Root Company, The American Bee Journal, Dadant & Sons, any mercantile agency, and others will tell you who we are.

The Penn Company . . Penn, Miss.

TRADE NOTES

BEESSWAX MARKET.

There is an improved export demand for beeswax which warrants our increasing our price to the rate prevailing before the last drop—namely, 28 cents cash, 30 cts. trade delivered at Medina, New York, or Philadelphia. If you have a supply available, now is a good time to convert it into money or goods.

CHIPPED TUMBLERS CHEAP.

We again have a supply of two or three hundred cases of 2 dozen each of tin-top tumblers holding 6 1/2 oz. of honey, or 1/4 lb. of jelly. They have the edges slightly chipped so they cannot be sealed airtight for shipping, but will serve as a cheap container for some uses. We offer them, while they last, at \$2.00 for ten cases of 2 dozen each, including the tin tops.

METAL-TOP COVERS ADVANCED IN PRICE.

The increased cost of galvanized sheet metal has made it necessary to mark up the price on all metal-top hive-covers, and all hives equipped with them, 5 cents each. This applies to such covers in our catalog as are listed under the letters R, K, and Y, both eight-frame and ten-frame. This advance applies to retail, wholesale, and jobbing prices.

SQUARE TIN CANS.

The greatly advanced prices on tin plate will make higher prices on square tin cans imperative when next catalog is printed. On such stock as we buy now at distant points where we are not covered by a contract we have to pay prices which are more than 20 per cent higher than we paid last winter. We can continue the old prices for the present from Medina only, because we have a good supply bought at old prices. The new prices effective now from our branch offices and agents, except as shipment is made from Medina, are as follows:

- 5-gal. square cans, 1 in box, 60c; 10 boxes, \$5.50.
- 5-gal. square cans, 2 in box, 90c; 10 boxes, \$8.50.
- 5-gal. sq. cans, 27 to crate without boxes, 30c each.
- 1-gal. sq. cans, 10 in a box, \$1.70; 10 boxes, \$16.
- 1-gal. square cans, 100 to a crate, \$12.00 per 100.
- 1/2-gal. sq. cans, 12 in a box, \$1.70; 10 boxes, \$16.
- 1/2-gal. square cans, 100 to a crate, \$10.00 per 100.
- 1/4-gal. sq. cans, 24 to a box, \$2.60; 10 boxes, \$25.
- 1/4-gal. square cans, 100 to a crate, \$9.00 per 100.

BUSHEL BOXES.

We have on hand, ready for immediate shipment, a good stock of these boxes, packed as shown in catalog. They are made with oak corner posts and bottom end slats to receive the nails, the remainder of the box being basswood. They are very convenient, and popular for handling potatoes, apples, onions, and other farm crops. They hold a heaped bushel level full, so they can be stacked any height desired. To reduce stock we offer them for a short time at the following special prices:

- All slatted bushel boxes, per crate of 14, \$2.25
- Slatted bushel boxes, per crate of 12, \$2.10
- Galvanized bound boxes, per crate of 12, \$2.75.

In lots of 10 crates or more, 5 per cent discount.

The all-slatted is the cheapest, and the most popular style. Two are nailed in each package, and sufficient nails are included for the remainder.

EARLY-ORDER CASH DISCOUNT.

The usual custom of allowing a discount for early cash orders for goods for next season's use is continued this season. The discount begins with 5 per cent for September cash orders instead of 7, which was given in former years. The discount applies to the latest revised prices with the usual exceptions on certain classes of goods. No discount will apply on orders for shipping-cases, cartons, labels, tin and glass honey-packages, bees, queens, paint, bushel-boxes, hothed sash, seeds, honey, and printed matter.

Where goods named in the list of exceptions form not more than 20 per cent of a general order for hives and other beekeepers' supplies, the discount may be taken on the entire order. The discount is allowed only for payment of cash during the month of September, whether goods are shipped or not. For payment in October the discount will be 4 per cent; during November, 3 per cent; during December, 2 per cent.

**Be Efficient in
BEE CULTURE**

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER.** By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE.** By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES.** Our new complete catalog, mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER.** Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES.** The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING.** Just the thing for the up-to-date housewife. Price 10 cents.
- BEEES AND POULTRY,** how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES.** A book of 225 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE ABC OF BEE CULTURE.** A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES.** A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.
- THE BUCKEYE HIVE,** or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET CLOVER,** the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE.** A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth. \$1.00 postpaid.

Better Queens and Bees for Less Money

20 years of select breeding gives us bees and queens of highest quality---Queens for Honey production---Queens of unusual vitality---Queens that successfully resist European foul brood

Our select colonies for breeding purposes, larvæ, and select drones are those of the highest standard, the choice of over 1000 hustling honey-producing colonies of pure Italian bees. These select colonies are located at such a distance from all other bees as to assure pure mating, and thus effective use of our select drones. The larvæ we use in grafting is as small as can be seen and handled, having just come out of the egg. These are placed in cells, which in turn are placed and nourished in strong ten-frame colonies, which, when honey is not coming in sufficiently, are heavily stimulated by feeding. Thus we get large well nourished cells, which in turn produce large, long-lived, and hardy queens that give workers unexcelled for honey production. We use no baby nuclei. All our queens are hatched and reared in strong three and five frame full-depth hives. Thus natural conditions are preserved, and the best queens produced.

Price List of our Three-banded and Golden Italian Queens. Ready by Return Mail.
Untested, 50 cts. each or \$45.00 per 100 Tested, \$1.00 each or \$ 90.00 per 100
Select Untested, 65 cts. each or \$60.00 per 100 Select Tested, . . . \$1.25 each or \$115.00 per 100
All queens are warranted purely mated. Wings clipped free of charge.

Price List of Our Swarms of Bees for Fall Increase.

1-lb. swarms with select queens. \$1.75 2-lb. swarms with select queens. \$2.50
3-lb. swarms with select queens. 3.50 5-lb. swarms with select queens. 5.00

All orders filled at once, or as desired.
We have no disease of any kind. Satisfaction we always guarantee.

M. C. Berry & Company Hayneville, Alabama

Queens--Queens--Queens. We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

W. J. FOREHAND & SONS FORT DEPOSIT, ALABAMA

Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

	June and July	August and later
Select Tested Queens	1 for \$1.75; 12 for \$19.25	1 for \$1.65; 12 for \$18.00
Tested Queens	1 for \$1.05; 12 for \$12.00	1 for \$1.00; 12 for \$10.75
Untested Queens	1 for 60 cts.; 12 for \$ 7.00	1 for 55 cts.; 12 for \$ 6.00
Very best queens for breeding, \$3.00.	1 lb. bees in package, \$1.25; 2 lbs. in package, \$2.00.	

Add price of queen. If any of our untested queens should prove to be misnamed we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

W. D. ACHORD, FITZPATRICK, ALABAMA.

EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

Special Bargains in Shipping-cases

With the bountiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

4 crates of 50 each, 9½-inch, 2-row, at \$4.00 per crate.

19 crates of 50 each 10-inch, 2-row, at \$4.00 per crate.

15 crates of 50 each, 6¼-in. 3-row, at \$4.00 per crate.

56 crates of 50 each, 12-pound cases, at \$4.00 per crate.

All of the above have either 2 or 3 inch glass, and take 12 sections 4¼x4¼x1½ plain.

There are also for the same size section, packed 10 in a crate:

10 crates of 10 each, 9½-in. 2-row at 85 cts. per crate.

4 crates of 10 each, 6¼-inch, 2-row, at 85 cts. per crate.

4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.

For the 4¼x1½ beeway section we have:

4 crates of 50 each, 15¼-inch 2-row, for 15 sections, at \$4.50 per crate.

6 crates of 10 each, 15¼-inch, 2-row, for 15 sections, at 95 cts. per crate.

12 crates of 50 each, 11¾-inch, 2-row, for 12 sections, at \$4.00 per crate.

6 crates of 10 each, 12-lb. safety cases with cartons, at \$1.20 per crate.

3 crates of 10 each, 8-inch, 3-row, for 12 sections, at 85 cts. per crate.

2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate.

For 24 sections, 4¼x1½ plain:

2 crates of 10 each, 9½-inch, 4-row, at \$1.75 per crate.

3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.

For 12 sections 4x5x1½:

26 crates of 50 each 3-row cases, at \$4.00 per crate.

ADDITIONAL SHIPPING-CASES AT BRANCH OFFICES.

At Washington, D. C.

- 3 cases, 10 each, 12-lb. cases for 4¼x1½ sections, at 85 cts. each.

- 4 crates, 50 each, 24-lb. cases for 4¼x1½ sections at \$8.00 per crate.
- 4 crates, 10 each, same, at \$1.70 per crate.
- 4 crates, 50 each, 16-lb. cases for 4¼x1½ sections at \$4.50 per crate.
- 7 crates, 50 each, 12-lb. cases for 3¾x5x1½ sections, at \$4.00 per crate.
- 5 crates, 10 each, same, at 85 cts. per crate.

We also offer the following glass jars, to close out at special prices, subject to previous sale.

At Mechanic Falls, Me.

- 5 gross ½-lb. square jars, with corks, at \$4.00 per gross.
- 29 cases of 2 dozen each, Simplex or Federal 1-lb. jars at \$1.10 per case.

At Philadelphia Branch.

- 1 gross ¼-lb. square jars with cork, at \$3.25.
- 10 cases ¼-lb. square jars with cork, 75 cts. case of 2 dozen.
- 1 gross ½-lb. square jars with cork, at \$4.00.
- 8 cases ½-lb. square jars with cork, 90 cts. case of 2 dozen.
- 4 gross 1-lb. square jars with cork, \$5.00.
- 3 cases 1-lb. square jars with cork, \$1.10 case of 2 dozen.
- 5 gross 2-lb. square jars with cork, at \$7.50.
- 37 cases 1-lb. Simplex jars, 2 dozen per case, at \$1.30.

At New York Branch.

- 4 bbls. of 7-oz. tumblers, 24 doz. to barrel, at \$5.00 per barrel.
- 11 gross of 2-lb. square jars with cork, 6 dozen to case at \$7.50 per gross, \$4.00 per case.
- 13 cases of 2 dozen each ½-lb. square jars with cork, at 90 cts. per case.

At Washington, D. C.

- 3 bbl. 12 dozen 1-lb. Simplex jars at \$5.25 per bbl.
- 1 bbl. 12 dozen 1-lb. No. 25 jars at \$5.00 per bbl.
- 2 crates 12 dozen 1-lb. Simplex jars at \$5.00 per crate.
- 1 case 2 dozen 1-lb. Simplex jars at \$1.10 per case.

These are fine for exhibition purposes.

- 4 dozen ½-lb. Hershiser jars with nickel tops at 50 cts. a dozen.
- 11 doz. 1-lb. square Hershiser jars with nickel tops at 65 cts. a dozen.

THE A. I. ROOT COMPANY, Medina, Ohio

SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

Shipping-cases in Flat, without Glass.

No. 1 . . . holding 24 sections, 4 1/4 x 1 7/8, showing 4	10,	\$2.00;	100,	\$18.00

 where the good beehives come from.

GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.
Honey in badly stained or mildewed sections.
Honey showing signs of granulation.
Leaking, injured, or patched-up sections.
Sections containing honey-dew.
Sections with more than 50 uncapped cells, or a less number of empty cells.
Sections weighing less than the minimum weight.
All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L. A.," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.
Honey contaminated by excessive use of smoke.
Honey contaminated by honey-dew.
Honey not properly strained.

YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

WARDELL'S ITALIANS

Descendents from the Famous Root \$200 Queen

I was head queen-breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

Untested	September and October,	\$1.00	Tested	September and October,	\$2.00
Select Untested	" " "	1.25	Select Tested	" " "	3.00

Our supply of untested and select untested is likely to be small after October.

Prompt delivery assured. Address all orders to **F. J. Wardell, Uhrichsville, Ohio**

Queens--Queens--Queens. We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

Can furnish bees on Danzenbaker and L. or Hoffman frames.

Above price on bees by pound, nuclei, and colonies does not include queen. You are to select such queen as you wish with the bees, and add the price.

Queens from now on are mailed promptly by return mail.

Free circular and testimonials.

H. G. Quirin-the-Queen-breeder
Bellevue, Ohio

ITALIAN QUEENS

Untested remainder of the season 75 cts. each; \$4.25 for six; \$8.00 for 12. Tested, \$1.00 each in any quantity. Satisfaction in all cases or money refunded. Been breeding queens for sale for 25 years, and we know how.

L. H. Robey, Worthington, W. Va.

Golden and Three-band Italian Queens . . . 45c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more, for big money? Virgins, 25 cts.; untested, one, 45 cts.; 12, \$5.00; 100, \$40.00; tested queens, 75 cts. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. The Italian strain of bees have proven themselves able to resist foul brood to a greater degree than any other strain, and they are, therefore, the strain to buy if you have foul brood in your locality.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

To inquiries:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.
G. C. Miller.

Marengo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested 60 cts.; 12 for \$6.00. Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00. Will replace inferior queens.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

The Stover Apiaries
Mayhew, Miss.

Italian Queens---Northern Bred

make extra hardy queens for Canada and Northern States. I reduce price on untested August and September, 75 cts. each; \$8.00 per dozen. Select tested, \$1.50. Write for prices on larger numbers and get my price list in full. Plans "How to Introduce Queens," and "Increase," 25 cts.

\$1.00 per year. When paid in advance: 2 years, \$1.50; 3 years, \$2.00; 5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60c per year postage.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. Notice is given just before expiration. Subscribers are urged, if unable to make payment at once after expiration, to notify us when they can do so. Any one wishing his subscription *discontinued* should so advise us upon receipt of the expiration notice; otherwise it will be assumed that he wishes GLEANINGS continued and will pay for it soon.

HOW TO REMIT. Remittances should be made by draft on New York, express-order or money-order, payable to the order of The A. I. Root Co., Medina, Ohio. Currency should be sent by registered letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

FOREIGN SUBSCRIPTION AGENTS.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents at the prices shown:

PARIS, FRANCE.—E. Bondonneau, La Korrigane, Avenue de la Gare. A Juan-les-pins. France. *Per year, postpaid, 8 francs.*

GOODNA, QUEENSLAND.—H. L. Jones. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/7 p.*

DUNEDIN, NEW ZEALAND.—Alliance Box Co., 24 Castle St. *Per year, postpaid, 6/7 p.*

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

CLEVELAND.—Only very little new comb honey in market yet. Demand also continues light. There is still a little old honey in market at \$2.00 to \$3.25 per case as to quality and condition. Comb honey, new, fancy, brings \$3.85 to \$4.00.

C. CHANDLER'S SONS.

Cleveland, Sept. 6.

ALBANY.—On account of the threatened railroad strike and also the fact that few producers have any great amount of honey ready to ship, there is but little stock on our market, and it is just as well with present warm weather and limited demand. A large stock would tend to weaken prices. Comb honey, per case of 20 combs, \$2.50 to \$3.00, according to weight. No. 1 buckwheat of 20 combs, \$2.50 to in cans, 7 to 8; amber in cans, 7.

CHARLES MACCULLOUGH.

Albany, N. Y., Sept. 9.

ST. LOUIS.—Our honey market is quiet. Receipts of extracted honey have been quite large within the last two weeks. Our quotations are unchanged, but no firm price has yet been established on new crop of comb honey. We quote extra fancy, per case, \$3.50 to \$3.75; fancy, \$3.25; No. 1, \$3.00; No. 2, \$2.50 to \$2.75. Extracted white brings 9 cts.; light amber in cans, 8 cts.; amber, in cans, 6½; barrels, 6 cts. Clean average yellow beeswax brings 28½ cts.

R. HARTMANN PRODUCE CO.

St. Louis, Sept. 7.

KANSAS CITY.—There is quite a little honey on our market. The demand in the small towns is somewhat slow, on account of the heavy crop of native honey produced early in the season. The city is well supplied, selling at the following prices: Fancy, \$3.25; No. 1, \$3.25; No. 2, \$2.75 to \$2.90. Strictly fancy white extracted, 8½; light amber, in cans, 7½; amber, in cans, 7c. Clean, average yellow beeswax brings 25c.

C. C. CLEMONS PRODUCE CO.

Kansas City, Sept. 11.

CHICAGO.—The receipts of the yield of 1916 from the adjacent territory are liberal, and the quality is of the best; sales are being made at the prices named, but the supply is in excess of demand, as it is early. Prospects of sales are encouraging. This market sells by weight; extra fancy per pound, 16 cts., in closed cartons; fancy, 15 cts., with or without cartons; No. 1, 13 to 14 cts., with or without cartons; No. 2, 8 to 12 cts., with or without cartons. Extracted white, per lb., 7 to 9 cts.; light amber, in cans, 7 to 8 cts.; amber, in cans, 5 to 7 cts. Clean, average yellow beeswax brings 30 to 32 cts.

R. A. BURNETT & Co.

Chicago, Sept. 2.

MATANZAS.—The price of honey in this market, at the present time, is 45 cts. per gallon, including barrel. Beeswax per lb. 29 cts.

ADOLFO MARZOL

Matanzas, Cuba, Sept. 6.

FRAUDULENT ADVERTISING.

It rejoices my heart to find the following, which I clip from *Farm Life*:

ADVERTISE HONESTLY SAVS THE ASSOCIATION OF NATIONAL ADVERTISERS.

The following Declaration of Principles was unanimously adopted by this Association at Dayton, Ohio, May 5, 1916:

Resolved, That we, members of the Association of National Advertisers, are opposed to advertising of the following kinds:

All advertising that is fraudulent or questionable, whether financial, medical, or any other; all advertising that is indecent, vulgar, or suggestive, either in theme or treatment; that is "blind" or ambiguous in wording, and calculated to mislead; that makes false, unwarranted, or exaggerated claims; that makes uncalled-for reflections on competitors or competitive goods; that makes misleading free offers; all advertising to laymen of products containing habit-forming or dangerous drugs; all advertising that makes remedial, relief, or curative claims, either directly or by inference, that are not justified by the facts or common experience; and any other advertising that may cause money loss to the reader or injury in health or morals or loss of confidence in reputable advertising and honorable business.

Resolved, That we recognize our own obligation as advertisers to conform to these principles.

Resolved, That we urge upon all publishers and upon all sellers of advertising space or service, a strict adherence to these principles, and that, in so far as the exigencies of our individual business will permit, we direct our advertising to those mediums which make the observance of these principles their rule and practice.

The Association of National Advertisers represents the leading advertisers of America. They stand as one man behind these resolutions. They are determined to do everything in their power to make it impossible for the advertising fraud to live.

Convention Notice

The annual meeting of the Northern Illinois and Southern Wisconsin beekeepers' association will be held in the supervisor's room in the courthouse in Rockford, Ill., on Tuesday, Oct. 17, 1916. All interested in bees are cordially invited to attend.

R. KENNEDY, Sec.

Rockford, Ill., Sept. 1.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted----

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

WHY IS THIS TRUE? BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who "has been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis Sections in a season, and has not found one section in the whole lot that was not perfect. Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.

G. B. Lewis Company, Watertown, Wisconsin

Catalog on request giving nearest distributor.

DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me.

A. W. DARBY, Alburt, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

EDITORIAL

Honey versus Sugar Syrup for Winter Food

WHILE good ripened honey is probably superior for a winter food, is not our good friend Dr. Miller attaching too much importance to iron which is found in very minute quantities? If honey is superior to syrup it is probably due to inversion and to the protein contents—namely, pollen.

The Rosy Side of Beekeeping

Do not fail to read the article by Mr. Alard in this issue, and then remember that there is another side. This year, 1916, in the eastern states, has been one of the good years; but it is fair to say to the beginner that he cannot do as well every year as he did in 1916, but what one has done some years others can do under the same conditions.

Consumption of Winter Stores in Indoor and Outdoor Wintering

In this issue, page 853, Mr. Shiber refers to a current belief that bees consume less honey in a good cellar than bees well housed outdoors. This is something more than a belief—it is a real fact. The question undetermined is whether the larger consumption of stores outdoors does not yield stronger colonies in the spring. If our subscribers have any evidence to offer we shall be pleased to get it.

Old Dobbin Giving Way to Gasoline

J. E. CRANE & SON are now using an automobile truck for their out-apiary work, and have turned their horse out to grass. No horse or team can compete with gasoline for outyard work. We have proved it to our own satisfaction. A team is too slow, and, besides, incurs the liability of stings

and a general spill. Since the recent reduction in the price of the Ford automobile, one can now have a half-ton truck for about \$350. A good team and wagon costs as much with only a fraction of the capacity for miles.

Rabbit Spacers versus Spacers on the Frames

MR. LOUIS H. SCHOLL, in this issue, page 844, has come to the same conclusion that we and all others have who have tried frame-spacing rabbits; namely, that they fall far short of real self-spacing frames like the Hoffman. We do not know of a case in this country where self-spacing rabbits have passed much beyond the experimental stage. Beginners with them are enthusiastic at first, but they soon discard them.

The Ohio Field Meeting at Medina.

ON Friday and Saturday, August 25 and 26, beekeepers of Ohio came trooping into Medina by auto, trolley car, and train until over a hundred and fifty had registered. Dr. Phillips and Mr. Dadant were unable to be present but several of the Ohio inspectors were here, as well as Mr. House and Mr. Clark from New York State, and there was no lack of good live speakers.

In our next issue we shall have some pictures as well as some notes of what was said and done.

Variation in Colonies of Bees; the Washboard Act

MR. DOOLITTLE in his regular department in this issue has an interesting article on this subject. It will pay to read it. Among other variations he speaks of one colony that he had that spent its time in scraping the entrance-board, washboard fashion.

We have seen this same performance dozens of times among our own bees after the main honey-flow was over. We have been asked time and time again what it meant or what the bees were doing, but have never been able to explain it. Does any one know?

Honey-crop Conditions and Prices

THERE is nothing new to report since our last issue, page 774. As soon as the crop begins to pour into the market we shall be able to get more definite information. Apparently many beekeepers are making the mistake of waiting too long. A little later, when every one begins to unload, there is danger that prices will sag. The market is probably as good now as it will be later in the season.

Old comb honey of last year is pretty well cleaned up; but some of it after it granulated sold at a sacrifice.

Our Cover Picture

THERE are many different schemes for locating a hive in an apiary to avoid long straight rows and yet to have a system making it easy to locate any hive in the yard by its position in any certain group. The apiary seen on our cover for this number shows a very unique plan used by R. A. Marrison, of Cataraqui, Ont., Can. Mr. Marrison, as the picture indicates, locates his hives in groups of twenty-seven. There are three rows forming the sides of a triangle, nine colonies in each row, all facing the center.

The yard is surrounded by two rows of trees, including apple, plum, cherry, pear, mulberry, black-walnut, and butternut. The picture was taken from the roof of the dwellinghouse, and shows only a part of the yard. In all, there were 204 colonies at the time the picture was taken.

Packing Hives in Newspapers for Winter

MR. BOND, in this issue, page 854, has had success in wintering bees in newspaper-wrapped hives with a winter case over all. Where one has hives screened by buildings and fence as shown in the picture of his apiary, the plan will give excellent results, but it will hardly be adequate where the hives are out in the open exposed to a strong wind-sweep.

We have come to believe that windbreaks for outside wintering are very important factors. If we had to choose between windbreaks and packing we would accept the

former; but both are very important. Mr. Bond's little apiary is surrounded on one side by a picket fence. Such a fence, more or less surrounded by buildings, affords an excellent windbreak.

Sugar-fed Comb Honey Not a Commercial Possibility

MR. WILLIAM COX, in last issue, page 805, goes on to show how sugar-fed comb honey is not possible, even if the business were legitimate. Years ago many attempts were made to produce the product. But in almost every case sugar feeding to fill out sections was given up. The nectar from the fields costs nothing; but when one has to pay for the sugar, and add its cost to that of the labor, and the cost of materials and equipment, he will find that he cannot compete with the other fellow who uses only the nectar of flowers that costs nothing.

While there is an art in feeding back or in feeding sugar syrup, the amount of loss under most conditions between the amount actually fed and the amount actually stored is considerable.

Proper Temperature to Heat Honey for Bottling

MR. SHIBER, in this issue, page 853, brings up this question. A temperature of 160 degrees F. will keep honey liquid—that is, from granulation, for a longer period than honey heated to 130 and then sealed. But the latter honey will have a little better flavor to the connoisseur and to the beekeeper who knows the quality of honey just as it comes from the combs. But the average consumer—yes, the great mass of them—will detect no difference between the honey heated to 160 and the other to 130. But if a bottle of honey shows granulation, even the slightest trace of it (and it will show up at 130), that same average consumer becomes suspicious and does not buy.

If the bottler could be sure his goods will be sold in six or even nine months, in a warm room the 130 temperature would be better than 160; but the average jobber and dealer puts his honey in cold storage. Such honey will granulate in less than a year. For this reason the bottler raises his honey to 160 before bottling.

Honey in the Trenches of Europe

WE have now information from a source which we are not now at liberty to reveal, that honey is being used in the European trenches along with sugar. Both of these

articles are energy-producers, and in many cases honey is cheaper than sugar. We have ascertained that the United States during the last fiscal year imported twice as much honey as it has done during any previous year.

When the war broke out in 1914 the prices on medium grades of honey began to sag until there was no demand. In the meantime sugar began to climb. The war lords of Europe, when it came to the matter of rations, soon discovered that honey, an energy-producer, was much cheaper than sugar (also an energy-producer), and consequently honey has been going into the trenches, and is going there still. Apparently only the medium grades are being used, because they furnish as much energy per pound as the finer and better-flavored table honeys that cost as much or more than sugar.

Swarming Dependent on the Strength of the Honey-flow

MR. J. A. HEBERLE, in this issue, page 869, says: "It is generally known that good honey years are poor swarm years," and *vice versa*. "The same colony which showed no swarming impulse in 1911 may in 1912 swarm excessively." The relation of swarming to the honey-flow may not be as generally recognized in this country as it is in Germany; but we believe that our correspondent is right when he says that good honey years are poor swarm years; or, rather, we would modify it this way: When the honey-flow is light and continuous, swarming is apt to be furious. When the flow is heavy—so heavy, indeed, that the queen is "honey-bound," swarming almost entirely ceases. This matter has been proven again and again, principally in the southern states. In Texas, as a general thing, swarming begins during the early part of the season when the flow is light and intermittent. As soon as the flow becomes heavy, swarming almost entirely ceases.

Years ago, in talking with the late W. Z. Hutchinson on this point we compared notes; and we finally concluded that the same characteristics that show up so strongly in Texas also show up in the northern states *when conditions are the same*. Swarming, therefore, is not a matter of locality but of conditions.

Making Honey Sales for Cash Directly at the Beward

MR. POWERS, in this issue, page 849, has struck upon a novel scheme of putting a

honey-sign directly over an automobile highway where hundreds of cars are passing daily. The scheme is as unique as it is effective. Automobile drivers have frequently noticed melons, peaches, and apples in baskets on sale along the side of the road. We know of a number of cases where fruit-growers have sold their entire crops to passing cars. All that is necessary is to display the fruit.

Our basswood yard is located on an automobile highway from Columbus to Cleveland. One of our young men, Mr. Arlie Pritchard, whose apiary is in sight of the road, has a honey-sign on display and honey ready to hand out. He has sold hundreds of pounds of honey to automobilists, who are willing to pay a good fair price, because they say this is real honey, and because they can see the bees and the hives.

In this year of a large honey crop beekeepers should utilize this means of selling honey right at home; and do not forget the value of the advertising effect. One driver will tell another; and the result will be that a regular trade will be established. The good housewife and the children can do all the work, and, besides, will have ready cash in the house, and plenty of it.

C. H. Boccock, the Isle of Wight Expert and His Tentative Conclusions

IN our issue for July 15, page 583, and again in Aug. 15, page 711, we referred to Mr. C. H. Boccock, of Newmarket, England, a representative from the Board of Agriculture of Great Britain, who was here to study bee paralysis and other diseases of adult bees in the United States. In this issue, page 851, we are glad to introduce him more formally to our readers. He is evidently a thoroughgoing beekeeper as well as one who is familiar with the Isle of Wight disease as found in Great Britain. If we understand it, he came to this country at his own expense in order that he might determine whether there is a direct relation between the adult bee diseases in Great Britain and the same disease or diseases that have been showing themselves in various parts of the United States for the last three or four years. In the engraving Mr. Boccock is seen leaning over one of the hives; and if one could see him and shake hands with him, he would find him to be a quiet unassuming gentleman, a good beekeeper, a scientist, and one familiar with the diseases of bees. He left a pleasant impression on our American beekeepers, and goes back to his own country with our best wishes.

He was fairly sure of one thing; and that is, that the Isle of Wight disease is probably not the same as the bee paralysis of the United States. He also found here specimens of infected bees that may or may not be affected with the disease from the mother country.

Mr. Bocock, careful investigator that he is, did not assume to draw any positive conclusions, but very modestly gave his tentative opinions about as follows:

1. The Isle of Wight disease and bee paralysis are probably not one and the same thing.

2. The disappearing disease found in this country may be the Isle of Wight disease.

3. It is doubtful whether the Isle of Wight disease would make any serious headway in the United States with our climatic conditions and American Italians.

4. He found *Apis nosema* in some bees in this country that appeared to be normal and also in some that were not normal.

5. *Apis nosema* may be the cause of Isle of Wight disease, but probably it works with some other organism before any serious symptoms show up.

6. A vigorous strain of Italians in Great Britain seems to be more immune than the native black bees.

7. American Italians may be partially immune to the English disease.

Introducing Queens Daubed with Honey

WHILE our correspondent Prof. Baldwin, in his department in this issue, page 845, does not claim originality for the method of introducing queens daubed in honey, we are of the opinion that he has brought out a modification that is original and important. His plan differs from the old one in that he uses a whole cupful of honey instead of just a mere daub. The queen is dipped in a cup of honey, when both are poured over the frames. The general spill and apparent ruin of the combs so diverts the attention of the bees that the queen is forgotten. After they have licked up the combs and the queen which, in the process, is made to acquire the odor of the colony, the new mother is accepted as a matter of course. In fact, she is only an incident. Merely daubing the queen with honey focuses the attention of the bees on the queen. Baldwin diverts them away from her. See the difference?

A year ago last spring we fed up a whole apiary by smearing Porto Rican honey over the combs of about fifty colonies. There

was probably a cupful or even two cupfuls poured on the frames. The result was magical. Every bee was engaged in the operation of putting things to rights. We found we could go back to those colonies and lift the cover without smoke, and give them another dose, because they were busy in cleaning up. Busy people do not ordinarily get into mischief. It is the idle, waiting for something to turn up, that make trouble, and so with bees.

If Prof. Baldwin has introduced an improvement it would be perfectly legitimate to call the method Baldwin's. While A. C. Miller did not introduce the method of introducing queens with smoke he did introduce a very valuable improvement, and hence the plan is called today the Miller smoke method.

Sweetened Spraying Solution

THERE has been conflicting testimony regarding the effects of spraying on bees. Where a spraying solution is sweetened with molasses, either to make it stay on the foliage better or to make it more inviting to the insects that it is supposed to kill, it seems to us that the danger to the bees would be very much greater. On the first page of *The Pennsylvania Farmer* for May 20 a recipe for rose-chafers is given as follows: 10 pounds of arsenate-of-lead paste, 8 quarts of molasses, and 50 gallons of water. The explanation is given that the insect is fond of sweets, and in eating the molasses gets the arsenate of lead.

If this solution were used in a wholesale manner we see no reason why bees in large numbers should not be poisoned. Since this insect does considerable damage on roses, grapes, and cherries, we suppose there is a possibility that such a solution or a similar one might be used a good deal.

If a sweetened solution is the only one that such insects will eat it would hardly do for the beekeeper to deery such practice, perhaps, and yet in a way this is a serious situation: for this liquid, whether it were sprayed on the blossoms or on the leaves, would be attractive to the bees at certain times of the year when they could get no nectar from the flowers. Two or three rains would wash it off, but considerable damage might be done meanwhile. In the clipping above referred to the statement is made that these insects are the most common on light sandy soil, but they are scattered pretty well, nevertheless. What is the beekeeper to do in a locality where a sweetened spraying solution is used on a large scale?

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

P. C. CHADWICK, please quit talking about a laying worker heading a colony, p. 653. Dozens of 'em, if there's one.

REMEMBER, Mr. Editor, how the bees were working like crazy when you and Dr. Phillips were here last year? At it again, exactly the same way, now.

H. H. KOLLOSTER, you say, p. 737, "I can use factory-made hives if I can afford to buy foundation." I can't afford *not* to buy foundation. I wonder really if you can.

R. F. HOLTERMANN doesn't want to "leave me a leg to stand on." He says, p. 682, if he were at the clipping business with me he'd never stop at clipping off one leg, but would take off both. What a vindictive cuss he is! Well, anyway, I'm glad to get off without having my head taken off too.

CHARLES E. DUSTMAN says, p. 723, that sealed worker combs are one inch thick, and drone 1 1/4. When I read that, I said to myself, "With the usual spacing, 1 3/8 inches, two combs of drone brood would have only 1/8 inch between them, allowing no bee to pass." Then I went to the apiary and cut out sealed brood of both kinds. Sure enough, the Dustman measurements were all right. To be sure, it was old comb, and new would measure less. But bees often have old comb. Now, how do they manage with that 1/8-inch space?

J. L. BYER, you say, p. 651, you don't see how you could object to a man, owning property near you, keeping bees, but you do object to a specialist with a large apiary, and you seem to wish there might be a law against the last fellow. Now, if it's all right for your neighbor to have half a dozen colonies on his own property, why isn't it right for him to increase gradually to 100 and become a specialist? I have neighbors with half a dozen to 25 or more colonies, and there's no hard feelings between us, but I'd prefer to have it so that no one could have bees in a certain territory, of course paying for my privilege, just as, by paying for it, I can say that no neighbor can keep his cattle on a certain piece of ground, not even if that neighbor has only one cow.

A. I. ROOR says, p. 750: "Years ago I decided that a pound of honey in the comb, well ripened and sealed up, was worth a good deal more than a pound of sugar in preparing bees for winter—perhaps twice

as much. I should like to know what Dr. Miller thinks about the comparative cost of this manner of feeding."

With a fine article of extracted honey at 6 cents a pound (see p. 711), and sugar at present prices, one would hardly make a lot of money to feed sugar in place of honey. But when sugar is 5 cents a pound, and honey 10, and one feeds 20 pounds for winter, isn't there a clear gain of a dollar a colony by feeding sugar? But wait. When winter is over, those bees that have fed on honey, with its iron and other matters that are entirely lacking in sugar, will have a vigor at building up and storing, as compared with the sugar-fed bees, that may easily recoup several times over the extra dollar for the winter food. Yes, friend Root, you are quite conservative when you value such honey as you describe at double the worth of sugar for winter.

JOHN H. LOVELL asks some questions, p. 710, "Did Dr. Miller examine the pollen in the anthers of fresh flowers?" Never. "Has Dr. Miller examined the pollen in his hives under a microscope?" Never. But as to the color of white-clover pollen, I appeal from Lovell the botanist to Lovell the beekeeper. The former is a man for whom I have great respect, and whose statements I would not lightly question; the latter is a friend of mine with whom I feel on a level; and when I read that white-clover pollen was something else than brown, it never occurred to me that it was the botanist talking, but the beekeeper talking about what he saw in the comb or on the bees' legs. Honest Injun, I never thought of the powdery stuff on the flowers at all. In botanists' language, I'm ready to accept that the pollen of white clover is yellow, but in beekeepers' language it's brown; for in beekeepers' language, pollen is the stuff in the cells or on bees' legs. "Brown balls, evidently composed of white-clover pollen," says beekeeper Lovell, p. 728. One more question: "Is he certain that white-clover pollen is as abundant as he supposes?" Reasonably certain. When bees are bringing in honey from white clover by the ton, working almost exclusively on it, and that for weeks, and during that time bringing loads of brown pollen on their legs, it's reasonable to suppose that the mass of brown pollen accumulated in the combs is from white clover. Yes, friend Lovell, you're right, I've considered the matter chiefly from the hive end. That's because I'm a beekeeper, and not a botanist.

J. E. Crane

SIFTINGS

Middlebury, Vt.

From that interesting article on page 494, June 15, it looks as tho we shall have to revise our methods of bottling honey by using a lower temperature for a longer period. More and more, honey is coming to the front as a most valuable food.

"The beginner should understand there is a large amount of risk in trying to introduce a laying queen to a colony that has been queenless for a week or ten days," says the editor, page 518, July 1. Yet this is the method advised by queen-breeders fifty years ago.

The greenish yellow pollen from clover that Prof. Lovell speaks of, page 477, June 15, here appears to be a greenish brown; and, while not abundant in each flower, it proves to be very abundant in the aggregate, as I believe bees gather more of it than any other kind.

August 14 the Vermont beekeepers met in this town for a summer meeting. I believe it was the largest gathering we have ever had, owing in part to a large crop of honey in this immediate vicinity and the presence of C. P. Dadant, editor of the *American Bee Journal*.

It is decidedly interesting at this season to watch the growing fruit, and cut open imperfect ones and discover that the cause of the imperfect development of the fruit which, in almost every case, is the lack of the proper fertilization of the flowers, and, as a consequence, the lack of growth of seed and fruit.

The crop in our county will be abundant this year; but last week I was inspecting bees in the next county south and was surprised to learn that the crop there would be very light—not half that of last year. This week I met two beekeepers from the north part of the state, from two different counties, who say they have secured very little honey this year.

There is a fitness in using so much of the space of the Aug. 1st number to the marketing of honey. As Mr. C. P. Dadant remarked a day or two ago, the future of profitable beekeeping will depend on our ability to increase its consumption. I am glad to know the A. I. Root Co. are enter-

ing on a vigorous campaign of honey advertising—page 646, Aug. 1.

It seems that Massachusetts has recently passed a law prohibiting misstatements in advertising. It prohibits untruthful statements of values in excess of advertised prices; false declarations that the advertiser employs; misleading statements designed to induce the public to go into the establishment of the advertiser, and other intentionally deceptive advertising, etc. Let the good work go on.

Three or four weeks ago we began to wonder how we were to get our honey home from the outyards. We could not hire a truckman; farmers were busy with their haying; livery teams were expensive, and our own horse was getting tired out. We bought an International motor truck that has given us no end of pleasure. It solves the problem of transportation to outyards, and our horse has been turned out to pasture.

When I see an article by Allen Latham in GLEANINGS I always "sit up and take notice," and his discussion of European foul brood on page 479, June 15, is no exception. While I am not prepared to accept fully his theory as to the spread of the disease (he may be right) I am quite sure the disease spreads from nurse bees entering a neighboring hive. There may be more than one way in which it spreads. With me I have found a hive standing near another having the disease much more subject to it than those further away.

Mr. Latham assumes that the reason Italian bees are more immune to European foul brood is because they remove the diseased larvæ bodily. If this theory holds true, then we may believe that in removing the dead larvæ by first sucking the soft parts the blacks get germs into their stomachs, and so transmit the disease to other larvæ. Now, I have found Italian bees much more resistant to American foul brood than black bees. When I go thru a yard of bees for the first time where American foul brood has recently broken out, and find every colony of black bees in bad shape from the disease, and the Italian bees but slightly affected, and perhaps some of them showing no indication of disease, I have great respect for their ability to resist this form of disease, as well as European foul brood. Let us be thankful for the lemonade treatment.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Allen Latham's queen-rearing plan as given on page 592, July 15, is good, for I use it and know that it is excellent. If the cells are placed in the colony and allowed to be polished for a few hours before giving them the larvæ a goodly number may be accepted without the use of royal jelly if the grafting of the larvæ is done rapidly and the combs returned to the hive at the earliest possible moment.

On page 645, Aug. 1, the editor says: "Even as it was, we instructed the boys to burn all such combs." Now I scold and scold about burning things valuable about the apiary that can be otherwise cleansed, with the feeling that I surely will impress the idea, and then you come along and recommend the burning of combs! The word "burn" should have no part in the cleansing of bee supplies, and to my mind should be discouraged entirely.

SOME OF THE DIFFICULTIES IN CO-OPERATIVE SELLING.

The subject of co-operation in selling honey, in the Aug. 1st issue, was well handled; but there were too few details in many instances to give the desired information to the casual reader.

State Market Commissioner Harris Weinstock has under consideration the problem of organizing the beekeepers in California in the form of a state-wide marketing organization. Mr. Weinstock sent out 2200 letters of inquiry to beekeepers of the state some time ago, and the enthusiasm with which they were received may be best told by saying that only six per cent of them were answered, or about 120. This fact alone was sufficient to discourage any but the strongest in intent and purpose; so, inasmuch as it did not discourage Mr. Weinstock we must place him at the head of the column. He has recently issued another letter, I suppose to those who were interested enough to answer (this is my presumption, as I doubt if he would continue writing to those who showed no interest), asking for their judgment as to the advisability of calling a conference to discuss the subject of a state-wide marketing organization.

In my first answer to the commissioner I did not speak very encouragingly of the possibilities of organizing the beekeepers

into a successful organization for marketing purposes. My chief reason for so writing was the experience in that line that has now passed into history of organizations. But the efforts of Mr. Weinstock are so commendable that I feel he should be given all the support possible, for it may be that just ahead he may be able to show us a successful organizing plan.

That there is need of an organization is evident, and yet there are many reasons why it will be difficult. The article by J. Edgar Ross, page 655, Aug. 1, goes right into the heart of some of these reasons. He goes into history and points out the very thing that causes the downfall of the majority of beekeeping organizations. Then there are other reasons that make for failure. One of those is, say what we may, the buyers as a rule are following very closely the trend of the market, and are offering prices that many times allow them only a fair profit for dealing in this commodity; yet at times we know that, when the market is on the downward trend, the buyer gets crafty and the producer gets panicky, and the tendency is in favor of the buyer. At these periods an organization would be of far more value than at any other time, if the object of holding the producer from "dumping" could be worked out. But, as Mr. Ross says, "Co-operation requires the yielding of individual co-operators, and without the press of necessity it can never be a success." There is the situation in a nutshell. Last season when we were begging buyers to take our white honey at five to five and a half cents, it would have been much easier to form an organization than at the present time when honey has moved at a good figure and readily. Last season the buyers were accused of having a gentleman's agreement which may or may not have been true, while this year almost every one secured more for his honey than he thought possible early in the season, and the beemen do not care whether the buyers are working together or not. This goes to show that the producer has no real concern about organization when he is prosperous; but when he is not prosperous he is down in the "dumps" and is all concern. But for all the argument pro and con we are indebted to our State Market Commissioner for the interest he is taking in trying to persuade us to co-operate for our own good, and he should receive our most hearty support.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

Co-operation and organization should be the slogan of the beekeeper. Never before in my own beekeeping experience have I seen a greater need for it than now.

Texas has had an excellent honey crop for 1916. There were some important beekeeping sections that did not fare as well as others. The north central and the northern parts of the state did not harvest the cotton honey until the fore part of August.

Texas honey prices have been anything but satisfactory this season. With an increased cost of production and low prices commercial beekeeping cannot last long; and not only the beekeeper, but all who are dependent upon him, must eventually suffer. Any effort in the direction of obtaining better prices for our product should be welcomed by not only the beekeepers themselves but by the supply dealers, foundation-makers, bee-journal publishers, manufacturers, merchants, and all others who appreciate the beekeeper's dealings.

It is a fact that Texas honey has been selling at a considerably lower price this year when compared with the advanced cost of all other products and commodities on the market. It is also passing strange that such a condition should exist when the demand for honey was hardly ever better, and when the honey prices in competitive markets of other states were from 1½ to 2 cts. per pound higher. The lack of organized effort on the part of the beekeeper is to blame. There does not seem to have been an overproduction in the state; and on account of the higher prices in other states there has been no danger of competition. There should have been a better system of marketing.

NIX ON THE RABBIT-SPACERS.

Just recently I had an occasion to assist an extensive beekeeper in apiary work and in the honey-house with hives and supers equipped with metal frame-spacing rabbits. Plain frames are used, and these hang in the notched rabbits; altho I had never had any actual experience with them before, the idea that they are not very practical has always possessed me. Here this proved true, for, being used to the self-spacing Hoffman frames that can be "thrown" into

hive or super and become properly spaced, or that can be handled in pairs or trios, or even fours, it was quite difficult for me to become used to handling each frame individually. Neither could I spread frames apart for the easy removal of a comb or shove them from one side of the hives or supers to the other. There was not that stability of the frames in the filled hives and supers so essential for hauling them, especially when filled with tender comb honey, of which we produce so much. Besides the greater expense in addition to the above apparent drawbacks, this kind of equipment did not appeal to me as well as the simpler and (in my hands) more easily manipulated self-spacing frames.

FRENZIED SELLING.

Honey prices have been driven still lower by competitive dealers as well as by producers who were anxious to sell honey quickly. If the selling could be regulated so that the honey crops might find their way to market gradually, and thus prevent the apparently flooded markets, better prices would obtain. The main trouble is brought about by those who are over-anxious to sell and by those who are after handling a great volume of the honey business so as to enable them to make their per cent of profit irrespective of what the producer will get. A lower price of one to two cents per pound amounts to a difference of something like \$50,000 to the beekeepers of Texas. Is this worth taking care of? It is time efforts were being made for a thoro organization.

CLEAN VS. DISORDERLY YARDS.

The condition an apiary is kept in makes a material difference in the manner the bees in such yard will be cared for. My experience has been that the bees in the yards located in the more attractive places, or even those kept in clean and orderly condition, if not so ideally located, have given us the better returns. In the more neglected apiaries the bees were continually more or less neglected also, while much more careful attention was given them in the case of the former. It affords one not only greater pleasure to work in an apiary in a more favorable location, with everything in the apiary in "apple-pie order;" but the work is done with greater enthusiasm and interest in what needs to be done for the better welfare of the bees and best results for their owner. It affects the owner as well as the employees in the same manner.

E. G. Baldwin

FLORIDA SUNSHINE

Deland, Fla.

FLORIDA A LAND OF SURPRISES.

No two years are alike in Florida, except that they have 365 days. I refer to honey-flows. Mention has already been made in these columns to the very late orange-flow. Even into mid-June honey was stored in supers from the orange-blossoms. Orange usually ends in early April. Our man at Glenwood yard has just extracted (Aug. 6) a fair crop of late orange and palmetto honey, "blended by the bees." It is fairly light in color, good flavor and body, tho not as clear as pure orange.

By the way, it always seems to me about *any* blend of two clear honeys is never quite as light-colored as either one in its purity, and I should be glad to know of others' experiences in this line.

Now comes our second surprise. Cabbage palmetto is usually done blooming by July 20. This year it yielded even up to August 10 or 15, slowly but steadily, honey of an excellent quality. Such a late yield from this source is quite phenomenal. Never before have I known of so late a flow from this, the tree-palmetto. The blossoms are on huge racemes six feet in length, at times of a delicate cream tint, as fragrant as they are beautiful.

The cabbage palmetto referred to seldom yields oftener than once in three years, tho it blooms regularly and profusely. Excess of heat or rain is alike fatal to nectar secretion.

The late yield from this source is very gratifying to beemen within range of the trees, for the honey-outlook at the opening of the year was very unpromising. At the beginning of the season Dame Nature said, "Nothing for you this time," and then flung wide her hands and showered out an unexpected gift.

SWARMING IN AUGUST.

In our home yard there are signs of swarming in August. It is the late and lingering flow from cabbage palmetto that is producing the condition. Swarming in August is almost a thing unknown in Florida, generally speaking. This year there was practically no swarming from the orange-honey flow. These two facts may give a clue to the causes and effects in the matter of swarming. Here is the summary. Bees do most of their swarming on the first main flow; after that swarms are but desultory and scattering, even if late flows do appear. The swarming instinct (whatever that may be) seems satisfied. This year no swarming from orange at the usual season (March);

then late orange and a lingering flow from palmetto with resulting tendency to swarming. But the later flows never seem to produce so wild and intense a desire to swarm as does the first early and profuse honey-flow of the year.

ANTIGONON LEPTOPUS.

The common names are pink-vine, Mexican vine, and Spanish vine. It is a vigorous, tho non-hardy, vine, with broad pendant leaves and showy clusters of delicate pink blossoms. It is cultivated, not wild, and grows so easily, and is so widely cultivated, that bees in many localities are helped materially in brood-rearing by it. From early summer to late fall it blossoms, is always covered with flowers, and the flowers are always alive with bees. Probably no surplus is obtained from it, tho one of our correspondents from Nampa reports that his bees do seem to get even a surplus from it. However, this latter fact is not yet proven. Let all beemen note it well, and encourage the planting. Once started, it requires no further attention, and is withal a beautiful and attractive ornament to any arbor, trellis, or veranda.

POUR HONEY IN WITH THE QUEEN.

Dr. Miller has asked me to describe in detail the method of queen-introduction by the daubing or smearing plan. Well, Dr. Miller, as I said in my former note in GLEANINGS, neither is the idea new in the bee-world, nor is this plan original with myself. I can add very little to what I stated before. The plan, in essence, consists in dipping the queen to be introduced into half a teacupful of honey and pouring her, honey and all, down over and between the frames of the colony to which she is being introduced. The merit of the plan—nay, the secret of success, if secret there be—seems to lie in the completeness with which the queen is daubed with the honey, and the amount of the honey poured in with her. That is to say, she must be thoroly covered with honey.

The amount of honey poured in with her and after her seems also to aid—it may even be essential. Then close the hive-top and see that the entrance is narrowed to a point where robbers can be kept out—according to the strength of the colony.

Since my former report I have lost no occasion or opportunity to test out the plan further; but I should like to hear reports from others, and would advise experimenting at first with some queens, not too valuable *at first*.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

VARIATION IN COLONIES OF BEES.

"Is it a fact that colonies of bees differ in their individual characteristics? I supposed that they were as near-alike as two peas."

With domestic animals we find much variation. No two dogs or horses are exactly alike. There is a difference in size, disposition, temperament, etc., and why should there not be with colonies of bees? Any one who has had even a little experience with bees will readily admit that some colonies are more vicious than others. Some colonies will allow you to stand directly in line of their flight for an hour at a time, patiently going around you to get to and from their hive, while with others two minutes will be sufficient for making you stand out of the way.

The hives of some colonies can be opened with no fear from stings. Others resent all such interference. I remember one such colony. It was with the greatest difficulty that the hive could be opened, even in a good honey-flow, and this trait remained permanently until a new queen was given.

Then I had one colony that persisted in not attaching their combs to the sides of the sections, even in a very profuse yield of nectar, while other colonies with fewer bees and during a light yield of nectar, would occupy every available bit of space, even filling the corners so that there would be no passageways there.

Some colonies will gather pollen to an extent sufficient to crowd out the honey and brood, (apparently leaving the more laborious employment of gathering nectar, thus filling their brood-combs and crowding them mother-bee for room.) The work of one colony was very noticeable this year along this line.

Before the advent of comb foundation the difference in comb-building was very marked. Some colonies would build their combs as straight as a board, and all within the frames, while others would build them crooked or across the frames, even where starters were used.

The business thrift of some colonies is very marked. With a small number of bees they make the most of their conditions; and at the end of the season they will have much more to show than will colonies that were more populous in early spring. Some will work extra early in the morning; others late in the evening.

The swarming impulse is very strong in

some colonies—so much so that, unless you let them have their way, or do something to satisfy them, they will sulk and do little or nothing. Other colonies will work with a vim without any swarming, nor is any manipulation from the beekeeper for its prevention needed. Such colonies will roll up a large surplus.

Some colonies will gather much more propolis than others, daubing the inside of their hive with it until it runs down the sides. They will even leave the legitimate pursuit of nectar-gathering to daub the insides of their sections and half-finished combs with a liquid coat of bee-glue.

I had a hive this season in which numerous bees seemed to spend much of their time standing with their heads down over the front of the hive, moving up and down with their mandibles rubbing against the hive as if trying to scrape something offensive off on the upward movement. No other colony in the apiary showed any sign of doing such a thing.

A few years ago I had one colony the bees of which seemed possessed with the idea that it was necessary to tear down all the foundation placed in the sections before they would do any work in them, while at the same time the rest of the apiary would have their sections nearly full of drawn-out comb and ready for the honey-flow. When the flow comes on, then this colony would go to work building comb, only to have its supers fairly commenced when the flow of nectar ceased.

Most persons will admit that different varieties of bees are quite different; but if these same persons are close observers they will find that there is nearly as much difference between colonies of the same variety as there is between different varieties. The observing apiarist understands that all of these various traits of character are represented in the queen of the colony, and that the character of the colony depends upon the queen and the drone with which she is mated. Aside from the characteristics of her offspring, the queen has traits peculiar to herself; as her size, her willingness to remain in sight on the comb and continue her egg-laying when the comb is removed from the hive, and, more important than all others, her ability to lay eggs. Therefore the most successful apiarist will have an eye to having his hives stocked with the *best* queens that have mated with the *best* drones.

GENERAL CORRESPONDENCE

THE ROSY POSSIBILITIES OF BEEKEEPING

Wake up, Mr. Sapp, and Look Around a Bit

BY J. A. ALLARD

The *National Stockman and Farmer* for July 29, 1916, contained an article on bees written by Mr. C. H. Sapp, of Ohio. I was much surprised at some of the statements made in this article, among which was the following: "Spurred on by the stories of great (often fabulous) wealth which has been reported to come to the apiarian, many people have invested in bees and the accompanying necessary supplies and tools. While some of these have obtained a supply of the coveted sweets, it is safe to say that a majority of them would have obtained a larger supply if they had spent their money for honey," etc.

The author of this article claims to have had a life-long experience with bees. If this is the case, he either lives in a very poor location or is a poor beekeeper. Our location in central Pennsylvania is no better than thousands of others. Yet last year I had one colony which gathered more than a hundred pounds of section honey after the 15th of August.

We have people in this section who give their bees scarcely any attention, and yet harvest at least half that much in good years. It is certain that, if the little workers are given any kind of care, they will pay for their keeping and something more.

A few years ago the *Beekeepers' Review* published a series of articles by prominent beekeepers in which they described their best years, or the years in which they made the most from their bees. For the benefit of those who may not have read these articles, I am going to quote a few of the notable successes.

The first of whom I shall tell is the "Grand Old Man of Beedom," Dr. C. C. Miller, of Marengo, Ill. I quote from Dr. Miller's own story, "In the year 1908, from 129 colonies, spring count, I took 19,480 sections, or 151 sections per colony, increasing to 160 colonies."

And all the work connected with harvesting this surprising crop was done by Dr. Miller himself and his sister-in-law, Miss Emma Wilson. If the doctor sold this crop for only 12 cts. per section he received \$2300 for it.

The next I shall mention is Dr. O. M. Blanton, of Greenville, Miss., who, in 1908,

secured 22,000 pounds of honey from 215 colonies, and increased to 290 colonies. Altho the doctor was in his eighties at that time, he did all the work with the help of one negro. Such a record is enough to put some of us younger fellows to shame.

In 1910 Mr. E. F. Atwater, of Meridian, Idaho, had a crop of 71,000 pounds of honey from 900 colonies, spring count; increased to over 1150 colonies, besides selling a carload of bees during that spring. This crop was extracted honey; and if Mr. Atwater received but 6 cts. per pound for it, he received \$4260.

I quote the following from the Feb., 1911, *Review*, from an article written by Mr. Frank Coverdale, of Delmar, Iowa: "I find that my best season was 1903—350 colonies stored 32,000 pounds of comb honey, which sold at 12½ cts., bringing in \$4000."

Mr. Coverdale says that in 1908 and 1910 his crop almost equaled this.

In 1910 Mr. H. C. Ahlers, of West Bend, Wis., made \$4000 from successful migratory beekeeping, getting a crop in the South, and shipping the bees north in time to catch the late summer and fall flow.

In 1908 Mr. R. D. Bradshaw, of Payette, Idaho, produced 43,200 sections of comb honey from one yard of 500 colonies, and sold the crop for \$4679.

Mr. J. E. Crane, of Middlebury, Vt., produced 42,000 pounds (about ¾ comb honey) from 650 colonies. No doubt this crop netted Mr. Crane between \$4000 and \$5000. This was, I believe, in 1906, and I think Mr. Crane has had even larger crops since that time.

In 1909 Mr. H. G. Sibbald, of Claude, Ontario, with the help of one young man, attended to 350 colonies, harvesting a crop of over 50,000 pounds which netted him \$5000.

In an article in the *Review* for September, 1911, Mr. E. D. Townsend, of Remus, Mich., says that his best year was 1909, when, with 600 colonies, he produced 36,000 pounds of comb and extracted honey, none of which brought less than 8 cts. per pound, and increased to 700 colonies.

Mr. M. A. Gill, of Longmont, Col., in 1907, with a little less than 1000 colonies,

produced \$7640 worth of comb honey, which was sold to C. H. W. Weber & Son, of Cincinnati, Ohio, at above price, f. o. b. Longmont.

The year previous Mr. Gill harvested a crop which netted him \$6400 from 700 colonies.

In the *Review* for January, 1912, Mr. Oliver Foster, of Boulder, Col., said that 1900 was his best year, when, with 587 colonies, spring count, he produced 79,000 pounds of honey, and in addition almost \$200 worth of wax from cappings.

Mr. M. H. Mendleson, of Ventura, Cal., at one time produced 101 tons of honey from 1870 colonies, which, if sold for only 6 cts. per pound, brought more than \$12,000.

Last, but not least, I shall mention a woman beekeeper, Mrs. S. W. Frey, of Sand Lake, Mich., whose net profits, after deducting all costs of production, were \$1000 per year for 1907, 1908, and 1909.

The beekeepers mentioned cover a wide range of territory, which proves that successful beekeeping is not confined to any one location.

Those mentioned are only a very small portion of the big beekeepers of this country. They are the only ones for whom I have seen figures. It may be that they have since had much larger crops. There are dozens of others who have been equally

successful—some who have been much more successful—but these are the only ones of whom I happen to have statistics.

Brother beekeeper, is it not time that you become alive to the possibilities of beekeeping on a large scale, as a profession rather than a hobby? What others have done you can do, if you only think so. Methods and tools are constantly improving. You can be a third more efficient than the beekeeper of fifteen or twenty years ago.

If a man in his eighties can and does produce a carload of honey yearly; if a woman can make a net profit of a thousand dollars yearly, and you, Mr. Beekeeper, can hardly supply your own table, I pity you. Better get into some hobby for which you are fitted, or improve your ways.

Oh! take a lesson from the bee,

And dig in without waiting.

Time flies, your crop will take wing while

Your woes you are relating.

Osceola Mills, Pa.

[Dr. Miller, at least, has made a better record than the one given. In 1913 he averaged 266 sections of comb honey per colony. Of course, these are some of the record yields, and are not to be obtained every year. But any such sweeping statement as that by Mr. Sapp, in the *National Stockman and Farmer*, is very far from the truth.—Ed.]

EVOLUTION OF THE HONEYBEE

BY ALLEN LATHAM

That is an interesting letter on page 293, April 1, from the Reverend Mr. Goodacre. His logic is good till he reaches number 5. Queens do transmit that which they themselves do not possess. It is not a question of "can they," for they actually do. Mr. Goodacre's argument can be turned back upon itself. He says the first swarm of bees must have been created outright. Very well, let us assume such for the sake of argument. When thus created was the queen of that original swarm given the power to transmit to her offspring that which she never herself experienced? If the answer is negative, then that first colony must perforce die out, for all progeny of queen and drones must be queens and drones. If the answer is in the positive, then wherein lies the strength of Mr. Goodacre's argument? Can God not give the power to a queen-bee to transmit to worker bees strange functions not possessed by herself in more than one way? Can he not give it thru the

mazes of evolution as well as by direct creation?

It is not well to destroy without rebuilding. Allow me, Mr. Editor, to suggest the possible evolution of the honeybee. We cannot, of course, go back in time and discover the secret. We must discover it thru analogy. Fortunately we have living today bees of various sorts, also wasps and hornets. As the astronomer, unable to read the history of our own sun in the sun itself, seeks its history in a study of the heavenly bodies in view of his telescope, bodies which are suns in various degrees of development, so we can find in the habits of other bees what our honeybees may have gone thru in past ages.

There is the solitary bee which reproduces only the true males and females. There is the social wasp which is but little advanced. Then come the bumblebees. These produce during part of the warm season various types of worker bees, but in fall

the full-fledged males and females. The mated females live thru the winter and start the new colonies the next spring. They must do all the work at first; but soon they have six or eight workers to help, and then the "old lady" stays at home. As the season advances the workers grow smaller and smaller. Unlike the honeybee, the bumblebee has not reached a definite type of worker bee. Hornets and certain wasps have a life-history much like that of the bumblebee.

Let us now make a jump away back in time. One of the earliest of all recorded forms of life on the earth is that of the bee. It came down to us imbedded in amber, preserved for our edification. We know that the bee has had a tremendous lapse of time in which to develop the wonderful traits that never cease to arouse our interest. There was plenty of time to allow for the honeybee to exist thru centuries without the worker-bee. The queens were the workers—possibly living solitary at first, later becoming social. Then there sprang up a jealousy, let us suppose, among those equal females. One was sufficient for the colony; why such waste of economy? The next step then was the undeveloped female, brought into existence simply because there was no call for so many egg-layers, but there was a call for

laborers. Wonderful and difficult to explain, but it must have happened. We have them with us, and they must have come about in some way.

At first queens alone lived thru the season of dearth, as the queen bumblebee does today. Then workers acquired that power. Possibly they did not have to acquire it, since they could easily retain it, having been once in their life-history regular queens. It is not difficult to surmise how the honeybee struggled up to its present perfected system of life. It is wonderful, and almost inexplicable, but not at all difficult to picture for one who is willing to let his reason have a little freer rein.

Now for one last statement. The queen does not possess the power to transmit to her offspring that which she never possessed. She once performed all the functions of the worker. Doubtless there was a time when the queen possessed a longer tongue, a stronger sting, wax-producing organs, etc. In the long lapse of time these functions have become abortive in her, but not lost, for she gives them to her worker offspring. And the hand of God is here just as strongly as tho the whole wonderful bee-colony was brought into instant existence instead of having to "climb" from a lowly start to the dizzy heights it now holds.

A HONEY-FOR-SALE BANNER CLEAR ACROSS THE ROAD

BY S. POWERS

I am sending a picture of a sign which I put up as soon as I secure surplus, and take down as soon as sold out. Some sea-

ons this sign moves as much as 1200 sections, and often the demand is for much more than I produce.

Can't help seeing a sign like this.

This year our comb honey from our early flow was almost a failure on account of bad weather. Four to five days frequently went by when bees flew only enough to secure water; but when it was possible for them to fly they found it.

This sign, which, of course, is home-made, cost 46 cts., hangs across the main road from Philadelphia to Beach Haven, N. J., and to several popular fishing-points. We often have 600 cars pass us in one day Saturday or Sunday.

My extracting-yard

in the swamp location has done well. I have used Danzenbaker frames for brood-rearing, but am now changing by degrees to Hoffman, but am going to raise the center pin in the Danzenbaker and use them for extracting rather than destroy them.

I have a converted "Ford" for pleasure or business. An out-yard of 48 colonies is 16 miles away. My home yard contains 29 colonies. I am building up another out-yard, which at present contains 9 colonies. I run strong colonies for comb honey in 4 x 5 x 1 $\frac{3}{8}$ sections, and the weaker ones for extracted.

At the time the picture was taken I had

"And the little old Ford rambled right along."

a load consisting of 32 Danzenbaker bodies, 52 bottoms, 48 tops, some tin, some canvas, 12 supers, and some 40 pieces $\frac{1}{2}$ x 4 x 24-inch strips of lumber. "And the little old Ford rambled right along."

Wading River, N. J.

THE MYTH OF DANIEL McFADYEN WINTERING BEES UP TOWARD THE NORTH POLE IN CANADA

SUMMARY BY MORLEY PETTIT

The story comes from about 150 miles from the arctic salt water in James Bay, an extension of Hudson Bay, in a great plain where bloom abounds for about two months. The honey-flow was said to be great while it lasted, getting 200 lbs. per colony. The bees were wintered in a cave buried in snow.

About ten years previously Daniel McFadyen was crossed in love, went north into the forest with gun, knife, and dog, fell among Indians, learned their language, married the daughter of the chief, and at time of writing had five children, healthy and plump, and as nimble as otters.

The method of wintering was as follows: The first cold night they uncovered the hives so they would get perfectly cold thru, then kept them in a cool place in the shade with covers on loose so as to keep them dry. As soon as a good fall of snow came, a certain cave was packed with lots of snow, then dry bark and the hives on the bark, with bark above the hives, again covering over with dry snow. The secret of success was to keep them frozen and dry all winter, covering over with hemlock brush to keep out the sun. The bees were said to hibernate, eating nothing all winter, but coming out strong and healthy in the spring.

He and his Indian friends kept about

250 colonies of bees, and sent the honey down the waterways toward the settled districts, selling to Indians on the way down, exchanging for furs which were taken down to be sold at the trading-posts.

During these ten years he had produced about 6000 lbs. of beeswax, which he had stored in a wigwam. D. A. Jones, then editor of the *Canadian Bee Journal*, started negotiations with him to purchase the wax, which he was willing to bring down to North Bay and sell at about 10 cts. per lb. Of course, the wax never materialized; but a very ingenious story was sent to account for its non-appearance. The story was as follows:

They had agreed to supply another tribe with bees to start an apiary. Chief Ottomee and thirty of his strong men came for the bees, with ponies. They selected sixty good half-story hives and fixed them up secure with ventilation holes covered with grass. They paid for these in furs and deer-skins. Ottomee and his men started home quite contented with their bees, satisfied with the bargain. They had about seventy-five miles to go, and it would take them about four days to get home. The third day about noon the bees had gnawed the grass covering or netting over the holes and began to come out. They attacked the ponies, and there

was a stampede. The ponies ran wild, and the Indians had to run into a swamp. Some of them got home ahead of the men, which made the Indians at home think that there had been war, and fifty started out with ponies, armed, to avenge their people. They met the others next day in a sore condition, both in body and mind. They thought the white man called Dan was linked with the spirits of rattlesnakes and wildcats, which had possessed the ponies. They were going to kill him, but he had wisely taken to the woods. They then started setting fire to wigwams, and among the others fired the wigwam containing the 6000 lbs. of beeswax. The wax got to burning, and produced such a hot flame, and burned such a length of time, that they were sure they had finally got rid of the spirit of the white man, and went off contented. This was McFadyen's ingenious story to prevent investigation of his wonderful yarn of "beekeeping in the North."

In the *Canadian Bee Journal* for 1888, Vol. IV., page 632, J. H. Martin, who was

afterward so well known to readers of *GLEANINGS* as "Rambler," tells a story to match Mr. McFadyen's story.

He says, "We find that the Dog Rib Indians living near the Great Bear Lake annually consign a greater portion of their tribe to the bottom of the lake in hermetically sealed cases, where they remain with animation suspended for several months, and upon the approach of warm weather they are fished out and restored by the animate portion of their tribe. In corroboration of the above there are Hindoo jugglers who will allow themselves to be buried several days with seemingly no injury.

"It would certainly be an economical method for both bees and beekeepers to get thru the winter with suspended animation. In fact, they will be obliged to if we have many more seasons like the past."

In a postscript Mr. Martin avers that there is as much truth in this story as in Daniel McFadyen's, and wants it accepted in the same sense.

Guelph, Ont.

Mr. C. Hanson Bocoek, the expert on bee diseases sent to this country by the British Government to investigate the new disappearing disease found in this country. See editorial, page 839.

Winesap apple-tree. This is in the orchard shown on the cover for GLEANINGS for April 15, 1916. Sales of apples in one year were over \$8000 in value, the trees covering some 25 acres in extent.

THE DANGER-POINT IN HEATING HONEY

BY GEORGE SHIBER

On page 98, Feb. 1, Mr. Doolittle says that granulated clover and basswood honey will be as clear as when first extracted when heated to no more than 145 degrees. The latest edition of the A B C that I possess, 1903, on pages 130 and 132, gives 160 degrees as the highest point that granulated honey can be heated. Of course that was orthodox some years ago; but I believe that later editions have lowered the figure.

My experience makes me feel that all of the above temperatures should be lowered, and that 130 degrees is as high as we can go if we wish to preserve a fancy article that has granulated. My experience has been entirely with basswood and clover honeys. Mr. Doolittle's "time," tho, is about what I allow for seven one-gallon cans.

I have a square galvanized boiler three or four inches higher than the one-gallon cans. A wooden false bottom on which the cans rest, about 1½ inches from the bottom of the boiler, protects the honey in the bottom of the cans. The boiler is filled with water, and slowly heated to 130 degrees—no higher—and left to remain at this point for three hours. The honey will be practically as clear and fine-flavored as when first extracted. But it will lack just the least little bit in color and flavor. To tell the truth, I have not found a perfect plan for liquefying candied honey. Of course, this slight difference would not be detected, as a rule, except by those who are experts in honey taste; but if we allow the temperature to reach 145 or 160 degrees the color and flavor will deteriorate to a very marked degree.

The directions on my labels say that the water should be no hotter than one can bear the hand in. This is not very definite; but one can feel sure that the honey will not be burnt. However, I have seen my own clover honey, originally fine and light-colored, made like black molasses by a customer who thought he knew just how to do it. I do not know of any way that clover honey can be put up for the trade that will be granulation proof, but I am studying the question. Heating it to 130 degrees and sealing while hot, or at once, is the best way I know of, and works very well; but there is an occasional exception where such honey will granulate.

THE SAVING OF STORES IN A CELLAR.

On page 114, Feb. 1, Mr. J. L. Byer figures on 35 pounds net as the safe amount

of stores for winter in Ontario, and he estimates the cost at 6 cts. a pound, which would be \$2.10. Looking at it from every angle it seems to be expensive wintering. Western New York has some pretty cold weather, as a rule; yet I would feel safe in wintering outdoors with 25 pounds net, costing, according to the above, \$1.50. This is expensive enough.

A few years ago I changed from cellar to outdoor wintering, and wintered fairly well. I found out one thing, however, and that was that it took more stores to carry them thru to settled weather in the spring; and while I have never weighed stores to see how much had been consumed, I think inside wintering can be done at a saving of one-third in stores up to the time the colonies are carried out in the spring. I feel pretty sure that 12 to 15 pounds will carry strong colonies thru the four to four and a half months of confinement; and those same bees, if wintered packed outdoors, would consume, I believe, four or five pounds more. This would make a saving of twenty-five or thirty cents, and that would pay for carrying them in and out. But I would rather have colonies which had consumed only 12 pounds during confinement than those which had used 18 pounds during the same time. I should consider that, the more they had eaten, the weaker they would be.

WHEN IS THE GREATEST LOSS IN WINTERING?

My experience says after about the middle of February, whether wintered outdoors or in the cellar. The wintering problem is very easy up to that date; but after that time is when the losses occur. Some years I have had the greatest loss in April; and judging from reports I see others have had the same experience. The strong colony that consumes the least and stays quiet usually makes the best showing. These are some of the reasons why I have dispensed with packing-cases and have almost all the bees in the cellar according to the way I used to winter, and the method I have found the most satisfactory.

On page 116, Feb. 1, the editor says, "If you can shake more than three pounds on the average from your colonies in early spring, you are going some." Well, I should say so; and he might add to the above that one could take 12 framers too. Why, there is many and many a colony of but two pounds of bees the last of April (or early spring) that will be up to the mark when

the crop is harvested if they have plenty of stores.

The most valuable bees are those that have not been more or less worn out by

dysentery brought on by poor stores or excessive eating to maintain the required heat.

Randolph, N. Y.

NEWSPAPERS AND TELESCOPING COVERS FOR WINTER PROTECTION

BY F. R. S. BOND

The photograph shows the bees in my back yard. They are facing the south, and are just behind a hen-house which is nearly

super-covered; then a super filled full of folded newspapers. This was covered with another super-cover, and the five thicknesses

F. R. S. Bond's backlot apiary in winter quarters, Worcester, Mass.

20 feet long. This was taken in the spring, showing the hives just as they wintered. The paper wrapping under the covers can be seen on some. Over the body was the

of wrapping-paper were folded over the whole, and covered with the telescope cover pressed on. Every colony came out strong. Worcester, Mass., June 6.

IN THE HIVES BUT NOT IN THE CANS

BY F. GREINER

When I read the editorial, Aug. 1, in which special mention is made of the McIntyre plan of obtaining *all* the honey from cappings, I expected to find something more satisfying than I did. The heading of the article is misleading to begin with. It is a misnomer, for you don't obtain the honey at all except that which drains from said cappings in the uncapping-box. I am here reminded of the sailor boy who dropped the captain's golden drinking-cup overboard by accident; then, in his consternation, came to the captain and asked him

if he considered a thing lost when he knew where it was, to which the unsuspecting captain replied: "You little dunce you, how can anything be lost when one knows where it is?" The cunning little fellow then said, "Well, then, the captain's drinking-cup is not lost, tho it is on the bottom of the sea."

It is a good deal so with the honey the bees extract from the cappings by the McIntyre plan. It is in the hive but not in the sixty-pound can.

It seems to me the McIntyre plan has no advantage over our long-practiced plan of

placing the cappings in the solar after they have had a day or two of time to drain in the uncapping-box. The McIntyre plan has the disadvantage of making an extra very bulky implement necessary. We have already more such than we want. The old plan makes no such demand. The solar separates the honey from the cappings without cost, and gives us the wax in a solid nice cake besides. It is true the honey obtained by the solar melting process is not as nice as the honey that drains from the cappings; but we get it. It answers well for feeding. The comb-honey producer can use it to advantage for feeding back to have unfinished sections finished up. I never have any too much of such honey for my purpose. The honey obtained at the close

of the season from unsealed combs, together with this exceptionally heavy honey from the solar wax-extractor, is usually just about sufficient to have the 30 or 40 cases of unfinished honey, which I usually have, finished up by feeding it back to six or eight well-working colonies at the close of the season.

Some years ago we used to wash the honey out of the drained cappings and make vinegar from the sweetened water, either in combination with cider or pure; but honey vinegar does not find favor with the general public. Even the best cider vinegar finds a slow sale, so we have discarded that practice and put the cappings thru the solar as stated.

Naples, N. Y., Aug. 26.

BEE-NOTES FROM HOLLAND

Our Wintering Problem

BY J. H. J. HAMELBERG

As has already been pointed out, our skeps require but little preparation for winter. Whatever may be said against these old-fashioned structures, they surely are ideal winter-homes. I have wintered blacks in them without finding a single dead bee on the bottom-board in early spring. I really consider it a pity that a modern hive, without losing the advantages of easy handling and accurate fitting of its fixtures, cannot be made of straw bands, twisted by hand and held together by stripped bark or cane, as is done with skeps. Of course, one could make a board skeleton and have it covered with straw all around; but it would not be the same. Neither would a hive of compressed straw answer as well. It seems that this platting of the straw by hand is just the thing for the right kind of ventilation and the proper escape of moisture; but this handwork at the same time prevents obtaining the accuracy in dimensions needed for the fixtures of a modern hive.

For those who keep their bees in hives, the wintering problem offers far more difficulties. Our winters can be very cold and can last long, altho in late years we have had only mild winters. But my experience is that these mild winters, with their lasting rains and fogs and sleet, and the thermometer still not rising much above 40 degrees, are far more to be dreaded than a spell of freezing weather. The comparatively mild temperature causes the bees to move about too much, to consume a great amount of stores, and to commence brood-rearing too early. Besides, my experience is that it is

much easier to protect bees against cold than against moisture.

All beekeepers have their own fancies and hobbies, and act up to them, and this applies especially to our systems of wintering. Some prefer wide entrances, others think they can hardly make them small enough. One believes in leaving plenty of room between the bottom-board and the bottom-bars of the brood-frames; others consider a passage a trifle over a bee-space quite sufficient, etc. It would take up too much room to describe the different ways in which bees are wintered in this country, and so I will give only my own, not because I consider it the best, but because I am most familiar with it.

To combat the danger of moisture gathering in the hive I always take particular care to use plenty of absorbing material in and over my hives, which, as is general in this country, are wintered on their summer stands. For absorbing material I have never found anything superior to what is called peat-dust, being the refuse which accumulates in the drying and transportation of peat. It can be bought for \$3.00 to \$4.00 per ton, packed in compressed bales of about 200 lbs. each. On either side of the brood-nest I put a follower the width of an ordinary brood-frame, filled with this material. However, I do not nail up the sides of these followers with thin boards, but tack stout yellow cotton over them, as any moisture is thus more readily absorbed by the peat-dust inside; and these followers, not being thicker than an ordinary

brood-frame, they allow room for eight frames of stores which I used in my Danzenbaker hives. Above the inner cover I put a super, filled with the same material to about an inch from the top, and then put the cover over all. When the bees have not had the time to seal the inner cover of the brood-chamber with propolis (which may happen on account of feeding them up too late in the season as a result of a late delivery of sugar by our beekeepers' association), I paste strips of paper over the cracks between the inner cover and the brood-chamber. I consider an entrance of $2\frac{1}{2}$ by $\frac{1}{4}$ inch quite sufficient, and close the summer entrances up accordingly.

The inner covers I use in wintering all have a hole in the center to fit the mouth of a common fruit-jar, which enables me, if

necessary, to feed the bees in early spring without disturbing them, and with no fear of robbers. Before putting the peat-dust in the supers, this hole is covered, of course; but I think it essential to use a very thin board for this purpose, and I prefer to have it fit not too nicely, so that the moisture, rising up from the center, may be absorbed readily by the peat-dust above.

With this system of wintering I lost a colony only once. This colony had been fed in autumn with syrup made of unrefined cane sugar. I found the top-bars of the brood-frame of this colony smeared with excrement, and I noticed a sour smell coming out of the hive, which convinced me that the food and not my system had been at fault.

Soest, Holland.

WINTER PROTECTION WITHOUT LOOSE PACKING

BY H. H. SMITH

I have tried nearly all methods of packing bees for outdoor wintering. While I have had success with most of them if the colonies were in good condition, with young bees and good stores, I have found that nearly all the methods have some serious drawback. The single-colony double-walled hive is expensive, and heavy to handle. Properly made cases to hold four colonies cost nearly as much as the four hives, and

I never could get used to the muss of loose packing material in the fall and spring. Besides, there is not one part of a packing-case which can be used for any other purpose during the season after bees are taken from the cases.

The drawing shows the way I wintered a part of my yard last year. I make a frame of 2x4 scantling, large enough to hold four colonies, 2 colonies facing east and 2 west. Two pieces of 2x4 scantling, 6 inches apart, run across the center of the frame to support the back ends of bottom-boards of each pair of hives. This arrangement allows the hives to be spread apart during summer.

At feeding time in the fall two outside combs are taken from each colony, and a chaff-packed follower or division-board is put on in their place. These division-boards are made of a frame of $\frac{1}{2}$ -inch pine 2 inches wide and $\frac{1}{2}$ inch shorter than the hive is long inside. The sides are made of wall-board, manufactured by the concern that makes paroid

roofing. Chaff or sawdust will do to fill the space between the sides. To make the division-board fit snug when put into the hive, a piece of burlap is made into a roll about the size of a lead-pencil, and tacked to the two ends and bottom.

At packing time the four hives are placed close together, and a box holding four inches of packing is fastened at each end of the group as shown in the drawing. Over all is placed a large cover holding 6 inches of packing, the packing held in place by burlap tacked 2 inches from the lower

edge of the cover. This arrangement has all the advantages of the large packing-case, and none of the muss caused by loose packing. The end packing-boxes can be set up in groups of twelve, still filled with the packing material, and covered during the summer with one of the large winter covers. The chaff-packed division-boards are very useful during the summer for protecting weak colonies. With this wintering arrangement no extra bottom is needed, as with the large-case loose-packing plan.

Palermo, Ont.

WINTER PROTECTION FOR TWO CENTS A COLONY

BY DANIEL DANIELSON

For more than thirteen years I have lived in Colorado and have tried nearly all plans of wintering. I have tried the cellar but that is not satisfactory here, as it is too warm. I have left the colonies outdoors unprotected, and in some winters they do fairly well; but in other winters there are severe losses. Therefore I concluded to try outdoor protection.

For the last three years I have put my hives together in the fall in long straight rows, running north and south, alternating the entrances east and west so there is an entrance only at every other hive on the same side of the row.

I always winter my colonies in two-story hives, the bees usually staying in the upper story during the winter.

I cover the whole row with felt or tar paper, putting one roll of paper on each side and folding both upper edges over the top of the inner cover, and then put the regular

cover above as shown in the picture, page 362, May 1. I nail lath on each side below the cover to hold the paper in position. The material for this method of protection costs about two cents per colony, and the labor is a very small item. For Colorado I find this protection is cheap and practical. When the sun shines on the paper in the winter it warms it up even on a cold day.

EASY WAY OF BUILDING UP THE WEAK ONES.

By removing the outer cover I can fold back the paper and examine any colony that I wish by removing the inner cover, afterward putting the paper back in position as before. I leave the protection on until May, when all the colonies are scattered around, so as not to be in regular rows. At the time I make this change, if there are any colonies that are weak I leave them in the row temporarily, and they catch the stray bees and thereby become as strong as the rest.

Brush, Colo.

COMMERCIAL QUEEN-REARING IN SOUTHERN CALIFORNIA

BY HOMER MATHEWSON

The subject of this sketch, Mr. Henry Perkins, was born in Hamilton, Ontario. When but a small boy his parents emigrated to San Diego Co., Cal., where the father is still engaged in beekeeping.

Under the direction of his father he became a successful beekeeper; and when the possibilities of Imperial Valley became known he emigrated to Heber, where he established the first large apiary in the county. This venture was crowned with success. The following year he shipped the first car of honey from the valley. He continued to maintain a large apiary here for some years. Disposing of his holdings here he went to Ventura Co., Cal. Here

he spent a year with Mr. Mendleson, who counts his colonies by the hundreds. After much prospecting he finally located at Artesia, Cal., and commenced the rearing of queens upon a commercial scale. His apiary is located on the banks of the San Gabriel River, about a mile from the town. For this industry the location is ideal. The yard shown in the illustration covers about four acres. The surrounding country produces enough honey for building colonies nearly the whole season, but not enough for profitable yards, hence their absence, making it possible to get pure matings.

At present Mr. Perkins has 300 twin mating-boxes, and 125 single ones, making

725 mating nuclei in the queen-rearing yard of Henry Perkins, near Artesia, Cal.

725 units on stands convenient for manipulation; 75 colonies are used for cell-building.

Mr. Perkins uses practically the same method as other breeders. The cells are transferred to the upper story of strong queenless or superseding colonies to make sure of being well fed. The cell-building colonies are fed while cell-building is in progress. After ten days the cells are given to the nuclei for mating. It seems that, the smaller the nuclei, the more sure the mating. Each nucleus will average seven

queens per season, and oftentimes two per month. An allowance of 20 per cent is made for loss in mating and poor queens. The nuclei are fed once a week with a very heavy syrup.

The feeder used by Mr. Perkins is one of the best I ever saw; but it is not adapted to cold climates, inasmuch as it is on the outside of the hive. It is of his own invention, and it comprises several features. Each feeder is double, serving one or two colonies at the same time. Being on the outside of the hive, and so constructed that no robbing

can take place, it is possible to feed at any time of the day.

This industry represents the investment of several thousand dollars. The capacity in the height of the season is above 800 queens per month. One of the interesting features is his system of signs indicating the condition of a nucleus, whether queen-right, virgin, or queenless. In filling the cages for shipment he has a method of getting the queen to run into his half-closed hand where she is held prisoner while the cage is supplied with bees, and then the

queen is run in of her own accord, never being pinched or handled in any way.

One of the little "big things" which time and patience have perfected is the idea of using pure wax for cells, using nothing but the best new white comb.

Mr. Perkins has finally exterminated all black bees in his range, hunting them out of trees, stumps, buildings, and, in one case, from under a water-tank. In some cases the queen and drones were sifted out and the bees used for nuclei.

Lexington, Ky.

After the battle. By accident, a batch of cells was left a day or so too long in a cell-building colony. The first virgin that hatched, true to her nature, waged an unfair war upon her helpless sisters still in their cradles. Every cell was ruthlessly torn open, and the little white queen inside killed. A virgin queen will not stand for competition.—See next page.

AS GLIMPSED THRU THE CAMERA

BY H. H. ROOT

The pathway of a queen-breeder is not always strewn with roses; there are unexpected thorns. The weatherman plays unkind pranks, and takes delight in making the most experienced prophet so badly mistaken that he will prophesy never again. Just when the breeder gets everything going fine, sudden cool weather will come on followed by cold rains, and all plans have to be set aside and new ones made. One week the breeder may have a big surplus of queens; then in just a few days there won't be a queen in sight, nor immediate prospect of getting any. The unhappy victim of circumstances has little to do but look out on the cold dreary world and look in on the letters from his angry customers

tore great holes in the sides of the other cells and mutilated the helpless inmates, the bees meanwhile organizing a "wrecking-crew" and clearing up after her, as best they could.

The engraving shows one of the bars of cells, every cell a complete wreck. Whether the young queen tore all of the side of the cell away herself in her frantic efforts to kill her rival, or whether the bees removed a part of the wax in cleaning out the remains, I do not know.

CLIPPING QUEENS.

To the beginner this process is one that is cordially dreaded. It is not difficult, however—the easiest thing in the world, in fact.

The easiest way to clip a queen.

demanding that their orders be filled or their money returned.

But it is not of the weather that I intended to write. The queen-breeder has to be a careful man, and withal a good book-keeper. If there is any mistake in his figures that mistake is likely to be a costly one—so costly that the breeder groans to himself that "life is just one blame thing after another, anyway."

This summer, for once in his experience, Mr. Pritchard happened to make a mistake of one day in his figures. Two bars of cells were left a day too long; and the first virgin out, true to her instinct, immediately slaughtered all her unborn sisters. With the one passionate idea of reigning supreme or not reigning at all she

It is well to practice on a few drones first, catching them by the wings between the thumb and forefinger of the right hand. Transfer the bee to the thumb and forefinger of the left hand, placing the under side of the thorax on the ball of the finger with the head toward the other fingers, the thumb meanwhile pressed very lightly on the thorax just enough to keep the bee from getting away. Particularly in case of a queen, always try to catch the wings on both sides in order that she may be prevented from buzzing around and getting badly frightened. When she is in position between the thumb and finger her legs will grasp the end of the finger and the wings will nearly always stick straight out. There is then no danger of clipping a leg, and the

wings are clipped in much less time than it takes to tell about it.

If you are timid about picking up the queen from the comb, take a piece of soft iron wire about No. 16 and bend a small loop or eye in each end. Bend the piece of wire around, forming a letter U, so that the two eyes are not over three-quarters of an inch apart. Tie a rubber band across, and by holding the wire in the left hand it is not at all difficult to imprison the queen as she walks about on the comb, by setting the rubber band down on her back. In this position she may be clipped with the scissors in the right hand while thus held on the comb; or, after being caught, she may be picked up by the thumb and finger of

A sample of natural comb with the rows of cells running vertically, and two parallel cell walls horizontal.

Another sample just like it.

the right hand, transferred to the left hand, and clipped as described above. I believe, however, that the queen is less frightened if calmly picked up from the comb and quickly transferred to the left hand without any rubber band or any other device.

WHICH WAY DO THE BEES BUILD COMBS?

Every now and then some one tries to start a discussion by arguing that the bees when building natural comb always build it in such a way that two parallel cell walls are vertical so that the rows of cells are horizontal. There is abundant proof to show that bees often build comb the other

way. Most of the pieces of natural comb that I have seen are built with the rows of cells running horizontally; but here are two pieces of comb that I found this summer, both of them with two parallel walls horizontal so that the rows of cells are vertical. I doubt whether it makes very much difference to the bees. It is claimed that the comb is less likely to sag if not built this way. This I am ready to believe, altho I have never seen any positive proof.

If it happens to be more convenient when cutting up foundation to cut it in such a way that the rows run vertically is there any objection to so doing?

SOME ADVANTAGES OF A BEE-EXCLUDING FRAME

BY MARK W. MOE

A frame covered with wire netting, which might be called a bee-excluder, will be found convenient for several purposes. The outside dimensions should be the same as those of the hive it is to be used upon, with a bee-space on the upper side, the same as a queen-excluder, bee-escape, or any other article used on a hive. It should have *two* layers of wire netting, because, if only one layer is used with supporting-strips, it would allow too much space under the frames in the hive-body or super above it. If used without supporting-strips the wire netting would be likely to sag enough in some cases for bees to pass under division-boards resting upon it. If no bee-space is provided on top, there is danger of killing bees, and sometimes queens, under the frames.

I much prefer to use this bee-excluder instead of tacking wire netting on the bottom of a brood-chamber, as advised in the A B C and X Y Z of Bee Culture, for mating queens in nuclei in an upper story, and I also prefer having the outside entrances made in the bee-excluder rather than in the brood-chamber above it.

Among the uses which may be named for the bee-excluder are:

1. To close the hive in moving bees.
2. To separate a weak colony from a strong colony below, for the purpose of building up the weak colony, when, for any reason, it is feared that either queen might be lost if a queen-excluder were used.
3. For the purpose of introducing a queen with absolute safety, by releasing her on frames of hatching brood over a colony. The bee-excluder is placed between.
4. For providing a place to put brood,

with part of the bees adhering, in carrying out any of the shaken-swarm methods.

5. For mating queens in an upper story. Simply fasten it to an empty brood-chamber, with hive staples; provide bee-tight division-boards, and canvas or enamel-cloth to lay over the frames. When thru mating queens, remove the bee-excluder and your brood-chambers are ready for any other use, with no unsightly holes in them.

Also, if a beekeeper happens to be using closed-end frames he can still use an upper story for queen-mating nuclei just the same, and without cutting away any part of the ends of his frames.

6. By providing one or two holes for bee-escapes, to be covered with metal slides or pieces of sections when not in use, the bee-

excluders can be quickly transformed into ventilated bee-escape boards.

In one of my screens I have four outside entrances. This is for the ten-frame hive. I would have only three for the eight-frame hive, one on either side, and two at the back. My idea is, to place a small alighting-board on the back, long enough to reach under both entrances, with an upright partition coming just between them, with the

opposite sides painted different colors. If I find that this does not work satisfactorily I can give one middle compartment a queen-cell, and, about five days later, one to the other middle compartment, keeping a zinc queen-excluder over the entrance to the latter until the first queen is mated, then transfer the zinc queen-excluder to the entrance of the mated queen.

Bristol, Col.

WHY I NEVER LOST A COLONY IN WINTER

BY J. F. KIGHT

The clover harvest closed here about Aug. 1; and while the bloom was more abundant than has been known in this state for a long time the flow of nectar was not more than fair.

Sweet clover came in a little earlier than usual, and seemed to have quite a lot of nectar. Today, August 17, it seems to be about all gone to seed.

White aster will be the next on the bill of fare, and there seems to be an abundance of it. It remains to be seen whether or not it produces a good flow of nectar. I am extracting rather closely from the outside frames of the brood-chamber with the hope that these combs will be filled with the aster honey. For outdoor wintering I have no fears from it whatever.

I wish to tell the beginner how I manage to bring my bees thru our Indiana winters with no loss of colonies. In the first place my hives are all ten-frame. I see that each colony has not less than 35 lbs. of honey the 15th of October. I then go thru them and place the lighter combs with no brood on the outside, thereby moving the honey nearer the center. After this is done I place the queen-excluder back in its place, put on the shallow super empty, and fill it with some kind of absorbent of moisture. First I place a very thin piece of muslin over the queen-excluder; then fill in with dry leaves or anything dry that will take up the moisture.

About Nov. 15 I wrap each hive with a thin tar paper to keep the wind from entering the hive only in front. The entrance is now contracted to the regular winter entrance, viz., $\frac{3}{8}$ by 5 inches. I hear some say, "Why keep the queen-excluder on?" To keep the bees from having to go around the end of the frames when it becomes necessary to change to another honey supply, when all they have to do is to crawl between the top-bars of the frame and the queen-excluder, which is a space of $\frac{1}{2}$ inch.

I have never lost a colony of bees from cold weather wintered in this way. If the apiarist lives in Indiana climate he should not remove this covering until settled warm weather, which is from April 20 to May 10. Don't hurry; more harm is done by this mistake than one would surmise.

Indianapolis, Ind.

Bumblebee making it hot for a honeybee. Some of the other bees took part in the fight, but too late. Both bees were dead when found.

IS IT A NEW OR OLD TROUBLE?

BY W. C. MOLLETT

Last winter I began to notice that there were more dead bees at the entrances of some of the hives than I had ever seen before. These were mostly very strong colonies. I did not think there was a disease, but rather thought the condition might be due to the weather, and I expected they would be all right when the weather became better. The winter was very changeable—very warm for a few days, and then suddenly cold, and there was considerable rain and damp cloudy weather.

I thought also it might be due to the kind of honey the bees had gathered, or some little matter which would soon right itself. I began to notice closer, and I perceived after a cold night there would be a great many apparently dead bees at the entrance of the hive; but when the sun came out a great many of them would begin to crawl around, and try to get back into the hive. I noticed also that the bees were carrying out many bees that were not dead, but seemed to be affected in some way. When I opened the hive a considerable number of bees would begin to crawl over the tops of the frames in a slow manner, as if they were just about to die. These would usually be of a very dark color as if the fuzz had all been worn

off them, and they usually seemed to be smaller—considerably more so than they should be. When any of them were carried out or brushed off the frames they would crawl around for a while and then fall over on their backs and tremble, and keep their legs moving for some time and then die.

These conditions kept on till spring came, and the colonies were so weakened that they could not build up enough to gather any honey to notice. Some of the bees seemed to get well when the weather was warm—at least the dead bees did not show up so much; but some of the colonies kept on in the same way all summer, and are still dying just as they did in the winter.

I first thought it was spring dwindling; but this disappears early in the summer. I am under considerable uneasiness lest it may keep up and finally affect all the colonies, which would completely ruin the prospect, for the time at least. It seems to affect only the adult bees, and does not have an odor of any account.

Stonecoal, W. Va.

[This is probably a case of bee paralysis. Usually in such cases a change of queen will affect a cure.—Ed.]

Straw skeps made large enough to cover an ordinary hive and super, making the scene artistically old-fashioned, and providing considerable protection as well. From C. GALBRELL, Newburyport, Mass.

IS A LAYING-WORKER COLONY WORTH SAVING?

BY E. S. MILES

There has been a good deal written on the subject of laying workers. On page 879, Nov. 1, 1915, Dr. Miller gives a good description of the indications that they are present in a colony. It might be added, however, that the unsealed larvæ from laying workers will not be regular and even in size as from a normal queen. Sometimes a defective queen will have scattering and uneven-sized larvæ, somewhat similar. An experienced apiarist will also nearly always detect an unnatural action of a colony with laying workers, altho this can hardly be described so a novice would understand. One more thing, noticeable in many cases, I think, is several eggs in a cell of any drone-cells in the brood-nest.

"The cure?" Doctor Miller says, "The best cure is to break up the colony." I cannot agree with our good friend, unquestioned authority tho he be on bee matters in general. I have found that a laying-worker colony will accept a ripe cell in most cases, if found soon after this abnormal condition begins. If not found soon, and the colony is weak and the bees all old, they are of no value to another colony, and quite liable to be killed rather than be accepted in uniting. My experience has been that workers take to laying only when the season is so that the bees are anxious to breed, and no queen is present, nor brood from which to rear one. At such a time normal stocks are strong with plenty of brood, and the addition of a few old bees, even if one succeeds in uniting, is of no practical value, and, unless one has more colonies than desired, the following process is recommended to get rid of the laying workers and at the same time build the colony up.

Go to any colony strong enough to spare one or more frames of brood, and select

combs that are well filled with sealed brood—hatching brood if possible—putting in their place the combs of laying-worker brood, after having brushed all the bees from them. Select, in this way, and give to the laying-worker colony as many combs of normal brood, a good share of it sealed, and ready to emerge, as they had of the abnormal brood from the laying workers. From two to four frames should do; and let it contain also some eggs and young larvæ. If the laying workers have been neglected until they have considerable sealed brood, take a sharp uncapping-knife and shave the heads from it before putting it into the normal colonies, and they will promptly throw it out and use the combs aright.

The laying-worker colony treated this way any time during the working season, when a living or more is being gathered, will usually rear a fair queen; but the best way would be to have a ripe cell from good stock to give them in from three days to a week after giving them the normal brood. It would be well, too, if giving a ripe cell, to destroy any cells built on the brood. I am not up on the philosophy of this treatment, but suppose that the removal of the abnormal brood, and giving a good supply of normal brood perhaps leads the bees to neglect the laying workers; and plenty of young bees being on hand by the time the larvæ from the eggs given are of proper age for queen-rearing brings the colony to about the condition of a colony whose queen has been suddenly removed; hence they will build cells and accept cells ready to hatch. I have had this experience on quite a few colonies with laying workers. Let others try it and report whether it is successful as a general rule.

Duulap, Iowa.

TIDBITS

BY ARTHUR C. MILLER

What is the homing instinct of the bee? Does a bee find its home by appearances? In the language of an ancient investigator. "Can a bee remember a hole in the air?" Search me if you wish, but I carry not the evidence. However, on September 2, 1915, bees flew from a nucleus for a short time one morning, then the hive was closed and removed. At night about 150 bees were clustered on the concrete walk near where the hive had stood. Each noon thereafter

a few bees were to be seen hovering near the place. At nightfall, September 16, on the same spot 126 bees were gathered. What is a bee's home, anyway? And, say, do you suppose they had their own hive odor? I might ask some more awkward questions, but I guess these will suffice now.

* * *

Ever watch crows circling about a tree where an owl was roosting? Ever watch king-birds darting down at a crow or other

enemy? Saw a half-dozen bees acting thus over a clump of grass. Couldn't hear any "cawing" nor any scolding chatter; so, being sure they were neither crows nor king-birds, I investigated. Discovered that all the bees were not in the air. One was tail up under the palm of my hand as I put it down. Also discovered a clipped queen crawling rapidly about. Guess she was tired of housekeeping or else was a suffragette. Belonged in a baby nucleus about six feet away. She had filled things with eggs, and gone forth for a larger world to rule over or for some other near reason. No, the bees had not swarmed out. She had just ambled forth on her own account. She was returned to her hive, and a week later was found in another nucleus ten feet away and around a corner of a building. She had destroyed a fine queen-cell and gone to housekeeping again. Fickle jade! Are you good at guessing? Go ahead.

There are two trees which do not make good neighbors to a beeyard—"balm of Gilead" poplars and pines. Too much and too sticky propolis. Recently I went from a yard close to the seashore and far from trees to one among pines. I was very much stuck on the hives of the latter, so was everything else that got next to their insides. My! but wasn't that propolis soft and sticky that hot August day? Ever notice how it runs down combs and accumulates along the bottom edge? Bees are not always directly to blame for the thick gummed-up bottoms of combs. Don't blame everything on them. Sometimes you do not give them enough entrance. Why do you persist in ignoring Dr. Miller's good advice?

"Hello! Are you the bee inspector? Say, sorry to have 'phoned you so late (woke me from my sound beauty sleep), but what does foul brood smell like?"

"It has three kinds of smells—that is, there are three kinds of foul brood with three different smells—one smell for each kind. One smell is real rotten; the next is almost as rotten, and the third is only sour; and this is not foul brood, only pickled. Some folks don't agree as to how rotten the smell should be to be really truly foul, and the descriptions of the strength of the smell vary all the way from that of a bad cigar to that of an egg which explodes when you shake it close to your ear. You remember that, of course. How does yours smell?"

"Pretty much like sour swill. The yard is full of the smell, and it's just pouring out

of every hive. Had I better burn them right up?"

"My friend, that is the odor of new goldenrod honey. You just let that smell keep pouring out. Congratulate yourself that things are as they are. At the present rate the bees will not only pack things solid for winter, but give a surplus as well. No, the honey will not smell like that when it is ripe. Good night."

I have that lesson by heart now, for about two or three times a day or night I get the question. And here is one for you. How do you suppose the bees can gather such smelling stuff and keep it down, even for a time?

DIFFERENT RESULTS FROM APIARIES CLOSE TOGETHER.

Item—sixty colonies of hybrid bees on a gently sloping hillside—a Rhode Island hill if you please, where the highest mountain is only about eight hundred feet. Twenty of said colonies were moved half a mile, as the crow flies, southeast, over the crest of that hill which was exactly one hundred feet above the first apiary. Forty feet below the crest of the hill, on the side opposite the first apiary, the twenty colonies were placed. That happened in the spring of 1915. The forty colonies stored not a pound of white nor even light honey, or leastwise all they got was submerged in dark bitter honey-dew from scrub oak. The twenty-colony yard put up a big crop of the very best light honey and not a drop of honey-dew to be found in it. And they put up more pounds per colony than the other yard. Does memory serve me right, that some one or two or three or more have said that apiaries should be at least three miles apart?

Another item: Two apiaries of pure Italians, all of the same breeding, are on a ridge—just a little Rhode Island hump—the yards being less than a quarter-mile apart—one on the crest of the ridge, one about thirty feet below the crest on the east slope. One yard gave a fine crop of fairly light-amber honey while the other put up a lesser crop of darker honey.

Will some one (say from near Marengo) tell us how to pick a "location" and define what "location" means?

How do you pick up workers for filling queen-cages? Most persons reach for a bee with its head in a cell, and with thumb on one side of the bee and forefinger on the other, "pinch" at the wings. A bland and amiable gentleman commonly called "Charlie," living not a thousand miles from

Johnstown, N. Y., most painstakingly showed me how *he* did it. Makes a grab for any bee that is hiking across the comb, and, with forefinger down and thumb up, sends the finger straight after the bee, hits *ends* of wings which slide up on to the forefinger; thumb at same time shuts down on them, and the trick is done. Very swift and neat as he did it. Tried it myself lately. Finger went too low. Now I have a suspicion that some things one has shown to him had better not be meddled with. It's more than a suspicion—it's a conviction.

AT THE SHOW.

A lot of single-comb observatory hives, some of the well-known commercial type, some of the new type having the ventilation wholly along the bottom of each side. In the former the bees were uneasy and racing about, while in the latter they were quiet and attending to household duties in a perfectly normal manner. And, by the way, do you know that it is a fine art, putting up a nucleus for exhibition? The color of the comb, the color of the bees, and the color of the hive must all be considered. If the hive is dark in finish the comb should be light and bees dark. If hive is light in color, a dark comb and light bees fit. Then one must not have too many old bees nor too many bees of any one age. The quantity of bees must be sufficient to keep the brood warm and yet not crowd things; and in this connection the two panes of glass on each side and ventilation only at the bottom help immensely. If you are to follow the shows next year, just take time this winter to study hive colors and comb colors. He who does it best will stand the best chance of winning.

Another "show" item. Exhibition of queens is more often than otherwise a disappointment to the visitors. In a nucleus the queens are hard to find except by the experienced. When in cages the light is poor and the queen is often hidden under the bees. Queens show best in a special cage about four inches square. The front is glass, ventilation is a small opening near one lower corner, and is wire-screened; glass is only one bee-space from back of cage, and candy food is in the bottom of cage. Thus arranged the queen cannot hide. Hang such cages up like pictures and you have a queen exhibit that is worth while.

When showing queen-cells, arrange the display so the bees cannot completely hide

them by clustering in front of them. Glass on one side only; and that close to the cells with plenty of room behind the cells works nicely if two panes of glass are used with a confined air-space between. There is a knack in getting cells built for show purposes, as you will discover if you try. And you will also discover that making a comprehensive exhibit of queens and queen-cells is an art by itself quite different from other branches of bee culture.

"Don't touch," said the sign; but the finger-prints in the surfaces of the comb honey told a woeful story of the illiteracy of the spectators. I wish the public would learn to read. The managers of some of the shows furnish glass cases for honey and similar exhibits; at others the exhibitors must do so or take their chances. The premiums as a rule do not warrant the risk in showing, to say nothing of the expense, unless one may sell at their exhibit or near it. Wonder if the beekeepers' societies cannot consider these things and take them up with the show managers. They can accomplish more than individuals. I think it is worth considering, and I believe that, if rightly handled, the exhibitions can be made a much greater influence in spreading the use of honey. Some of you "know-hows," please get busy.

Varying with your point of view it is "strange," "interesting," or "funny" what different things arrest the attention of different persons. There was a display of combs arranged to show the difference between the profitable and unprofitable kinds, and also an old black comb with "wax-worms" at work in it, and a few of the moths (dead) pinned to it. It was all a good instructive exhibit, and was fully labeled so he who ran could read. That bunch of worms caused more talk than all else. Poor morbid humanity! But it did stop people, and gave the desired opportunity for talking bees and good beekeeping. And, mind you, there was no honey shown anywhere near that exhibit. Worms and honey is not a combination that it is well for the public to associate.

I saw an excellent exhibit of hives and appliances at a county fair. Every part of the hive was labeled after this manner: "Model hive, simple, efficient, reasonable price." "This size entrance is best for warm part of the year." "Queen-excluding honey-board for keeping queen out of the surplus-honey chambers. Always to be used

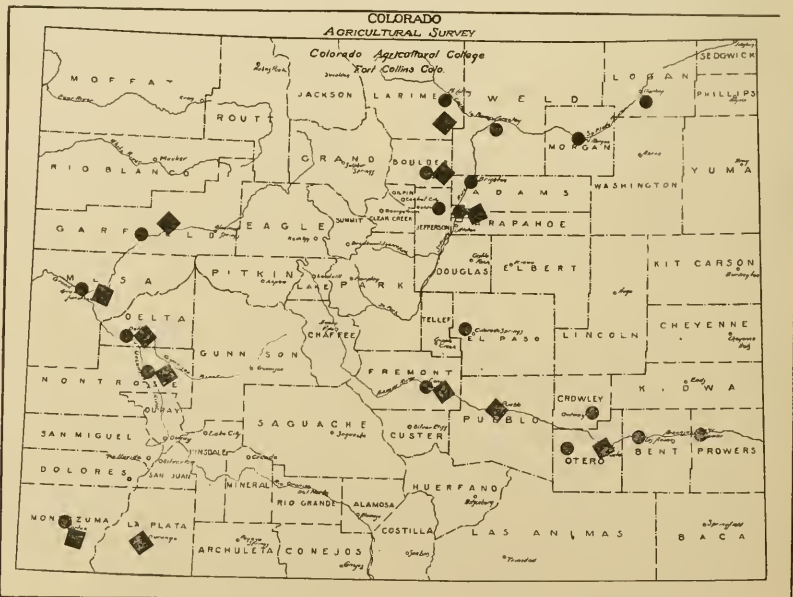

this side up." And thus all thru. It was a liberal education to the inexperienced and farmer beekeepers.

You may be interested to know that it was an exhibit by the educational section of a state body. The supply men may rise to the occasion some time—perhaps when they have a smaller variety of hives and things.

Mr. Chadwick, in the August 15th issue for last year, expressed doubt as to bees making but ten trips a day. Then he proceeds to cite the great activity of bees working on a bait. I wrote to him, calling attention to the fact that bees robbing—working on "bait"—were not working normally as we all know. He replied by referring to their activity during a heavy honey-flow. I will admit that sometimes a secretion of nectar may be so great as to cause bees to be unduly industrious; but I will at the same time repeat that bees *average* but ten trips a day. This estimate of their labors was arrived at independently by several observers in this country, and by at least one

abroad. To this statement Mr. Chadwick replies that it is not possible to mark a bee so that said marking will not interfere with its normal actions. Unfortunately for him the facts contradict his belief. A little suitable color can be put on the thorax so that the bee does not even notice its application. He may reply that, even so, it does have its effect on the bee. This was taken into consideration long ago, and was proved to be without basis by comparing the actions and trips of bees thus marked with those of bees of special colors in colonies of a different color, as goldens among blacks, etc. Beliefs, suppositions, and prejudices go down before facts. But the gist of the whole matter is this: Bees are not making as many trips as the whirl and confusion before a hive suggests, and are not as busy as legends have it, whether their daily average be ten or twenty trips, so it behooves us to have as many bees as possible in each colony—a condition which will be furthered by good combs and prolific queens producing vigorous, long-lived bees.

Distribution of Bee Inspection in Colorado

The squares indicate horticultural inspectors; the circles, bee inspectors.

By statutory provision, 1909, the Professor of Entomology of the college is State Entomologist charged with the horticultural and bee inspection of the state. He is assisted by deputy horticultural inspectors in thirteen counties, and a deputy who is state bee inspector with deputies in 19 counties.

In addition to their regulatory duties, these men give a good deal of their time to spraying demonstrations in fruit districts of the state, and lectures, printed matter, and personal visits to the fruit-growers.—*From the Colorado Agricultural College Series 15, No. 8.*

NOTES FROM GERMANY

Is a Non-swarming Strain of Bees Desirable?

BY J. A. HEBERLE, B. S.

Of late a number of articles have appeared relative to the question of breeding up by selection of a non-swarming strain of bees. Rev. F. Gerstung, one of the foremost beekeepers in Germany, started the discussion with an article in the *Deutsche Bienenzucht*, of which he is the editor. The following is a translation of the article, abridged. The reader must bear in mind that the writer had in mind only conditions prevailing in Germany.

Is the swarming impulse a quality or property that is by heredity transmitted to the offspring? Gerstung says it cannot be. He considers it impossible to breed up a strain of non-swarming bees, and holds that all endeavors in that direction will prove a failure.

He says, for argument's sake, let us suppose we could eliminate the swarming impulse—what would be the result? The strongest impulse, the propagation of the race, upon which the healthy development and the continuation of the race depends, would be weakened; the bees would become degenerate, and slowly, yet surely, would go toward extinction.

For comparison he writes, let us take the same aim for a breeder of domestic animals—say, for instance, the breeder of hogs in order to get a race that would readily take on fat, the impulse for propagation should be eliminated. The absurdity is at once obvious. But is not the elimination of the swarming impulse the same? That the propagation by non-swarming bees may be effected artificially does not affect the case, since after the elimination of the swarming impulse, degeneracy remains.

With bees the case differs in so far that the supposed elimination of the swarming impulse by select breeding is a delusion. The swarming impulse or the lack of it is not a quality or peculiar characteristic that may by inheritance be transmitted to the offspring.

PROOF OF THE FOREGOING ASSERTION.

Is the swarming impulse a quality of the single bee—the queen or of the colony—just as are size, color, or the sexual organs? Surely not. It is generally known that good honey years are poor swarm years, and *vice versa*. This means that swarming is not a quality or fixed trait of the bees, but a natural consequence of the surrounding weather and flora. In other words, the same colony which showed no swarming

impulse in 1911 may in 1912 swarm excessively. This is not a supposition, but a fact. We (Gerstung) called attention to this in the swarm year 1912, in which all the colonies swarmed, including those that had been bred as non-swarmer.

Notwithstanding this convincing proof, the teaching that the swarming impulse could, by select breeding, be eliminated, was continued, tho it had been conclusively proven that the surrounding conditions stimulate or subdue the swarming impulse.

WHAT STARTS OR STIMULATES SWARMING?

A rich pollen pasture in spring with a moist warm temperature causes a rapid expansion of the brood-nest. The queen finally cannot increase the egg-laying any further, and the young nurse-bees lack opportunity to dispose of their chyle (Fütter-saft); this causes a certain physiological tension which leads the young bees by supplying working larvæ with royal food to raise queens that may furnish more eggs—i. e., young larvæ to find use for the chyle—to satisfy the breeding instinct of the bees. As soon as this development has reached this stage the swarming impulse is awaked. If this height of development under different and less favorable conditions is not reached, the swarming impulse is not developed—does not manifest itself.

This may be proven by experiment. If, at the height of the development, we remove the queen, the process which leads to swarming is artificially started. The queenless bees rear for themselves queens. The first queen that is hatched swarms out with her followers. It follows that swarming is the result of favorable conditions of weather and pasture, but is not a quality or trait of the bees or queens which might be transmitted to offspring.

Notwithstanding this, the swarming impulse is treated exactly as the yellow bands of the Italians or the ill temper of the Cyprians. They (certain beekeepers) select and operate with this imaginary quality as if it were a trait that the offspring may inherit from the parent. They do this, altho swarm years from time to time show conclusively that they pursued a phantom.

NON-SWARMING BEES; APPARENT SUCCESS.

How is it that some beekeepers claim they have been successful in breeding a non-swarmer strain? Gerstung believes that, on account of too much skill in rearing the

queens, and especially on account of the baby nucleus in which the queens must await the awakening of the sexual instinct and the mating, might cause inferior or less fertile queens. Colonies with such queens do not reach the height of development which must precede the swarming impulse. This is degeneration of the worst kind—not successful breeding. Our queen-breeding methods are moving on a declining plane. We glory in methods that have succeeded in producing a non-swarmling strain while we have produced only a degenerate strain—this strain which, by their not coming out to swarm, show that nature has condemned them to extinction, and this is today considered an achievement of modern beekeeping! Beekeepers, go back to nature.

IS THE SWARMING IMPULSE REALLY AN IMPEDIMENT TO SUCCESS?

Gerstung says, only for a bungler (Ger-

man condition). Swarming is the summit in the development in brood-rearing on which, aside from the honey-flow, all success depends. It is the brood which furnishes the workers who at the right time are to gather the crop.

The better one understands how to guide the development, the brood-rearing, to further his own ends, the greater the success.

When we (Gerstung) at the height of the development receive a swarm of 6 to 7 lbs., we consider this an extra addition to the crop. We are glad when our colonies, after having made the most of the honey-flow, give large heavy swarms. We know the swarming colony is rejuvenated, and we have a good productive colony more for the next year's crop. As a matter of course, the beekeeper must understand how to keep the control of the development in his hands.

Kempton, Bavaria, Germany.

THINKING IT OVER

BY GRACE ALLEN

A beekeeper sat by an open hive—
On hill beyond hill how the day was alive!

“ He sorta sneered, that store clerk did,
In town the other day,
When I spoke up proud about my bees.
What made 'im do that-a-way?

I aint slicked up when I work, that's true,—
He's allus slicked up, hisself.
But I wouldn't swap this I-talian queen
For all the duds on his shelf.

It's pants 'n coats 'n shirts all day,
A-trying to make folks buy,
' N me with my bees in the orchard here
A-watchin the rascals fly.

Shet up in a store where he caint well breathe,
With crowds 'n noises 'round,
' N me in the sun—with the hills like this—
' N the bees the only sound.

He sorta sneered, he sorta sneered—
What made 'im do that-a-way?
Law me, I reckon he never see
A day like this ere day!

It's suns 'n hills 'n sechlike things,
' N thinkin a bit, by gum,
That keeps a man frum sneerin at folks
' N jes makes 'im wish he could hum!”

The beekeeper smiled as he closed the hive.
On hill beyond hill—how the day was alive!

Heads of Grain From Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

When the other fellow tells somebody who tells you about robbing a bee-tree the story goes that they get about a wagon load of honey, but when you do it yourself you're ashamed to say that you got more than a barrel or two—they might not believe you.

The Second Tri-State Field Meet.

The second field meeting of the beekeepers of Illinois, Wisconsin, and Iowa was held in Union Park, Dubuque, Iowa, August 1 and 2. The meeting was called to order by Mr. E. J. Baxter, of Nauvoo, Ills., the president of the Illinois Beekeepers' Association. The excursion and luncheon given by the Commercial Club of Dubuque on the steamer Sidney was greatly enjoyed by all present.

The attendance was about ninety. The beekeepers were honored by the presence of C. H. Bocoek, expert in apiculture of the British Beekeepers' Association; Dr. Phillips, from Washington; also inspectors France, of Wisconsin; Kildow, of Illinois; Blaker, of Minnesota; Pyles, of Illinois, and Elmore, of Iowa. Prof. Jager and his assistant, Mr. France, were also present from the Agricultural College of Minnesota.

The question-box was in charge of Mr. Kildow, of Illinois, and a goodly number of questions of vital interest were discussed, such as weight of sections, prices of honey, differentiation of American and European foul brood, etc.

Mr. Bocoek gave a very interesting talk on the Isle of Wight disease. He told of the

spread of the scourge over the British Isles, and of the great destruction of bees in that country. He is not sure that any cases of this disease have been found in the United States.

A motion was passed providing for a committee made up of one member appointed from each state to bring before the Interstate Commerce Commission the urgent need of the same freight rate on comb honey in the western as in the eastern states.

Another motion was passed to continue the organization, but change the name to the Mississippi Valley Beekeepers' Association. There will be another meeting again next year some time during the first part of August. The committee selected to make arrangements for the next meeting is as follows: Mr. France, Wisconsin; Prof. Jager, Minnesota; Mr. Kildow, Illinois; Mr. Miller, Iowa. J. W. Stine, Sec.

Packed Snugly in Pine Needles.

I have tried almost every thing recommended for use in packing. Some of the materials are good, others medium. I have finally come to the conclusion, after several years of experience, that white-pine needles make the most ideal packing.

Those who live close to woodland, where the stately white pine may grow, may have noticed that, after a rain or snow, when other litter on the ground is damp, the bed of these dead pine needles, sometimes quite thick, is nearly always dry and warm to the touch. This was the reason I was induced to try it years ago; and as an absorbent of moisture and retainer of heat it is far superior to any other packing material that I have ever used.

For want of a better arrangement I take two lath the length of a super inside, and tack three or four lath on these crosswise, cut the width of the super. I then place this rack on the frames; then fill a burlap sack with packing and place it over all. As spring approaches I take one part of the packing out; and when all danger of cold that might chill brood is over I remove the sack.

Just One Good Way to Get Rid of Them.

Have had the worst time in years with yellowjackets. Five weak colonies have been wiped out. I am trapping yellowjackets at the rate of about a pint a day. This has been going on for four weeks, and I begin to see a decrease. Another season I shall have more traps and earlier setting, and I hope this will give better control.

Replying to "Subscriber," page 716, Aug. 15, use a wire-screen fly-trap baited with fish heads or any fresh meat.

Queens Whose Colonies are Weak in the Fall Not Worth Saving.

That we had no loss last winter may be attributed to our belief in fall uniting. Not a fall passes that we do not have colonies lacking, both in stores and strength, to winter perfectly otherwise.

So much regarding the poor wintering qualities of goldens has been said in "Gleanings" that we were somewhat surprised to find our yellowest stock surpassing all last spring. While we have had a few yellow colonies winter poorly, the cause, more probably, was from the queens having gone thru shipment than from degeneracy.

Within recent years we have done practically no feeding. Tho not always, colonies short of stores in fall are quite generally deficient also in other respects, and not up to standard. The queens of such colonies should not be kept, but removed in uniting. Tho it is true that open winters call for an increased amount of winter stores, the rule applies only to a given locality. While in the north from 25 to 30 lbs. is necessary, half that amount will run a colony thru our short winters.

Each winter we have a few days of snow and ice, but not to such an extent as to demand other protection than is afforded by the single-walled hive. For mutual protection, however, against raw winds our hives are crowded into a long compact row. Separation will become advisable only when young queens begin mating, and the row will be scattered widely in forming increase and nuclei.

Lee Ellis Kerr.

A Frame-spacing Tool.

I have been much interested in the articles which have appeared from time to time regarding the merits of self-spacing frames. While the Hoffmann frame seems to be the established favorite, yet there are many, like myself, who prefer the plain old-fashioned $\frac{7}{8}$ frame, firstly, because any one of them can be easily removed from the hive by pressing over its immediate neighbors slightly; secondly, there are no awkward projections in the way at extracting time; and, lastly, they are easily and cheaply made at home by any one who possesses a saw-table and a small circular saw.

As to the rabbet-spacing plan, the bees of this locality are so liberal in their use of propolis that I have never considered that as very practicable.

I have a little device which I have used in my own apiary for six or seven years with much satisfaction, and which is neither of the hive nor of the frame. My hives contain 12 Langstroth frames, $\frac{7}{8}$ x $\frac{7}{8}$ top-bar. The rabbets are plain wood, with bee space below the frames. The hives are 18 inches wide inside—that is, permitting $1\frac{1}{2}$ -inch spacing. One will infer from this that in my early beekeeping days I read "Langstroth on the Honeybee," and was an ardent disciple of Dadant.

I have a spacing device that I have used with much satisfaction for spacing the frames. I take two pieces of spruce or other light tough wood, $\frac{3}{8}$ x 2 x 19 inches, and bevel off one edge of each piece. Then between the two I insert 13 pieces of the same

wood, $\frac{3}{8}$ x $\frac{1}{2}$ x 4, as teeth, leaving space between to slip loosely over a top-bar. The projecting part of the teeth are rounded off and tapered to a blunt point. After examining a hive and replacing the frames I take this spacer from my wheelbarrow (which I use almost continuously in my apiary work), and by pressing it down at each end of the frames they are all spaced exactly. By having the edges beveled, and using a puff of smoke, it is seldom that a bee is crushed.

Craigvale, Ont., Can., April 24.

What is a Stand of Bees Worth?

To one who keeps bees this is a question that is frequently asked, and is probably the most difficult to answer correctly. To those who know nothing about bees it appears that they ought to sell at a standard market price, the same as corn or wheat; but, instead, bees sell more like skilled labor, according to their ability to deliver the goods.

I have seen colonies that could not be bought for \$15 at the beginning of the honey-flow, and others that stood alongside of them that would not sell for the price of the new hive they were put in only two seasons before.

If a man should walk out to my yard and point out a single hive and ask what it is worth I could give the questioner a fairly intelligent answer; for, knowing the condition of the interior of each hive in the yard, I would be prepared to make a fairly correct answer. To show some of the possibilities I will show what I have done this season. Last spring I had six colonies which I wintered thru in good condition. Each colony had a young Italian queen which had been introduced as soon as the honey-flow stopped in the fall of 1915. I bought queens this spring as soon as I could secure them from the South, and divided until I had 18 stands. These went along until the swarming season opened up. I caught two stray early swarms, making 20.

I held the bees under control till the first of July. By cutting queen-cells, six of the

colonies became so strong I thought it better to make a little more increase, so I let the six swarm, making a total of 26. Out of this number 20 colonies produced surplus honey, some of them filling six and even seven 24-section supers, while others filled but one or two. Up to date I have taken 72 twenty-four-section supers from the 20 colonies, or from a spring count of six colonies. This honey is bringing me an average of \$3.25 per case, making a total of \$234 for a honey crop from a spring count of six colonies, or \$39 per colony.

J. W. Admire.

A New Type of Bottle Feeder.

I am sending a sample of my bee-feeder. One of the features of this feeder is that it can be closed up without in any way disturbing the bees. In the second place, one can see whether the bees have eaten all their feed or not. Third, the bees have room enough to take the feed away fast. Fourth, it keeps the bees warm during late feeding in autumn. Fifth, from the very least quantity up to two quarts can be fed, as one can use a bottle on both sides; but still one bottle will generally suffice. Sixth, when feeding no smearing results, and, consequently, no robbing takes place.

After the feeder has been applied to the hive-entrance I fill one of the bottles with feed, put the cork with the little tube (the latter may be made of aluminum) in the bottle, and hold my finger on the slanting slit of the tube. I then draw the bottle toward me, and let the tube go into the feeder thru the little hole. As the little tube

goes into the small hole I withdraw the restraining finger. By driving two small nails in the hive, the bottle can be bound to the hive with string. The tube must rest on the bottom of the feeder. As the bees take the feed away it flows continually out of the bottle.

Grand Ridge, Ill.

Joseph Garré.

[Mr. Garré's feeder-block is long enough to close completely the entrance. Except in cold weather we believe it would be better to have it a little shorter so as to provide a small entrance.—Ed.]

Paper Division-boards for Introducing Queens and Uniting.

The following plan for introducing has proven successful. Remove the old queen and three frames of broodless combs. Replace with a three-frame nucleus and queen, putting it on one side of the hive. Next put in a division-board between the nucleus and the rest of the colony, made as follows: Take a thin board the size of the inside of the hive, having most of the center sawed out, and a sheet of newspaper pasted over the opening. Next lay a sheet of paper over the three frames. Put a screen over entrance in front of the three frames. Make all other spaces bee-tight, i. e., space over rabbets and space by the entrance between the screen and division-board. That is all.

I use a two to three frame nucleus in a ten-frame Langstroth hive, with division-board between for mating. If desiring increase, after removing one nucleus and queen I replace with three or four frames of brood and the old queen that is being replaced by a newly mated queen, using a solid division-board temporarily. Later, after both sides are well filled, replace the solid division-board with one having a paper center, after killing the old queen.

I use a combination feeding super-cover and bee-escape board which I think is handy. It is an ordinary bee-escape board with a hole sawed in to receive a 10-pound pail to be used as what is called a pepper-box feeder. After feeding in the fall I tuck a screen over the hole to give upward ventilation. If no ventilation is wanted I place a thin board or enameled cloth over the screen. The screen has a small hole to receive a Porter bee-escape when used as an escape-board. Heretofore I have had trouble in losing chilled bees when transferring lids or feeders in cool weather. This lid is put on early, and the bees can be fed very late in fall, and none lost when pail is removed. In the spring, after brood-rearing starts, I discontinue upward ventilation by covering the screen.

When using the paper division-board don't change frames after bees appear to be united. By putting the queen and her three frames in the center, after the paper had been removed by bees I lost a queen. One colony built cells on the other side of the hive, in which the combs had not been

moved. These bees previously had been superseding an old queen. I destroyed the cells and no more appeared.

St. Louis, Mo. J. H. Fisbeek.

Pollen on Shoulders from Snap-dragon.

On page 727, Aug. 15, Mr. Lovell mentions a peculiar deposit of yellow pollen which he observed upon the shoulders of his bees, and asks an explanation. During the season of 1914 there was a great abundance of blossoms on the plant known to me as snap-dragon, growing on wet, springy ground which had been cleared of birches and willows the autumn before. The blossoms are lemon yellow, a sort of deformed cornucopia shape, and large enough to admit a bee out of sight unless looked for. The bees enter these blossoms and remain two or three seconds, meanwhile moving more or less. When the bee emerges there is some pollen on its shoulders, and each flower entered adds to the deposit. There are no snap-dragon blossoms this season, and no such pollen-marks on the bees.

Some time ago I visited a beekeeping friend forty miles away, and he had noticed this yellow mark on some of his bees. I suggested snap-dragon, and a short search discovered some blossoms and bees working on them, with pollen on their shoulders.

I take it the deposit is entirely incidental. In looking into the hives many bees so marked were seen, but there did not appear to be any attempt by the bee or bees to remove it.

Hoboken, N. J.

C. D. Cheney.

Italianizing a Locality by Supplying Queens for 25c.

I believe a lot of good can come to the beekeeping industry if we will all do a little work in trying to bring to those who keep bees some helps on "preparedness." This is what we are doing when we get our neighbors to take the bee-journals and join one of the beekeepers' associations. The beekeeper needs just as much to be prepared as the farmer, the merchant, or any of the trades, if he is to be successful.

The way I go about getting people interested in bees is very simple. Any one can do it. I made this threefold combination offer in getting my names. Gleanings 6 months, membership in the State Beekeepers' Association, one tested Golden Italian queen, all for one dollar. Association membership is 50 cents; this leaves me 25 cts. for the queen. Some will say that one cannot possibly raise queens for 25 cts. I know this is true; but there is another motive in letting my neighbors have these queens, even tho I might give them away. I am helping to get all the people in my locality to raising Italian bees, and it is thus easier to keep my own bees pure. Every beekeeper in town, and within a radius of three miles, has given me his name and money for this combination

offer. I expect to raise a few young queens at one of my out-apiaries for my own use in replacing the queens taken from those colonies which are preparing to swarm in filling these orders for queens.

Stockport, Ia.

J. W. Stine.

Can You Match This?

Altho I am just a beginner in bee culture I have found that matches are not always handy when I am ready to light up the smoker. On the top of the smoker is a coiled-wire handle for opening the cap. The

space between the two coils is a trifle less than the diameter of a match. Four or five matches may be held, between the wires, and these are usually enough for a day's work. If more than one match is held, heads should be alternated.

Medina, Ohio.

Wesley Manville.

Does Sound Pretty Convincing

I was interested in reading the third item by J. E. Crane, page 714, Aug. 15, referring to the better pollination of fruit trees nearest the bees.

About 50 feet west of my small apiary is a King apple-tree. Last year this tree bore quite heavily on all sides; but it was quite noticeable that the yield was the heaviest on the east side, toward the bees. This year practically all the fruit is on that side of the tree.

Madison, Conn.

F. C. Dowd.

Can bees be kept in the attic of a house? Moline, Ill., July 6.

B. A. King.

[Bees can be kept in the garret, providing sufficient ventilation can be given to prevent combs from melting down. It is usual to put the hives near an opening in the side of the building where the direct sunlight from the windows may not strike them. It would be advisable during the hottest part of the year to have one or more windows open in the garret so that it does not get too hot for the bees.—Ed.]

A. I. Root

OUR HOMES

Editor

For God so loved the world.—JOHN 3:16.

Thy kingdom come; thy will be done on earth as it is in heaven.—MATT. 6:10.

Please notice, friends, the word *world*, "for God so loved the world." It does not read that God so loved the United States, nor England nor Germany, nor any other nation. It is the whole wide world. It is not the American nor European nor German, nor the negroes of Africa. God so loved us all, and sent his only Son to save us all. If that only Son has not yet been presented to every land and every nation, we, his followers, are more or less responsible.

Once more, that wonderful prayer the Master gave us is that God's kingdom may come on *earth*—this whole planet of ours. God is not only no respecter of *persons*, but he is no respecter of *nations*. I confess I did not think of this until quite recently. In *Our Homes* for Aug. 15, under the head of "True and False Patriotism," I said "Love of one's country may not only be a mistake but an instigation of the devil." After I put it in print my conscience troubled me somewhat. I feared I was putting it too severely. Let me now talk about something else, for just a moment, before we get back to "patriotism."

Years ago, when I was new in the Christian work, we had a beloved pastor. He was young, like myself; but I was so much in sympathy with all he was trying to do that I never missed a word from him in the pulpit, prayer-meeting, teachers' meeting, nor any other gathering. He was a man of wonderful talent and ability, together with a bright cheerful outlook in regard to the work of spreading the gospel. Well, among many other kind words I hold in my hand a letter (just received) from him, which reads as follows:

My dear Friend:—Almost a lifetime has passed since you and I shook hands for the first time, and I came among you in Medina as the immature pastor of your splendid church. I remember, with increasing gratitude and gratification, those dear old days in Medina, and you, my dear friend Mr. Root, were always cordial and appreciative of your pastor, co-operative in every good word and work, and a stimulus and comfort to him. A good many of the people that I knew there have passed away. I often think of you and your home, and all the friends who made my years of service there bright and fairly radiant.

GLEANNINGS comes to me regularly, and I enjoy it very much. The copy for Aug. 1 reached my desk yesterday, and I turned to the pages of "Our Homes." The tribute to Mr. Ford is impressive, and I think he is worthy of it. It is a mighty good thing to get a little of the phrase as well as the sentiment of the Scriptures in a periodical.

Please remember me to any friends who may not have forgotten me, and believe me now and always,

Most sincerely yours,

New York City, Aug. 5. C. J. RYDER.

One thing that pleased me about the letter was that he appears to indorse what I said about the possibility of Ford being a Christian, *without knowing it*. Now, if you please, let us go back to that matter about true and false patriotism. With the letter I speak of came a little pamphlet, and I am going to make some clippings from it because it so strongly indorses what I said about patriotism. Below are the clippings:

THE WORLD PROBLEMS OF THE A. M. A.

Secretarial Paper by CHARLES J. RYDER, Sec.

Certain forces which we have thought strong and adequate have proved inefficient in the last few months. Let us note these briefly.

Patriotism has proved a painfully inadequate element in the redemption of humanity. We look across the seas and witness the horrible slaughter and the great crime of the centuries being perpetrated. And yet each nation of either group appeals to patriotic enthusiasm as an adequate motive for these crimes. Patriotism as a motive power for the uplift of humanity is failing wretchedly and miserably.

But in the same terrible conflict science has proved disappointing. Instead of devising means solely for the alleviation of human suffering, science has largely surrendered herself to the production of destructive machinery; of explosive gases; of self-igniting fire, to the disgrace of the name of science and to the horrible murder of human beings. Science has failed. Neither the American Missionary Association nor any other great movement can depend upon science for its impulses of uplift.

Again, secular education has failed. It is impossible to read the utterances of famous university professors in their disgraceful defense of the horrible cruelties and barbarisms without admitting that secular education has failed as a force in the redemption of humanity.

It is a question whether organized Christianity is not failing. Now, if we analyze carefully we discover that the real reason why these forces fail of beneficent results is because they have had no larger purpose than the advancement of their own power and advantage. The patriotism of the European countries that are plunged in war has been a selfish patriotism, a patriotism that sought the aggrandizement of its own nation—not the benefit of the world—but to crush other nations and enlarge its own domain. Education has been used to suppress rather than promote the interests of all humanity. Artificial barriers have been put up around investigation and discovery and research so that the advantages of educational results might be enjoyed only by a single group or nation.

Even organized Christianity represented by the churches has often drawn the lines of demarcation and sought narrow and selfish advantage. Prof. John Briery emphasizes this fact in the following:

"And yet the world's greatest spirits have figured often enough as opponents of human law! Again and again we see them setting the might of their personality against a whole system of regulations, of customs, of authorities. Socrates attacks the Athenian orthodoxy and drinks the hemlock; Jesus puts his 'I say unto you' against the old religion, and is condemned by the church authorities; Lu-

ther, with his 'Here stand I; I can no other,' fronts the whole might of the empire and of the hierarchy; Bunyan breaks the Conventicle Act and find himself in Bedford gaol; Wesley, contrary to episcopal authority, takes to field preaching, and is cast out of the Establishment. Here, you may say, is disobedience, here is defiance of the established order; here is a tremendous self-assertion, a pitting of the single ego against the whole system held as authoritative and sacred.

And why has patriotism proved so inadequate? The reason is not difficult to find as hinted above. Germany has sought her own advantage, and patriotism has simply meant to her and to her citizens the development of her own life and the enlargement of her own opportunities, with no purpose to contribute to the advantage of other nations—the greed of commercialism rather than a generous purpose to divide. And the same has been true of the other contending nations to a great extent. When it comes to an armed conflict the selfish view of national relationships is the dominant view of the so-called patriot. They strive to crush and exterminate rather than to bless and elevate. If the United States presents no larger conception of national duty than that which we see across the ocean, patriotism will fail here as it has failed there. And it ought to fail. The real test is the value to the world and not the advantage to a single national group. We are bound to cultivate and promote this conception of patriotism. Nothing short of this can meet the demands of the world's progress.

In view of the above, I have been wondering if our Fourth of July were not in some respects, especially the way in which we have been celebrating it, a mistake. I do not know whether at this present time England sympathizes with our Fourth of July or not; and I do not know whether any nation besides the United States recognizes the Fourth of July. While considering the matter it rejoices my heart to recognize that the use of firecrackers and toy pistols and cannon has been for the last few years largely done away with.* *Christmas* is a *world-wide* anniversary. All nations can unite in celebrating the birth of our Lord and Savior; and would it not be well if, at this present stage of affairs, we should choose *holidays* that *all the world* can unite on in celebrating? Down in Florida they have a fashion of having their fireworks and things of that sort on Christmas as well as on the 4th of July; but as I have not been in Florida in July I cannot speak from experience.

Right here let me give you a little tract that was sent me by some good brother. It seems to me it points out the outcome of all our trouble, and points to the glad time when God's kingdom shall have come, and his will be done on earth as it is in heaven. I have read it over and over, and every time I read it it gives me a thrill. Here it is. Now see if it does not give you a glimpse of the glad time coming:

* A grandfather, a neighbor of ours in Florida, made each of two boys a Christmas present (?) of a little gun. Shortly after, while shooting fish, one accidentally shot the other, killing him instantly.

OTHERS.

Lord, let me live from day to day
In such a self-forgetful way
That, even when I kneel to pray,
My prayer may be for *others*.

Help me, in all the work I do,
To ever be sincere and true,
And know that all I do for you
Must needs be done for *others*.

Let self be crucified and slain,
And buried deep, and all in vain
May efforts be to rise again
Unless to live for *others*.

And when on earth my work is done,
And my new work in heaven begun,
Let me forget the crown I've won
While thinking still of *others*.

Others, Lord! yes, *others*,
And none of self for me;
Help me to live for *others*,
That I may live for thee!

All that is necessary to make the above apply to patriotism instead of individuals is to substitute "our country" in place of the word "me." Is it not likely that we as a people, say here in the United States, have been praying too much for our own nation and too little for other nations? God knows our nation just now is in sad need of the prayers of Christians; but is it not possible that our nation would be raised up and helped by praying for *other* nations as well, instead of ourselves only, or for our own United States?

The third verse takes hold of me particularly:

Let self be crucified and slain,
And buried deep, and all in vain
May efforts be to rise again
Unless to live for *others*.

May the great Father above bless the message of this Home paper.

~~~~~  
"WHAT HAVE WE TO GAIN BY HURTING ONE ANOTHER STILL FURTHER?"

We clip the following from the *Christian Herald*; and, if I am correct, they take it from *Collier's Weekly*:

What have we been fighting for? What are we fighting for? Do you know? Does any one know? Why am I spending what is left of my substance, and you what is left of yours, to keep on this war against each other? What have we to gain from hurting one another still further? Why should we be puppets any longer in the hands of crowned fools and witless diplomats, even if we were dumb and acquiescent before? Does not the blood of our sons now cry out to us that this foolery should cease? We have let these people send our sons to death.

It is you and I who must stop these wars, these massacres of boys. Massacres of boys! That indeed is the essence of modern war, the killing off of the young. It is the destruction of the human inheritance; it is the spending of all the life and material of the future upon present-day hate and greed.

I think the above hits it pretty well. Modern warfare is the business of killing off our brightest and best young men, and that, too, right in the prime of life. I might add it is the killing-off of the most *courageous and useful* young men the world can produce; and the responsibility, as hinted at above, of having this awful carnage continue, rests on the shoulders, more or less, of every one of us.

Here is something from the *Independent Farmer* along the same line. With what a fine piece of sarcasm they dignify the killing business as a new "industry"!

THE EUROPEAN KILLING INDUSTRY.

The war in Europe is now reaching out toward the two-year mark. Its murderous ramifications now embrace the earth, sky, sea, and subsea. Its industrial and commercial phases and requirements reach to the ends of the earth, and influence the labor and culture of all civilized nations. The war has been so insistent, so steady going in its homicidal enterprises, that the world has come to regard it somewhat as a great industry, not of mining nor of commerce, but of killing. We have become so habituated to the tragedies of this war that any sudden termination of it would give the world something akin to an intellectual shock. The mood, the spiritual attitude would be voiced by the words: Is it possible? Can it be that those demon spirits that have been actuating the warring rulers of Europe

so long have loosed their grip on the mentality of those kaisers and czars and kings and sultans, and that reason has once more been enthroned in the seats where wars are made? There is little doubt that when the end of the war appears it will come upon us suddenly and from an unexpected source.

PREPARING FOR WAR TO PRESERVE PEACE.

We clip the following from the *Christian Herald*, written by Rev. R. C. Helfenstein, pastor of the First Christian Church, Urbana, Ill.:

I believe our nation had a thousand times better make an appropriation for a billion dollars to relieve the suffering millions in Europe today than to spend a billion dollars in preparation for human destruction. I believe America had a thousand times better spend a billion dollars in seeking to promote peace than to spend it in seeking to prepare for war. Suppose we spend a billion dollars in building battleships that are superior to any owned by England or Germany. Those countries would not rest until they had built ships just a little superior to ours, and equipped them with guns that would carry just a little further than ours, and so the game would continue indefinitely. As long as preparedness for war is in vogue, no nation is going to rest until it outdoes the others in efficiency of armament, and hence there will be no rest. Wars and rumors of wars cannot cease so long as nations follow the damnable policy of preparing for war to preserve peace.

POULTRY DEPARTMENT

God blessed them, saying. . . and let the fowl multiply in the earth.—GEN. 1:22.

AN OPEN-AIR "SLEEPING-PORCH" FOR CHICKENS: MY CHICKEN STORY.

For several years past there has been much talk and quite a little excitement about sleeping outdoors in wire-screened sleeping-porches; and a lot of good people sleep practically out of doors in winter as well as in summer, even up here in the North, where we have zero weather; and I believe the general agreement among doctors and everybody else is that outdoor air is of great benefit. Of course elderly people as a rule cannot stand as well the outdoor sleeping-porches in the dead of winter; but the whole wide world has, I am sure, been greatly benefited by what has been said and done about outdoor air, especially during the hours of sleep. There is one queer thing about it that I have never been quite able to understand fully. If I sit down by an open window, especially with my back turned toward the breeze, I am sure to catch a cold. We are told that a "draft," especially on the back of the neck, is apt to do harm. But when one is right out in the wind no harm comes at all. I remember reading about a man who

camped out in California. As long as he slept outdoors on the ground, no matter how cold and windy, he was all right; but when he slept indoors, even with the windows and doors all open, he caught cold, because indoors there was a "draft," or what people call a draft; but right outdoors, say on top of a hill, there is absolutely no such thing as what people call a draft. I can remember the time when doctors told their patients that the "night air" was bad and unwholesome, and advised them to shut every door and window. Yes, I have a few times been obliged to sleep in rooms with every door and window closed because the other occupants of the room could not stand a bit of draft; and it was down in Florida, too, but it was years ago. I have been in church when the doors and windows were all shut tight because some old "granny" couldn't stand the breeze. Well, the whole wide world is "getting wise," at least I hope so, on the importance of outdoor air.

Does some one say, "I thought by the heading that this was going to be a chicken story"? Well, friends, we have just got to the point. I have been telling you all along about the Lady Eglantine chickens. Well,

My "outdoor sleeping-porch" for the Eglantine chickens.

when the hot weather began to come on, they protested against being obliged to sleep in the little poultry-house you see in the picture. They wanted to climb up among the evergreen and maple trees; and some of the enterprising pullets did get away up in the tree-tops. I finally caught them and clipped one wing close, besides clipping the lower branches of the trees, so that the fowls could not roost any more in the tree-tops. Then they got on top of their domicile, and looked so longingly for a branch of a tree that they could reach in spite of the clipped wing that I felt sorry for them. I nailed a pole across just high enough to enable them to hop up on it; and one dark night when they had settled down for their snooze in the open air, Huber, by means of a flash-light, photographed the whole "happy family." The big rooster, four and a half months old, evidently did not wake up. Some of the younger pullets opened their eyes, as you see.

Now, friends, how many of you are keeping your chickens under cover during this hot July and August weather when they would be a thousand times better off in the open air? Don't you believe you would get more and better eggs and more chickens, and better chickens, by having a special sleeping-porch for the *chickens*, as well as one for yourself? Read that first chapter of Genesis, and see how many times mention is made of the "fowls of the air." When it comes toward zero weather up here in the North, very likely they need shelter to prevent freezing the combs. My experience is that, when the fowls have been accustomed to roost outdoors, say in trees, they are loath to go back inside, even when freezing weather comes; but by taking a little pains this can be easily managed.

The spikes that hold the pole are not driven clear in. When the nights become too frosty I propose to take the pole down and teach them to roost inside. When you are traveling again, just take a look at the poultry-houses everywhere. Many of them have glass sashes, which may be all right here in the North for winter, but just see how many houses you can find with glass windows all in place, *all summer long*. By the way, the same thing is true more or less with our stables for horses and cattle. Windows are splendid things in cold weather; but when July and August come along, for humanity's sake *do* pull every window *clear out*; even if storms do beat in a little during the summer time, the harm they do does not begin to counterbalance the lack of abundance of good air. I honestly believe a lot of the troubles with poultry, horses, and cattle, and perhaps pigs also, are the outcome of poorly ventilated sleeping arrangements. See how happy those chickens look on that pole. I can go up in the evening and pat them on the back, and say "Good biddies," and they give me kind words in their own language in return. There are two pullets that will be five months old the first of September. Today is Aug. 23. They have big red combs, and they are singing every day as if they contemplated laying eggs. Don't you believe the outdoor air during these hot months helps them to think of laying eggs?\* Let me digress a little.

Years ago one of my most intimate friends was a beekeeper by the name of Blakeslee. We used to do a lot of visiting

\* Later, Aug. 29.—I hold in my hand a little egg weighing 1½ ounces, just laid by one of my "Lady Eglantines." As nearly as I can figure she will be five months old Sept. 1; so she laid her first egg when 4 months and 29 days old. There is one more

back and forth. He bought my big wind-mill years ago, and paid me for it in bives of bees. Well, one of his daughters is not a beekeeper, but she is a "chicken woman." She has now something like 2000 Leghorns, big and little, and 900 laying hens. These laying hens are shut up in rather close quarters, and never get out to have the run of the farm—that is, after they commence laying. No males are permitted among her laying hens. Miss Blakeslee has one

A GLIMPSE OF THE CHICKEN BUSINESS AND GARDENING DOWN IN FLORIDA IN JULY.

The letter below is a rather long one, I admit; but so many people are wanting to know about Florida in summer time, especially in regard to chickens, gardening, etc., I have thought best to give it entire.

*Mr. A. J. Root:*—The last issue of GLEANINGS has just arrived. I was much interested in reading about your little Eglantines, and had been wondering how they were coming on. I am glad you are having such good luck with them. I used to be very enthusiastic over White Leghorns; but as I am not as spry as when younger, and have a lame back, my enthusiasm has waned. A chicken that is easy to handle, and that will "stay put" suits me better now, so I have taken up the Buff Orpingtons and like them first rate. They are quiet, and good layers. I am trap-nesting a pullet that I call "Lady Valentine" because she laid her first egg on Saint Valentine's day. She has now, in a little over five months, laid one hundred and twenty-five eggs, and is still pegging away; so it looks as if her year's record were likely to be pretty good.

Baskets that brought the nine chicks from Bradentown, Fla., to Medina, Ohio. Three of the chicks were four weeks old, and the other six only one week old.

About two weeks ago I took off a brood of little Valentines. They are husky chaps, and are

pullet that began to lay, I think, when it was only four months and five days old. Well, as many pullets begin to lay when four or five months old, how old must a brother of hers be in order to do his part in the way of "replenishing and multiplying" the "fowls of the air"? This was a query; so I purchased two two-year-old hens of Miss Blakeslee, hens that practically had never seen a male bird since they began to lay. I put the two hens among the Eglantines. They are close to that young rooster there on the perch. You will notice they are apparently "good friends." At this date they have laid 15 eggs, and these 15 eggs are under a sitting hen. When she has had them five days I can tell whether they will hatch or not. If it were not counting chickens before they are hatched I might go on and tell you that I am planning to ship the whole outfit, chickens and all, down to Florida about the first of November. Meanwhile some veteran poultryman might tell me if chickens from those two old hens mated with that cockerel, four and half months old, will produce good strong chickens.\*

doing finely so far, tho I believe July is considered the least favorable month of the year for raising little chicks in Florida. I feed plenty of thick sour milk, and that helps wonderfully to keep them healthy and growing. I suppose the greatest danger that threatens them is that they may get beaten down in one of our dashing summer rains some time when I am not around to hustle them under shelter. I am getting quite a few eggs now from my early spring pullets. I have thirty that were hatched February 3, so they are not six months old yet, but nearly half of them are laying. One began when she was just four months and eighteen days old; several others when they were about five months. I have never had pullets of any of the large breeds reach maturity quite as soon as these. Their mother did not lay till they were seven months old. I attribute their early development to special care in raising them. One thing in particular was—no crowding. I weeded out the cockerels for eating purposes when they were from two to three months old. Then the hens have scarcely known what it was to feel hungry. Plenty of

let mentioned has also commenced laying, as has also one of the pullets hatched three weeks later; or, in other words, this last-mentioned pullet laid an egg when four months and eight days old; and not only that she laid an egg the next day, and still another the third day, and just now promises to lay an egg every day. Of course, the egg is small, but it is an egg. Just one thing more: This pullet has a comb so large, standing straight up, that I feared she was going to be a rooster; and, in fact, she looked like a rooster as she sat there on the nest. Her juvenile cackle (no "rooster") when she comes off the nest is genuine "music" to your old friend A. I. Root.

pullet of the same age which I expect to lay soon. Of course I shall keep a record of the eggs laid by each of these two pullets, and we shall soon know if she promises to be a "chip of the old block."

\* I am sorry to tell you that the sitting hen I put on those fifteen eggs proved to be unfaithful to her task, and not an egg turned out fertile. But in a second setting of 13 eggs, every one proved fertile, so my 5-months-old cockerel is O. K. so far.

Still later, Sept. 5.—The companion to the pul-

grain and green stuff and milk, and a dish of dry bran was kept before them all the time to pick at in their leisure moments.

In a recent copy of the *Rural New-Yorker* I notice they recommend feeding moist mash to hasten maturity in pullets. It has always been a hobby of mine that young chickens thrived best on dry feed entirely; but judging by these Orpington pullets I rather think there is a little something in the mash theory; for when they were small, and till they were perhaps three months old, I was very busy with my farm work, and my wife took charge of feeding them. Contrary to my advice (you know women will do as they please sometimes), she literally stuffed those chickens with mash "because they loved it so." She said I needn't worry about its hurting them any, and it seems it did not. Not a chick was sick, and the only loss was three captured by a hawk. They surely did grow fast. The cockerels weighed nearly three pounds in less than three months, and a pullet laid in less than five. It looks as if the joke was on me. Nevertheless, I still maintain that such treatment would not do for Leghorns, and may be it was only mixing the mash with sour milk that preserved the Orpingtons from acute indigestion.

I see you are raising corn and velvet beans on your Florida land this year instead of feterita, etc. Well, so am I. Last summer my Egyptian wheat, chicken corn, and feterita grew to perfection, making a magnificent crop of heads, and I thought I was going to have an abundance of feed for my poultry; but my experience was similar to yours—the birds did the harvesting. As soon as it started to ripen, the blackbirds came in flocks and droves and stayed till it was gone. I managed to get a few heads by cutting them before they were ripe; but of course that was not much good, so the whole thing was practically a failure, and I made up my mind quite emphatically that this year I would raise something they could not get. I have fifteen acres of velvet beans and eight acres of corn. The beans crushed make a good chicken feed. If there is a mill handy to you in Bradentown you might try some of them next winter. Mine are mostly the Chinese variety. They grow in such big clusters that they are easy to gather; and when I have picked what I need I shall turn my hogs and cattle in to finish the job. I planted velvet beans in my cornfield in the row with my corn, and now they have climbed to the tops of the tallest stalks and have yards of vines waving around up there looking for new worlds to conquer.

We are having plenty of rain here this summer, and things are growing finely. I am going to have a fine corn crop, and my cassava, chufas, Japanese sugar cane, etc., are all looking well.

I must tell you a cassava story that amused me very much. One day last spring I had a long root of it lying on the back porch, which I was showing to a friend from the North.

"My," he said; "I wouldn't want to plant any of that stuff. Think of having to dig down into the ground six or seven feet to get out a crop! How in the world do you ever manage it?"

He was quite relieved when I explained to him that cassava roots have the obliging habit of growing horizontally a few inches under the ground instead of vertically.

Your great-granddaughter surely takes a good picture. She is a mighty bright-looking baby for only eighteen days old, and you can't be too proud of her. Dade City, Fla., July 24. C. H. TRDD.

There are several points in the above letter that interest me greatly, especially the matter of getting pullets to laying when only five or six months old. I have repeatedly hatched chickens almost every winter

month; but so far as I could discover none of them began to lay until they were pretty well toward a year old.

In regard to the feterita, we had a great crop; but the birds had gathered every seed before I got there except a few heads that were gathered and stored away until I got around. And a blight of some sort killed most of the second growth, so we had quite a job of turning the great mass of stalks, some green, and some dead and dry, under the ground. Indeed, it was a benefit to apply this humus, but nothing like the velvet bean or some other *legume*.

#### A. I. ROOT, JR., AND SOME OTHER THINGS.

The readers of GLEANINGS may not all be aware that there is another A. I. Root "coming on." This younger A. I. Root is now eleven years old, and he goes around with his father, E. R. Root, when the father lectures on bees. The son assists also in the handling of bees before the audience. With the above explanation the following letter to Alan I. Root will be understood:

*To Master A. I. Root, Jr.*:—The boys and girls of Empire School have become exceedingly interested in bees. At least two boys have been promised the chance to raise bees this summer at their country homes, and they hope to handle them as did the little Medina boy they saw exhibiting bees.

Three different times the teachers have had tiny soda biscuit and honey for the noon lunch; and a certain home in Lakewood is to include honey on the bill of fare.

Miss Dawson and myself, who are the science teachers, hope by another year to install glass hives, such as your father spoke of, in Empire School. Miss Dawson was very sorry not to meet your father personally. Her grandfather was in the bee business years ago, and her father was one of the earliest subscribers to the "Bee Man." Miss Dawson's sister is trying to make Cleveland a "flyless" city. Doubtless you have heard something about her efforts, and really she has almost accomplished her purpose. Isn't that wonderful?

You chose a very fine gentleman to be named after. Much of the best there is in Medina is directly due to your grandfather. That you will know by and by.

With best wishes for your happiness and success,  
MARY C. PHILLIPS.  
Empire Junior High School, Cleveland, O., May 20.

It was my pleasure a few days ago to meet the good lady who has been the moving spirit in banishing flies from the great city of Cleveland; and, if I mistake not, she has not only (thru the *press*) extended her crusade to the surrounding homes but to surrounding farms in the country.

We have been having the hottest July and August I think I ever witnessed, and hence the weather has been unusually favorable for the propagation of flies; but there are fewer flies in and around our

home, and I think I may say in the office too, than I have ever known before. The fly crusade is proving to be a success. Just

consider for a moment what one woman can do when she has an inspiration: and she is not a very big woman after all.

# TEMPERANCE

## MOB LAW AND THE SALOON BUSINESS AT LIMA, OHIO.

On this first day of September the papers are printing big headlines in regard to a mob of about 3000 that stormed the jail at Lima, Ohio, because a big colored man assaulted a young wife, slashing her with a knife, and because the sheriff refused to tell them where to find the culprit whom he had taken prisoner. They put a rope around his neck and threatened to hang him. See the following from the *Plain Dealer*:

LIMA, Aug. 30.—Sheriff Eley, who escaped the mob, was found hiding in the Elks' home. He was taken to the principal street corner by 1000 blood-crazed men, a rope placed around his neck, and the end thrown over a street-railway pole. The mob threatens to hang Eley unless he tells where the negro is hidden. Efforts of police to reach Eley were futile.

The mob cut the trolley rope from an interurban car and knotted it about Eley's neck. Police are powerless. Chief McKinney has called on all citizens to join his forces, but no one has responded.

If I am correct, this good sheriff refused to hand over the prisoner to a crazy mob, even tho his refusal might cost him his life. Read the following:

Doris, four years old, daughter of Sheriff Eley, died in the city hospital tonight. The child, seriously ill last night, was carried from the sheriff's house when part of the mob went thru the building in search of the sheriff. She died this evening with her bruised and battered father at her bedside.

A sister of Mrs. Eley, a nervous wreck as a result of the violence, is in the same hospital.

### SAY GRUDGE WAS REASON.

Lima officials without any equivocation charge the roughest element of the city with making yesterday's assault on Mrs. Vician Baber by a negro giant an excuse to settle a grudge it has borne Sheriff Eley for a year. County Prosecutor Ortha O. Barr has a list of nearly fifty of the ringleaders of that drink-inflamed mob that wanted to lynch the negro, and then wreaked its vengeance on the sheriff who foiled its plot.

Swift retribution is promised the ruffians who broke into the jail and dangled the naked sheriff at the end of a rope because he would not reveal the hiding place of Charles Daniels, the herculean assailant of Mrs. Baber. Prosecutor Barr will submit his list of names and full details of the orgy to the grand jury next Tuesday.

Mayor Bayliss Simpson and Chief of Police Rollie H. McKinney corroborate the assertion of Prosecutor Barr that the attack on the sheriff was the culmination of a year of persecution following Sheriff Eley's appeal to the militia to stop a prize fight in Lima last Labor Day. Both the mayor and the chief of police have assured Prosecutor Barr they will back him to the limit in his determination to punish the ring-leaders.

There are several things in the above to which I wish to call attention. First, if I am correct this same crazy drunken mob lynched a negro some time ago. Second, it was not their righteous zeal to avenge the wrong suffered by the young woman so much as it was to vent their spite on this righteous and courageous sheriff. About a year ago he was instrumental in stopping a prizefight that was going to be "pulled off" by this same crowd. The county prosecutor tells us there were nearly fifty "drink-inflamed" ringleaders, and things were in such a wretched state of affairs at Lima that a crowd estimated at 3000, full of drink, followed the drunken rabble. I do not know how many saloons are now running in Lima. When the trouble first started, somebody had sense enough to order the saloons all closed. I do not know whether the order was really *carried out or not*.

Just one thing more. There were two saloons in the city that were run by negroes. If any town or city permits colored men to run a saloon, selling to black or white or anybody else, is it anything strange that a colored man, crazy with drink, should assault a defenseless white woman? Nothing is said in any of the papers, so far as I can gather, about going to the bottom of the matter, and closing the saloons, *for all time to come*. The order was given to close the saloons *after* the drunken mob got under way; but it did not seem to occur to anybody that the saloons running day and night, full blast, would, as a matter of course, bear just such fruit as Lima is now gathering. Has not the prohibition wave reached Allen Co.? and is it not about time that she decide, like the rest of the world, that it is the *saloon* that is the real guilty party—not the negroes nor the Indians, nor low-down white men? May God help us.

"MOB TONIC;" SHALL OHIO CONTINUE TO SUPPLY IT?

After the above was in print I found the following in the *American Issue* for Sept. 8. Notice the concluding words:

### LIMA MOB STARTED FROM A SALOON.

According to press reports, it was a liquor-inflamed mob which disgraced Lima last week, and which resulted in the sheriff nearly losing his life, and in the death of the little daughter of the sheriff from the shock of the mob's attack on the jail to get a prisoner to lynch him.

Dispatches are to the effect that the nucleus of the mob was formed in one of Lima's "respectable" licensed saloons, and that the drinking of liquor nerved the men for their lawless act. The evening of the day following the work of the mob, the saloons of Lima were closed at 6 o'clock to prevent further trouble.

This is the first work of an Ohio mob since last January, when drink-crazed men burned and looted East Youngstown and destroyed a million dollars' worth of property and killed several persons.

John Barleycorn is right on the job when the mob plans its lawless deeds, and the booze demon gloats over the havoc for which he is largely responsible.

The tragedy at East Youngstown last January, and the inexcusable action of the mob at Lima last week, furnish two more cogent reasons why Ohio should rid herself of this mob tonic.

#### THE CONSUMPTION OF LIQUOR; IS IT ON THE INCREASE OR DECREASE?

So many statements are made in *some* (?) papers, to the effect that the consumption of liquor is on the increase I thought best to refer the matter to the General Superintendent of the Anti-saloon League, and here is his reply:

*Dear Mr. Root:*—All the *Vindicator* says may be true, which does not mean anything, for these reasons: First, when liquors are withdrawn from bond they appear on the Internal Revenue Report as "consumed," while they may not be consumed at all. They may be withdrawn and placed in warehouses for various reasons, as is often the case. But the Internal Revenue Department puts this down at once as *consumed* because the Internal Revenue Department cannot follow them to their ultimate destination. There may have been an exceptionally large quantity, as is often the case, withdrawn in that particular month.

Second, it may be possible in the consumption of beer that May showed an increase. The great munition factories that are running full heat, and employing hundreds of thousands of men at large wages, many of whom are drinkers, may have consumed a good deal of beer during that month. It should be remembered, however, that there was a decrease in the consumption of beer last year of about two million barrels, and this supposed increase is not an increase over the original amount consumed, but an increase over that consumed last year, which was a great decrease over preceding years. These things fluctuate when regarded by the month. It is year by year that shows the steady throttling of the traffic.

P. A. BAKER, General Superintendent  
Anti-saloon League.

Westerville, O., Aug. 18.

In addition to the above I think I have seen it stated that large amounts of alcohol are now being used in the manufacture of explosives for the "war industry," and that this has been counted in with the consumption of liquors as a beverage. The finances of the various breweries as given in our newspapers indicate also that the booze "industry" is on the decline.

After the above was dictated we found the following, which I clip from the *National Daily* for Aug. 21:

#### SLUMP IN LIQUOR CONSUMPTION.

WASHINGTON, D. C., Aug. 19.—The liquor-revenue collections for the fiscal year 1916, exclusive of

emergency revenue, shows a decrease in receipts on beer of \$1,155,327.35 as compared with the previous year. This is according to the preliminary report of Internal Revenue Commissioner Osborne.

According to the Commissioner's report, there was produced, during the past year, 32,613,050 gallons of denatured alcohol, used exclusively in the arts, industries, and for scientific purposes, of which 19,666,901 gallons were used in the manufacture of munitions and smokeless powder.

It is estimated by experts who have examined the preliminary report of the Internal Revenue Commissioner that the full report will show that the amount of whisky consumed for beverage purposes the past year is 1,609,343 gallons less than the amount consumed in the fiscal year of 1915; while the slump in the consumption of beer in 1916 as compared with 1915 is 1,182,193 barrels.

#### ALMOST A MILLION DOLLARS' WORTH OF LIQUOR DESTROYED.

\* We clip the following from the *American Issue*:

Grard is a little town along the Georgia-Alabama border. Liquor producers piled booze into the town, expecting to ship it over all the dry territory. But the dry laws of Alabama and Georgia interfered. It is estimated that nearly one million dollars' worth of liquor was stored in the town. The judge ordered the stuff destroyed, and every day a deputy sheriff and a posse of men have been engaged in smashing bottles and emptying kegs.

It is estimated that \$300,000 worth of intoxicants was poured into the river in one day. An attempt was made to stop this wholesale destruction of the liquor, but the judge ordered the officers to proceed. Some of the fellows engaged in handling the stuff are being handed out heavy sentences. C. G. Phelps was fined \$2500 and sentenced to three years in prison. Benjamin Edwards was fined a like sum, and sentenced to prison for 30 days.

If this kind of work continues, the liquor people had better pack up and retire as quickly as possible.

Here is something more from the *American Issue*, along the same line:

#### TRYING TO ESCAPE THE STORM.

Philadelphia saloonkeepers are alarmed at the tidal temperance wave which is sweeping the country, and 240 of them want to quit the business. Dispatches say that more than 1000 saloons thruout Pennsylvania are on the ragged edge, and are seeking customers. Real-estate brokers making a specialty of handling this class of property are loaded down with lists. What is worrying the saloonkeepers of Philadelphia is the probability of the coming legislature enacting a local-option law.

#### "GOD'S KINGDOM COMING."

We clip the following from the *Youth's Instructor*:

When the province of Ontario goes dry September 16, by act of the provincial legislature, Toronto, with 400,000 population, will be the largest dry city in the world.

One of our office force informs me that he was in Toronto only a few days ago; and he said the whole great city was actually busy in "preparedness" for the coming temperance victory. He says he met one man who said something like this: "It is

true I have been drinking more than I ought to; and I, for one, am 'confounded' glad of what is now coming."

"FORTY DISTILLERIES AND A DOZEN COTTON-MILLS;"  
NOW, "SIXTY-EIGHT COTTON-MILLS, NO  
DISTILLERIES."

For many months I have been reading your temperance articles in GLEANINGS, and enjoy them very much. I want you to see what has been done in this county along that line. I am enclosing you a small folder showing the advancement that Gaston County has made. I am a young man, but I can remember when Gaston Co. had more than 40 distilleries and a dozen cotton-mills. Today this county has 68 cotton-mills and, of course, no distilleries.

Gastonia, N. C., Feb. 23. J. L. BEAL.

We clip as below from the folder:

Indeed, the old order of things has changed. Less than 34 years ago the good old home-grown "corn liquor" whose excellences of quality one so often hears extolled, flowed, almost as free as water, in the valleys and on the hills of Gaston. It was made on the banks of every stream, and was dispensed at the rate of "all you can drink for a nickel" at almost every cross-roads grocery in the county. Today you can't legally get a nickel's worth "for love or money."

"LOOK AT THE MONEY THAT WAS IN IT."

I presume our readers have noticed a statement in the papers to the effect that a fiend in human shape in New York has confessed to being instrumental in getting *hundreds of young girls* into the white-slave traffic. The clipping below from the *American Issue* gives us the particulars:

The New York *Evening Sun* of August 16 recounted how Yushe Botwin, seated in the center of a circle of newspaper men in the private chamber of District Attorney Swann, told his amazing tale of his life in the underworld. The story was so startling as to cause District Attorney Swann to exclaim:

"This man has told me a story which amazes and shocks me, and I am frank to say that I did not think anything so terrible could exist in this city."

The *Sun* said:

"Thruout his entire story the feeling of Botwin that the District Attorney had done him an irreparable injury to deny him the means of a livelihood was apparent. The question of right and wrong has never entered his mind. His arrest, he thinks, was a great injustice, and should never have taken place. "Did it never enter your mind what a great wrong against society you were doing, and how you were deliberately ruining the lives of hundreds of innocent young girls?" Mr. Swann asked the prisoner.

Botwin shrugged his shoulders, and with an amazed look on his face, as tho that were an entirely new idea, said: "Look at the money that was in it."

The liquor interests rest their claim for existence exactly upon that same foundation—the money that is in it. "Great is Diana of the Ephesians!"

White slavery and the liquor-traffic travel hand in hand.

The above holds up to the whole wide world the real attitude, not only of the white-slave traffic, but of the entire liquor-traffic, in a way I have never seen it before. This fellow, after his confession, seemed to think the "big money" that was to be made in the business was a sufficient *excuse* for entrapping and debauching and sending down to ruin innocent young girls—just such girls as we have in our own homes. If there ever was a human being on the face of the earth that is not fit to be permitted to live another twenty-four hours, it is this fiend in human shape who gave as an excuse or as a plea for letting the business continue. "Look at the money that was in it."

# HIGH-PRESSURE GARDENING

## BEES AND "GRAPE JUICE."

There has been a good deal said about the importance of bees to fruit-growers; but I have never before seen an intimation to the effect that bees were in a like manner an important adjunct to a good crop of grapes. I clip the following from the *Florida Grower*:

### BEES HELP POLLINATION OF GRAPES.

Having heard many complaints as to Muscadine type of grapes not bearing well, and also having numerous failures ourselves here at Oneco, I wish to state to the readers of the *Grower* that I think the matter is easily solved. It is not the lack of pollen only, but lack of a carrying agent; and where bees are kept the grapevines are annually loaded with fruit; where there are no bees, the vines have very few or no grapes.

It is absolutely necessary, we have decided, to keep bees near grape-orchards if one expects to get any fruit regularly, so we have invested in a lot of bees, having seen our neighbors with bees enjoying a big

crop of grapes every year. The Mish grape now ripening is the earliest of the Muscadines, and to our personal taste the finest grape that grows—vines simply loaded down, with bunches up to 20 or more grapes each, perfectly sweet and delicious. Now we know that bees insure a crop of grapes, there is apparently no reason why all these various Muscadines cannot be grown in enormous quantity all over Florida and the South.

E. N. REASONER.

I am very glad indeed to get the above, especially as it comes from such an excellent and reliable authority as our good friend E. N. Reasoner, of the Oneco Nursery. So far as I know, grape-growing has not assumed such importance in Florida as to grow grapes enough to furnish the grape *juice* that is now getting to be such a staple article all over the great wide world. May God *hasten* the time when fruit juice and milk will take the place of beer and other intoxicants.

## THE AVOCADO (OR ALLIGATOR) PEAR.

On pages 170 and 171 of GLEANINGS for Feb. 1, 1915, I gave you quite a little in regard to the above fruit which is making so much of a stir in California and Florida. The tree in California that was valued at \$30,000 is still bearing fruit and buds. From the *Good Health Clinic* I clip the following statement from an address delivered by the Governor of New York.

Flynn tells us that we would live forever if we ate the avocado (alligator pear) every day, because it gives us meat, vegetable, and fruit combined; but that is rather begging the question, because there are not enough raised to supply one person in one thousand, and in the Northland they retail for \$6 to \$8 a dozen. There would be just as much sense in the Esquimaux telling us that we should all live upon whale's blubber.

From the quantity of fruit that had set on the trees when I left Florida toward the first of May, it looked to me as if the price would soon come down from what it had been. I hardly think our trees are large enough to bear fruit this year. The trees belonging to our neighbors, close by us, and across the way, were literally loaded down with fruit. Everybody seems to praise it. It is very likely, however, as suggested in the above, that nature provides, or at least provides within easy reach, the food that is particularly beneficial in any particular climate. I have often thought of this, when partaking of our delicious grape fruit that grows in such abundance right before the open door, that seems to be provided particularly to quench the thirst and give health and enjoyment to the people who live where frost and snow are almost entirely unknown.

## SWEET CLOVER TAINING MILK AND BUTTER.

We clip the following from the *Country Gentleman*:

## SWEET CLOVER AND MILK.

We are learning new things about new and old crops all the time. Many growers claim that sweet-clover pasture will not affect the flavor of milk, but the subscriber who wrote the following letter knows that it did do it in at least one case:

"A year ago we planted a patch to sweet clover. As our winter oats froze out it was our earliest pasture, so we put our cow in this field. The clover tainted the milk, however, and I could not sell the surplus butter, as the customers did not like the sweet-clover flavor. We now have the cow in the woods pasture, and there is no unpleasant odor or taste to her milk or the butter.

"We put her on the sweet-clover pasture in the morning and kept her in the oats-field at night, and there was a vast difference in the taste of the morning and evening milk; now the taste is the same at both milkings.

"We will plant sweet clover again this fall, but not as a dairy feed."

The above is indeed a surprise to us. In all the reports we have had for years past

in regard to sweet clover for milch cows we cannot now recall ever receiving a word in regard to its tainting milk, and we must think this report is an exception to the general rule; and we are inclined to think, also, that there is a possibility that this sweet clover is peculiar, or that there is some other explanation for it. Will our readers report if they have ever had the same experience? We ask this because we have had so many reports favoring sweet-clover hay and sweet-clover pasture for both milk and butter.

## DANDELIONS AS A HONEY-PLANT.

You say dandelion is a great honey-plant. I have been looking it over of late years, but have seen but one bee on it. You must have a different kind of plant, or a different bee. Most of the bees about here are blacks or hybrids, and they do not bother dandelion at all.

I like your journal. I too am getting to be an old man. I am in my 70th year, and I have never been under the influence of strong drink, and I do not know what lager beer tastes like. I think any man that gets drunk has nobody but himself to blame. The saloon-keeper has no power to compel any one to drink his stuff.

I am a great-grandson of a private in the Revolutionary War. His name was Henry Jamison.

LEMUEL B. JAMISON.

Englishtown, N. J., May 8.

My good friend, dandelion, like almost all other sources of honey, has its off and on years; and I suppose locality has much to do with it. With us here, as it is about the first thing that the bees can work on most seasons, there is a great roar over the fields of dandelion. Sometimes the bees get only a little honey as well as pollen.

You are right, perhaps, in saying that "saloons have no power to compel," etc.; but the fact that they do by some means get hold of our boys and lead them astray is reason enough why they should be done away with.

We are glad to hear from a descendant of one of the heroes of the Revolutionary War.

## ANARCHY, RIGHT HERE IN OUR UNITED STATES OF AMERICA.

We clip the following from the *Youths' Instructor*:

During 1915 there were in this country sixty-nine lynchings, seventeen more than in 1914. In four cases it was later proved that the victims were innocent. Three of those lynched last year were women. Leading universities of the Southern states are starting a movement to put an end to this lawlessness, which is a disgrace to the country.

God hasten the time when law and order shall rule, and not crazy mobs that defy law.

## DANGER MYERS

**TREE DISEASE IS PREVENTABLE BY SPRAYING MYERS WAY**

## SPRAY PUMPS

FOR SPRAYING PAINTING OR DISINFECTING

TO the man experienced in fruit growing Fall Spraying means healthy trees that will require but little more care the following spring. Fall is the season to successfully fight scale and similar tree diseases by spraying, and you want the best equipment obtainable for this work. MYERS will fill the bill, and whether your orchards are extensive or include but a few trees there is a MYERS OUTFIT that will just fit your needs. Myers Spray Pumps are also adapted for painting, disinfecting and similar work.

The Myers Line includes Bucket, Barrel and Power Pumps and Complete Outfits with such improvements as our patented easy operating Cog Gear Head on Hand Pumps and Automatic Pressure Controller on Power Pumps—You get these and many other exclusive features when you purchase a MYERS. Write today for large Catalog. It's free and a postal will bring it to your door.

**F. E. MYERS & BRO.**  
NO. 351 ORANGE ST.  
ASHLAND - OHIO.

### QUEENS AT FIFTY CENTS

These queens are guaranteed to be as good as money can buy. They are bred by the same and with the same care as the high-priced ones. They are bred from imported mothers, the best in the world, and will produce bees that are the best for honey-gathering, gentleness, and not inclined to swarm.

Golden Italian queens that produce golden bees; the highest kind, gentle, and as good honey gatherers as can be found; each, \$1.00; 6, \$5.00; tested, \$2.00; breeders, \$5.00 to \$10.00.  
J. B. BROCKWELL, Barnetts, Va.

Golden Italian queens, bred strictly for business, that produce a strong race of honey-gatherers. Untested queens, 75 cts. each; \$8.00 per dozen; \$60 per 100. Prompt service and satisfaction guaranteed. L. J. DUNN, box 338J, Rt. 6, San Jose, Cal.

**GRAY CAUCASIANS.**—Early breeders, great honey-gatherers; cap beautifully white; great comb-builders; very prolific; gentle; hardy; good winterers. Untested, \$1; select untested, \$1.25; tested, \$1.50; select tested, \$2.00. H. W. FULMER, Andalusia, Pa.

**FOR SALE.**—Italian bees, 1 lb. with queen, \$2.25; one-frame with queen, \$2.00. Queens, 75 cts. each. Safe delivery guaranteed; 30-page catalog with bee-keeper's outfit for stamp. THE DEROY TAYLOR CO., Newark, N. Y. (formerly Lyons).

My bright Italian queens will be ready to ship April 1, at 60 cts. each; virgin queens, 30 cts. Send for price list of queens, bees by the pound, and nucleus. Safe arrival and satisfaction guaranteed. M. BATES, Rt. 4, Greenville, Ala.

**FOR SALE.**—Three-banded, hardy, northern-bred Italian queens, bred from the best honey-gatherers obtainable. Untested, \$1.00; select tested with wing clipped, \$3.00; also Golden and Carniolans at same prices. F. L. BARBER, Lowville, N. Y.

My breeder, a daughter of one of Dr. Miller's best queens, is proving superior to any I have been able to procure. Daughters of this queen, untested, 75 cts. each; \$8.00 per dozen.

J. I. BANKS, Dowlstown, Tenn.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, beautiful and gentle. Mated, \$1.00; 6, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SONS, Wilcox St., Binghamton, N. Y.

Queens for requeening. Best on market. One untested, \$1.50; 12, \$12.00; one tested, \$2.00; 12, \$18.00; one select tested, \$3.00; 12, \$24.00. Special low price on 50 or more. Write. Safe delivery and satisfaction guaranteed. THE J. E. MERCHANT BEE & HONEY CO., Canton, Ohio.

The Stanley Improved Cell-starting Hive and Queen-rearing Outfit, complete, \$5.00. The same with a choice breeder, \$6.00. Warranted Italian queen, 60 cts. each. Tested, \$1.00. Virgin, 25 cts. Choice breeding queens, \$2.25. ARTHUR STANLEY, 1907 Washington Blvd., Chicago, Ill.

**QUEENS.**—From a strain of Italians, wintered for thirty years in the foothills of the Adirondack Mountains out of doors. Hardy, gentle, industrious, and fine resisters of disease. \$1.00 each, or \$9.00 per dozen; also nuclei and full colonies.

CHARLES STEWART, box 42, Johnstown, N. Y.

**QUEENS.**—Improved three-banded Italians, bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.

H. C. CLEMONS, Rt. 3, Williamstown, Ky.

**TENNESSEE-BRED QUEENS!** My three-band strain that has given such universal satisfaction for over 40 years. Orders filled promptly or money returned by first mail. 1000 nuclei in use. Tested, in June, \$1.75; untested, \$1.00; in July, \$1.50 and 75 cts. Postal brings circular.

JOHN M. DAVIS, Spring Hill, Tenn.

**HOLLOPETER'S** honey-gathering strain of Italians are now at their best. This strain has a record of 100 lbs. more honey per colony than the average colony. Safe arrival by return mail. Untested queens, each, 75 cts.; 10 for \$6.00, 20 for \$10.00. Tested queen, each, \$1.00. 1 lb. bees with queen, \$2.00. We are booking orders now for spring delivery. J. B. HOLLOPETER, Pentz, Pa.

**FOR SALE.**—Three-banded Italian queens and bees from the best honey-gathering strains obtainable. Untested queen, 75 cts.; 6, \$4.25; 12, \$8.00; tested queens, \$1.25; 6, \$7.00; 12, \$12.00. For select queens, add 25 cts. each to the above prices. For queens in quantity lots, or bees by the pound, write for prices. ROBT. B. SPICER, Rt. 181, Wharton, N. J.

Famous Howe's, Root's, Moore's, Davis' select strain of honey-gatherers, disease-resisting. None better for all purposes. Untested, one, 75 cts.; doz., \$7.50. Select untested, one, \$1.00; doz., \$9.00; ½ doz., \$5.00; tested, \$1.25; doz., \$10; select tested, one, \$1.50; ½ doz., \$8.00; extra select \$2.00. Bees by the pound, \$2.50 with queen. Honey crop short. Will have plenty of bees in June.

H. B. MURRAY, Liberty, N. C.

**PURE ITALIAN QUEENS.**—Golden or three-banded by return mail. All queens are warranted purely mated. They are large and long-lived. They have proven themselves highly disease-resistant in many localities. One select untested, \$1.00; 6, \$4.25; 12, \$8.00; 100, \$60.00. Tested, \$1.25. Bees by the pound, nuclei, colonies. Safe arrival and satisfaction I guarantee. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

**THE BARGAIN OF THE SEASON.**—Listen: *The Beekeepers' Review* for two years would be \$2.00; 10 three-banded Italian untested queens at 50 cts. would be \$5.00; total, \$7.00. Send us only \$5.00 and receive the *Review* for 1916, 1917, mailing you the back numbers for this year, and 10 untested Italian queens direct from our breeders in the South. Prompt delivery. To get this exceptional bargain, address all orders to THE BEEKEEPERS' REVIEW, Northstar, Mich.

**FOR SALE.**—65 colonies Italian bees, \$250; all in hives used about two years; 8-frame L., wired full sheets; combs enough for 30 or 40 colonies extra. These bees produced 60 lbs. of honey this year; bee-ware comb-honey supers for above hives, never used; new Root automatic reversible extractor, storage tank, feeders, queen-excluders; in fact, every thing a beginner would require; every thing good and up to date; honey enough on hives (white clover) to winter bees; no disease. Write if you mean business.

M. E. BABB, Rt. 7, Xenia, Ohio.

## Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER. By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE. By "The Spectator," of the Outlook. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES. Our new complete catalog, mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER. Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES. The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING. Just the thing for the up-to-date housewife. Price 10 cents.
- BEES AND POULTRY, how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES. A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE. A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES. A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.
- THE BUCKEYE HIVE, or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET CLOVER, the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE. A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth. \$1.00 postpaid.

## TRADE NOTES

### SECOND-HAND 60-LB. CANS.

Our supply of second-hand cans at New York has been disposed of; but we still have a good supply both at Medina and Philadelphia of choice cans suitable for use again in shipping honey. These we are selling at \$4.00 for 10 cases; \$8.50 for 25 cases; \$30.00 for 100 cases.

### NEW 60-LB. CANS.

We will still furnish, from Medina only, new 60-lb. square cans, 2 in a case, at the prices listed in our catalog—85 cts. per case; \$8.00 for 10 cases; 25 cases or more, at 75 cts. To buy new stock from the factories at prevailing prices we should have to pay 25 per cent more than they cost less than a year ago. If you need any, send us your orders.

### HOTBED SASH AND GLASS.

The season for using hotbed sash is approaching. We are prepared as usual with a choice grade of cypress sash which we will continue to furnish at former prices, viz., \$1.00 each, K. D.; \$4.75 for 5, or \$9.00 for 10. The regular size, which is furnished when no other is specified, is 3 1-3 feet wide by 6 feet long, made for four rows of eight-inch glass. Bars are grooved for glass to be slid in end to end. We also furnish them rabbetted for glass to be lapped and set in putty. If you prefer this style be sure to mention it in ordering.

Glass prices are greatly advanced, so that we must ask for 8x10 glass, \$3.50 per box of 90 lights.

BUSHEL BOXES.

We have on hand, ready for immediate shipment, a good stock of these boxes, packed as shown in cut. They are made with oak corner posts and bottom end slats to receive the nails, the remainder of the box being basswood. They are very convenient, and popular for handling potatoes, apples, onions, and other farm crops. They hold a heaped bushel level full, so they can be stacked any height desired. To reduce stock we offer them for a short time at the following special prices:

All slatted bushel boxes, per crate of 14, \$2.25  
Slatted bushel boxes, per crate of 12, \$2.10  
Galvanized bound boxes, per crate of 12, \$2.75  
In lots of 10 crates or more, 5 per cent discount.  
The all-slatted is the cheapest, and the most popular style. Two are nailed in each package, and sufficient nails are included for the remainder.

### EARLY-ORDER CASH DISCOUNT.

The usual custom of allowing a discount for early cash orders for goods for next season's use is continued this season. The discount begins with 5 per cent for September cash orders instead of 7, which was given in former years. The discount applies to the latest revised prices with the usual exceptions on certain classes of goods. No discount will apply on orders for shipping-cases, cartons, labels, tin and glass honey-packages, bees, queens, paint, bushel-boxes, hotbed sash, seeds, honey, and printed matter.

Where goods named in the list of exceptions form not more than 20 per cent of a general order for hives and other beekeepers' supplies, the discount may be taken on the entire order. The discount is allowed only for payment of cash during the month

of September, whether goods are shipped or not. For payment in October the discount will be 4 per cent; during November, 3 per cent; during December, 2 per cent.

### COMB HONEY SHIPMENTS IN WESTERN TERRITORY.

Since the first of September all local or less than carload shipments of comb honey in territory west of Chicago and Mississippi River are rated double first class, making the shipping charges so high as to be almost prohibitive. When we learned some weeks ago that this change in classification had been made we gave notice of it in the editorial columns, suggesting that those interested should write to the chairman of the committee protesting the increase. We are now in receipt of a notice from the chairman of the committee, that, under docket No. 914, the Western Classification Committee will, on Thursday, Oct. 26, take up and consider a proposed change, making second-class rates apply on comb honey in less than carload lots, and fourth class in carloads. Interested parties desiring to appear and present argument will be heard at 3:45 p. m. in the committee conference room, 1836 Transportation Building, Chicago, Ill., on the date named. We plan to be represented, and suggest that concerted action by associations of beekeepers be taken, arranging with some one to represent their interests, to appear. This change, if it can be brought about, will mean thousands of dollars saved to the beekeepers in transportation charges on their product. This change cannot well be made soon enough to be of benefit on shipment this fall; but if we may look with hope for some relief for the future it will encourage some to continue producing comb honey who otherwise would give it up in favor of extracted.

THE A. I. ROOT CO., MEDINA, O.

## Special Notices by A. I. Root

### THE ANTI-SALOON LEAGUE YEAR BOOK FOR 1916.

I hold in my hands the above book of 310 pages. It gives correct statistics in regard to temperance and the use of intoxicating liquors covering the whole wide world. First an extensive account is given in regard to prohibition in Russia. The statements are from absolutely reliable sources; and after Russia a review is made of every nation in the world, noting both past and present conditions, and giving a birdseye review of the progress of temperance laws and temperance legislation. The above includes South America and American possessions not belonging to the United States. Then a vast array of facts is given in regard to the progress of each separate state of the American Union. Great numbers of wet and dry maps are given in order that one may note the astonishing progress, especially the progress being made at this time from wet to dry. For instance, Florida has only five wet counties containing saloons, and only nine towns or cities not under prohibition. Those of you who have been getting discouraged in regard to the slow progress of temperance had better have this book and look it over. Of course the liquor forces have published a similar book. I think they give it away, and there is scarcely a periodical now published that will accept statements from them, in defense of the liquor-traffic, unless it is a *paid advertisement*. Now, when somebody raises the question as to which is right, the liquor people or this year-book, call his attention to this fact:

The Anti-saloon League Year-book is gotten up by Christian people. It is the work of the churches and schools and colleges, and the physicians and scientific men of our land. Their evident desire is to benefit and uplift, not only our nation, but all the nations of the earth. In contrast with this I hardly need tell you the book put out by the liquor people is solely selfish. It is the inspiration of greed and avarice. They want to prevent their business or "industry," as they call it, from being driven entirely from the face of the earth. As a matter of course you can get their books free of charge; and they have millions of money, or at least they have just now, to push their hellish schemes. The Anti-saloon League tells us that *business men* everywhere have most cheerfully furnished facts and material for the book. The price in paper covers is 25 cents; bound in cloth, 50 cents. Address Anti-saloon League of America, Westerville, Ohio.

# A Wonderful Book . . . .

This is the judgment of  
every thinking man  
who has read

“The Story of  
the Soil” By Prof.  
Cyril G. Hopkins

It covers the whole field of life on the  
farm, soil fertility, and perma-  
nent agriculture.

---

## What They Say About It

“Holds the intense interest of the read-  
er.”

—Ohio Farmer.

“The farmers owe Mr. Hopkins a debt  
of gratitude.”

—Chicago Tribune.

“Worth millions to the farmers of  
America.”

—Prairie Farmer.

“Ought to be in the hands of every  
farmer in the world.”

—Farmer and Breeder.

“I enjoyed every word of it. A fasci-  
nating novel about the soil.”

—Editor American Agriculturist.

“A wealth of information.”

—Editor Wallace's Farmer.

“The book is destined to do more good  
and stir more thought among the farmers  
of this country than any other publication  
that has yet appeared.”

—Ex-Gov. W. D. Hoard.

---

## Don't Wait Till They are Gone

This book formerly sold for \$1.62 in cloth binding. A few days ago we secured from the publishers the entire remaining stock of this great book in paper binding and can offer it with “Gleanings in Bee Culture” for one year at \$1.15. When this consignment of these books is exhausted we shall be unable to furnish more.

**DON'T WAIT.** Get in your order today.

# Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

|                         |                               |                               |

# Special Bargains in Shipping-cases

With the bountiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

- 3 crates of 50 each, 9½ inch, 2-row, at \$4.00 per crate.
- 19 crates of 50 each, 10 inch, 2-row, at \$4.00 per crate
- 13 crates of 50 each, 6¼-in. 3-row, at \$4.00 per crate.
- 56 crates of 50 each, 12-pound cases, at \$4.00 per crate.

All of the above have either 2 or 3 inch glass, and take 12 sections 4¼x1½x1½ plain.

There are also for the same size section, packed 10 in a crate:

- 10 crates of 10 each, 9½-in. 2-row at 85 cts. per crate.
- 3 crates of 10 each, 6¼-inch, 2-row, at 85 cts. per crate.
- 4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.

- For the 4¼x1½ leeway section we have:
- 4 crates of 50 each, 15¼-inch, 2-row, for 15 sections, at \$4.50 per crate.
- 6 crates of 10 each, 15¼-inch, 2-row, for 15 sections, at 95 cts. per crate.
- 10 crates of 50 each, 11¾-inch, 2-row, for 12 sections, at \$4.00 per crate.
- 6 crates of 10 each, 12-lb. safety cases with cartons at \$1.20 per crate.
- 3 crates of 10 each, 8-inch, 3-row, for 12 sections, at 85 cts. per crate.
- 2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate.

- For 24 sections, 4¼x1½ plain:
- 2 crates of 10 each, 9½-inch, 4-row, at \$1.75 per crate.
- 3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.

- For 12 sections 4x5x1¾:
- 15 crates of 50 each 3-row cases, at \$4.00 per crate.

## ADDITIONAL SHIPPING-CASES AT BRANCH OFFICES.

- 4 crates, 50 each, 24-lb. cases for 4¼x1½ sections at \$8.00 per crate.
- 4 crates, 10 each, same, at \$1.70 per crate.
- 4 crates, 50 each, 16-lb. cases for 4¼x1½ sections at \$4.50 per crate.
- 7 crates, 50 each, 12-lb. cases for 3¾x5x1½ sections, at \$4.00 per crate.
- 2 crates, 10 each, same, at 85 cts. per crate.

We also offer the following glass jars, to close out at special prices, subject to previous sale.

### At Mechanic Falls, Me.

- 5 gross ½-lb. square jars, with corks, at \$4.00 per gross.
- 29 cases of 2 dozen each, Simplex or Federal 1-lb. jars at \$1.10 per case.

### At Philadelphia Branch.

- 1 gross ¼-lb. square jars with cork, at \$3.25.
- 10 cases ½-lb. square jars with cork, 75 cts. case of 2 dozen.
- 1 gross ½-lb. square jars with cork, at \$4.00.
- 8 cases ½-lb. square jars with cork, 90 cts. case of 2 dozen.
- 4 gross 1-lb. square jars with cork, \$5.00.
- 3 cases 1-lb. square jars with cork, \$1.10 case of 2 dozen.
- 5 gross 2-lb. square jars with cork, at \$7.50.
- 37 cases 1-lb. Simplex jars, 2 dozen per case, at \$1.30.

### At New York Branch.

- 4 bbls. of 7-oz. tumblers, 24 doz. to barrel, at \$5.00 per barrel.
- 11 gross of 2-lb. square jars with cork, 6 dozen to case at \$7.50 per gross, \$4.00 per case.
- 13 cases of 2 dozen each ½-lb. square jars with cork, at 90 cts. per case.

### At Washington, D. C.

- 3 bbl. 12 dozen 1-lb. Simplex jars at \$5.25 per bbl.
- 1 bbl. 12 dozen 1-lb. No. 25 jars at \$5.00 per bbl.
- 2 crates 12 dozen 1-lb. Simplex jars at \$5.00 per crate.
- 1 case 2 dozen 1-lb. Simplex jars at \$1.10 per case.

These are fine for exhibition purposes.

- 4 dozen ½-lb. Hershiser jars with nickel tops at 50 cts. a dozen.
- 11 doz. 1-lb. square Hershiser jars with nickel tops at 65 cts. a dozen.

THE A. I. ROOT COMPANY, Medina, Ohio

## SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

### Shipping-cases in Flat, without Glass.

|                   |                                      |                          |

## HONEY GRADING RULES

GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

### COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY 6, 1915.

### COMB HONEY.

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight. All such honey should be disposed of in the home market.

### EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed, in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L. A.," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

### STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

## YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

**THE FRED. W. MUTH CO.**  
"THE BUSY BEE MEN"

204 Walnut Street.

CINCINNATI, O.

## HONEY MARKETS

### BASIS OF PRICE QUOTATIONS.

The prices listed below, unless otherwise stated, are those at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

LOS ANGELES.—Most of the honey is harvested, and the limited crop has been a great disappointment; even Imperial Valley (the sure-crop country) fell down worse than ever before. The whole of southern California has not produced over twenty-five per cent of a crop, or one-half as much as in 1914 or 1915, which were about fifty per cent seasons. Most of the extracted honey has been sold at high prices, but the demand is falling off and prices range about one-fourth of a cent lower. Prices being paid producers, f. o. b. common shipping point, in carloads: Extracted, white, 6¾; light amber, 5½ to 6; amber, 5. Comb ranges from \$2.25 to \$2.75 per case. We were offered a car of No. 1 and fancy white Inyo County comb today at \$2.75 per case.  
Los Angeles, Sept. 7. G. L. EMERSON.

ST. LOUIS.—Weather conditions will soon improve the demand for honey. Our market is in good condition for receipts of extra fancy comb honey, as receipts from local growers so far have been very light. Southern extracted is in good demand, with stocks just about ample. We quote comb honey, extra fancy (per case), \$3.25; fancy, \$3.00; No. 1, \$2.75; No. 2, \$2.50; extracted white, per lb., 8½ to 9; light amber, in cans, 6½ to 7; barrels, 6 to 6½; amber, in cans, 6 to 6½; in barrels, 5 to 5½. Clean average yellow beeswax brings 28½.  
St. Louis. R. HARTMANN PRODUCE CO.

PHOENIX.—Demand good; in light orders, less than car lots, a shade better than at the opening of the season. Car lots of amber are somewhat lower—at least ¼ ct. per lb. Extracted honey, white, brings, per lb., 7 cts.; light amber in cans, 5½. Clean average yellow beeswax brings 26 to 27.  
Phoenix, Sept. 13. WM. LOSSING.

IDAHO FALLS.—Demand this season exceeds the supply, as the crop was almost a total failure. Practically all of the honey produced has been sold, and we have nothing to offer for market. We quote fancy comb honey at \$3.25; No. 1, \$3.00; No. 2, \$2.75. Extracted white brings 7½ to 10.  
IDAHO HONEY-PRODUCERS' ASSOCIATION.  
Idaho Falls, Sept. 25.

CHICAGO.—The supply is heavy, but the quality is of the best where it has been properly ripened. Dealers are expecting to sell more than the usual quantities, as the flavor is of the kind that asks for the second helping. We quote extra fancy comb honey, per case, 16 cts. in sealed cartons; fancy, 15, cartons or plain; No. 1, 14; No. 2, 12 to 13. White extracted, per lb., 7 to 8; light amber, in cans, 6 to 7; barrels, 6 to 6½; amber, in cans, 5 to 6; in barrels, 5 to 5½. Clean average yellow beeswax brings 30 to 32.  
Chicago, Sept. 16. R. A. BURNETT & Co.

ALBANY.—Increased demand for honey as soon as the weather is cooler. Receipts are light, more on account of beekeepers delaying getting ready than lack of honey. Honey-producers make mistake in not sending their honey to market as early as possible for best prices. Extra fancy comb, per case, 16; fancy, 15; No. 1, 14 to 15; No. 2, 13. White extracted honey, 8½ to 9; light amber, in cans, 7½ to 8; amber, in cans, 7½. Clean average yellow beeswax brings 32 cts. per lb.  
Albany, Sept. 20. H. R. WRIGHT.

KANSAS CITY.—Honey demand is slow; offerings in car lots are increasing. We quote extra fancy comb honey, per case, \$3.00 to \$3.25; No. 1, \$2.75. White extracted honey brings 8½ in jobbing way; light amber, in cans, 7 to 8; amber, in cans, 7. Clean average yellow beeswax brings 25 cts.  
C. C. CLEMONS PRODUCE CO.  
Kansas City, Sept. 20.

INDIANAPOLIS.—The demand for both extracted and comb is not as good as it should be for this time of the season. Very little honey has reached us so far, and what has is not of extra-good quality. However, we are quite sure there will be a heavy demand for glass goods next month. No. 1 comb brings \$4.00 per case; No. 2, \$3.50 and \$3.60. White extracted brings 10 to 11.  
Indianapolis, Ind. WALTER S. POWDER.

CINCINNATI.—The demand for comb honey is not as good as it was last season. We are selling No. 1 comb honey, 24 sections to the case, at \$3.75 per case; lower grades are not wanted at any price. White-clover extracted honey in 60-lb. cans, 7½ to 9; amber extracted in barrels, 6½ to 7½. The above are our selling prices, and we buy at less than the above prices. We are paying 28 cts. per lb. for choice bright yellow beeswax.  
Cincinnati, Sept. 16. THE FRED W. MUTH CO.

CLEVELAND.—There is no special change in our market since our last quotations. The supply is very limited, but is fully equal to the demand, which is extremely light thus far. We quote fancy comb honey, \$3.85 to \$4.00 per case; No. 1, none in market.  
C. CHANDLER'S SONS.  
Cleveland, Sept. 18.

PORTLAND.—Reports in general are of a good honey crop, far above the average, A1 quality, with mountain districts still to be reckoned with. No. 1 is selling at 20 cts. per section; 2 for 35 cts., retail; wholesaling at about \$3.00 per case of 24 lbs.  
Portland, Sept. 19. PORTLAND SEED CO.

PITTSBURGH.—Demand not as yet opened up. Moving out slowly. We quote comb honey, extra fancy, per case, \$4.25; fancy, \$4.00; No. 1, \$3.75; No. 2, \$3.00 to \$3.25.  
Pittsburgh, Sept. 26. W. E. OSBORN CO.

MONTREAL.—Clover crop this year was up to the average; quality very good. Buckwheat crop is late, and below the average in quantity. We quote extra fancy comb honey, 16; fancy, 15; No. 1, 14 No. 2, 12. White extracted honey brings 11; light amber, in cans, 10; in barrels, 9½; amber, in cans, 9; in barrels, 8½.  
GUNN, LANGLOIS & Co.  
Montreal, Sept. 20

HAMILTON.—Honey is a good crop, quality fine. We quote comb honey, extra fancy, per case, \$2.35 per dozen; fancy, \$2.25; No. 1, \$2.00; white extracted, per lb., 12, in 60-lb. cans; light amber, in cans, 11½.  
MACNAB ST. BRANCH, F. W. FEARMAN CO., Ltd.  
Hamilton, Ont., Sept. 20.

TORONTO.—The honey crop in Ontario, Canada, was of good quality, and abundant; and, owing to the scarcity of fruits, it is expected that good prices for honey will obtain. We quote white extracted, 60-lb. tins, at 12½.  
Toronto, Sept. 16. ELY-BLAIN, Ltd.

MATANZAS.—Amber honey in barrels and cans, 46 cts. per gallon.  
ADOLFO MARZOL.  
Matanzas, Cuba, Sept. 20.

MEDINA.—We have had an active demand for comb as well as extracted honey the past month, as is usually the case in September. Offerings of eastern honey are much larger than usual, and average prices slightly lower than last year. Western prices are variable, due to crop conditions. Old stock (1915) comb honey seems to be nearly all cleared up. Offers were received from Ohio producers today on first-quality white-clover extracted at 7¼ cts. f. o. b. shipping-point. Others are holding at 7½ to 8. Comb is being offered us at \$3.00 per case for fancy white; No. 1 at \$2.75 delivered at Medina.  
Medina, Sept. 28. THE A. I. ROOT CO.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; untested, 60 cts.; 12 for \$6.00. Tested, \$2.00; select tested, \$3.50; breeders, \$5.00 to \$10.00. Will replace inferior queens. Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

The Stover Apiaries, Mayhew, Miss.

### Special Notices by A. I. Root

#### THE NATIONAL TEMPERANCE SOCIETY OF NEW YORK.

I feel ashamed to confess that it is only recently my attention has been called to the fact that the National Temperance Society of New York is not only the oldest temperance society but perhaps one of the best equipped of any in the land, or may be in the whole wide world. As it is non-partisan, like the Anti-saloon League, I cannot understand just why the Anti-saloon League has not had more to say in regard to it or why it has not been more closely affiliated with it. Well, this temperance society publishes three bright and beautiful periodicals—first, the National Advocate, now in its 51st year; second, the Youth's Temperance Banner, also in its 51st year—one of the brightest and prettiest little monthlies that I have ever gotten hold of, and *The Water Lily*, a monthly for children, that is worth its price, and ever so much more, to look at the pictures if nothing else. The price of all three periodicals is ridiculously low. The weekly is only \$1.00 a year; the *Youth's Temperance Banner* is only 30 cents, and the *Water Lily* only 15 cents. If you do not subscribe, send at least for sample copies and see if I am not right in thinking them among the very best periodicals for the home—especially a home where there are children.

#### NOT CERTAIN HE IS GUILTY.

As we go to press we learn by the papers that the colored man mentioned in last issue may not be the guilty party after all. What about mob law and the work of "mob tonic" now?

#### STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., OF GLEANINGS IN BEE CULTURE, PUBLISHED SEMI-MONTHLY AT MEDINA, OHIO, REQUIRED BY THE ACT OF AUGUST 24, 1912.

Editor, E. R. Root, Medina, Ohio; Managing Editor, H. H. Root, Medina, Ohio; Business Manager, J. T. Calvert, Medina, Ohio; Publisher, The A. I. Root Co., Medina, Ohio.

Owners: The A. I. Root Co. Stockholders holding 1 per cent or more stock as follows:

A. I. Root, Medina, Ohio; E. R. Root, Medina, Ohio; H. H. Root, Medina, Ohio; A. L. Boyden, Medina, Ohio; L. W. Boyden, Medina, Ohio; J. T. Calvert, Medina, Ohio; Frank Spellman, Medina, Ohio; H. E. Aylard, Gdn., Medina, Ohio; A. A. Bostwick, Seville, Ohio.

There are no bondholders, mortgagees, and other security holders, holding 1 per cent or more of total amount of bonds, mortgages, or other securities.

(Signed) E. R. Root, Editor.

Sworn to and subscribed before me this 28th day of September, 1916.

(Signed) FRANK SPELLMAN,

Notary Public.

(My commission expires Feb. 17, 1917.)

## BANKING BY MAIL AT 4%

# Only One Dollar

That is all that you need to open a savings account in this strong safe bank, BY MAIL, where 4 per cent interest, compounded twice a year, is paid.

Complete safety for all deposits is assured by our capital and surplus of \$100,000, conservative management, and strict state supervision.

Deposits may be safely sent by mail in the form of a check, draft, money order, or the currency by registered letter.

## "If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

**Walter S. Pouder, Indianapolis, Ind.**  
873 Massachusetts Avenue

# New Bingham Bee Smoker

has been on the market nearly forty years, and is the standard in this and many foreign countries. It is the all-important tool of the most extensive honey-producers of the world. For sale direct or by all dealers in beekeepers' supplies.

- Smoke Engine, 4-inch stove.....\$1.25
  - Doctor, 3 1/2-inch stove......85
  - Two above sizes in copper, 50 cts. extra.
  - Conqueror, 3-inch stove......75
  - Little Wonder, 2 1/2-inch stove......50
- Hinged cover on two larger sizes. Postage extra.

## TIN HONEY-CANS---LOW PRICES

Five-pound friction-top pails, lots of 50 at \$2.75; 100 lots, \$5.20; crates of 203 at \$10.00.

Ten-pound friction-top pails, lots of 50 at \$4.00; 100 lots, \$7.50; crates of 113 at \$8.30; 565 at \$40.00, f. o. b. Chicago.

Sixty-pound cans, two in a case, 70 cts. per case. Quantity lots, 67 cts. per case; crates of 50 at \$12, f. o. b. Chicago or Ohio factory. Prompt shipments are being made at this time.

A. G. WOODMAN COMPANY, Grand Rapids, Michigan

## PENNSYLVANIA BEEKEEPERS

Our 1916 catalogs now out. Postal will bring you one. Root's goods at Root's prices. Prompt shipment.

# Wanted--Honey

## Both Comb and Extracted

If comb honey, state grade and how it is put up, and your lowest price delivered Cincinnati.

Extracted honey, mail a fair-sized sample, state how it is put up, and your lowest price delivered Cincinnati.

If prices are right we can use unlimited quantities.

---

C. H. W. Weber & Company, Cincinnati, O.  
2146 Central Avenue

## WHY NOT

### Order Your Supplies for Next Season Now?

---

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 4 per cent discount during October. Send in your order just as soon as you find out just what you require and we will take care of it promptly.

---

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

## HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual ones. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found that when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

### Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. **PREPARE!** Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

#### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

G. B. Lewis Company, 51 Watertown, Wisconsin, U. S. A.

Send for catalog giving name of distributor nearest you.

## DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

### Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me.

A. W. DARBY, Alburg, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

NO. 19

## EDITORIAL

Don't fail to read honey-market quotations this issue, page 893.

Mr. Latham is a good beekeeper and a careful observer.

THE beautiful picture of basswood on our cover for this issue is the work of Dr. E. F. Bigelow.

### Wrapping Hives in Newspapers for Winter

THIS practice will do very well where the climate is not severe. The plan spoken of by J. A. Allard, on page 936, will answer some winters; but it should not be relied on. A super with packing on top is quite important; but better by far have packing on four sides as well as top.

### Net-weight Law Not Effective in Iowa

THE pure-food commissioner of Iowa has explained to our representative that the Iowa law, as it now stands, does not make it necessary to mark the minimum or net weight on sections mentioned by Mr. Pellett on page 773. While this may be true, we still feel that it is very important that every Iowa beekeeper mark the minimum weights on his sections as has been explained in these columns.

### Italians Less Inclined to Swarm than Blacks

MR. J. L. BYER, in his department in this issue, exactly voices our opinions and experiences in opposition to Mr. Allen Latham when he says Italians, in the production of extracted honey, are much less inclined to swarm than Caucasians and blacks; and why Mr. Latham finds the reverse to be true he is not able to understand. We shall have to charge up the difference to locality, for

### Two-colony Winter Cases

THERE is a good deal in favor of a double winter case as described by Mr. Wiggins in this issue, page 916. The expense of housing a colony of bees, however, is necessarily a little more than where four hives are put in a case. It is a question whether the extra expense fully compensates for the disadvantage.

### Sealed Covers vs. Absorbents

MR. W. S. WIGGINS, in this issue, page 916, wishes to know why we advocate sealed covers in place of absorbents. We advocate it only for this locality; if Mr. Wiggins will turn to our book, the A B C and X Y Z of Bee Culture, he will see we distinctly state that the matter has to be determined by local conditions.

### A Division-board when it is Too Much of a Good Thing

THE average beekeeper, when he gets a hive with a full complement of frames and division-board, seems to have the impression that the division-board should be left in the hive. Ordinarily the division-board should not be used except when there is less than the full number of frames. We therefore agree with Mr. Tarlton-Raymont on this point on page 920 of this issue.

### Mid-winter Breeding

IT will be remembered that some years ago we were successful in building up some weak colonies in one of our bee-cellars by feeding candy during January and February. Ordinarily the practice is not to be recommended; but our colonies were short of stores in one of the yards, and we were

compelled to feed. They were not only short but quite weak. The candy feeding in the spring resulted in some fine booming colonies. We succeeded that winter but we did not succeed another winter. Taking it all in all, we quite agree with our correspondent J. E. Hand in what he says in this issue on page 915.

### Easy Way of Selling Honey

LAST winter we had a visit from G. W. Bell, of Bell's Landing, Pa. Mr. Bell has a unique method of disposing of a part of his crop without any effort. He lives on the New York Central Railroad, and there are six passenger trains a day, besides a number of freight trains. Of the twelve conductors on the passenger trains there is only one who does not buy honey. The brakemen also buy considerable, as do also some of the crew of the freight trains.

The trainmen first started buying honey by seeing shipments of his honey, and so they gradually began buying, taking more and more until he disposes of about 1000 pounds of comb honey a year in this way with absolutely no effort on his part.

Mr. Bell produces comb honey principally, altho he does considerable extracting as well. He has a rack for holding sections, and he extracts all the honey from the unfinished sections, and uses the combs for baits the next season.

### A Honey-Advertising Campaign

THE A. I. Root Company's full-page honey advertisement in the *Ladies' Home Journal* and *Good Housekeeping*, reaching five million readers, is apparently having its effect. When all the prospects looked favorable for a big crop of honey in the East, and when it was apparent early in the season that the honey market was on the toboggan slide, going down, down, down, an aggressive movement was decided on. The campaign featured the advertising of honey as a food, and, of course, the Airline brand in particular.

The October *Ladies' Home Journal* reached the housewives, the particular buyers of honey, Sept. 20, all over the United States.

Later.—What one of the largest distributors of honey in the West thinks of this is shown by the following:

We have just seen the October number of the *Ladies' Home Journal* and have admired the full-page advertisement your firm has in same regarding Airline honey. It is certainly very tastily gotten out and ought to bring

good results. Every beekeeper should appreciate what you are doing to popularize the use of honey in the home.

The Colorado Honey-producers' Ass'n,  
F. Rauchfuss, Manager.  
Denver, Col., Sept. 22.

### The Disappearing Disease in Mrs. Allen's Apiary

IN this issue, page 907, Mrs. Allen describes exactly the symptoms of what was supposed to be the Isle of Wight disease in the western part of Ohio, and which created quite a stir in the newspapers, especially when it was learned that a representative from Great Britain, and two or three representatives from the bee-inspection department of Ohio, were to make an investigation. As our readers now know, nothing very serious was found, and the trouble has entirely disappeared. It seems that Mrs. Allen found exactly the same thing in one of her colonies. At all events, she gives the exact symptoms that we found at Weston. Whatever it was or is, the disappearing disease has disappeared. The same disease that showed itself in Oregon, down the Mississippi Valley, in parts of Texas and Oklahoma, and which threatened to wipe out whole colonies last season, did not appear this year.

### Wintering Hives Buried in the Snow

ON page 322 of this issue Mr. John Mack shows his hives almost entirely buried in snow. Notwithstanding the hives were buried from November till March 25, he wintered without loss. But when the climate is such that the weather changes from warm to cold, so the snow thaws enough to cause the water to run into the entrances, and then freeze, there is danger of a severe loss. At outyards where it is practical to get the snow away from the entrances it is best to do so when the weather is changeable. On the other hand, where the weather is mild and there is changeable weather, the snow will not be very deep. Where the climate is cold enough so that it does not warm up all winter, bees can lie buried in the snow without much danger. Like everything else in bee culture, this is a matter of locality.

### Diagnosing Colonies by External Indications

WE regard Mr. J. L. Byer, of Markham, Ontario, as one of the best beekeepers on the continent. He started with absolutely nothing, raised a family, and now is one of

the successful producers in Ontario. It was with no little interest that we read his endorsement of our editorial on page 775—especially where he says that that method of diagnosing has been a common practice with him during the past season. We feel sure that many beekeepers are wasting time in digging down into the brood-nest and lifting heavy supers in the busy part of the year, and when it is practically impossible to hire skilled help. A good many, if they only think so, can determine the condition of their colonies, so far as mere room is concerned, in a very short time, and without taking out a single frame.

If one is running for the production of *comb* honey, he may have to pull out some frames to find queen-cells; but in the production of extracted honey he can often keep ahead of the bees, as Mr. Byer explains in this issue, without doing any heavy lifting or pulling out the frames. Of course, a beginner or an ordinary beekeeper could not do this kind of diagnosing.

### Honey-crop Conditions and Prices; Market Recovering

AT this time we are in possession of definite information showing that the honey crop in the great West is somewhat lighter than usual—so much so that the large crop in the East may not be able to take care of the market demand. At all events, it is apparent that the general market on honey has stiffened. Whether it will go higher than present quotations, as shown by our Honey Column, we are not able to say. Apparently all of last year's comb honey has been cleaned up, and the demand for both comb and extracted at this writing is brisk.

The rising prices on other food commodities and the fact that the total amount of honey produced in the United States, including the East as well as the West, is possibly no larger than usual, will have a decided effect in making the market firm, altho it is very doubtful if it will reach the quotations of last year. About the time beekeepers begin to dump their comb and extracted honey in the big marketing centers (and that will be from the first to the middle of November), prices will probably ease up. This is strictly in accordance with all past experience. If possible, producers should get their crops on the market earlier before the usual congestion.

A careful survey of the government weather maps (which we are getting daily) shows that the drouth of late summer has probably been broken in most clover local-

ities. Some reports already in show that clover is recovering nicely. On the other hand, our Canadian correspondent, Mr. Byer, refers to the drouth in Ontario as being so severe that buckwheat is practically a failure.

*Later.*—Since the above was written, later quotations printed on page 893 would indicate a more conservative trend in the market than what we have indicated.

*Still later.*—The following report from Idaho Falls, Ida., dated Sept. 25, has just been received from the Idaho Honey-producers' Association, and gives the honey-supply condition in a section that last year produced an immense amount of comb honey. "Our crop has been practically a total failure this season. What little there was is all sold, and we have nothing to offer for market. There will be no honey in this section until another crop is raised next year."

### European Foul Brood being Brought under Control in Colorado

IN this issue our correspondent, Mr. Wesley Foster, tells us that European foul brood is being brought under control in Colorado; and he hopes that in the near future it will be stamped out.

Nearly all beekeepers in Colorado produce comb honey on a commercial scale. Most of them are good beekeepers—men who are posted in regard to the latest developments concerning this disease. Italian queens of resistant strains are being introduced. The dequeening and requeening treatment is being employed without the destruction of combs with good results.

The Colorado beekeepers are right in line with the very best practices now in vogue with respect to the European disease. It is probable that this disease will never make very much headway in Colorado or among up-to-date beekeepers—those who are posted; but it will eliminate the careless and the ignorant. One who does not take a bee-paper of any kind, and has only a few colonies on the farm, is being forced out of business.

### Glassed vs. Cartoned Comb Honey

SINCE the net-weight provisions of the national pure-food law went into effect, sections of comb honey with glass panels have almost entirely disappeared from the market. Formerly the glass was sold at the price of the comb honey; and under this order of things the producer could well afford to glass his sections, for he could sell the glass at the price of the honey and make

a big profit; but that day has passed. When Uncle Sam put out the ruling that comb honey would hereafter have to be sold at its actual or minimum net weight, exclusive of its container, sections, carton, or glass, it eliminated the glass and put cartons to the front.

A correspondent from Buffalo writes us that he has about 3000 lbs. of the last year's crop of comb honey, glassed on both sides. He has been trying to find a buyer for it, and he appears to be willing to take any kind of offer. He says it is all New York state comb honey, but apparently nobody wants it. He has been to great expense in putting it up in glass, and now he must sell it, if he sells it at all, at the mere price of the comb exclusive of the weight of the section and glass.

We cautioned our readers against putting up comb honey in glass, at the time the new ruling went into effect; but apparently some of the beekeepers of the state did not see it; or if they did they did not see the point—namely, that glass cannot be sold any more at the price of comb honey.

In this connection it is interesting to observe that cartoned honey is becoming more and more popular. Cartons are inexpensive. They protect the section as well as the comb honey, and practically eliminate broken comb honey during shipment, because they cushion the delicate combs in such a way that they absorb the shocks and jars incident to transportation. Moreover, they are more sanitary. Some cities have already passed ordinances requiring all packages of food to be sealed, away from flies and dust. 'Tis well.

### Extension Work in the South; Increased Appropriation for Bee Culture in Washington

THE members of the National Beekeepers' Association will remember that a committee of two, consisting of Mr. Frank C. Pellett, of Iowa, and E. R. Root, of Ohio, were appointed to see what they could do toward securing an additional appropriation for apiculture in the Bureau of Entomology, Washington, D. C. Both Mr. Pellett and Mr. Root appeared before the Agricultural Committee. Altho they did not secure as large an appropriation as they hoped, they did succeed in getting an increase of \$5000. While there was some opposition on the floor of the House, Congressman Leaver, chairman of the committee, and Congressman Anderson, an influential member of the committee, put it thru,

This increase of \$5000 makes a total appropriation for apiculture of \$25,000. As to how the \$5000 increase is to be used will be explained in a letter from Dr. Phillips from the Bureau, which follows:

Mr. E. R. Root:—You may be interested in learning that the present agricultural appropriation bill carries an increase of \$5000 for the work in beekeeping in this Bureau. It is proposed using this fund to inaugurate extension and demonstration work in beekeeping in the southern states, similar to the work done by Mr. E. G. Carr for this Bureau last year in North Carolina. Arrangements have already been completed for the continuance of the work in North Carolina, in co-operation with the North Carolina Department of Agriculture, and Mr. George H. Rea, former inspector of apiaries of Pennsylvania, has gone to Raleigh to begin work. Negotiations are under way for similar work in another southern state, concerning which announcement will be made later. A third man is to be employed to do work of a more general character thruout the South, in co-operation with the Office of Extension Work in the South of this Department. In all cases the men employed are to work in close co-operation with the County Agricultural Agents.

The southern states offer great opportunity for beekeeping, and much interest has been shown in this work. There are no sections of the country where there are more bees, altho many of them receive inadequate care. An interesting fact is that the South now consumes almost all of its own honey, and buys some from other sections of the country. For these and many other reasons, it has seemed best to confine this work for the present to the southern states.

E. F. Phillips, Apiculturist.

Beekeeping in the South, in many portions, is in the box-hive or log-gum stage. While it is true that there are many good beekeepers there—some of the very best in the country—there are thousands and thousands who are keeping bees in the old-fashioned way. The bee-moth kills off a large number of the colonies, and bee disease is just making a start. Extension workers are already in the South, and it is now proposed to send experts to enlighten these extension workers so that they in turn can show these log-gum beekeepers how to keep bees, and at the same time vastly increase the yield per colony.

While the present appropriation for the work is only a drop in the bucket, it will mean a good start. The Southland has wonderful possibilities in the way of honey production; and as soon as its beekeepers are taught modern methods of honey production, the resources of these states will be vastly increased.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

A MISSOURI correspondent asks how late in the season bees will build comb. They will build it as late as they gather any surplus, provided they need it for storing.

PAPER division-boards for introducing queens and uniting, p. 873, seems a variation of the newspaper plan that was born here. The variation is, no doubt, effective; but the plain newspaper plan is no doubt just as effective, and a good bit simpler and easier. Kill the old queen, lay a sheet of newspaper on the top-bars; over this set a hive-body containing the nucleus having the queen, and close bee-tight. That's all; in three, four, or more days you can shift brood-combs from upper to lower story.

MR. EDITOR, it might be a good plan to have a lot of labels printed with the words "Demaree plan," so as to label properly the plan every time it is sent in as something new. Its latest appearance is at the top of page 804, Sept. 1. Briefly, Put in upper story all but one brood, leaving in lower story one brood with queen, and filling vacancies with frames filled with comb or foundation. An excellent plan to prevent swarming, but please let it always have the proper label. [The suggestion is a good one. As the Demaree plan has been spoken of considerably it will be incorporated under the head of "Swarming, to Control," in the next edition of the A B C and X Y Z of Bee Culture.—Ed.]

JOHN A. MCKINNON has sent me two queen-cells I would not have supposed possible, and I am forwarding them herewith. The extreme length of one is  $\frac{1}{2}$  inch; of the other 9-16. They are sealed, and he says contain larvæ less than 48 hours old, built by a strong three-story colony

fed a quart of syrup daily. I don't think I ever before saw a sealed queen-cell with a larva less than 72 hours old, and the cell was always full length.

P. C. CHADWICK, p. 718, I'm with you and fornenst Wesley Foster. I'm a bit skeptical about there being such a great danger of disease thru surplus sold on the market. I've had some experience in feeding honey stored by colonies having Euro-

pean foul brood, and never knew it to convey the disease. Of course that doesn't prove it never does. I know of two cases of American foul brood treated in this way: The colony was allowed to store a story of sealed combs. In the fall its brood-combs were exchanged for this story of sealed combs. Thus it was left with no honey but that which it had itself stored. Next year no sign of the disease appeared.

H. H. ROOR, even tho you claim the role of the "little dog," the beekeeping fraternity is indebted to you for a valuable contribution to apicultural literature. In nicety of exactness, that report of M. T. Pritchard as to the stages of the development of a young queen, p. 805, is the best of anything I know of on record. Many thanks, Mel. The most difficult thing I found in such experiments was to know within an hour just when the eggs were laid; but I never thought of emptying eggs out of the cells. Of course there will be variations, but under proper conditions for queen-rearing it is likely that Mr. Pritchard's figures may be taken as standard: from the laying of the egg to hatching, an hour or two less than 3 days (which agrees with the orthodox "three days" of many years); time from hatching of egg to sealing, from 5 days to 5 days 3 hours, which agrees with Cowan's 5 days (I have known larvæ in sealed cells so small that the time could hardly have been more than 3 days); and the time from laying of egg to emergence from cell from 15 days lacking 2½ hours to an hour more than 15 days. This last is the most important item. It agrees with observations I made, pleading that, instead of continuing to say "16 days," we should call it "15 days." Fifty-five years ago it was 17 days, then for many years 16 days, and it's time now that we should say—correctly—15 days.

You give my estimate of time from hatching of egg to sealing in direct quotation, "never more than five days." Please play fair, Huber. I made no such positive assertion—didn't know—merely asked the question, "does it ever happen in more than five days?" Replying to your question, "What would these figures have been under less favorable circumstances, cool weather, weaker colony, etc.?" I reply, if it's any comfort to you, that the time might be "six to eight days" or more; but do we want to raise queens under such circumstances?

I'm ready to sic, but hardly see occasion to sic the "big dog."

Grace Allen

## THE DIXIE BEE

Nashville, Tenn.

Now that we have requeened the rest of our little yard, we have nothing but pure-bred 1916 Italian queens in every hive. We hope in this way to winter well, to have no cross bees to bother our nice, polite neighbors next summer, and to be more nearly prepared to resist foul brood—when it comes; and come it surely will if not wiped out of this neighborhood promptly, for it has only to come down the pike a bit to start playing in our back yard.

\* \* \*

I am increasingly aware that I can not handle full-depth supers. Right now, in mid-September, when they are nowhere near full, I come in really over-tired after lifting a few of them off and setting them back on, to get into brood-chambers. Eventually we shall probably be forced into shallow supers, and I don't happen to like them—nearly twice as many frames and bodies to handle, practically double the work getting the equipment put together, and a whole lot more expense. But—not much more than half the weight.

\* \* \*

Tennessee farmers are adding every year to the acreage put into crimson clover, as well as sweet clover—a fact that rejoices the heart of the beemen as well as the farmers themselves. In a letter written this spring, Mr. Ben G. Davis says of Maury County, "Before the farmers began to use crimson clover here, we had a dearth of nectar from apple bloom till white clover. Now this is filled in nicely, as we have hundreds of acres of crimson clover all around us. We have also one neighbor who put in 25 acres of sweet clover this spring, another 20, and still another 5, so in a few years we hope for a midsummer flow, as I feel sure more of them will go into it when they find how fine a soil-builder it really is." Incidentally, those great fields of crimson clover in full bloom are wondrously beautiful.

\* \* \*

Interesting indeed is the article, page 447, June 1, "The Changes which Occur in the Egg," by Dr. James A. Nelson. In the constant presence of such marvels as described therein, it would seem impossible for any beekeeper to lapse into the Peter Bell attitude of mind. Rather let us realize, with Dr. Nelson, that the "real riddle of development still remains unanswered," and

feel the same awe and wonder and reverence in our contemplation of a bee-egg in the waxen cell that Tennyson and the scientist who quoted him in the classroom felt toward the "flower in the crannied wall."

\* \* \*

Referring to painting hives, I notice that Mr. Miles, page 475, June 15, says that paint for the first coat on new work should be thinned with pure linseed oil. Our paint-man tells us that for new work on *pine* the first coat is better thinned with linseed oil and turpentine mixed, 1-3 oil and 2-3 turpentine; for the second coat, reverse the proportion, making it 2-3 oil and 1-3 turpentine; for the third coat, all oil, no turpentine. This heavy proportion of turpentine in the first coat is particularly important on southern pine, he stated, while for northern pine a smaller per cent might be used, the third coat in each case being thinned with the pure linseed oil.

\* \* \*

I believe it was the lack of shade that lost us a swarm. Ten days after we had requeened a certain strong colony with a very disagreeable disposition, they cast a swarm. Knowing that the queen, whether the one given them or one of their own rearing, was unclipped, I labored mightily that hot day to hive them. Mr. Allen was in town, four miles away, and standing in the tippest top of a step-ladder, reaching up into space and the bees and a peach-tree, was strenuous work, especially for one taking things a bit easily this summer; but finally I had them more or less inside an unpainted shallow hive, the only one I had, with several drawn combs. I was wise enough that day to give them shade—such a hot little home—but as the improvised shade-board was an essential part of a chicken-house it was removed that evening. In the morning I neglected either to replace it or to provide another; and while I was away from home, out came our swarm and flew to parts unknown, leaving eggs behind. Well, the next time there'll be shade.

\* \* \*

The editor asks for reports from those who have tried the Fowls adaptation of the Alexander method of making increase. Both last year and this we tried it in a limited way, and it has worked satisfactorily both seasons, except that, with us, the bees in the original brood-chamber, set off later to the new stand, have not stored any surplus. Of

course last year there was practically no surplus stored here by any colony, but this year things are different. Yet these bees with the old brood and the queen-cell, tho they have gathered some honey, have put it all into the brood-chamber, apparently not being strong enough to go up into the shallow supers. In the case of the old queens, however, left on the old stand with one frame of brood and nine sheets of foundation, things were better. Super work is continuing nicely this year, and there has been no lack of interest in the lower stories, as Mr. Brumfield experienced, page 457, June 1. Both years the foundation was drawn out rapidly, and soon the queens were laying in the new combs.

But Mr. Brumfield departed from Mr. Fowls' method in at least two points. He placed the old brood-chamber immediately above the queen-excluder, whereas Mr. Fowls especially emphasizes the necessity of two or three empty supers between. He also gave the upper story an entrance at the back, which Mr. Fowls does not. These points of difference may not account for the condition of neglect in the lower hive complained of by Mr. Brumfield; but, again, they may have been contributing factors. At any rate, does not swarm control thus practiced become an adaptation of the Fowls method rather than the Fowls method itself?

\*\*\*

One day, about the first of June, we were greatly alarmed at the behavior of one colony. On the alighting-board, and on the grass all around the entrance, there were bees crawling and climbing, most of them apparently unable to fly. At the entrance, a first glance seemed to suggest that the colony was defending itself against robbers; yet there were no robbers in evidence. But every minute or two one or more bees would suddenly attack another and try to force her out, off the alighting-board. The ones so attacked always resisted, drawing back toward the hive, often into it and quite out of sight. Out they would ultimately be dragged, however, and it was a sorry spectacle indeed to see them all struggling, and finally dying there on the grass. The next day there was still a little of this same behavior, tho much less, and soon it had disappeared entirely. Nothing similar showed up in any other colony. I couldn't see anything peculiar in the appearance of the unfortunate bees, unless it was that so many of them had their tongues out! That seems comical, doesn't it? But there they were, tho I don't claim to have been a particularly close observer. This colony hasn't stored

much since then, but neither have the others, so we attribute that fact to the weather. There was nothing queer or different (that we noticed) in the interior of the hive when it was opened a few days later.

\*\*\*

#### FOR BEGINNERS.

Better look over your hives once more this month. Be sure that no colony is queenless. Then see that each one has ample stores to get thru the winter, twenty-five or thirty pounds per hive. If you find some of them short, and have no extra honey to give them, make a syrup of two parts sugar to one part boiling water. Stir till the sugar is thoroly dissolved. You probably haven't any regular feeders. Just put an empty super on the hive to be fed; pour the syrup into an ordinary pan; place chips or tiny bits of wood on top for floaters for the bees to feed from; set the pan on the top-bars of the frames, and close the super. It is better to do this toward evening, as there is less chance of starting robbing. It is a good thing too to feed it warm. Count on giving them a pound, or nearly a pound, of sugar so prepared, for each pound of stores needed.

If you winter on summer stands you will soon be contracting the entrances; and if mice are troublesome in your neighborhood, you might put a strip of coarse wire cloth across the entrance also; about three wires to the inch is good. This will keep out mice, yet allow the bees to pass thru easily.

\*\*\*

#### Evening.

Gently down the evening drift the quiet  
brown and amber;

Slowly thru the meadow trails the dusk  
on drowsy feet;

Softly from the fallen fence where honey-  
suckles clamber

Steals a twilight witchery of dewiness  
and sweet.

Wonderment and yearning irresistibly en-  
fold us,

Pausing where the shining rows of hives  
beneath the trees

Murmur so and murmur. Ah! what secrets  
they have told us,

Secrets of the questing and the homing  
of the bees.

Living out the miracle, questing on and  
questing,

Drinking of the beauty of some distant,  
dim desire,

Homing then at evening to the silence and  
the resting—

Heart of mine, O heart of mine, what  
more does life require?

# NOTES FROM CANADA

J. L. Byer, Markham, Ont.

The severe drouth that started July 1 is still prevailing in many parts of Ontario at this date, Sept. 14. True, we have had a few light showers lately, but no rain to soak the ground, and, as a result, clover will be scarce in many parts of the province next year. No doubt some localities have been blessed with more rain than we have had here in York Co. as well as in the north part of Simcoe Co., where we have one apiary; but generally speaking it can be safely assumed that, in contrast to the great clover season of 1916, 1917 will be a lean year in that respect.

\*\*\*

Page 362, May 1, Allen Latham uses a phrase that is hard for me to understand. "Italians will swarm where the blacks work contentedly" is what I have reference to. Personally I have never been a booster of the Italians, as many know; for altho I have had a lot of fine stock of this race, yet rarely do we have the uniformly populous colonies as when we had more of our favorites, the Carniolans. I have had lots of what would be called "blacks" too, I suppose; and if there is anything I have praised the Italians for above other things it is that they so rarely swarm when producing extracted honey, as compared with the Carniolans or black bees. I gave up trying to solve the question why Allen Latham finds just the reverse to be true in his case, and once more we shall have to call to our help that old and much abused word "locality."

\*\*\*

## RESULT OF THE HARVEST NOW KNOWN.

At this date full results of the season are now known to all. The crop has been above the average for a white-honey yield, practically all of the surplus coming from clover. Basswood seems to have been a failure all over the Province and in Quebec as well, by what I have been able to learn. The demand has been exceptionally keen, and prices have been fair. Of course, as usual in a good season, some beekeepers got nervous and sacrificed their crop, and wholesalers were ready to pick up such consignments. Personally, all our honey was sold in early September, the local demand this year taking thousands where hundreds filled the orders last year.

Owing to continued drouth, buckwheat is almost a total failure in most sections. To

show what one good rain will do I might say that of the four yards here in York Co. only one stored any buckwheat to amount to anything—about 40 pounds per colony. That yard had a good rain during buckwheat bloom. At home, just 7 miles away from this yard, no rain fell, and no buckwheat honey was stored.

\*\*\*

## NO FEAR FROM BUCKWHEAT HONEY.

Mr. A. T. Brown, in September *Beekeeper*, says of buckwheat stores for winter, that they are "unsuitable as a food for bees," and to back up this sweeping assertion he stated that in the fall of 1914 he extracted his buckwheat honey and fed it back to the bees, and, as a result, lost 37.5 per cent of his apiary. One swallow does not make a summer, and I imagine I see many old-time beekeepers in the buckwheat regions smile.

Some of the best wintering we have ever had has been on buckwheat stores; and if the crop is gathered during hot weather in August, and no honey-dew is gathered along with it, buckwheat honey is fine for wintering. Mr. Brown extracted the honey and fed it back — a bad practice, generally speaking, as there is risk of spreading brood diseases unless honey is boiled, and then the bees would surely die. If fed as it comes from the extractor, as a rule much of it would granulate in the comb, and bad wintering would follow. While I have done little feeding of honey in the fall, whenever such work was done the honey was diluted with warm water to the proportion of two parts of honey to one of water.

While I prefer good clover honey or sugar syrup from best granulated sugar to any other kind of winter stores, unquestionably I would not worry if I knew all colonies had full combs of well-ripened buckwheat honey. This year the bees go into winter quarters with the most clover honey in the brood-nests that we have ever experienced; so, all other things being normal, good wintering may be looked for.

\*\*\*

## ONE TIME WHEN DRAWN COMBS ARE INDISPENSABLE.

Often the question is asked as to what drawn combs are worth. This year I have been figuring that their value is hard to reckon under certain conditions. On Monday, July 3, I was suddenly taken ill, and for six days I could hardly crawl around—

in fact, the doctor said I should go to bed. As I was all alone, my son having gone to the north yard where swarming was bad, with four yards of bees to look after right in the rush of the honey-flow, surely things looked rather blue. Two yards are four miles from home, and one eight miles away; but with the help of the auto, distance did not count much. I could not even lift up full supers to place an empty one underneath, so I simply piled on the empty supers as needed in so far as I was able to do so. Combs that have not been used since 1913 were called into use, and today the hives are piled higher than my head, in many cases. Swarming was headed off in most cases so far, but I suppose many will soon go to pieces in spite of all I can do. I am getting back to health again; but a week's knock-out right in the middle of the flow makes quite a handicap to overcome.

But the question I had in mind was, "How much were all those drawn combs worth to me under the circumstances outlined?" While I do not contend that I shall get as much honey as would have been the case if we had been able to extract sooner, yet what would have happened if I had been short of combs? No doubt the greater part of the colonies would have swarmed and left, for I in my poor health at the time could not think of going thru the hives, let alone do any extracting; and as for getting help, any beekeeper knows the impossibility of getting skilled help in our line. As it is, hardly any colonies have yet swarmed, and there is a nice pile of honey tiered up in the four yards. Actually, I think that each set of drawn combs was this year worth at least \$4.00 or more to me. Am I placing the value too high?

\* \* \*

#### WEEKLY EXAMINATIONS TOO MUCH FOR ME.

The editorial on page 775, Sept. 1, regarding the matter of diagnosing colonies without lifting out frames or taking off supers every week is interesting to me because that is a common practice with us during the honey season. Some time ago friend Holtermann, in advocating a weekly examination of every colony during the honey season, asked me what I would suggest to do away with this weekly grind (he did not call it by that name), when I stated that, if I had to make an examination of every colony every week I would go out of the business. While I have not the time to tell what I would do, or, rather, would *not do*. I will say that, during the season just passed, I was entirely alone for four weeks

following July 1, and had four yards to look after. At the close of the season I had help to extract, but not a helper was in sight so far as keeping back swarming, putting on supers, etc., was concerned. After careful examination I found that about half a dozen swarms had left the yards. That was easy; and, aside from the fact that it would have been a physical impossibility for me to lift off all supers and examine every colony each week, the work would never have been paid for even if it had been performed. No; I repeat again that, while weekly examinations sound all right, and look well on paper, if one is alone for a season and has a lot of bees to look after, he will soon find that something else must be depended upon to help him out. What that is, will have to be worked out by each one to suit his own locality, peculiar management, etc.

While discussing this question I want to make the bold unorthodox assertion that great large entrances do not materially, if at all, help to keep down swarming. As stated on many previous occasions, by reason of buying bees in all sorts of hives, and running them for a number of years, I have had abundant proof to satisfy myself on this question. Possibly very few beekeepers have less swarming than we do; and when honey is going we generally get our share with the rest, and assuredly large entrances do not contribute to our low average in swarming, as we have very few entrances indeed that would be called *large* by the average beekeeper. This year one large powerful colony was left in a packing-case all summer, and by actual measurement I find their entrance was 2 inches long by  $\frac{3}{4}$  deep. Not because of the very small entrance, but in spite of it, I suppose, that colony about headed the yard, stored over 300 pounds of clover honey, and never offered to swarm. The strain of bees had nothing to do with the non-swarming, for last season that same colony in a single-walled hive swarmed, and there were only three or four swarms all told, that season in that apiary. The secret of the colony storing so heavy and not swarming lies in the fact that the bees entered the supers early in the season, and at all times they had abundant super room, over 150 pounds of honey being on the hive at the last extracting.

Before some one calls me to account for backing up the use of such a ridiculously small entrance as I have mentioned, let me say that I admit that it was too small, but at the same time I consider the very large entrance, as advocated by many, to be just as ridiculous in the other extreme.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

A field meet was held in Riverside recently. Those attending report a very successful meeting. Another will be held in Redlands, Oct. 7.

\*\*\*

The blue-curl season is now at its height (Sept. 11); and while it is not considered as being a surplus-producing plant, yet there is no wild flora that is more valuable as a stimulating source. In the very late season, after the bees in many localities have been practically idle for several weeks, they are given sufficient stores from the source to encourage late breeding.

\*\*\*

A writer concludes that the efficiency of the Italians in keeping down disease lies in the fact that they are better house-keepers. Good house-keepers have always been in demand. The experience of finding out who are the good house-keepers has caused many an hour of regret.

\*\*\*

Mr. J. E. Crane, page 722, Aug. 15, advances the theory that the climate of California affects the bees as it does people, giving this as the reason that the bees are able to fly a greater distance here than in Florida. The theory seems to be perfect, but I am a little skeptical as to the realities of the case. However, I am not ready to say that Brother Crane has not advanced the proper idea as to the cause, but do not see exactly how it is to be proved.

\*\*\*

When a small boy, and just becoming interested in the bee business, I was not only eager to learn, but I was about as gullible a mortal as could be found. There was an old Kentucky gentleman in the neighborhood who told me many remarkable things about his experiences with bees, one of which was that he once had a colony in a starving condition that he saved by boiling a piece of chicken very tender and slipping it into the hive where the bees had access, and, strange to say, the bees lived thru the winter (I think the chicken had nothing to do with it, however).

\*\*\*

Howard L. Rann, a humorist, has recently tackled the bee. Mr. Rann is contributing some funny thoughts to the daily pa-

pers, and, like the great majority of our population, he seems to have very little accurate knowledge of the habits of the bee, and incidentally throws himself in a very ridiculous light by venturing some comic matter on the subject. I quote: "Bees do not believe in equal suffrage. The male bee is not allowed to look or dress different from any other bee, and is the most henpecked individual in existence. It is a sad sight to see a swarm of masculine bees trooping forth to work in the morning, bossed by a queen-bee who probably does not know how to vote the Australian ballot." To the average person this is undoubtedly very witty; but to one who has some knowledge of the habits of the bee, it certainly puts Mr. Rann in a ridiculous light.

\*\*\*

## WILL THE LOCAL ORDINANCES HOLD?

Some recent decisions by our state courts lead me to the conclusion that it may be a good time for us to ponder over some of our many different county ordinances relative to bees. By the terms of a decision handed down by the third district court of appeals in Sacramento, August 10, there seems to be a case that nearly parallels our county ordinances. The substance of the decision was that the state fish and game laws cannot be circumscribed or otherwise restricted by local enactment. A similar decision was given some months ago relative to the speed laws governing automobiles in municipal limits, in which it was held that the state law was superior to the city ordinances in regulating speed, thus practically annulling all city ordinances on the subject. In the first case it seems that the Board of Supervisors of Humboldt County, acting upon a clause in the county government, making further restrictions on the game laws of the state, had precipitated the matter into the courts where it was held that the state laws were the recognized game laws, thus ignoring the county ordinance.

I have expressed my opinion at various times regarding the probable results if some of these restrictive ordinances should be questioned in the courts. The decisions mentioned above seem to verify my conclusions. There is little doubt that arbitrary and restrictive bee ordinances such as some of our counties possess, and which come under the police powers of the state, would suffer under a decision of the courts.

# BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

## THE FALL FLOW.

Bees have gathered some honey in September this year; but the man who has not provided extracting-combs for bees has secured little of it, as comb-honey supers are not the thing for such a slow flow. The quality of winter stores is good, and wintering promises to be good.

## THE ALFALFA WEEVIL.

The Government bulletin on the "Control of the Alfalfa Weevil" states that the infested area is widening about ten miles per year. There seems to be no way of preventing the spread of this pest, so we shall all doubtless suffer sooner or later.

The center of infection is in Utah and has extended into Idaho, but has not reached Colorado—that is, it has not been officially reported to have reached Colorado. A western-slope farmer told me he had a piece of alfalfa infested by the weevil; but if so, the authorities had not yet found it out.

## BOULDER COUNTY FAIR EXHIBIT.

The Apiary Department of the Boulder County Fair was well taken care of this year. Mr. D. W. Spangler was the able superintendent and Mr. J. C. Aikin, of Loveland, judged the exhibits. Entries were made in nearly all classes. The exhibit of fancy comb honey was the best the writer has seen anywhere. First premium for the best six cases of fancy comb honey was won by Milton Cantonwine, of Longmont, and second premium by A. J. McCarty, of Longmont. Mr. Seph Francis, of Longmont, got first premium for best and largest exhibit of apiary products. A feature of the exhibits was the use of honey in canning and cooking. The educational value of this is not small.

Thursday, September 7, Seph Francis and W. H. Foster, of Boulder, gave live-bee demonstrations before interested crowds.

## EUROPEAN FOUL BROOD A RESPECTER OF PERSONS.

European foul brood plays favorites with beekeepers more than does American foul brood. European foul brood is a respecter of persons, and American foul brood is not. If you are an alert, up-to-date beekeeper, keeping all colonies strong, and headed by young queens of resistant stock, you can be reasonably free to laugh at European

foul brood, altho it rages all around you. You will need to be a queen-breeder, and also to be prepared to feed your colonies, should a lull of sufficient importance occur in the flow. It seems no strain of bees is absolutely immune unless you give them a chance, and a good chance too.

It behooves every beekeeper, whether he is ten miles or five hundred from apiaries infected with European foul brood, to secure resistant stock of Italians, and keep young vigorous queens of this stock in his hives. It will pay in honey crops, and be insurance against European foul brood also.

One interesting fact concerning the spread of European foul brood is that the diseased district in Colorado has moved, *so far, only* to the eastward. The area of diseased apiaries has moved eastward three or four miles, and, so far as known, has not spread westward at all. The bees fly in an eastward direction in the spring, as the wild flowers are more profuse on the hills to the east in this locality. The direction of the prevailing wind is eastward in the daytime and westward at night in this diseased locality. What effect may the wind have on the spread of the disease? As the bees are a fair grade of Italians, European foul brood has spread very slowly in the last two years, and it should be possible to prevent its further spread and stamp it out. We shall see what the result will be.

This disease, we think, is being brought under control in Colorado, and it may be possible to prevent its spread to other parts of the state. The infected apiaries are still confined to an area not more than five miles in diameter. The beekeepers have purchased hundreds of queens of golden stock, and are getting results. The majority of the beemen are learning to handle the disease and will be able in the future to secure crops of honey, even tho some disease may be present.

We have no success to report from caging queens. Removing the brood and requeening seems to have good results. Keeping colonies strong and uniting weak ones for this purpose is essential. It is probably not necessary to destroy combs; but those badly infected had better be destroyed. It is much cheaper to practice a few short-cut methods than keep the disease always present, even if it is under control. It is certainly a pleasure to see beekeepers get control of the disease by introducing new stock of queens and improved apiary practices.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

## SHIPPING COMB HONEY.

"The season for shipping comb honey is here, and I am lucky enough to have some to ship to a distant market. But how to fix it for safe shipment is something I do not feel competent to do. How is this best done?"

I used to ship my comb honey by canal in my earlier years of shipping to New York, and found this much better than sending by express, as nearly all comb honey was sent in the 70's. Boats on the Erie canal would stop at a place about 15 miles distant and take a few thousand pounds of extra freight on top of their loads of grain if they were notified beforehand. By having the honey there on the arrival of the boat my whole erop would be put on in an hour or so, and I could see that it was carefully handled and put on top of the leveled grain, while the captain would see to its careful handling at its destination.

Next to the boat comes freight. At first sight it would seem that express would be safer than freight, on account of the heavy shocks freight-cars are liable to receive, and it was with much trembling that I loaded my first freight-car. Wool-sacks were filled with straw and put in each end of the car to give a cushioning effect instead of a thump when the cars were coupled. Much to my satisfaction this carload went thru in perfect shape, this giving me great confidence for the future.

Since then I have had some small breakage, but I still adhere to that way of shipment where the canal boat cannot be used from the start to destination.

Much can be done by the beekeeper to avert the matter of broken comb honey. The first step is to produce the article in the best shape by having the combs built solid to all four sides of the section; and to do this to a certainty it is best to use full sheets of very thin section foundation, fastening it in good and true with a good foundation fastener. Comb honey in which the combs are attached only partially to the sides and bottom of the section should be sold in the home market rather than shipped long distances. Then the combs should be built evenly in the sections so that no "fat" or "lean" combs will have to be experimented with to keep the nice cappings from touching each other. The only sure way to secure such combs is to use separators, then the cappings of the honey will not scrape off in shipping.

Care should be used in packing, to see that the honey is all of a thick ripe grade, and all sealed, in perfect condition and strongly built. If there is any unfit to ship long distances, use it at home, put it back in the hive for completion, or dispose of it as "chunk" honey. Don't allow it to go with the long-distance honey, for damaged honey means low prices for all, and the ultimate harm to the market for others. To gain the best results in shipping comb honey it should be well cured; and to gain this end it should be kept in a warm, dry, well-ventilated room for from three to five weeks. The temperature nearest 85 to 90 degrees will do the best curing. Five weeks of such curing will cause any honey in the few unsealed cells that may be next the section to become so thick that it will not run, even tho the section is laid down flat or handled at any angle. When thus ripened it will not get thin enough to run before it reaches the desired destination, even tho the weather while it is in transit be damp, foggy, or rainy. The merchant to whom it is consigned should be instructed to keep the honey on its arrival in such a place as it was during the five weeks previous to shipment, in order that it may reach the consumer in a shape that will lead him to enlarge his purchases of the product as the years go by.

Shipping-crates should be made to hold eight twenty-section cases to insure the most care in handling by freight men. The practice of shipping comb honey in single 20 to 24 section cases, that can be easily thrown about, is not to be tolerated, especially in small or less than carload shipments. By making the crates large enough so that they will require two men to handle them—say those that will hold from 150 to 200 pounds gross weight—such will not be thrown about, but picked up and set down more carefully. If handles are furnished they will be used.

If in addition to the glass that shows the nice comb in the outside cases, the crate is marked with a request to handle with care; placing it crosswise when loaded on a wagon, and lengthwise in the car, the shipper will have little to fear in regard to its arrival at its destination. Say a kind word to the freight agent or the one under him. Give each a section of honey when you pass your shipment on, and it will pay big in dollars and cents, to say nothing of the satisfaction such a course will bring to you.

# GENERAL CORRESPONDENCE

## SACBROOD MORE DISASTROUS TO COLONIES THAN HAS BEEN GENERALLY SUPPOSED

BY BURTON N. GATES

*Associate Professor of Beekeeping, Massachusetts Agricultural College, Amherst.*

Beekeepers are inclined to disregard the presence of sacbrood in their colonies. It is often imperfectly understood that this disease may be disastrous in an apiary. If it occurs in even a slight form, it is depleting. Accurate figures of the damage which it can cause are difficult to obtain. Its virulence apparently differs in different seasons, apiaries, and colonies. The strain of bees apparently has much to do with the evident symptoms of the disease. Not infrequently a beekeeper says that his bees are not subject to sacbrood, or that if sacbrood occurs it is soon cleaned out. Occasionally colonies are found in which disease is not readily suppressed, either thru the efforts of the beekeeper or by the bees themselves. Sometimes beekeepers treat or shake to rid the colony of sacbrood, the same as they would a colony diseased with European foul brood or American foul brood. It is not, however, usually necessary to resort to these drastic measures. The introduction of a more vigorous strain of bees—that is, the introduction of a queen of virule type, will usually do away with the disorder.

During the season of 1915 several severe cases of sacbrood came under the observation of the writer, in which the infection was exceptionally pronounced. In fact, a careless glance at the combs suggested the presence of American foul brood. The apiaries in which this infection was found have had sacbrood for some years, varying from time to time in intensity. General observations around Massachusetts indicate that such conditions are not infrequent. With proper measures, however, the disease can be obliterated.

It is not the purpose of this discussion to consider the nature, cause, or treatment of the disorder, but more especially to give a graphic account of extreme cases of sacbrood. For concreteness, three cases are presented.

Case 1, count made by the writer June 24, 1915, Newburyport, Mass. A colony which was obviously badly infected was selected. At random, a block of brood on one of the combs was marked off, 18 cells by 25 cells, making in all a group of 450 cells. By count of these cells, there were 125 which contained either sacbrood scales

or larvæ. There were, besides, a considerable number of empty cells, or cells with eggs among irregularly arranged healthy brood in all stages. Thus about 27+ per cent of the brood was infected with sacbrood.

Case 2, count made by the writer June 24, 1915, Newburyport, Mass. The comb used in Case 1 was reversed, and a block of cells 13 by 45 was marked off, containing 585 cells. The block of cells was selected at random. Of this group of cells 50+ cells were sacbrood or 8+ per cent.

Case 3, count made by the writer June 29, 1915, Rowley, Mass. A typical, bad case of infection was found. From the center of the brood-nest was removed a comb upon which was marked off a group of 800 cells, 40 cells in a row and 20 rows. Counts were made as follows:

|                                                 |     |
|-------------------------------------------------|-----|
| Total number of cells.....                      | 800 |
| Number of empty cells or cells with honey ..... | 98  |
| Balance } cells of healthy larvæ..              | 330 |
| } cells of sacbrood.....                        | 372 |
| Per cent of infection, 53.                      | 702 |

The 20 rows of 40 cells each extended from the top to the bottom of the frame, thus affording a complete section of the brood-nest. In order to furnish a more complete comparison the data for each row of cells are tabulated below:

| Row | Cells of sacbrood |
|-----|-------------------|
| 1   | 17 Top of frame.  |
| 2   | 20                |
| 3   | 14                |
| 4   | 24                |
| 5   | 30                |
| 6   | 21                |
| 7   | 24                |
| 8   | 21                |
| 9   | 18                |
| 10  | 18                |
| 11  | 21                |
| 12  | 29                |
| 13  | 20                |
| 14  | 20                |
| 15  | 15                |
| 16  | 16                |
| 17  | 19                |
| 18  | 8                 |
| 19  | 9                 |
| 20  | 8 Bottom of frame |
|     | 372               |

Cases 1 and 2 show how the disease apparently varies within a given colony and within a single comb; but the 8-per-cent infection presented, even to the untrained eye, the appearance of marked infection. Thus it is presumable that the majority of colonies which show only a few cells of the disease are of a low-per-cent infection.

It is somewhat surprising, however, to most beekeepers to learn that 30-50 per cent of their developing bees are dying of sacbrood. They realize that the disease is present, but they rely upon the energies of their colonies to clean the disease out, knowing that from time to time apparently this occurs. These figures, which probably typify conditions elsewhere in the country

other than in Massachusetts, should stimulate the beekeepers to select stock which will not tolerate the presence of sacbrood. A 1-per-cent infection should not exist in any colony. To breed from such a colony may mean the perpetuation of the weakness and inclination of this race of bees to the infection.

The writer would be glad to describe to the beekeepers the method of making these counts, if such details are desired. A group of several hundred cells can be accurately compared by simple means within relatively few minutes. It may be that inspectors elsewhere in the country can procure comparative data, and that in the future further information will be available.

## WHAT QUEENS SHALL WE BREED FROM? AND SOMETHING ABOUT THE DRONE PROBLEM

BY DR. C. C. MILLER

With all my heart I believe that every beekeeper, beginner or veteran, should make it his constant business to improve his stock. He may get one or more queens as a start, wherever he thinks he can get anything better than the stock he already has, but that's only a beginning. His steady job, for the rest of his life as a beekeeper, is to see that each year his bees shall be at least a little better than they were the year before.

To do this we must keep close tab on each colony, putting down in black and white its performance. Without neglecting the matter of temper and other points, the chief thing to be considered is the amount of honey stored. No guesswork about it; but each time a pound of honey is taken from any colony, put it down. For many a year past I can turn to my record-book and tell you just how many sections each colony gave. A little trouble—yes, but I couldn't get along without it.

Having, then, the standing of each queen, he can rear his young queens from one or more of the best. I do not mean that he shall make a wholesale job of requeening each colony each year. A colony that is doing as well as the average, or better, may well be left to itself, even requeening itself at its own will. But in the usual course it will sometimes happen that a colony will go queenless, and then it is a nice thing to go to a nucleus and get for it a young laying queen of best stock. It will be well, also, to replace with a queen of better stock any queen whose colony falls below the average in its performance.

In deciding what queen or queens shall be used to breed from, two courses are open.

One claims that it is not best to use for a breeder a queen whose colony stores an amount away above the average, such a queen being a sport, or freak, whose royal progeny will vary widely in characteristics; but, instead, breed from stock a little above the average, thus securing more uniform results, and gradually but surely raising the standard. Another claims that, by constantly breeding from that queen whose colony stores the most, the habit of heavy storing will in time become a fixed characteristic.

I don't know which is the better way; but I do know that by breeding constantly from the queens which make the highest scores, freaks, if you so choose to call them, I have very materially increased my average per colony.

You can do the same.

What about drones? One cannot control the mating of a queen; but one can control the rearing of drones in his own apiary, and thus increase the chances a young queen shall have for meeting a drone of best stock. In carrying this out in practice, here is the plan I followed for many a year: I selected half a dozen or so of the queens standing at the head of the list for heavy yields. The very best of these I chose as the one from which to rear virgins; the rest were chosen as drone-breeders; allowed a considerable amount of drone comb; and drones were suppressed in all other colonies in the apiary.

I think most beekeepers would endorse this course. I know that some of the best of them do endorse it. But I am sure it is wrong in principle. To make clear what

I feel sure is the right way, I think I cannot do better than to close by quoting from an article I wrote lately for *The American Bee Journal*, as follows:

"A certain colony in the apiary, in an average season, yields a surplus of 100 pounds, and we call the queen of that colony a 100-pound queen. Of course, it is the workers that do the storing, and a worker of that colony depends for her character, not only upon her mother, but also upon the drone with which her mother mated. In other words, that worker is the daughter of her mother and also of her father, her father being the drone with which her mother mated. While it is true that the worker is the daughter of her mother and of the drone with which her mother mated, it is not true that the drone is the son of his mother and of the drone with which his mother mated. As the drone proceeds from an unimpregnated egg, he is not at all influenced by the drone with which his mother mated. He is the son of his mother alone; or if you insist that he must have a father, then he is the son of his grandfather, the drone with which his grandmother mated. He is of the same blood as his mother was, without any reference to her mating; that is, his blood is the product of the combined blood of his grandmother and the drone with which she mated.

"As his grandmother gets her rating from that combined blood, whether she be a 50-pound queen, a 100-pound queen, or whatever she may be, the drone will have pre-

cisely the same rating as his grandmother on his mother's side. If his grandmother is a 50-pound queen, he is a 50-pound drone. His mother may be a 25-pound queen, a 75-pound, or something else. That doesn't make any difference; he is a 50-pound drone because his grandmother was a 50-pound queen.

"Now let us see how it will work out to have half a dozen of the best queens, using one for rearing virgins and the others for drones. Suppose they are all 150-pound queens. Any one of them is all right for rearing queens, but how about drones? One of them may be the product of a 200-pound queen and a 100-pound drone, and her drones will be all right. Another may be the product of a 100-pound queen and a 200-pound drone, and drones will not answer. Just remember that, in considering the value of a drone, we are not to consider his mother but his grandmother.

"With this view of the ease we have the comfort of knowing that the problem of securing the best drones is made immensely simpler and easier. For if all our queens are reared from our best stock, the matter of drones takes care of itself automatically. No matter if a queen has mated with the poorest scrub stock of a neighbor, her drones are just as good as any, for they come from the same grandmother.

"So, rear queens persistently from best stock, and suffer no drone that has not a respectable grandmother."

Marengo, Ill.

## MID-WINTER BREEDING

BY J. E. HAND

Occasionally a progressive beekeeper becomes quite enthused about winter breeding in cellars when stimulated by feeding with hard candy. It is well to understand in this connection that a moderate amount of voluntary breeding in winter is a purely normal function; but feeding to stimulate excessive winter breeding in cellars is abnormal, because it is always accompanied by an abnormally high temperature, excessive activity, and excessive consumption of carbonaceous food—a combination that, without frequent cleansing flights and free access to water, is likely to culminate in exhausted vitality, distended abdomens, dysentery, and death. While this calamity may, perhaps, be averted by carrying them out and giving them a mid-winter flight, in my opinion the labor involved is in excess of the advantages gained, aside from the risk incurred.

Winter is a season of rest and comparative inactivity of bees; therefore any condition of abnormality that causes excessive activity of bees in winter should be regarded as a possible and probable calamity. An *experienced beekeeper* can manipulate bees with impunity during a warm spell in winter; but a wise beekeeper will provide ample food and adequate protection in October, and let his bees severely alone during winter and early spring. In my opinion, winter meddling and spring tinkering, erroneously called "stimulation," is not a component principle of a competent method nor a necessary qualification of a thoroly competent beekeeper.

I would not convey the idea that winter breeding is an undesirable function, except in cellar wintering, for it has been ascertained beyond a doubt that a moderate amount of normal voluntary winter breed-

ing may be practiced with impunity outdoors in the latitude of northern Ohio, as a purely normal function without any attention whatever, except that given in October preceding. Here is my recipe for perfect outdoor wintering accompanied with voluntary winter breeding. 1. A 14-frame colony in October; 2. Contract it with a thin-wall eight-frame inner chamber 12 inches deep, on the convertible plan wherein the hive proper serves as a winter case; 3. Provide adequate internal insulation, 3 inches on sides and 7 on top, with none on the front end; 4. Provide 40 lbs. of honey or sugar syrup.

A colony in this ideal condition in my lo-

cation will not draw together in a light cluster except as suspended in the deep space under the frames, except possibly in zero weather, and will rear sufficient brood to make them stronger in April than in November preceding. The component principles of successful wintering are extreme contraction, adequate insulation, an abundance of bees, and 40 lbs. of stores. The convertible method is a synonym for economy of equipment and efficiency of service. Birmingham, Ohio.

[Mr. Hand's 14-frame convertible hive is described and illustrated on page 276, April 1.—Ed.]

## THE TWO-COLONY WINTER CASE

BY W. S. WIGGINS

I have read a good deal about winter cases for one, two, four, or more colonies, but have come to the conclusion that for me, at least, the two-colony case is the best.

I have always had some objection to the four-colony case in that it necessitates moving the hives to place the bottom of the case in position, and two of the hives have to face in an opposite direction from the others; whereas in my estimation they should all be facing south; moreover, it takes two men to handle such large cases. If all four hives could face the same way or the bees could be moved to the four-colony case in the fall without confusion then I would be in favor of the four-colony case. My

colonies, however, all face south and are packed on the summer stand without moving in any way, with the exception of a few old eight-frame colonies which are packed in long eight-colony cases as shown in one of the pictures.

I have seen colonies winter without any protection whatever, and come thru in good condition. I have seen colonies with a few corn-stalks thrown over them, or with a few boards loosely placed around the hives and packed with straw, come thru in good condition with apparently no greater loss than those wintered in cellars or in carefully built cases. Is it necessary to have our cases built so warm? My two-colony cases

A late summer view of a portion of W. S. Wiggins' apiary at Muir, Mich.

The same apiary in winter quarters, showing the two-colony cases. This also shows three eight-colony cases in which are housed the eight-frame hives.

contain no bottom whatever, and in this way I figure that two of the cases can be built for about the same money that one of the four-hive cases can. There is no disturbance to the bees when the cases are put on in the fall. One man can set them up, place them over the hives, and put in the packing without any help.

The cases are constructed to allow four inches of packing material on the back and two ends, and in front a space equal to the distance the bottom-board extends beyond the hive, which on my hives is only two inches. The cases extend about eight inches above the hive. This space I pack tightly with good straw or leaves, and over all I place the roof, which has a good water-tight covering of composition-paper roofing. These roofs have a two-inch strip all around the sides which come down over the case and prevent the water from working back into the case and wetting the straw. The cases extend about to the ground and the packing goes clear to the ground as tightly as possible, making the case as warm as tho it contained a bottom-board.

I first place a queen-excluding board over

the brood-chamber, then a burlap blanket, then a super filled with planer-shavings, and the hive is ready to pack. I use no sealed covers over the brood-chamber. Old beemen with whom I have talked advise against this. Why do you, Mr. Editor, advise this, and still advocate ventilation, which they certainly do not get with a sealed cover? [See Editorial.—Ed.]

It will be noted that the case does not quite touch the ground, and some may wonder how it is held in place. To begin with, a strip is placed over the entrance-boards. I use the wide entrance on the bottom-board for winter, and lay the board flat upon it. This I believe gives ventilation enough, and the board prevents the packing from getting into the entrance. Then I nail two blocks on the inside of the front of the case just high enough so that, when these blocks rest on top of the board over the entrance, the case will not quite touch the ground. Then on the inside of the back I nail another block directly in the middle of the long way of the case and about ten inches from the top. Then I take a two-inch strip, notch it in one end so that it will rest

over the edge of the hive-stand directly between the two hives in back, and cut it to such a length that, when the back of the packing-case is raised and the other end of this stick is placed under the block on the inside of the back of the case, it will make the case about level.

Muir, Mich.

The two-colony cases permit all the hives to face the south.

## THE REASONS FOR THE COLORS OF THE FLOWER

BY JOHN H. LOVELL

If you dip a red flower, as a rose, in a weak alkaline solution, as a cup of water to which a little ammonia has been added, it will turn blue; but if you dip it again in a weak acid it will at once recover its original red hue. A blue flower dipped in a weak acid becomes red, but becomes blue again in weak ammonia. In a recent number of the *Literary Digest* there was published an extract describing the color changes of red and blue flowers, and their relation to an acid or alkaline plant sap.

Red and blue flowers owe their colors to a large group of pigments dissolved in the cell-sap, and called collectively anthocyan. Yellow and green pigments are usually in solid granules. The red and blue pigments are believed by chemists to be derived from yellow pigments. If the sap of leaves or flowers is acid, then any anthocyan present is red-colored. There are families and genera which have the sap so strongly acid that, no matter under what conditions they grow, they never produce any blue flowers. There are no blue roses; and who ever saw a blue pink? In the great orchis family, which contains some 6000 species, there is only one blue flower, *Vanda coerulea*, of India.

While red flowers are comparatively rare (for there are only about 257 in all north-eastern America, red coloration is very common in leaves and stems, especially in spring and fall. As to its use, if it has any, there have been many opinions; but the most acceptable is that of Stahl who thinks it aids the plant by absorbing heat. The production of red pigment is increased by three factors—a low temperature, a bright light, and the presence of sugar in the plant tissues. In the Alps the leaves of plants are much oftener red than in the lowlands, because the night temperature is lower. In the intense light of alpine summits white lowland flowers sometimes become red-flowered. But it is to the influence of sugar that the most interest attaches.

A chemist by the name of Overton cultivated an aquatic plant (*Hydrocharis*) in a solution of water and sugar, and in a few days dark-red coloring appeared, especially in the new leaves. Other plants grown in pure water showed no red color. The cut stems of lilies and other land plants in a weak sugar solution soon developed red color; while the leaves of other stems in clear water remained green. He further found that low temperature, but above freezing,

and bright light, promoted the formation of red pigment. In arctic regions Wulff has observed that the leaves of plants are often rich in sugar, and red-colored. Red autumnal leaves are also said to contain more sugar than when they were green. These and many other experiments appear to prove that there is a relationship between anthocyan and sugar.

Since plants which have a rich sugar content have the cell-sap colored with anthocyan, there is certainly no improbability that the nectar secreted by such plants may contain more pigment, or be darker colored, than that secreted by plants with little or no red or blue pigments. That is, there may be a relation between the color of the honey and the amount of anthocyan a plant contains, but it must be admitted that we know very little about the matter. An acid or an alkaline soil has apparently very little effect on floral colors, for both red and blue flowers grow on both kinds of soil. Still, Kerner tells us that in the limestone Alps several flowers are blue or yellow which elsewhere have different colors. There are also other observations, according to which the colors of flowers have been changed by chemicals, as iron or arsenic, in the soil. But however it may be with the color of nectar, its secretion is certainly strongly influenced by soil and climate, or why should alfalfa and many other plants yield freely in one region and not at all in another?

Let us in conclusion briefly consider the effect of an alkaline sap on flower colors. In many flowers the cell-sap is only feebly acid, or neutral, or alkaline; for instance, in the forget-me-not and common borage the sap is at first acid and the flowers open red, but a little later change to blue as the sap becomes alkaline. If the sap is neutral the pigment may be violet-colored, or it may be invisible, which explains why some flowers suddenly lose their color; but in this latter case it may be again restored by the use of an acid. If the sap is alkaline the anthocyan turns blue; or if there is a yellow pigment present it becomes green. Sometimes one part of a flower may have acid and another part alkaline sap. A hyacinth has produced a flower-cluster with blue flowers on one side and red flowers on the other; also flowers with petals partly blue and partly red. A variety of phlox was clear blue in the morning, but gradually changed during the day to a beautiful deep rose. Red and blue cells may occur indiscriminately in the same petal, as in the

sweet-scented violet. Thus the transition from red to blue or from blue to red may often be very easily effected.

The shade of the flower depends upon the density of the coloring matter it contains. The scarlet poppy, tulip, and fire-red canna owe their colors to a mixture of yellow

grains and red cell-sap. The different pigments included under the name anthocyan are closely allied, yet they vary somewhat in composition and hue; and according as they occur alone or mixed they affect the color of flowers. A knowledge of these pigments is important to plant-breeders.

Waldoboro, Me.

## HOW TO PREVENT YOUNG QUEENS FROM MISTAKING THEIR OWN ENTRANCES

BY W. D. SELLERS

The first year that I wintered my bees on this ground, the hives faced due east. The result was that many colonies clustered on the southern side, because that side was warmed by the sun's rays. The next year I changed them so that they faced southeast, and now most of the clusters are in

which I expected a virgin queen to issue to mate; and upon going there I would find no queen. I would then look next door, and there she would be lying on the bottom-board dead. So far as I know I did not lose one queen this season in this yard. The hives being 8 ft. apart, and every other one

W. D. Sellers' queen-yard, Lancaster, Pa. The hives are eight feet apart, and every other one is painted yellow.

the center, altho a little toward the front of the hive. It is true that some of the clusters went to the extreme and located on the edges past the last comb. If my piece of ground faced to the south lengthwise I would then face the hives south. I propose to erect a windbreak on the north and north-west side, as this was certainly needed last spring.

It will be noticed that every other hive is white, the others being colored with ocher or yellow. I formerly had all my hives painted one color, and much closer together. I lost many fine queens this way, I am sure, because I had often marked a hive from

a different color, the bees now have a chance at 16 feet to make their goal.

My shop and honey-house faces east. During the middle of the day in the winter the sun shines thru the windows and makes the room comfortable. Facing south would be a better position, as at midday, when the sun is the hottest, it will hit the largest possible part of the shop and leave the smallest part or end to the cold northwest wind. The shop is shaded during the summer. A shop that is in a position to receive the sun's rays in the winter, and that is protected by shade in the summer, is ideal.

Lancaster, Pa.

## DIVISION-BOARDS NECESSARY ONLY WHEN WINTERING A NUCLEUS

BY TARLTON-RAYMENT

The recent advocacy of division-boards in connection with the eight and ten frame hives evoked a considerable discussion in GLEANINGS. Some of the writers went so far as to recommend altering the dimensions of the standard bodies to accommodate better the fixtures.

From our point of view this is a remarkable contention, because the only time we can utilize any style of division-board or "dummy" is when packing a weak colony in autumn. Even that contingency is so rarely encountered with the eight-frame hive under our system of management that the total absence of the division-boards would entail but little or no inconvenience. But to suggest varying the hive measurements simply to permit the use of what, in the opinion of many experienced apiarists, is a superfluous piece of wood—oh dear! no—not under any circumstances.

Some seventeen years ago we made our first hive. We, as the merest tyros, had just previously been conducted over a neat little apiary of eight-frame Langstroth hives fitted with beeway sections. Their obvious convenience, together with the snowy capings, made a deep and lasting impression.

At that time division-boards were not in our vocabulary; but we feel pretty certain that the model apiary was certainly not bothered with them. However, returning to our home-made hive, in the intrepid manner of the inexperienced we were convinced that it was altogether wrong to make the brood-frames  $9\frac{1}{8}$  inches deep and the honey-sections only  $4\frac{1}{4}$ .

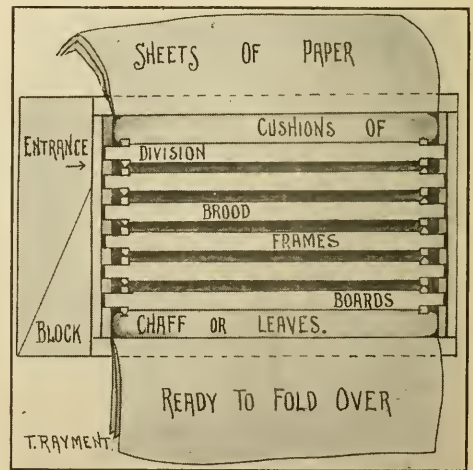

According to our reasoning, which, unfortunately, was logical, but opposed to the requirements of the bee, it should have been the other way about—honey receptacles  $9\frac{1}{8}$  and brood  $4\frac{1}{4}$ . "Why! look what a lot more honey would be stored!" So we constructed our first and only home-made hive on those ill-based principles. In our ignorance we unconsciously invented the shallow brood-frame. The bees did not settle down to work, but deserted their home, which catastrophe led us to seek further information.

A course of study enlightened us, and proved the principles enunciated by Langstroth to be soundly based. We have been taught by sheer necessity one or two additional facts about the fitments of the hive since that time; but the use of the division-board is not yet acquired.

The first consignment of hives we ordered was machine-made eight-frame size. Each

hive was furnished with a division-board  $\frac{3}{8}$  inch thick. We tried faithfully to handle them at the start, because all the text-books urged their use; but we were compelled finally to cast them aside as worthless. The hives were more convenient without them.

For eight or ten years we never handled a dummy of any description, altho we depended almost entirely upon the bees for our livelihood. Then a neighbor sold out and we purchased a number of new-pattern division-boards simply a plain board one inch in thickness surrounded by a Hoffman frame. They were very heavy, did not fit our hives, and so we removed the frames and had comb built in them. You see we could discover no reasonable use for the "dummy." The eight-frame body has only

Rayment's plan of wintering a nucleus in Australia.

sufficient room for the requisite number of frames; and why anybody should desire to insert something extra is beyond our comprehension.

It has been suggested that the boards are a necessity when colonies are to be packed for winter; but our efforts are concentrated on getting such a number of bees in the hive by autumn that when the supers are at last removed the brood-chamber is so crowded with bees that some are compelled to cluster outside. Obviously, then, there is no room inside the hive for anything more.

Of course some will insist that, without the dummy, one comb at least will be bulged or misshapen; but in all our experience we have never encountered any real annoyance from this source. And division-boards cost

money, add extra weight to the hive, provide additional shelter for various pests and diseases, and, finally, entail considerable loss of time by reason of their unnecessary manipulation.

We have used hives of many types; but we long ago arrived at the conclusion that the pattern of the bees' home is but a small factor in the apiarist's success. Personally we believe that, with the man himself, lies the secret. The personal equation is the determining influence there, for all other agents or mediums are merely subsidiary to the prosperous issue.

At various periods we have used the eight, nine, and ten frame (Langstroth pattern), the Long Idea, and the Heddon or Bolton hive—these names are synonymous

in Australia—but have failed to discover where one showed preponderating excellence. They are all good hives, and, as professional apiarists, we would be content to handle bees in any one of them. We feel sure that the same average yield could be obtained notwithstanding the pattern. The hives are splendidly effective.

But, to get back to the division-board: We find them convenient only when it is desired to carry mere nuclei thru the winter in standard bodies. The method of our procedure is explained in the diagram. Of course you will know the Australian winter is not nearly as formidable as that of the states. Indeed, the double-walled chaff hive is a curiosity under the Southern Cross.

Briarolong, Gippsland, Vic., Aus.

## AN EFFECTIVE ARMOR AGAINST STINGS

BY EMMA STROUT

Better and faster work may be accomplished among the bees when one is assured that there is no danger of stings. My veil is absolutely bee-proof, and yet it allows full freedom of the head, neck, and shoulders, regardless of the position the wearer may take, and, best of all, it can not become disarranged. The veil proper, as shown in the picture, is attached to the shirt, which

has to be tucked in around the coat collar. The elastic band around the sleeves and around the lower edge of the shirt makes it very comfortable and yet entirely bee-proof.

Kent's Hill, Maine.

[This seems to be a very good veil for one who desires absolute protection. It is somewhat similar to the one described by

A veil that gives absolute protection, and yet allows free movement of the arms.

may be slipped on over the head and instantly adjusted. Ordinarily, if desired, it can be slipped back over the head, being kept on the shoulders, but ready for instant adjustment if desired. In this way it takes much less time to put on than a veil that

Chalon Fowls, page 558, Sept. 1, 1910, altho the Fowls veil is so made that it can be detached from the shirt. Mr. D. H. Cogshall used to wear a veil very much like the one described herewith. This was illustrated on page 1497, Dec. 1, 1907.—Ed.]

Plenty of snow and cold in Montreal, Can., does not prevent John Mack from securing good crops of honey.

## WINTERING IN MONTREAL WITHOUT LOSS

BY JOHN MACK

My bees did not have a flight from November, 1915, until March 25, 1916, and for three months have been buried completely in snow.

I started in 1912 with five colonies, and have doubled every year since, and wintered outdoors in double-wall hives without any loss. I have not fed any in fall or spring, taking my surplus away early in September, and not disturbing the brood-nest until the following spring.

The honey-flow here has not varied very much since I started in 1912. My surplus last season was about 4000 lbs., one colony

giving about 283 lbs. The white clover and basswood gives us the heaviest flow, but we have a great deal of dandelion and sweet-clover honey. The market here is exceptionally good; but bottlers buy up all grades of cheap honey, and the quality is not uniform.

I have seen pictures of apiaries in the southern countries, but have not noticed very many from our northern country, and I wish to show that, while we have lots of snow and cold weather, we can produce a good quality of honey and lots of it.

Montreal, Can.

## MARKETING EASY IF THE HONEY IS RIGHT

BY G. W. BERCAW

The question of marketing honey is a broad one, involving as it does the entire country from the Atlantic to the Pacific. Many suggestions have been set forth along this avenue of commerce—some good, some bad, some indifferent. Climatic conditions have some influence on the demand for honey, for I am led to believe that in cold climates more honey is used than in warmer latitudes. Honey as a food produces heat, and is more adapted for eating in cool or cold weather. Our heaviest demand comes

during cool weather or winter, as we call it here in California. My observation shows that a half more is handled and used as a food during cold weather.

I believe in advertising strictly pure honey, then supplying the honey when demanded. It should be put up in packages adapted to the trade served. Only the best and lightest should be put up. It is not necessary for the honey to be "water white." A light-orange tinge will sell just as readily. Either glass or tin containers may be used,

but I am not in favor of putting comb honey in glass cans with extracted honey. The size of package will depend upon the trade and the class of customers in general. "Strained" honey should not be advertised, and, as far as possible, the grocers should be discouraged from handling it as "strained." Have them call it "extracted," nothing else. Glass can be used for samples, also in local stores and for public exhibition and sale; but glass cannot be successfully used in parcel-post shipments.

I believe in advertising. I think it is a good plan to use little stickers on all stationery, and, if possible, to use booklets as

an aid to publicity. We have been using them for the past eight years. Honey ought to be advertised as a strictly clean sanitary article, suitable to use in any household. People must understand it that way.

We have no difficulty in selling all the honey we can handle, but it is necessary to have good fully ripened honey, not a lot of green unsealed stuff mixed with milky brood, such as has been produced in some southern California beeyards lately. Right here is the great argument in favor of queen-excluders to keep queens out of the supers.

## SOME THEORIES ON THE COLOR VARIATION IN HONEY

BY W. I. LIVELY

There has been much discussion as to whether the same plant always produces the same article of honey in color and flavor. I have been waiting to see if some one would spring a theory in accord with my own pet ideas on the subject. Mr. M. H. Tweed, p. 988, Dec. 1, has come very near doing it.

Here in the Salt River Valley, in Arizona, alfalfa is our staple honey-plant. In fact, during a large part of the season it is the only source available. Arizona beekeepers do not spend any time discussing whether alfalfa always yields the same grade of honey in color and flavor. They know to their sorrow that it does not. It varies in different seasons, and it even varies at times during the same season. Now Mr. Tweed comes forward with the theory that this variation is caused by the difference in climate and temperature, and I suspect he is partly right at least; at any rate this is the only theory that sounds reasonable to me; and, moreover, it coincides with my own observations and experience.

Owing to a vast increase in irrigation and cultivation, our climate has changed greatly in the last few years. Summer temperatures are not so high, and there is a marked increase in atmospheric humidity. In correspondence with this change the alfalfa honey has materially lightened in color. Of late we have produced the whitest honey ever known in this section—so white and well flavored that it is comparing favorably with the northern alfalfa, and running close in competition with white clover. Where it used to range from a dark amber to a light amber, it now runs from light amber to extremely light, almost water-white.

The increased irrigation has not only affected the temperature and humidity, but also the amount of moisture in the soil.

This causes a ranker growth of the alfalfa-plant, and I believe that this has something to do with the grade of the honey. I think a honey gathered from the plant when it is short of moisture, dwarfed in size, and blooming rather prematurely, has a tendency to be thicker and darker. Last year I extracted four different times during the season, and no two lots of honey were exactly the same in color. The darkest was in the hottest, driest part of the season when the plants were making their least vigorous growth. The best color was obtained in June and early July when the alfalfa was at its best, and the irrigation was heavy.

Now I also suspect that the color of honey is regulated somewhat by the volume and rapidity of the flow. When the blossoms are secreting rapidly and heavily, and nectar is just "rolling in," as we say, I suspect it is lighter in color than when it is coming more slowly.

I confess that this is all mere theory gleaned from my experience. The worst of it is, that every once in a while something will happen that seems to upset all the carefully worked-out theories; and conditions that ought to produce certain results will seem to obtain the opposite; but conditions and results as I have given them here seem from my experience to be the general rule of causes and effects, and possibly the occasional variations are the exceptions to the rule. At any rate, I am convinced beyond a doubt that here, at least, there is a variation in the color of alfalfa honey; and I think that some or all of the conditions I have mentioned, or perhaps, more strictly speaking, certain combinations of these conditions, produce the variation.

Glendale, Ariz.

Eighteen colonies owned by the Flintstone Farm, Dalton, Mass., that are kept to pollinize 3000 trees.

## BEES A GREAT HELP IN A 3000-TREE ORCHARD

BY RALPH ELY

We have an orchard here at Flintstone of about 3000 young trees, and in connection with this we are interested in beekeeping, as bees are essential to the success of the orchard. We now have about eighteen colonies which did extremely well this year, as there was a fine flow of honey.

We believe that the size of our apple crop this year was due in a great measure to our bees. We note in our vicinity that

the fruit did not set according to the amount of bloom, and hence we believe that bees are one of the essential factors in successful fruit-growing.

We are running to the leather and Golden Italian, and find that the Goldens, particularly, give us a great amount of honey, at the same time showing very little inclination to swarm.

Dalton, Mass.

## A SIMPLE METHOD OF FEEDING WITHOUT EXPENSIVE EQUIPMENT

BY L. C. LE MAY

I have had so many inquiries asking for more information on my article published Nov. 1, 1914, that I feel prompted to write a further article on my experience in feeding. The method that I outlined in 1914 is the most satisfactory of any plan that I have tried for cold-weather feeding; but to have it work properly the colonies should be prepared for it in the fall.

For feeding in milder weather to stimulate brood-rearing, storing up in the fall, etc., I have a method that works better than anything else I have tried. I take a super-cover and bore four or five holes 1 or 1 $\frac{1}{4}$  inches in diameter far enough apart to admit placing the Mason-jar feeders, mentioned below, over them without crowding, and yet not too far away from the center of

the hive. Over each of these holes I place a quart Mason jar with a perforated cover such as is used with the Boardman feeders, with a strip of tin soldered around the top or cap so as to raise it about 5-16 inch above the hole, allowing access to all the holes in the feeder. I have also used empty Crisco cans. By punching the cover full of small holes it makes a first-class feeder for this purpose. Another full-depth super must be placed on top of the super-cover and feeders with the hive-cover over that. For stimulating brood-rearing, all the holes in the feeder but two or three should be stopped up. One feeder for brood-rearing is enough, but for supplying winter stores as many may be used as desired.

This method works very well, and does

not cause robbing and stings. At the same time, it allows feeding the bees without disturbing them, which is a good feature.

If there are a few bees about the feeders when they are refilled it is well to use a little smoke to get them down out of the

way, and then close the holes with corks until the jars are refilled. All that is necessary to do when not using the super-cover for feeding is to plug the holes with corks, and then it is just as good as before.

West Hartford, Ct.

## WINTER LOSSES LESS THAN TWO PER CENT

BY JOHN A. STEVENS

My bees are located in a well-protected spot sheltered by my shop and honey-house, and by a large semi-circular hill covered thickly with a second growth of brush. It

ings and a plain board cover over the cloth. The case is large enough so that there is a four-inch space all around the hive when it is placed inside, which space is also filled

A winter case for one hive which permits a four-inch packing-space all around.

is an ideal place for an apiary; for when the wind is blowing a gale out by my residence, in the beyard it seems like a nice quiet day.

The winter cases that I make hold one hive each only. The bottom-board is 24 inches long, and the 2½-inch tray which rests on it is the same length. A board 4 inches wide is nailed on the upper end of the tray, over the notched opening for the entrance. This leaves 20 inches for the hive, which abuts against this board. This means that the bees are obliged to travel 4 inches besides the thickness of the tray and the winter case before they get out.

I place an inverted butter-chip on top of the frames crosswise, then a cloth cut from an old sack. An empty super placed over all holds the cloth in position. When I pack I fill the super with planer-shavings and then another cloth is placed over the shav-

ings, as well as the 10 or 12 inch space on top of the packed super.

With this particular arrangement I do not have to worry about the entrance becoming clogged with dead bees. In very

The case and the hive. The ample packing reduces winter losses to less than two per cent.

cold weather, or if the bees are not sheltered, I contract the entrances down to one inch. All the trays have  $\frac{3}{8} \times \frac{7}{8}$  entrances which correspond with the entrances of the winter case.

My losses with this method for the past

four years are less than 2 per cent; furthermore, the colonies come thru very strong. I have found new honey stored in the butter-chip over the brood-frame as early as May 10.

Mio, Mich.

## A SANE AND SENSIBLE BEE DEMONSTRATION

BY JOSEPH GRAY

---

There is no question but that live bees properly handled make most telling advertisements at county or state fairs. It is the purpose of this article to set forth a sensible exhibit that will always draw a crowd, and yet give the lecturer time to become calm enough to command the attention of his audience without resorting to silly stunts that raise a laugh but do not impress the mind.

### PREPARING THE BEES.

Two colonies of bees will rob and fight, if the day is not just right; therefore one only should be used, and it should be selected for its gentleness. Having the colony selected, the next point is to secure the queen, two drones, and four workers in a cage  $2 \times 3$  inches, and  $\frac{7}{8}$  deep; glass one side, and screen on the opposite side. Take care to have the cage supplied with sufficient candy and of the right consistency. The next step is to prepare the colony. This should be fixed up in a traveling-hive made from an ordinary ten-frame body with a one-inch space underneath the frames and a floor-board securely nailed on. The entrance should be arranged so that it may be quickly closed and fastened with one screw. A ventilated cover with handle completes the traveling-box along with a square of canvas for a quilt.

The combs should be well built and wired—neither too new nor too old. One comb should contain a portion of drone-cells and a couple of queen-cells. These are easily produced by taking two old cells and fitting into the comb a few days previous. The bees will tear down a live queen-cell, but will build in an empty queen-cell. Only a moderate amount of honey must be left in the hive, and it should be mostly sealed. The colony ought to be removed to a new stand two days prior to the show, so that most of the field workers will be left at home. It is the old fielders that do most of the stinging. Nearly all the brood should be removed, reserving only one or two combs that are necessary for show work. Such a colony does not have too many bees to travel with nor to handle.

### ABOUT THE TENT.

A tent should be secured, slightly off from the main stream of visitors, but sufficiently near to a scheduled exhibition ring so that, when the crowd turns from the ring, the people will be ready for the bee exhibit. The tent can be made of 4 panels 12 feet by 8 feet, the top half net or screen, the bottom canvas or board. It is well to put guy-ropes at the corners; for the pressure is often very great if a crowd of 1000 gathers round.

The hive should stand on a packing-case rolled into the center. The bees should be given free flights, either the day previous or early on the morning of the show. This enables them to locate and use the open top, to go and come.

### MAKING AN ARTIFICIAL SWARM ON AN ARTIFICIAL TREE.

When ready for the demonstration, prepare two or three carbolized cloths full strength (dry, not wet). Place the hive on the ground and adjust an artificial "bush." Here in Imperial Valley I use either the bough of a willow or cottonwood trimmed neatly and suspended from wires overhead so that it will just touch the middle of the table or box. Put on the veil. Don't be foolish about this—at least until you are sure of the temper of the bees. Have extra buttons on the cuffs so that you can button the sleeves tightly around the wrists. You may not need these preparations, but yet you may.

Open the hive, using the smoker. Hang the cage with the queen in the bush. The hive, being one comb short of its full number, is easy to manipulate. As rapidly as possible take out each comb and shake (not brush) the bees on to the table. As the crowd is increasing the air will be full of bees. Cover up the hive. Calmly lay a carbolized cloth at the edge of the bees on the table, and put another cloth on the opposite side. The bees will begin to run like a flock of sheep toward the bush. You can drive them and turn them at your will. Pick up a baby bee and throw it into the center of the bush. Urge up a few strag-

glers, pushing them forward with your hand. Hang the bush a bit higher, little by little, and the crowd will grow excited as they see a hundred bees hanging on to one hee. Hang the bush still higher, till at last the swarm is above, and the time for talking is at hand.

Few words are needed. Tell how you have made a swarm as near as possible to a natural swarm. Explain some of the inner

mysteries of the hive; exhibit the cage with the queen, drones, and workers, and then hive the swarm.

Simply tell the people what you know, just as tho you were talking to a friend. Use a few notes, if necessary, written on a folded card. After 14 years of lecturing you may forget something; yet the event will have been a success.

Heber, Cal.

## THE OHIO FIELD MEET AT MEDINA

BY E. R. ROOT

As announced in our last issue, page 837, this was held in Medina, August 25 and 26. All told, there were 150 that registered, and something over 100 that participated in a "honey" luncheon on the first day. As already explained, Dr. E. F. Phillips, of Washington, and Mr. C. P. Dadant, of the *American Bee Journal*, were unable to be present. But fortunately we had with us Mr. P. G. Clark, of the firm of Doolittle &

rator in connection with a special manipulation that he uses with shallow brood-chambers. He has been an invited speaker at many of the large conventions of the country and is a good talker.

Some years ago Mr. House was rash enough to champion the Alexander method of treatment for European foul brood at a time when the bee-inspectors of New York and every one else, nearly, discredited it.

FIG. 1.—The Ohio State Beekeepers' Association on the occasion of the field meeting at Medina, August 25 and 26. The luncheon consisted of rolls, cakes, salad, cereal coffee, and ice cream, all of which were made with honey.

Clark, of Marietta, N. Y., and Mr. S. D. House, of Camillus, N. Y. The former is a breeder of high-class queens—queens bred for good looks as well as for service—queens that have proven themselves to be highly resistant to European foul brood. Mr. Clark is also one of the best honey-producers in his state. Like his partner, he is a careful observer and a good business man.

Mr. S. D. House is a comb-honey expert—a man who, in his state, produces the finest comb honey, practically all of which grades "Fancy" or "No. 1." He does this by the use of the Betsinger wire-cloth sepa-

When we visited Mr. House at the time, he had cleaned European foul brood out of his yards, notwithstanding the disease was rampant in all the yards within flying distance of his own. He showed us colony after colony that he had treated by dequeening for ten days and then requeening with vigorous Italian stock. With no other treatment these colonies were in perfectly healthy condition on the same old crooked combs in the same hives. We were so interested we asked him to write up his method of treatment; and almost instantaneously the bee-inspectors all over the country criticised us for publishing such "nonsense." Some

FIG. 2.—Messrs. Raut, Clark, and House, our distinguished New York visitors, just getting the point.

even went so far as to say that such "stuff" would be the means of spreading European foul brood all over the country, because it would be impossible for the inspectors to have the orthodox treatment (the McEvoy) applied.

Some years later, when Dr. Miller had

the scourge of European foul brood, we advised him to follow Alexander's and House's plan, and the readers now know that Dr. Miller does not fear European foul brood. Today the Alexander-House-Miller method is accepted as orthodox. "But," said Dr. Phillips, whom we met recently,

FIG. 3.—A. I. Root, in his electric, telling the Ohio beekeepers something of his early experiences as a beekeeper.

"the treatment is all right in the bands of the expert and the careful; but with the negligent and the careless, additional treatment should be applied."

With this preliminary we will now introduce Mr. House, who is seen at the right, Fig. 2. In the center is Mr. Clark, of Doolittle & Clark; and at the left is Mr. Raut, another New Yorker, who came with the two other gentlemen. In Fig. 3 is seen A. I. Root in his electric automobile telling some of his early experiences as a beekeeper. He mentioned his mistakes as well as his successes. In recounting some of his blunders he provoked a smile on the faces of his hearers; and at just that strategic moment our artist caught the trio as in Fig. 2. In Fig. 3 A. I. Root is seen in one of his characteristic poses when he is just on the eve of bringing out his point. It is a very natural picture of him as we see him every day in the office.

Fig. 1 shows the beekeepers sitting on extemporized seats eating their honey luncheon and drinking their honey cereal coffee, winding up with honey ice-cream. Over at the extreme right is seen A. I. Root addressing the beekeepers. The seats are on the lawn of E. R. Root, under the apple-trees, with the house in the background.

Among other speakers of the evening were Mr. Fred Leininger, a breeder of fine queens, and President of the Ohio State Beekeepers' Association; Mr. House, Mr. Clark, and Bee-inspectors Ames and Phillips; Prof. Jas. S. Hines, of the Ohio State University, and Melville Hayes, an attorney at Wilmington, O.

On both days, modern extracting machinery, including a power extractor and an uncapping-outfit, were in operation for the visitors. All were given the privilege of going thru the factory buildings, including the honey-bottling department, where honey is being put up for the general market.

On the afternoon of the first day a moving-picture film showing many live-bee operations was put on for the benefit of the visitors, at the Princess Theater, Medina.

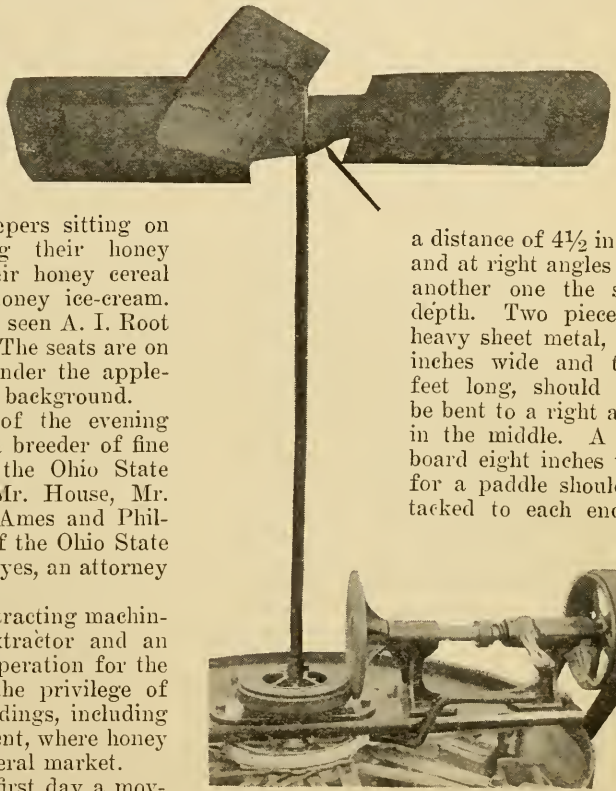

On the second day, the company were taken in automobiles to the queen-rearing yards north of town, where the entire operation of rearing queens was illustrated and described.

#### A FAN FOR HOT DAYS IN THE EXTRACTING-ROOM.

When the crowd reached the extracting-room there was considerable joking about

the "windmill" up over the extractor; but when we started up, the affair proved the truth of the saying, "Handsome is as handsome does." It was a hot day, and the breeze easily felt fifteen feet away was very welcome. This sort of fan means very little additional load for the engine, requires no extra belting or machinery, and can be constructed at a very slight expense. A half-inch pipe with a coupling on the lower end will just slip over the upper end of the vertical shaft in the extractor. There ought to be one or two set-screws in the coupling to hold the pipe firmly to the shaft.

At the upper end of the pipe there should be a saw-cut running down thru the middle

a distance of  $4\frac{1}{2}$  inches, and at right angles to it another one the same depth. Two pieces of heavy sheet metal, four inches wide and three feet long, should each be bent to a right angle in the middle. A thin board eight inches wide for a paddle should be tacked to each end of

the two pieces of sheet metal. When these wings thus made are dropped into the saw-cut a cap should be screwed on to the upper end of the pipe holding them solid. The fan is completed by giving each board a twist, making a uniform bend in the sheet metal next to the pipe.

When running, if the fan shows a tendency to wobble somewhat, a small hole may be drilled into the center of the cap on the upper end of the pipe, and wooden

braces run from there up to the ceiling. A single nail thru the lower end of one of the braces into the hole in the cap holds the upper end of the pipe securely and makes the fan run true.

On cool days, or whenever the fan is not

wanted, it is the work of but a moment to loosen the set-screws at the lower end of the pipe and lift the whole thing off.

The next Ohio field meet will be held at the apiary of Mr. Melville Hayes, Wilmington, O.

---

## MAKING COLONIES BY FEEDING SYRUP

BY PAUL FUNK

During 1915 the honey crop with us was a complete failure, consequently we had no natural increase of bees. Not wishing to lose a whole year of the bee business, and desiring more bees, I decided to make increase by feeding.

During the first week of July I started my increase with two single-frame nuclei of brood and bees taken from old colonies. To these two nuclei I introduced young queens. The new colonies were fed syrup made of 2 to 2½ parts of granulated sugar to one of warm water, stirred until thoroly dissolved. These colonies went into winter quarters with eight combs fully drawn out. Some of the frames had contained full sheets of foundation, and some only starters. Each hive was heavy with honey (sugar), full of young bees, and with a good portion of brood. The colonies wintered outdoors in good condition, coming out in the spring with plenty of bees, and with feed enough for spring breeding. There was no trace of dysentery. About one-third of the other colonies wintering on natural stores died, and some were left very weak.

As to the cost of these made colonies, the sugar was bought just before the 1915 sensational advance in price, for \$5.65 per 100 pounds. An average of 22½ lbs. was fed each colony. Therefore, for building up each nucleus to full strength and with sufficient stores for wintering and spring

breeding, the sugar cost \$1.27. The queens cost 65 cents, making \$1.92 as the total cost of sugar and queen for each. Surely this is a most reasonable cost for a strong colony of Italian bees with a young queen.

Last year, about Aug. 1, a colony superseded its queen. This colony cast a swarm which settled in two parts. The smaller bunch had probably half a gallon of bees, which were hived on full sheets of foundation. They were given a young Caucasian queen, fed 18 lbs. sugar, and this summer the colony was one of my best.

Some one will probably think that these made colonies carried in some fall honey. They got very little, for there was but little honey to get, and until late in the fall the colonies were not strong enough to do much field work. The bees seemed to have devoted their every effort to increasing from the sugar fed.

Warsaw, O.

[We believe that these nuclei, in spite of what our correspondent says, secured some honey from natural sources. If 22 pounds of sugar was fed, that would mean 33 pounds of syrup — barely enough under some conditions to winter a good colony, to say nothing of making the increase in bees, permitting the comb-building, etc. We fear that the figures given are low. Then no account is taken of the labor—an important item, surely.—Ed.]

---

## FEEDING IN TWO-QUART JARS OVER THE BROOD-CHAMBER

BY W. C. MOLLETT

I have tried almost all the bee-feeders on the market, and am not fully satisfied with any of them in all respects, altho all of them have some advantages. Lately, I have been trying another method which is not quite like any other, altho it is on the Boardman principle. The first thing necessary is a flat cover the size of the hive, and about ¾ inch thick. With a brace having an expansion bit I bore a hole in the center of the cover just the right size to admit the cap of a Mason jar, which is about three inches.

These feeder-boards are best made of one piece of lumber; but they can be made of a number of narrower pieces when necessary. After the boards are ready I get some caps for use in Boardman feeders, and then prepare the syrup as usual. Then I fill the jars with syrup and put a rubber ring on the cans as they are used in canning fruit, and put the caps on them. I remove the hive-cover and place the feeder-board upon the hive, and then I am ready to feed.

I go around to each hive to be fed, and

simply invert the jars and place them with the caps in the opening in the center of the feeder, and the sides of the jar rest on the board so that they will not turn over. This brings the caps directly over the bees in the most convenient position for them to carry down the syrup. By this means I can feed at different times during winter, as the bees can carry down the syrup when it is almost freezing cold. Of course it is always better to feed before the weather becomes very cold, but sometimes we are prevented by having other work, and are compelled to feed later than it should be done. For my use this method is far superior to any other, altho, of course, others might not appreciate it. I generally set an empty hive over the jars and replace the hive-cover to keep out dampness, and in this way there is no hurry about removing them.

Some of the advantages of this method are: It is possible to feed a considerable number of colonies in a short time. If the

syrup is not carried down at once it can remain until the bees find the weather suitable; also you can see at once just how fast the bees are carrying the syrup down; and it is possible to regulate the amount by stopping up some of the holes in the cap.

By using jars holding half a gallon, filling is necessary only once or twice. The bees can carry down about half a gallon per day when the weather is warm, and this makes it a short job to finish all the feeding for the season. This method makes it possible to feed without causing robbing. Also by feeding over the cluster it does not tend to cause the bees of the other colonies to become excited. I first learned this method from a neighbor, Wm. Damron, and so I call it the Damron method.

Stonecoal, W. Va.

[Mr. LeMay, p. 724, describes a plan very similar to this except that he bores smaller holes and more of them.—Ed.]

## APHORISMS, SUNDRY AND OTHERWISE

### What about Feeding Sugar and Requeening in August?

BY ARTHUR C. MILLER

[The following article, as will be noted, was written some time ago; but because of the crowded condition of our columns during the publication of the summer special numbers it has been held over. The reader will not properly understand what it is all about without turning back to Mr. Crane's interesting article on feeding sugar syrup, etc., page 145 of our Feb. 15th issue.—Ed.]

The editor is to blame—as usual. If he hadn't put the Greek into my title I would not have got in Dutch with Mr. Crane. At first reading of his come-back (February 15, page 145) I was inclined to think my notes were at fault; but now I see it is a matter of the difference between the Crane and the Miller policies.

When I have said requeening in August, I have usually taken pains to borrow Dr. Miller's saving phrase, and add "in this locality." Midsummer—July—is when our main surplus flow comes, and sometimes it runs well into August, so we do very little dividing then. When we divide after that, as well as at other times, it is a process of taking from more or less of the colonies one or two combs of brood each and making good colonies from them and giving each a queen. That keeps all in the "strong class." Thereby I gain over Mr. Crane's way. Did you ask if I never have any weak colonies? Certainly I do; and, furthermore, you will be pretty sure to find some of them being wintered, or attempted. But you can count them on your fingers, and generally on those of one hand. They are experiments.

Bees usually get abundant stores in August, September, or early October (or in

all three months) if the colonies are strong; hence I say, "keep them strong." When Mr. Langstroth first wrote that, he was a southern New England beekeeper.

As to feeding, much recent advice has been toward feeding thin syrup so the bees would "invert" the sugar. Others said feed, late and quickly, a thick syrup. Now the poor bewildered novice is in a nice state of mind; and, oh how often I find feeding put off until bees are slow to take the feed and then cannot properly store it! Unfortunately in our climate if we feed early—say about September 20—we may find so much brood that there is not much room for food. If we wait until a little later we may run into an early cold spell and find it almost impossible to get satisfactory storing. So in this locality we try to keep our colonies strong, then they will force down brood-rearing if the fall flow is good, and seldom need feeding; and if we have to feed, the colonies are big enough to handle it, even if we have a cool spell. But for five years prior to 1915 the late flow failed and a lot of feeding had to be done. In 1915 there was a fine fall flow, and the strong colonies forced down brood-rearing, packed everything, and went into winter quarters in ideal shape.

No feeding or fussing we can do will give results equal to those the bees secure when conditions favor, and those conditions are a flow and *plenty of bees* to take care of it.

Now 'tis said, "confession is good for the soul;" and if it were only equally good for material customs and habits it would help us a lot. Mr. Crane says he has fed "tons and tons of sugar syrup." If it were any one else I'd say he was a mighty poor bee-keeper; but I don't dare say it of Mr. Crane; but I can most positively say that the need of feeding can be materially lessened by different (improved) methods. (Phew! I almost said, "by better beekeeping.")

(Lest those who are not familiar with my chaffing should construe the foregoing as a bit at Mr. Crane, let me here say that it is *not*, but is intended to arrest attention and direct it to the costliness of many widely followed practices.)

As for "protecting combs from wax worms," his was a rather costly way. Just figure the labor and the food. He says it proved a financial success. I wonder how he figured it.

I can keep combs more cheaply than that; and if I wanted increase at that season (most of ours is made *before* the crop) those combs would have been traded for one or two frames of brood from every colony, and the new colonies would have nearly equaled the old from the start. It is quick, economical, and gives the best of results. But wax-moths bother me only where black bees are kept near.

Rather presumptuous for me to try to tell you how to keep bees, isn't it, Mr. Crane? To be sure I've not kept bees quite as long as you have (I began in 1880), and I have not so many as you (about 200); but my needs have compelled me to make short cuts, and my business training has led me to put the yardstick of cost on to my operations. Oh, yes! I do some things which are not economical; but that is where I am experimenting—that is my play.

Do you realize what it costs you to pro-

duce a pound of honey? (Comb and extracted are pretty much the same.) Do you know that it costs some specialists over ten cents a pound, taking good years and bad? Do you know that two or three go as low as two cents? But these latter sell their own crop, so they have only half a year's labor to charge up to cost of production.

There is the matter of annual requeening which I follow so carefully. Young queens and fine combs I consider the foundation on which all the other parts of my beework are built. But it is assailed by many because they say so many queens are good for several years. If they will tell me some way by which I can pick the good ones at the

"Bill" McLeod, whose apiary is shown herewith, according to the *Nepawa Press* (Manitoba), is a practical joker. At an agricultural fair he entered some specially prepared honey as soft soap, and the unsuspecting judges gave him the second prize. He kept the matter secret until he had secured possession of the blue ribbon, then gleefully started out, exhibiting his "soft soap" and the ribbon. Doubtless the judges had not tasted the soap.

start I'll consider their methods. When I see the miscellaneous assortment of colonies they have each spring, and hear them tell how they go to building up, etc., I am content to follow my plan, even if I do unwittingly destroy some queens which, if allowed to survive, would have proved to be sisters of some bee Methuselah. Then queens are so cheap I really cannot afford not to use them liberally. They cost me less than ten cents each.

In that same issue (Feb. 15), page 139, Dr. Miller takes issue with some one for saying that there is no need of having a queen a year old to determine if she is a good breeder. Well, I fear that I must take sides against the doctor; but with this qual-

ification, the "strain" must be known; however, my queens are at least eight months old before I pick the breeders—only one strain in my yards so far as I can manage it. It makes for economy, and is one of the reasons why I let out against late feeding; for so few beekeepers have all colonies alike, and so many have a lot of colonies short of young bees, and those are the ones which usually suffer the most from late feeding, particularly of thin food. Variation from normal proportions of old and young bees is at the bottom of many of our troubles in beekeeping at other seasons as well as in the fall. The only practical way to avoid such variation is to keep the colonies headed with vigorous queens *all the time*. Then "building up colonies" in the spring and feeding tons of sugar in the fall ceases to be a habit. (Dr. Miller's building up is quite a different thing from the common practice; but it is very costly in labor, and I have often wondered if he could not avoid the need.)

As to bees in orchards, I was talking of *my* bees while Mr. Crane was thinking of the *orchardist's*. For the sake of my peace of mind I want my bees "horse distance" away from where they are to be worked.

That phrase did just what I made it for—drew attention to the need of keeping bees and horses a safe distance apart.

If Mr. Crane will visit Essex County and some other sections of eastern Massachusetts he will see the curse of spray-crazy people. So long as orchardists are careless in such matters, so long they must buy bees to poison. I'll keep mine a safe distance away. It is the "times that spraying does kill the bees" that I am afraid of; and as I cannot tell in advance, I avoid the risk.

So far as perfect pollination of a big orchard in a stormy spring is concerned, the scattering of bees thru the orchard is the best, as I showed twenty years ago. But in the article Mr. Crane took issue with I was considering *my* honey crop, while he was thinking of the orchardist's fruit crop. I keep bees for honey, not to accommodate some one else. If my business and his work in harmony he is welcome to such benefits as my bees will give; but otherwise I shall move to distant fields, as I have had to do in one case.

So the reader will see that Mr. Crane and I are not so very far apart. We were simply looking at things from a different point of view.

Providence, R. I.

---

## HOW TO MOVE HIVES OF BEES SHORT DISTANCES

BY DR. C. C. MILLER

When a bee takes its first flight it spends some time in marking its location, not so much in noting the appearance of its hive as that of the surrounding objects. Change its hive, or the appearance of its hive, and it will show some confusion and hesitation about entering, but will soon accept the change. Move the hive to a new place, and just what the bees will do depends on circumstances. When I had only one colony of bees I moved the hive to a new place about a rod distant. When bees next returned from the field they went straight to the old place from which the hive had been moved. Surrounding objects had not been changed, and by them they were guided. After sailing about the old spot for a little while they began to search the neighborhood, and soon found their old hive in its new place. How far it might have been safely moved I do not know, but very likely it might have been ten rods or more, possibly much further.

But it's quite a different matter with the present number of colonies in my apiary. If I move a hive to a new location the bees returning from the field will be likely to

enter one of the hives *nearest the old location*. So it may happen that they will not find their hive if it be moved only four feet, if that leaves some other hive within less than four feet from the old location, as would happen where two hives are standing close together and one of them jumps to the opposite side of the other.

As a general rule a bee probably marks its location once for all. That lasts for its usual lifetime of about six weeks, and no doubt would last indefinitely if it were to fly daily. But after confinement for a time, upon its first flight again it will mark its location anew. How long a confinement is necessary to make it mark anew its location I do not know; but I know that it varies greatly according to circumstances. After the confinement of three or four months in winter the location is invariably marked upon the first flight in spring; yet even then, if a hive taken from the cellar is put on a stand other than the one it occupied the previous fall, the bees will in some cases be seen flying about the old stand, showing that it has not been utterly forgotten. On the other hand, at a time when a heavy flow

is on, if stress of weather confines the bees to their hive a very few days, they may be seen marking their location as soon as permitted to fly.

Bees may also be seen sometimes to mark their location anew after being confined to their hives a few hours, a few minutes, or not at all, if they have been under some great excitement, such as the excitement caused by being heavily smoked.

There seems good reason to believe that there is a more or less close connection between a locating flight and forgetfulness of location; in other words, that when bees mark their location at any time it is to forget all about where they were previously.

In a few words, then, we find that bees mark the objects surrounding the hive rather than the hive itself, and that confinement and excitement are elements that help to make them mark their location and attach themselves to it.

With these points in view we are ready to consider what must be done to make bees stay put when moved to a new location.

If a colony be moved ten miles from its old location, no precaution need be used, no matter when the change is made. There will be no danger of the bees returning to their old location, for it is beyond their finding. Nor need the distance be ten miles. In most cases probably a mile and a half, or even a mile, would serve. But, no matter what the distance, if the bees upon going afield from their new location should happen upon ground whereon they had previously pastured, it is quite likely they might return to the location they had always known as home.

Suppose, now, that we want to move the colonies of an apiary a short distance at a time when they are in daily flight. If the distance be only four or five rods, with no other bees nearer, and if the hives have the same relative positions in the new place that they had before, each bee might be expected to find its own hive without trouble. But at some point the distance may become so great as to make trouble, possibly at the distance of one or two city blocks. More or less of the bees upon their first flight would return to the old location. Everything would look homelike to them except that their hives were absent. We can imagine them circling about the old spot, perhaps to the distance of a few rods, looking, looking, for the old home, and finally settling down upon the old stand, saying, "Well, this must be our old home; everything looks homelike, only our hive is gone. No use to look any more; all we can do is to stay here and wait till it returns, if it

ever does return." And so they settle down despairingly to await the end that comes to them in due time. Clearly it would help matters if they could not recognize the spot as their old home; and that will be accomplished by changing appearances, moving or removing any old objects that are movable, and bringing upon the ground new objects, thus practically taking away their "location."

However long or short the distance, we may take advantage of the two factors previously mentioned — confinement and excitement. In the evening before removal the bees may be fastened in the hives or else in the morning before they fly, and not opened till some time the next day, care being taken that they are not left so long as to smother in a very hot day. An hour's confinement at a time when the bees are anxious to get into the field may equal a month's confinement in the middle of winter, for the bees become very much excited when they find they cannot get out. Instead of moving the bees so softly that they shall not know they are being moved, they may be left on the old stands till well on in the day, and then trundled on a wheelbarrow or taken by some other rough conveyance. The rough handling increases the excitement, which may be still more increased, if thought necessary, by pounding on the hives just before opening the entrances and by smoking. A common practice is to put a board before the entrance for the first flight. This, either on account of added excitement or for some other reason, helps to make the bees mark their location.

Suppose, now, that the bees have been moved, and that for fear of smothering them we have not been vigorous enough in our precautions, and that some of the bees have gone back to the old place, perhaps settling in clumps. The case is not at all hopeless. Set in the old place a hive containing a few combs, with or without honey, and in the course of the day all the returning bees will be assembled in this hive. Take them to the new location and give them where they will do the most good. Repeat the performance the next day if any more bees return. So effective is this treatment that it may be used as the only means to attach the bees to a new location. For the transition from the cheerless condition of being without a home or a mother to one where they have both is so great that the joyful excitement destroys all attachment for the old home and awakens a lasting attachment for the new.

# Heads of Grain from Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

*Uncle Benny Motherwort thought the sour smell around the home yard was foul brood. When they convinced him it was from goldenrod he was afraid to eat it for fear he'd get the hay fever. Benny's boy says his pap is such a pessimist that he chews his quinine pills.*

## Giving Away Stock to Requeen a Locality.

The thanks of the whole fraternity are due J. L. Byer for his graceful and manly defense of queen-breeders on p. 185, March 1. I have faith enough in humanity to believe that most of the queen-breeders are trying to do the right thing by their customers, knowing that, unless they do so, they can never hope to build up and hold a trade that will justify them in following the business as a vocation.

No doubt there are some who advertise themselves as queen-breeders who should never have attempted that line of business. They have been so excited over the great profits(?) to be made by selling young queens for 75 cents to \$1.00 each that they have rushed into the business without adequate preparation. Before one attempts that line of the bee business he should be sure that he has a superior strain of bees, not as shown by the yield of a few individual colonies, for that may be the result of robbing, but by the average results from all the colonies.

Then he should be sure that he knows how to rear the best queens. He should practice for several years, rearing his own queens

and noting how they turn out as honey-gatherers.

When he knows that he is fully qualified along both these lines he should next clean up all the hybrids and strains, other than his own, within mating distance of his queen-yard. This is not so difficult as it may sound. He must not expect his neighbors to purchase his queens at catalog prices. They are not enough interested in bees for that. If a neighbor has only a few colonies it is the cheapest plan to give him untested queens and introduce them for him. If he has from twelve to thirty or forty colonies the young queens may be reared in the man's own yard from cells grafted with larvae from our best breeders. A few colonies of pure stock will usually be found. The drones of those colonies may be allowed to fly, while the drones of other colonies should be trapped and the heads of all drone brood shaved off. This will generally result in a fair percentage of pure matings. Any mismated queens may be replaced later. I have found small beekeepers quite willing to co-operate in requeening their bees. In fact, they are usually delighted with the idea, when they find it is not going to cost them any money. If the would-be queen-breeder is too much of a "tight wad" to do that much for his neighbors, when it is himself that is to reap the greater profit, he'd better keep out of the queen business, for he will certainly be called upon to make greater sacrifices than that. When he thinks he has all the hybrids and bees of off color cleaned up in his neighborhood he will still have a queen mismated occasionally.

Mathis, Texas.

H. D. Murry.

## Newspaper-wrapped Hives.

The method I use to prepare bees for winter is not new, but it may be new to some. An escape-board is first placed on top of the hive-body, and, over the place where the escape should be, a piece of burlap. If the bees are short of stores I put on a paper pie-plate or more of hard candy, spaced from the escape-board by two or three small sticks, and then the burlap. A super is then set upon the escape-board and filled with planer-shavings.

I then take several newspapers or two thicknesses of building paper and wrap the hive up as I would a package (not the bottom of course), folding the paper over the top and then slipping the metal cover down over the super, first placing a small stiek or nail on the edge of the super to make a little air-space under the cover.

The paper is then tied tight at the bottom with a single piece of twine and pieces of lath tacked up and down where the newspapers overlap, or wherever the paper seems to bulge a little, driving the nails only part way in, so they may be easily removed in

the spring. One would think that the first rain would wash newspapers off; but such is not the case, as they will be almost as good when taken off the next spring as when first put on. If the entrance becomes clogged with dead bees or snow and ice, the bees will be able to get sufficient air overhead, thru the shavings. This location is very near the center of Pennsylvania, and this method of wintering has given me uniformly good results.

I find it a good plan to leave the super of shavings on until June 1, even tho the paper has been removed. It will greatly assist the bees in keeping up the temperature of the hive during cool nights, as the shavings absorb a certain amount of heat during the day and release it very slowly.

In case it is necessary to put a super on during fruit-bloom, all one has to do is to lift the escape-board, super of shavings and all, and slip the other super underneath.

When the shavings are removed, if they are placed in front of the hives an inch or so thick they will keep the grass and weeds down for a long time.

Osceola Mills, Pa.

J. A. Allard.

#### A Uniting and Feeding Screen.

For uniting I use a double screen that I think is very convenient. I make a frame  $\frac{3}{8}$  or  $\frac{1}{2}$  inch thick of strips  $1\frac{1}{2}$  or 2 inches wide, the outside measurements being the same as the outside measurements of the hive. I make mine  $16 \times 19\frac{3}{4}$ . Since my

strips are 2 inches wide, the inside measurements are  $12 \times 15\frac{3}{4}$ . I tack the wire screen on both sides, so that the bees will not be able to sting thru. I always have a number of these double-screen frames on hand.

Over the colony to which I wish to unite one or more colonies I place a screen, then the hive to be united, of course first removing the bottom of the upper hive. If another colony is to be added also, I put on another screen, and then the third hive on top of that, making sure that the upper hives have no outside entrances. The entrance of the lower hive is left open. After putting the cover on top of the pile I leave them this way for three days and nights. The third evening about dusk I lift up the upper hive carefully, just high enough so that some one else can pull out the screens. I always take out the lower one first. In the morning the bees will all be together just as tho nothing had happened.

If I want to do any feeding at the same time, I invert a ten-pound honey-pail having a perforated lid over the frames of the upper hive, placing another empty hive body on top to cover the pail. Of course, since the uniting takes only three days, the feeding can just as well be postponed until a few days after the screens have been taken off.

After the bees are all together I leave the extra hives on for four or five days until the bees have become accustomed to their new home, then shake them off their new combs in front of the entrance and remove the surplus bodies. This plan with me has never failed.

Wabash, Ind.

F. J. Rettig.

#### Candy the Principal Winter Food.

I have been keeping bees for 35 years in this locality, and I have so much faith in my system of wintering bees that I believe I could be successful in wintering them in Munetaha or Saskatchewan, if I can find a locality where the beeyard would be protected from high winds by a side hill or in a ravine, or any place where high winds do not prevail. I do not feel alarmed because of much snow or heavy frost; for if my double-walled hives or my bee-clamps are buried in snow, all the better. And in the cellar, if I can keep the temperature between 40 and 45 I have no fear whatever.

I use a great deal of bee-candy in the winter. I experimented on bee-candy for winter for 35 years, and I find it better than any other substitute for honey, as the bees have less dysentery. My outside bees have had a very few cleansing flights, and yet show very little spotting of the hives. I feed in the open air, spring and fall, 8 rods from the beeyard. I also feed artificial pollen in the spring till the willows and dandelions are out, then I dispose of artificial pollen.

I hear much about robbing; but I have had no difficulty along that line for the last 15 years. It is the careless beekeepers that have that bother. My correspondents frequently ask me why their bees die and leave lots of honey in the hive. There are many different reasons for that, but time and

space do not permit me to explain. Study the weather in the locality. All localities are not the same. The fall, winter, and spring management that might suit my locality might not suit yours, and yours might not suit mine.

Port Elgin, Ont.

Geo. Guyer.

### Letting the Bees Leave of Their Own Free Will.

My method of taking off comb honey does not include the use of bee-escapes. When there is a honey-flow I simply give a few puffs of smoke in the top of the sections to rid them of the majority of the bees, and then I lift the super off from the hive and set it down on the shady side of the hive with one end on the ground and the other end against the side of the hive. This permits a circulation of air thru the sections, and the bees will leave it rapidly.

I continue in this manner until I have taken off about 500 lbs., when those which were taken off first will be practically free from bees.

The sections are then taken from the section-holders and conveyed to the honey-house or any other place used for their storage.

When there is no honey coming in, this work will have to be done in a different way; however, the difference is slight. The honey is taken off, and the super put down on the ground at one side of the hive with the corner of the super about four inches from the end of the alighting-board, and a hive-cover put over it.

I now continue taking off honey in this manner as before until a few hours have passed, when the bees will leave the super under the cover, and robbers will not bother if the operator is careful (this method applies to telescope covers). When the bees have left the sections the operator can take the honey from the section-holders.

Sometimes during unfavorable weather the bees will not all leave the sections within the usual time, but they will collect in one corner of the crate and give no trouble in getting them out.

In my opinion this method surpasses the use of bee-escapes and all other systems in the matter of saving time when it comes to taking off comb honey; and I think others, upon trying it, will favor it likewise.

Roxbury, N. Y.

M. E. Ballard.

### Wintering a Teacupful of Bees in a Single-walled Hive.

Mr. Editor:—You tell Samuel K. Johnson, Dec. 15, that he will have to sacrifice some of his queens if his colonies are not strong. On account of a scourge of American foul brood a few years ago, and a hurry-up effort since then, I have had no little experience with colonies that were not strong. I have wintered bees that clustered between only two self-spacing Iloffman frames, and they were as strong, apparently, when they came

out of winter quarters as when they went in. These frames had drawn combs which were about half full of capped honey on the side next to the bees. I think I can winter a teacupful of bees in a single-walled hive out of doors.

Last winter I had seven very weak colonies in one row "heeled in." The hives were set close together, covered on the top and back with chaff, with about one foot of dirt on top of the chaff. The fronts of the hives are toward the south, and are exposed. On December 22 the bees had a flight and were out almost to a bee. I have never seen any mixing.

I have other colonies covered with chaff and boards, and others with chaff and dirt to the eaves. The front of the hive, however, is always exposed. So far I have had no loss in wintering weak colonies in this way. The weaker they are, the more I "heel." On warm days when there is snow on the ground, I stand a board in front of the entrance.

Don't sacrifice any good queens because your colonies are weak, for, wintered this way, they build up fast in the spring.

Westfield, Ind.

A. L. Beals.

### Floor-board with Adjustable Entrance under the Hive.

A short time ago some one described a floor-board which provided an entrance under the hive, and thus entirely eliminated the porch. The only notice taken of it was by one beekeeper who said that an entrance under the hive could not be watched against clogging-up, etc. I will describe the board I invented some years ago and still use.

The main floor of the hive is composed of boards of the right length nailed across battens on edge, say three inches by one. The front board is only three inches wide, and between this and the next is a space of four inches, after which the boarding to the back is solid. Of course the "well" thus made is protected at the sides by pieces of the same thickness nailed on to the battens. The front board has a V-shaped piece cut out from the under side to half its width, the point of the V to the front. The alighting-board slides close under this floor on ledges nailed to the battens.

When the alighting-board is slid right up to the front of the V-shaped groove, there may be an entrance of only a bee-space. As fast as it is slid back the entrance widens, till a slit is uncovered in the well itself; then that slit deepens till there is an entrance of fifteen or sixteen inches by four. It is quite easy to make the draft great by day and less by night by going to the back of the hive and pushing the alighting-board forward or pulling it back by means of a suitable handle nailed to its under side.

G. G. Desmond.

Sheepscombe, England.

**Handy for Emptying Cans.**

No doubt every one who handles extracted honey has experienced difficulty in pouring from the sixty-pound can, or any can, for that matter. I have overcome that difficulty for myself by taking a spare easy-fitting screw-cap, and, after cutting out the top, soldering to the band thus produced a tubular spout about 2 or 2½ inches long. To cut the top from the cap, file the edge all around until the parts will separate without using force. The greatest care must be used not to bend or spring the band out of shape. The piece for the spout, when cut out and ready to be rolled up, will look something like the sketch pattern. Bend the tin around

a piece of wood, but don't use the band, as the spout must fit the band without strain. The ends of the piece should be locked together and soldered before attaching to the band. There is no trouble in locking the ends—just turn the edges as seen in the cut, and drive the seam down close. (The spout might better be fitted to the cap before cutting out the top.)

When the spout fits easily and nicely the two may be soldered together. The best plan is to cut and fit a stiff paper pattern, by means of which the tin may be marked out just right with least trouble. A tomato-can will furnish the material and an old pair of shears will do the cutting. Any one who can do soldering can thus easily provide himself with this great convenience.

New Jersey.

C. D. C.

**Woolly Buckthorn as a Honey-plant.**

I am sending a honey-plant. My brother-in-law gave it to me for hogs. Hogs seem to like the haws, but I have not paid any attention to the tree until this week, or, rather, I had not thought much about it. It is in bloom now, and you will see that it is a heavy bloomer, and it bears accordingly. The berries are about the size of a black-

gumberry, and have a seed like the black-gum. But the bees around this tree put me to thinking of the probable value of this tree. I never saw so many bees about anything except a honey-tub. The tree is about 10 feet high, with a heavy top.

I want you to advise me as to planting a grove of them for bees. I believe they would be good for hogs. They seem to like them any way, but I don't know that it would pay as a hog feed; but if they are good for honey and hogs, I think it would pay to plant. I brought the tree from Florida.

Groveland, Ga.

T. E. Sullivan.

[This was sent to our botanist, who replies:]

This shrub or tree is woolly buckthorn, or *Bumelia lanuginosa* (Michx.) Pers. It is widely distributed in the woods of Florida, Georgia, and other southern states. It belongs to the sapodilla family, or Sapotaceae, the species of which are largely found in the tropics. Plantations of this tree for honey only would probably not be profitable. The cost of the land, the expense of planting, and the long delay before there would be an abundance of bloom, must be considered, assuming that the species is suited to the soil and climate. Experiments in planting trees and shrubs as honey-plants might well be made by state governments or wealthy individuals, but experience would seem to show that they are not advisable for those dependent on their farms or apiaries for a living.

Moreover, in Georgia there is, according to J. J. Wilder, a large area covered with gallberry bushes which is only partially occupied by beekeepers. He says it is difficult to overstock a gallberry region. Would it not be better to locate in such a section of the state, where a crop of honey could be obtained immediately, rather than to plant trees of the woolly buckthorn for some indefinite future time? As to the value of the berries as food for hogs I am unable to speak.

John H. Lovell.

Waldoboro, Maine, July 24, 1916.

**A Brand-new Idea for a Profitable Ad.**

I caused the following to be printed in local papers, and had a copy of it, with many recipes calling for honey, to be sent to every school in the county, the county superintendent helping me by volunteering to send out the circulars with his own mail, to the teachers.

**PRIZE ESSAY.**

To the Crawford County school child under sixteen who sends me the best essay on *honey* I will send a gallon of *Bonney Honey*, postage paid, as a free gift. The teacher must certify to the article. Time limit, December 15. The winning essay will be printed in the county papers.

DR. BONNEY, King-bee.

The Buck Grove Apiary, Buck Grove, Ia.

It has been but two weeks since I commenced this, and I have already got results. I think it is going to prove a very profitable advertisement.

Buck Grove, Ia.

A. F. Bonney.

### There are Goldens and Goldens.

I have been amused at the different opinions of golden bees as expressed in the recent discussions in Gleanings. As is often the case, the parties who disagree are talking about different things. There are two well-defined races or strains of golden bees which are frequently confused. One strain, in its purity, is very gentle, very lazy, raises little brood, but feeds the larvæ liberally. This is the race beloved of the queen-breeder. The queens are a beautiful golden in color, but usually rather small. The other strain is active and energetic, but usually vicious in temper. Both strains are generally good finishers of comb honey.

I tried for several years to get a good strain by crossing the two that have been mentioned, and succeeded in getting a few queens that were satisfactory. But their descendants mostly turned out common three-handers, or reverted to one or the other of the parent races. As I was not raising queens for sale I gave it up and returned to the common Italians.

The term "golden," as applied to bees, is a very indefinite one. The race can be kept true only by close inbreeding; and the closer they are inbred the more strikingly their defects appear. The wide difference in price between untested and tested queens as quoted by breeders of goldens shows the difficulty of breeding true.

I worked for one breeder of golden queens who had requeened every hive in his mating range with daughters of the same queen. The result was a very beautiful and gentle race, which made a fair showing in honey when no other bees were present for comparison. But in other apiaries, where his queens were introduced I find them invariably the poorest.

Newman, Ills.

C. F. Bender.

### Broodless Cell-Building Colonies.

Mr. Pritchard advises A. W. Kuenzli, in Heads of Grain, July 15, that only capped brood be used in cell-starting colonies, and that it be used for only a very short time lest laying workers get to be a nuisance. Mr. Pritchard has had more experience than I, but I am convinced he is wrong. Why keep any brood at all in your cell-starter after first dequeening it? No better cells will be built. The colonies I started with this spring are still queenless, and still starting the finest cells I could want. Besides, my cell-starters are very good surplus-honey colonies, having yielded about 150 pounds of extracted honey this year.

I can't afford to have backward colonies all over the yard by dequeening and requeening later. I can't afford the fuss. If you will shake a frame of young bees into the starter every other day they will build the finest cells, laying workers will never trouble and they will develop a field force that will put up a lot of honey in the frames of the hive. Note that I am talking of starters,

not builders, as Mr. Kuenzli seems to have the two confused, also that I could name some of the biggest breeders in the country who use my plan. I am surprised that a company like the Roots, with their efficiency, could tolerate a lot of colonies dequeened and requeened in a few weeks to build up for winter only, giving no surplus.

Plainfield, Ill.

Kenneth Hawkins.

### Natural Swarming Without Much Increase

The honey season has been good here this year, but my bees did lots of swarming. When I got all the swarms I wanted for increase, I returned the swarms to the parent colonies; but in most instances they swarmed again the next day. Then I gave them to other colonies, which had swarmed a day or more before, and it worked fine. They stayed and worked just as hard as swarms hived in empty hives. At first I was afraid the bees would fight, but they never did.

I hived the swarms in store-boxes. Sometimes, when several swarmed at the same time, I had more than a bushel in one box. The next morning before sunrise I shake them out on cloth-covered boards, set slanting to the entrance of the colonies I want to strengthen. I give about 5 to 7 lbs. of bees to each colony.

When the swarming season was over, from 105 colonies, spring count, 97 were strong and 8 weak (those which swarmed last); and besides this, I had 32 new colonies. Until today I found only two of them queenless. I got about 8000 lbs. of comb honey.

I like this way of swarm control better than anything I have ever tried before, and I expect to practice it again next year. I would not try it in a season when there is not a good honey-flow; but when the bees don't get much honey in this locality they don't swarm much.

Fred W. Wenke.

Pender, Neb., Sept. 13.

### Honey Saved My Baby's Life.

He was eight months old, and starving. I put honey in his milk.

We also gave it to our oldest daughter when she had typhoid fever. Milk, honey, and oatmeal, was all she ate for weeks.

I'm a great lover of honey. When available we use 800 to 1000 lbs. in our family. The keeping of a few bees is very little work, and we often sell that much.

Star, Okla.

Mrs. Ona Foliart.

How much corn syrup is necessary, when put in honey, to prevent it from becoming candied?

Ogden, Utah.

Ogden Bee & Honey Co.

[We do not know of any one who is mixing corn syrup with honey to prevent granulation. Such a mixture could not be sold as honey under the national and various state food laws. The corn syrup would not accomplish the desired result without interfering with the flavor.—Ed.]

# GLEANINGS FROM QUESTIONINGS

J. A. C., Ohio.—Is there any advantage in using acids in making sugar syrup for winter?

A. Yes and no. Some regard it as necessary, but we have fed up our bees without the use of acids in the syrups, for many years. The purpose of the acid is to invert the syrup, making it more like natural stores. If we could, by some artificial means, add protein or pollen, it would be better.

W. A. C., Ohio.—Why is bee-glue so abundant and sticky in the fall?

A. When bees have nothing to do they will gather gums and resins. It is their nature to chink up cracks and crevices in their hives to make them warm; therefore in the fall they will gather propolis and deposit it thruout the hive. New bee-glue is more sticky than old, and hence one notices it more in the fall than at other times of the year, simply because of its sticky nature. As the weather turns cold it hardens so that the frames are glued together. At such times it is necessary to use considerable smoke in separating the frames.

E. S. L., Jenkins, Ky.—What is honey-dew?

A. Honey-dew is a secretion from plant aphids. It is a sticky, sweet-tasting liquid that adheres to the leaves of the various kinds of trees on which the plant-lice work. It is something of a calamity when the bees gather very much of it, for, strictly speaking, it is not honey and cannot be sold as such. The flavor is often quite bitter, and the color cloudy and dark instead of clear. Some years much more of it is gathered than others. The year 1908 in many localities was noted for the large amount of honey-dew stored in the combs.

V. I. S., New York.—When is the best time to unite for winter?

A. The best way is to put the brood together in August and September; but if the matter has been delayed, the bees of two different out-apiaries may be united without any returning. Two weak colonies in the same yard side by side can be united by taking away one hive and placing the other between where the other two stood.

Ordinarily it is not practicable for beginners to unite bees of the same yard, on account of bees returning to the old stand; but it can be done. Wait till cold weather comes on after the first two or three frosts, and when all the flora is killed; then early in the morning place two clusters together. If the weather continues cool or cold for several days, not many bees will return to the old stand.

A. C. W., New York.—How old should a queen be to get the best results in wintering?

A. The younger the better. The one and two year old queens are apt to diminish egg-laying, sometimes stopping altogether during the latter part of August and fore part of September. The result is, their bees go into winter quarters too old to give the best results. It is desirable to have brood-rearing in August and September so that the hives will be filled with young bees in October and November. To that end young queens should be used, as they will lay right on. After breeding up in this way the colonies will need to be fed thru September and October with a syrup consisting of two parts of sugar to one of water. As the weather becomes cooler, the syrup should be made thicker—2½ parts of sugar to one of water.

A. B. C., Pennsylvania.—I have heard it said that windbreaks are very important for outdoor wintering. My bees are located on top of a hill where the wind strikes them from all directions. Will large quadruple winter cases with four inches of packing afford sufficient protection?

A. You had better by all means move the yard into a protected location 1½ miles from its present quarters. When cold weather comes on you can move the bees a distance of a hundred yards or so. We not only advise plenty of packing, but windbreaks in the form of trees, shrubbery, outbuildings, or natural barriers like a hill.

Placing an apiary at the foot of a hill without shrubbery does not always give satisfactory results. The wind will sometimes pass over the top of the hill, dive downward, and hit the hives with almost the same force as if they were on top of the hill.

X. Y. Z., New Jersey.—One of my colonies that was as gentle as kittens during the summer now seems to be very cross. What is the reason? The last time I handled them they stung my hands and clothing, and actually drove me out of the apiary.

A. If you handle the bees early in the morning, when the propolis is hard, and the frames come apart with a snap, you will be badly stung unless you use plenty of smoke, no matter what the strain of bees. Wait till the middle hours of the day, and use just enough smoke to keep the bees down. If you separate the frames when the propolis is soft you will have no trouble. Generally bees are crosser in the fall than at other times. A colony that has been gentle an entire season, even during summer, will sometimes be very ugly when the hive is opened. When there has been a heavy honey-flow, and it suddenly stops, all the bees in the yard will be more or less cross. It is advisable to avoid handling them more than is necessary before they get over their ill humor or disappointment, because the sudden flow of wealth (honey) has been suddenly cut off.

A. I. Root

## OUR HOMES

Editor

Oh how I love thy law!—PSALM 119:97.

I was glad when they said unto me, Let us go into the house of the Lord.—PSALM 122:1.

Forsake not the assembling of yourselves together.—HEBREWS 10:25.

During our pastor's vacation a stranger occupied the pulpit. He also was on his vacation, and told a little of his experiences. A part of his sermon concerning church attendance took a great hold upon me. I have several times before mentioned that when I started out to serve the Lord, in answer to the question if I should be put down as a visitor to the Sunday-school or at our regular services I replied, after considering the matter briefly, "Brother Thompson, God helping me I am going to be a regular attendant at our Sunday-school the rest of my life." This statement was made before a pretty good-sized Bible-class; and I did not realize until afterward what it meant. But I did realize that it included attendance on the preaching service as well as the Sunday-school; and may the Lord be praised that I cannot now recall having failed to attend church at least *once* every Sunday, when it was reasonably possible to do so; and I cannot begin to tell you what a benefit it has been to me for the last forty or fifty years.

This being the case, you can readily imagine how it pains me to hear people excuse themselves from going to church. They are "too tired;" they "do not feel like it;" "the weather is too hot;" "the weather is too cold;" "it is too rainy to go out," and no end of other and similar excuses. Many times I have said to near and dear friends after the sermon was over, "O my dear friend, you don't know what you missed by being absent today. In fact, I should not be surprised if you have, by staying at home, missed one of the best sermons of your life," etc.

Here in Medina we have a talented, up-to-date young minister. His sermons are always listened to. If anybody ever went to sleep while he was preaching, I did not know it. We are also paying him what a good many people think is a pretty good salary; and yet these same persons who contribute, perhaps quite liberally, to the salary, voluntarily stay away. They do not hesitate to make business arrangements that keep them away on Sunday. Sometimes they tell me they attended some other church while away; but too often I find they did not go at all. Sometimes the whole family go on an outing, perhaps to their summer home on the lake. When they get

back I ask the question about church and Sunday-school. With the automobiles that are now so common there is but very little difficulty in finding a church and Sunday-school sufficiently near by here in Ohio. But again and again I am pained to hear they were too tired with the busy cares of the week, and that they wanted one whole day of rest. Now, I do not believe—at least I cannot readily agree to the statement—that anybody *rests* better by staying at home reading papers and magazines, dozing, etc., than by going to church at least once on Sunday. And then the children—a break in the Sunday-school lessons means to a child that it is not so very important that he should be on hand at Sunday-school.

Some of the excuses I have heard are that the church near by is behind the times. One party who went to church (I think a good deal because I urged it) said the poor minister was so much put out by seeing a crowd of "resorters" who came to his church that he became embarrassed and made awkward work of resuming his sermon; and they gave that as a reason for staying away. It made me think of a reason a young friend away up in Michigan gave for not attending the weekly prayer-meeting. He said it was all "run down," so there were not more than half a dozen in attendance, and that was *his* excuse for staying away. Now, in the case of the young minister who was embarrassed because a lot of town people came in unexpectedly, perhaps in the middle of his sermon, there was a splendid opportunity to grasp hold of the good points in his talk, and, after the sermon was over, take him by the hand and give him a little encouragement that you could do honestly. I never heard a sermon in my life that did not contain something I could indorse and congratulate the good brother for saying. In fact, I usually do find a place to say "amen" one or more times in almost every sermon. By the way, this reminds me that one excuse of some resorters was that the nearest church to their summer cottage was one where the sermon was preached in German. Well, my advice is to go and hear a sermon preached in a language you do not understand, rather than not go at all. You can listen to the singing and enjoy it, for, thank God, music is a "universal language" understood by every tribe and every nation. Yes, even the domestic animals appreciate and enjoy music, as you may have noticed.

Now, after this somewhat lengthy introduction, listen to the good brother while he tells you about some people who were too busy to attend church on Sunday, or perhaps "did not feel like going." By the way, my experience is that the time when I do not feel like going to church or prayer-meeting is the *very time* when it is most important — perhaps I should say most *vitally* important—that I *should* go.

Here is the sermon, friends. I wonder if you can afford to say amen as you read it; and it would gladden my heart if you would put the amen on a postal card and sign your name to it. You can send a postal card also to the good pastor if you like.

SERMON PREACHED AT MEDINA, O., JULY 16, 1916,  
BY REV. C. L. PARKER, OF THE KINSMAN-UNION  
CONGREGATIONAL CHURCH, CLEVELAND.  
"THE JOY OF THE CHRISTIAN."

Restore unto me the joy of thy salvation.—PSALM 51:12.

This is the first time I have ever been in this church, and yet I have known it for the past twenty-five years as a church that has been taking obscure and unknown young men for its ministers, and in a few years turning them out as men of national reputation and influence.

I have been helped and encouraged thru all these years of my ministry by a recital of your kindness and helpfulness to one young man, a former pastor, who here grew to be a man able to take a position of national service and influence.

I do not come to you with a message as helpful in return as you have been to me; but I am sure I can, in good Methodist fashion, relate an experience. Sometimes it does not take a great deal of brilliance to do that; and yet sometimes it may do a great deal of good.

Last week it was my privilege to spend the week end on a visit to an uncle, aunt, and cousin who live in a small town noted thru the past hundred years for its churches and religious life. On Sunday morning I began to inquire as to the probability of our going to church. My uncle said he was slightly deaf, and usually went to sleep in service, and so felt ashamed to go. My aunt and cousin said that they had been so busy thru the spring season that they had not had time to supply and provide themselves with suitable clothes to wear to church.

So I asked to be excused, and went to church alone. I decided to go with my eyes open, not as a critic, but to learn what I might of conditions in that town. This is what I saw: The nearest neighbor of my uncle's was hoeing in his garden; the next one was hauling hay; the third one was shaking out some hay that had evidently just been mown that morning. A little further on was a banker who had recently purchased a chicken-farm. He was working with his chickens when I went and when I returned. A little further on was another farmer picking cherries. At church there were twenty men and forty-two women.

The sermon was a very good one, but might have been preached at any time in the Christian era as well as on that particular occasion. Evidently in the preparation, purpose, or delivery of it, the preacher had no thought of the conditions which I had observed along the way to church.

But the text was a good one. It was a prayer to live by. I resolved to make it mine thru the week, "Restore unto me the joy of thy salvation."

Now, joy is somewhat comparative. We rejoice sometimes in severe trials, thanking God that our

lot is no worse. So I set out to find whether my life as a religious man compared favorably in its happiness with those whom I saw "too busy" to go to church on Sunday. What was the fruit of their lives? Was it superior to the happiness I am finding in the "joy of my salvation"?

I began to inquire, discovering these facts: The man who was hoeing in the garden lives alone. He had a sister in the same town who "lives alone." They both live that solitary life, for each other's mutual happiness. Another man was having trouble with his wife. A third one had lately failed in business. The banker was having a terrible row with his mother-in-law. It takes something besides a bank and a chicken-farm to make a man happy, particularly if he has a perennial quarrel with his mother-in-law. The other man has a drunken son. "Restore unto me the joy of thy salvation, O Lord." We never had property enough to quarrel over; but, thank God for a Christian sister to occupy our parent's home, so that it continues to be home to us all. Thank God for a wife who, by her Christian forbearance and self-control, contributes to the "joy of salvation" which she knows very well.

Thank God for seven sons, no one of whom has ever drunk or smoked, who, we feel, are not only saved but safe, because they have Jesus Christ in their hearts. We have neither a "bank" nor a "chicken-farm," but we have a mother-in-law whose heart *Christ* has touched, and whose presence in our home is a benediction to us all.

All these are the "joys of salvation." I pray, "O God, make me as glad as I ought to be for thy salvation." But if I am going to pray this prayer I must be willing to do my part in a happy life. How may I live a happy life? What is my part? I recalled Alice Freeman Palmer's answer, probably familiar to us all. When challenged by a child of the North End of Boston to tell a company of children how to be happy, she told them to do three things every day: 1. Learn something good every day; 2. See something beautiful every day; 3. Do some kind act for somebody every day.

Time fails me to recount all my experience in carrying out these rules; but suffice it to say that they were exceedingly helpful. I learned something that will contribute lastingly to my happiness. From Dr. Worcester of "Psychotherapy" fame, I learned that nobody ever gets a roseate view of life between midnight and three o'clock in the morning, so I resolved not to castigate any of my delinquent church members during those hours when a Christian ought to be asleep. From Dr. Fosdick I learned that Jesus was not only a "man of sorrows," but he was also a most joyous person. The "joy of salvation" is the joy of dwelling with Christ, making him a resident of our homes, a companion in our journeyings, a partaker of all our experiences. But also these things included bearing fruit. Four times he speaks of this. Our lives are to find their type in your berry-fields, just now giving their bounty: your cherry-orchards, bearing their luscious fruit; your vineyards, fragrant in the autumn with the perfume of their vintage. Paul called Timothy and Titus and Philemon and the slave Onesimus "fruit" which he had from the Lord. So we have a joy and crown like Paul's by bearing fruit for him.

But, again, among the things that Jesus spoke unto his disciples for their joy was that they should love and be loved in return. "As the Father hath loved me, so have I loved you; continue ye in my love." The joy of Jesus' own life was in the fact that over him and round about him, like the very atmosphere he breathed, broad as the sky above him, was the heavenly Father's *boundless love*. It is this that Archbishop French meant when he said:

I say to thee, do thou repeat  
To the first man thou mayest meet,  
In lane, highway, or crowded street,

That he and we and all men move  
Under a canopy of love  
Broad as the blue sky above.

That doubt and trouble, fear and pain,  
And anguish all are shadows vain,  
That death itself shall not remain.

That weary deserts we may tread,  
Thru dreary labyrinths may thread,  
Thru dark ways underground be led.

Yet if one guide we will obey,  
The dreariest path, the darkest way  
Shall issue forth the heavenly day.

And we on divers shores now east  
Shall meet one perilous voyage past,  
All in the Father's home at last.

And ere thou leave him say thou this—  
One word more they only miss  
The winning of that heavenly bliss.

Who will not count it true love  
In which we all may live and move—  
Blessing, not cursing, rules above?

And one thing further make him know,  
That, to believe these things are so,  
This firm faith never to forego.

In spite of all that seems a strife  
With blessing and with cursing rife,  
This is blessing, *this* is life.

The poet has the right of it. He lives most who loves most and noblest, and his love promotes his everlasting joy.

Restore unto me the joy of thy salvation; that is, restore unto me a consciousness of thy presence—power to bear fruit unto him, and a love spirit that loves itself in seeking to love as he loved.

I was pretty sure when I listened to it that the good brother could not write it out exactly as he gave it. If I am correct about it he had no notes, but gave it off-hand. My recollection is that when speaking of the banker with his chicken-farm he said something like this:

"Brethren, a bank and a chicken-farm, no matter how extensive, do not make a man happy who is in a jangle with his mother-in-law."

May God be blessed for the above message; and may it awaken a lot of the readers of GLEANINGS to the importance of standing by the pastor of your church, giving him encouragement and a helping hand as he delivers his message from the great Father of us all.

#### "WHAT WOULD JESUS DO?"

Dear Mr. Root:—In GLEANINGS for January 1 you publish a letter by Mr. Sheldon, author of "In His Steps," answering President Wilson's challenge that any man who differs with him on the question of preparedness shall make it clear "how far and in what way they are interested in making the permanent interests of the country safe against disturbance."

If I understand Mr. Sheldon's position he differs with the president, first, because he "has not named a single country that threatens us with war." In

spite of such being the case, is it not reasonable to assume that, when he adopts any course that concerns the welfare of the country, he must have strong and sufficient reason for doing so—especially since he has used all the acumen of a trained, scholarly, practical mind to avert war, and with a will of iron and a noble patience and steadfastness under recrimination, sneers, and ridicule, has succeeded in keeping us out of an imbroglio with Mexico? Events have justified his far-sighted policy with regard to our neighbor. We find his judgment was good when he opposed intervention; can we not trust him when his decision is for preparedness in self-defense?

The fact that we are in friendly relations with all the world now is no guarantee that we shall continue so, and doubtless the President has information which it would be neither politic nor safe to give to the general public with unphoned spies on every side ready and eager to frustrate the plans of our government. Would it not be fair for our President to name any single nation whose designs he may have reason to suspect, however friendly it might appear at present, until such a power had given proof of its intentions?

Mr. Sheldon states that the money asked of the people (for their own defense) for warships and other necessary means of defense would answer the same purpose if expended on education, missionaries, and prohibition. It takes years to educate the people, Christianize the country, and carry thru the prohibition measure. Suppose while this money, instead of putting the country in a state of defense, were used for these purposes, our land should be invaded. Would education, religion, or sobriety repel the invaders?

Several years before the present European war broke out, a writer of one of the foreign powers published a book stating that the next war (this present war) would be fought along the lines that it has followed, and would include in its plans an invasion of the United States.

Mr. Sheldon speaks of "Christianizing Europe after the great war is over." The great war is not over, and no man can tell where it will spread; moreover, European nations consider themselves Christianized already. Does not the kaiser tell his troops continually that God is with them, and will give them the victory? As to the means he proposes, what does any reasonable being suppose would be the reception of "a party of our best young people sent over" to any one of the European powers for the purpose of Christianizing them? Yet this is Mr. Sheldon's practical(?) plan after the war is over. Even Mr. Ford, in his good ship "Fol-de-rol," is more practical—enough so, at least, to try to do something now when it is most needed.

As for our country's self-defense being "contrary to the spirit of Christianity," and as to what Jesus would do now, not after the war is over, with all the disasters it may bring even upon us, this is what I believe the Master would do: He would say: "Under the old dispensation my Father helped his people in their wars against the heathen that the oracles of God might be preserved—the oracles that foretold my coming and the regeneration of the world. I am come. In this land that I have given you, where worship in freedom the oppressed and enslaved of all nations; in this land where spirit may expand and rise to noble heights under free government; where hearts throbbest quickest in sympathy, and full hands are held out most readily to those suffering under the world's great disasters, you confess me in word and deed; this land defend. Let no barbarous flag proclaiming Old World standards of injustice and slavery supplant its star-spangled banner which leads all nations in freedom and brotherly love. Defend it; and he that loses his life shall find it."

Canutillo, Tex., Jan. 31. MRS. O. N. TURNER.

# HIGH-PRESSURE GARDENING

CORN, ALFALFA, COWS, SWINE, AND "BEES."

We clip the following from the *Alfalfa Journal*:

## AN IDEAL FARMING COMBINATION.

Did you ever try to figure out what the ideal crop and livestock combination would be to make you the most profit? Here is a suggestion: Corn, alfalfa, cows, swine, and bees.

Figure on this proposition a little and you will see that the corn and alfalfa will supply all of the feed necessary for the cows and for the swine. Put part of the corn into the silo, husk part of it, and grind it for feed. Use the alfalfa hay for the cows and also for the hogs. Use the pasture for both kinds of stock, but, of course, be careful in pasturing the cows.

To keep the soil in proper condition, about every five years switch the crops. Plow up the alfalfa and plant corn. Then sow alfalfa on the corn land. Wonderful yields will be the result, and real prosperity will be yours.

The bees are a side line, raised much too little. They will thrive on the alfalfa field. They board themselves, cost nothing, but make you good profit. There is always a good demand for honey, and honey is a mighty good food to use on your own table. Think it over carefully, this ideal combination: Corn, alfalfa, cows, swine, and bees.

The part of the above that hits us particularly is bees; and just now I wish to say something about alfalfa honey. Last evening I saw on Mr. Calvert's desk about the whitest and most beautiful comb honey I ever saw, and I started to take a section over to Mrs. Root; but before I got there I had a mishap, and a section was crushed. Mrs. Root stood out on the porch, and I called to her to get a dinner-plate and spoon in "double-quick" time. Well, the honey was so thick, and Mrs. Root is so "spry" (even if she was 75 years old on the 12th day of August) that we got the greater part of the honey before any could be wasted. Altho the thermometer on the porch indicated close to 90, this beautiful white honey, almost water-white, was so thick that it hardly ran out of the spoon when turned upside down, and the taste was simply delicious. Mr. Calvert thought the source was alfalfa and sweet clover mixed. And, by the way, I have just made a new discovery. Good thick honey is ever so much better with *oatmeal* than any sugar ever invented. My breakfast was principally oatmeal cooked a long while so as to be digestible; plenty of cream, and this delicious alfalfa honey. To my great surprise my strength and endurance held out "amazingly," clear up to dinnertime. Then I had some more of the same honey for dinner—all I wanted; and now, altho it is almost suppertime, I am feeling fine, even if I have not had my usual outdoor exercise.

The moral to all the above is, have some

alfalfa, if you have not any already, and have some bees if you have none already; and just now I am reminded that there is something else I had with my delicious breakfast. It was a cupful of milk right out of the refrigerator. You may have your tea and coffee, and everything else along the line of drinks; but give me some good cold milk together with oatmeal and honey.

## "THE RICHEST BODY OF LAND UNDER CULTIVATION IN AMERICA."

Our readers will naturally wonder *where* this wonderful piece of fertility is located. Well, it is claimed to be down in Florida. Now, please do not imagine that *all* Florida is that way; for no end of people have gone to Florida with fond anticipations in the way of growing crops, and have been grievously disappointed. The clipping below, from the Jacksonville *Times-Union*, tells you all I know about it:

Ocala, a town of 5,000 or 6,000 progressive citizens, is very properly termed the center of the agricultural and stock-raising section in Florida.

What is, without doubt, the richest body of land under cultivation in America is located about fifteen miles southeast of Ocala, in the abandoned river-bed of the Oklawaha River. This property is known as the Young & Ford farm, personally owned by Messrs. Young & Ford, and is for the first time this year planted on a large scale to corn. An elbow in the course of the river has made it possible for this tract of land to be drained. A canal has been cut from each point of the elbow, and the river course diverted into this canal. The old river course now serves as a drainage for these lands, and the lateral ditches are drained into the old river-bed. A dike is formed at one end, and not only drainage obtained, but by the manipulation of the dike during dry weather water can be placed back on the land for irrigation purposes.

The soil is simply the decayed vegetation of centuries. It ranges from twenty to forty feet deep of solid muck. When drained it is accessible for cultivation with either mules and plows or tractors, and it is sufficiently porous to take off rainfall without discomfort or interference with the crops.

Last year from four and one-half acres planted to corn an average yield of 142 bushels of corn per acre was obtained without the application of any fertilizer. This year 1100 acres is solidly planted to corn which averages over the entire acreage better than 100 bushels to the acre, all without any commercial fertilizer. It is a sight to behold! The cornstalks stand in almost solid mass from twelve to fifteen feet in height, and the quality of the corn is all that could be desired.

On page 755, Aug. 15, I told you of a 500-acre cornfield that they thought would grow 45 bushels to the acre; but the above clipping discounts that cornfield more than two to one. Just think of it—1100 acres growing more than 100 bushels to the acre! As the locality is not very far from our Florida home, I will try to get some further particulars in regard to it later on.

## THE CORN CROP IN FLORIDA.

It sounds a little funny to talk about Florida getting a good corn crop and shipping it up north instead of being obliged to send to Ohio or away off west to have corn to feed to the chickens. On page 755, Aug. 15, I spoke about the possibilities of corn-growing in Florida. Below is a clipping from the Jacksonville *Times-Union*:

## FLORIDA BECOMES A GRAIN-EXPORTING STATE THIS FALL.

For the first time in history, Florida is to become a grain-exporting state this fall. The corn crop of Florida this year is larger than ever before. From the crop reports it is believed that several thousands of bushels of corn will be sent north and east this fall.

## SELECTING EARS OF SEED CORN FOR NEXT YEAR'S PLANTING.

For several years past I have made mention of the way I pick out desirable ears in our cornfield. I have been in the habit of picking the ears as soon as I could find desirable ones sufficiently hard and mature so the husks would be dry; and by selecting the first to mature, season after season, I have succeeded in shortening the growing season quite a good deal. I was wondering whether I should keep on doing this. I have always been in the habit of getting ears that were the first to hang their tips downward; and while wondering whether I should continue doing this I wrote to our

Ohio Experiment Station. Below is their reply:

*Mr. A. I. Root*:—Director Thorne has handed me your letter of Sept. 14. Regarding the selection of seed corn, let me say that it is an advantage to choose ears that point downward at the tip. They are much more likely to furnish good sound seed, for the water will run off the ear instead of endangering it. Ordinarily one should select the earlier-maturing ears. The exception would be in the case of a very early variety that one wanted to render a little later. C. G. WILLIAMS, Chief.

Wooster, O., Sept. 15.

Perhaps I should explain again that, instead of getting my choice seed from a stalk that was the only one in the hill, I made the selection of a good ear where there were three or four stalks in a hill, in order to get a strain that would make a good big growth of ear in spite of competition. Then I tried to select ears with regular even rows instead of those with rows running zigzag, criss-cross, etc. I also used the ears having the corn clear down over the tip, etc. As a result, after having just traveled in the cars and in automobiles pretty well across the state of Ohio from north to south I have not found a cornfield that I thought equaled ours. Perhaps, however, I should add that, in getting this beautiful field of corn, we plowed under a pretty rank stand of sweet clover. It is another score for sweet clover for bringing up the fertility of the land.

## POULTRY DEPARTMENT

## SHIPPING CHICKENS BY EXPRESS.

On page 375, May 1, I mentioned sending nine chicks, three weeks old, and six one week old, from Bradentown, Fla., to Medina, for 69 cents. I have since then thought best to tell you how I did it, and have every chick come thru bright and lively. The picture on p. 879, last issue, shows how I arranged a common market-basket so as to make a light package.

Had the chicks been only a day old they could have been sent in a much lighter package, as no feed nor water was needed; but the three that were three weeks old were pretty lively; and as the weather was liable to be cool, especially at night, I put a division-board in the middle of the basket, and had their sleeping-room padded with cotton batting all around and overhead. If they got too warm in the middle of the day they could go over into the "dining-room." A large-mouthed bottle I planned to hold water enough; and their feed, mostly wheat, was scattered about the basket, with sawdust to absorb their droppings. One reason

why the express charge was so low was the lightness of the package. I have before mentioned that, as it took *four* days instead of two or three, as I had planned, they were out of both feed and water; and they were so hungry that they bit at my fingers when I let them out; but some warm bread and milk soon set them to rejoicing.

When my nine chickens got large enough I found there was one rooster among the three oldest ones, and one among the six younger ones. As a matter of course they soon began to quarrel. When the younger one was nearly four months old I put him in the same basket (taking out the partition), and sent it back to Bradentown. Well, the charge this time was 85 cents; but I suppose it would have been cheaper had I not put the value of ten dollars on the shipping-tag. The letter below from friend Abbott tells us in what condition they arrived.

*Dear Mr. Root*:—The cockerel came thru in nice shape. He is "as fine as silk." I have him in a small yard with one hen for company. I am feeding him oats, bran, and wheat, with a very little corn

nights. I will be very careful that nothing happens to him. I hope the pullets and the other rooster are as good as he is.

As to my bunch (about 500 pullets) I am keeping my head above water yet, but it gives me a chill sometimes when I think if they should stop laying and keep right on *eating*. When it comes to that I shall have to feed them honey, of which I shall have 3000 lbs. or more.

Ella says, "Everything you get you feed to those old hens;" but then, we all have to eat.

Bradentown, Fla., Aug. 14. D. W. ABBOTT.

Under date of Sept. 1, friend Abbott writes as follows:

*Mr. A. I. Root*:—The rooster is doing finely. I am still getting eggs enough to pay expenses. The last batch of chicks, hatched in December, are commencing to lay.

Bradentown, Fla., Sept. 1. D. W. ABBOTT.

I used a pint Mason fruit-jar to hold the water for the young rooster, and I fixed a little feed-box across one end of the basket for the feed. Some poultry-netting with one-inch mesh, about the size of the basket, was put clear up under the handles; and

then a strip of cotton cloth connected the edge of the basket to the poultry-netting. To cover the ragged edges of the poultry-netting, a stout wire was put around the outside edge.

#### DEATH OF "LADY EGLANTINE."

We clip the following from the *Cleveland Press*:

##### Poultry Wonder Is Dead.

GREENSBORO, Md., Sept. 13.—Lady Eglantine, the wonder of the poultry world, is dead. The single-comb White Leghorn laid 315 eggs in her pullet year. She won every prize for which she competed.

This is sad news indeed, not only for the owner but for the poultry world at large. I shall think more of my nine relatives than ever before. And, by the way, is it not possible that Lady Eglantine would have lived longer if she had been "turned out to grass" instead of being petted and fed "Pullman-car" style?

## TEMPERANCE

ARE YOU READY TO "STAND UP AND BE COUNTED"?

I think I have said one or more times, do not vote for any man to be put in any office who is not ready to stand up and be counted, and be counted on the side that demands the death of King Alcohol. Election day is not far off, and I am reminded of the matter by the opening article (given below) in the September number of *Good Health*.

#### PASSING OF A GREAT DELUSION.

King Alcohol is dying.

After a desolating reign of many thousands of years this greatest of all rulers of men has come to his end, and, in the words of Holy Writ, "None shall help him."

For ages the whole world lay in bondage under this merciless tyrant, which trampled to destruction the souls and bodies of men, women, and little children, desecrated every holy shrine of human affection and devotion, paralyzed every noble sentiment and aspiration, transformed the divinest impulses into beastliness, promoted every vice and every crime, every form of disease and depravity, daubed a blot upon the brain of its deluded victims, and filled the world with woe, degeneracy, and despair.

For half a century this diabolical ruler has shown symptoms of senility, and in recent years the trembling hands and tottering limbs of the old monster have shown that his days were numbered.

The magic spell of alcohol is gone, never to return. The brilliant sunlight of modern science has driven away the miasmatic fogs of error and ignorance and the alcohol delusion is exposed as a ghastly festering skeleton, dragged out of its closet.

For ages alcohol has been lauded as a "good creature of God." Today everybody knows it as a demon incarnate, without one redeeming quality.

Medical authorities for ages commended alcohol as a stimulant, an elixir of life; today the united voice of half a million medical men thruout the civilized world declares alcohol to be a narcotic, a vital de-

pressant of no use in shock or weakness, but the very opposite.

The whisky-bottle no longer figures largely in the first-aid outfit, except by its absence.

This magic philter, which has made of millions of domestic paradises veritable hells, peopled with demons, has lost its "spell" over the minds of men. The hoary-headed delusion has passed away, and King Alcohol is tottering into his grave.

Alcohol is already buried in twelve great states that have placed prohibition laws upon their statute-books. A score of other states are preparing to do the same.

In the present presidential campaign the alcohol question looms up larger than ever. The Progressive party put into its platform a prohibition plank. The Prohibition party has nominated Ex-Governor Hanly, of Indiana, to head its ticket, and will make a strong campaign.

Every man and every woman who casts a vote this fall should vote for the prohibition candidate for president if in sympathy with the prohibition movement, no matter how he may vote on state or local issues. This is an opportunity for the foes of alcohol to stand up and be counted. A million votes for prohibition would compel Congress to make the question a national issue at once. If you are a strong partisan in politics, a Republican or a Democrat, then *pair for prohibition*. You will thus inscribe your name among the friends of prohibition and will help in the good work of burying the stinking carcass of old Bacchus—and without impairing your favorite party interests.

*Pair for prohibition!*

#### SCANDINAVIANS AND THE LIQUOR TRAFFIC.

Mr. Roy A. Thompson, a beekeeper of Cedar Edge, Col., sends us the clipping below, but does not tell what paper it comes from:

Richard Jones, a Minnesota state senator, and very prominent in union labor circles, made a speech the other night before the Scandinavian Socialist

Club at Superior, Wis. In the course of his address, speaking about the claim that prohibition would throw many men out of employment, Mr. Jones said:

"We are begged not to vote men out of employment; but if a group of men are employed in a business which is destructive to society I would vote those men out of that employment and into something valuable to themselves and their fellowmen. I should like to have a chance to vote 5,000,000 men in Europe out of their present jobs. If this principle applies in one case, why not in another? To advocate peace in Europe would throw thousands of workmen in America who are engaged in the manufacture of munitions of war out of their present employment; but thousands of trade unionists and Socialists are today doing all in their power to spread anti-militaristic propaganda among their fellow-workers."

What would be said of the munitions manufacturer who argued against stopping the war because it would throw so many men out of employment?

What would be said of the workers in munitions factories who would plead for the carnage to continue in order that they might keep their present lucrative jobs?

And yet that is the cry that is raised in behalf of the gin-mills. If the poisoning of the people is stopped, if the saloons don't continue their work of debauchery and their bloody course, those who make profit thereby will have to seek other employment.

This is the argument that has been urged against the abolishment of every infamy that has existed since the foundation of the world.

*It is a tough traffic that can give no better reason for its existence than that those who make money out of it would lose some profit by its abolishment!*

#### "BOOZE" AND THE FARM PAPERS.

If there is a farm paper that takes the side of the liquor party, or even accepts a liquor advertisement, I have yet to see it among all our exchanges. Just now the *Country Gentleman* comes out with a suggestive illustrated article. Underneath a couple of pictures we read:

"It is a heap better, and less costly in the long run, to buy gasoline than rum."

In one picture you see a farmer bringing in a can of booze. Besides the wife there is not only a baby in her arms, but frightened children clinging to the skirts of her dress. In the companion picture the farmer has bought an auto. The wife and children are loaded up in it, while the farmer with long strides brings in a can of *gasoline*. They are a happy crowd, and the great contrast with the other picture points a mighty moral. By the way, I have been for days past watching the boys and girls, and men and women, as they enjoy their automobile rides during this sultry August weather. It is true they raise a dust more or less: but, oh dear me! what is a little dust, or a good lot of it, compared to seeing the farmer's money go for booze instead of for an automobile? Some one may suggest that the automobile costs more than the booze; but I am not so sure of that. When you come to count up the widespread losses

as the effects of the booze, such as poor-houses, lunatic-asylums, crippled babies, etc., the cost of the automobile is *nowhere*. Just see the figures that are being paraded just now in regard to the cost of intoxicants thruout the land.

Just a word more about the dust. During the springtime we had the road sprinkled in front of our bungalow; but something happened to the waterworks, and Mrs. Root put in a plea for an *oiled road*. One trouble with sprinkling is that, during the hot rainless season, the water lasts only a few hours; but the oiled road we have now is a "thing of beauty and a joy"—until it needs another coat of oil; and the outlook now is that the oil is going to be cheaper than the water sprinkling in the end. I thank God for the good time in sight when all mankind will have water to drink instead of booze. I thank him, too, for the oil to oil our roads, and the gasoline to take the place of booze to run our automobiles, not forgetting the beautiful and glorious means of transportation we now enjoy, without overtaking the tired horses when the weather is too hot and sultry for anything but an automobile.

#### BOOZE, AND ITS EFFECTS ON WOUNDED SOLDIERS.

We clip the following from a sheet dated Aug. 7, put out by the Methodist Board of Temperance:

The *Vindicator* publishes a statement by the greatest woman lawyer of France, Madam Maria Verone. In her address she declared that France had been robbed of the lives of vast numbers of its soldiers by drink. She declared it to be the invariable experience of physicians that wounds which scarcely affected normally healthy men were deadly in the case of drinkers. In conclusion she said:

"We will no longer tolerate from our parliamentarians the want of courage and initiative they have always hitherto shown in handling this drink problem. Bereaved mothers and widows from behind their mourning-veils cry to you to prohibit alcohol as a beverage. If you don't yield to them, they will turn you out at the next election."

Good for the women of France! May God grant that *they*, like the good women of the United States, may soon dictate what *sort* of men shall fill important offices for the nation.

In line with the above is the following from the pen of Wm. Jennings Bryan:

#### THE MOTHER ARGUMENT.

The strongest argument in favor of woman suffrage is the mother argument. I love my children—as much, I think, as a father can; but I am not in the same class with my wife. I do not put any father in the same class with the mother in love for the child. If you would know why the mother's love for a child is the sweetest, tenderest, most lasting thing in the world, you will find the explanation in the Bible: "Where your treasures are, there will your heart be also." The child is the treasure of

the mother; she invests her life in her child. When the mother of the Gracis was asked: "Where are your jewels?" she pointed to her sons. The mother's life trembles in the balance at the child's birth, and for years it is the object of her constant care. She expends upon it her nervous force and energy; she endows it with the wealth of her love. She dreams of what it is to do and be—and, oh, if a mother's dreams only came true, what a different world this world would be! The most pathetic struggle that this earth knows is not the struggle between armed men upon the battlefield; it is the struggle of a mother to save her child when wicked men set traps for it and lay snares for it. And as long as the ballot is given to those who conspire to rob the home of a child it is not fair—no one can believe it fair—to tie a mother's hands while she is trying to protect her home and save her child. If there is such a thing as justice, surely a mother has a just claim to a voice in shaping the environment that may determine whether her child will realize her hopes or bring her gray hairs in sorrow to the grave. Because God has planted in every human heart a sense of justice, and because the mother argument makes an irresistible appeal to this universal sense, it will finally batter down all opposition and open woman's pathway to the polls.

#### "GOD'S KINGDOM COMING."

We take pleasure in clipping the following from the *Union Signal*. I do not mean that I take pleasure in seeing anybody fail in business; but I take pleasure in the above because I am sure that the liquor people will be *better* and *happier* in turning their attention to some other source of livelihood.

#### SALOONS FOR SALE IN PHILADELPHIA.

The Philadelphia correspondent of *Bonfort's Wine and Spirit Circular* admits that "very little new business is being done or looked for" in his city, but ascribes the dullness to the hot season, etc. However, the real-estate men who handle saloon properties say they have been loaded down with commissions to sell during the last few months. The *North American* states that two hundred and forty saloonkeepers of the city are ready to "quit business before the tidal temperance wave which is sweeping the country puts them out," and that more than a thousand places thruout the state are likewise on the ragged edge, seeking a purchaser who is willing to risk his money on the chance that the whisky trust and the brewers may save the day for them.

#### IN KANSAS 32 COUNTIES HAVE ABANDONED THEIR PUBLIC POOR-FARM.

We clip the following from the *Christian Herald* in regard to Kansas:

Forty counties in the state did not send a single prisoner to the state penitentiary last year. In one county, the jail, which had been empty for two years, is now used as a corn-crib. Poverty and illiteracy are disappearing. Thirty-two counties have abandoned their public poor-farms, and in the whole state less than nine hundred paupers are being cared for in county institutions. The bigger part of the criminal cases tried in the state courts is due to the influx of liquor from other states, and in most cases the culprits are not Kansas citizens.

Kansas wants the whole Union to know the truth about these things. It has chosen a decent road for its people to travel, and it intends to go right along on this new and clean highway. Governor Capper's address in pamphlet form should be circulated and read wherever there is a liquor question. It is one

of the most convincing temperance arguments we have ever seen.

It seems that Gov. Capper does not propose to let the liquor people go unanswered in their desperate efforts to find some fault with Kansas.

#### A DRUNKEN CHAUFFEUR, AND HOW IT WORKS.

We clip the following from the *Kansas City Star*:

#### WHEN WHISKY SITS AT THE WHEEL.

The three young men who rode in the death-car Saturday night that ran into the crowd of young people at Fifteenth and Troost have been captured.

But the real driver of the car is still at liberty.

It was whisky that sat at the wheel and committed the murder. It was whisky that sent the car on its mad way after two of the young folks had been killed and others injured.

Whisky still is free and unrestrained. It was out bright and early this morning looking for other young men to act as its agents and ride with it on another death mission.

My impression is that not a few of the accidents from automobiles every day are caused by a drunken or drinking chauffeur. Right near our own town of Medina two automobiles ran into each other "head on" at a good speed. We were told the injuries were so great that there was but little hope of saving the life of at least one of the parties; but we do not know how it came out. I have since been informed that the parties in one of the automobiles, if not in both, stopped at a "roadhouse" saloon, just before the accident, and that the whole trouble was due to drink; but, as often happens, the friends or relatives of the injured parties took pains to have the *real* cause kept out of the papers.

#### "A STANDING ARMY (?) MADE UP OF INDIVIDUALS SUFFERING FROM PARALYSIS."

Dr. R. H. Bishop, Commissioner of Health for the city of Cleveland, in an article in regard to pneumonia, in the *Plain Dealer*, writes as follows:

Alcohol is another important predisposing cause of pneumonia. It is the sum total of effect of alcohol on all the cells of the body that gives one the feeling produced by alcohol.

The cells, which represent the standing army of the body, are more or less paralyzed. Their efficiency is partially destroyed and the condition is similar to what would occur if the standing army of the nation were made up entirely of individuals suffering from paralysis.

Is this overstated or overdrawn? The above reminds me of the time when Mrs. Root was near death from this same pneumonia. The doctor and nurses declared she would have to have brandy to "pull her thru." But she refused to take it, and I backed her up, and she is alive and well today. Who can say she would have been alive and well if she had followed the doctor's orders?

# YOUR LAST CHANCE

to get Queens of H. G. Quirin for this season, as it now is time to unite for winter, so hurry in your orders.

For prices see previous issue of Gleanings.

Honey for sale now in any quantity.

H. G. Quirin-the-Queen-breeder, Bellevue, Ohio

## \$3.00 CARNIOLAN QUEENS for \$1.00 EACH

To reduce our stock quickly we offer fine "Select Tested" queens raised this season, worth \$3.00 each, for \$1.00 each. Only about 100 of these choice queens for sale.

Now is your chance to get a fine breeder very cheap. Safe arrival guaranteed. Untested queens all sold for this season.

F. A. LOCKHART & COMPANY, LAKE GEORGE, NEW YORK

## Queens of MOORE'S STRAIN of Italians

### PRODUCE WORKERS

That fill the super quick with honey nice and thick. They have won a world-wide reputation for honey-gathering, hardiness, gentleness, etc. Untested queens, 1, \$1; 6, \$5; 12, \$9; 100, \$65. Select untested, 1, \$1.25; 6, \$6; 12, \$11; 100, \$75. Safe arrival and satisfaction guaranteed I am now filling orders by return mail.

Circular free J. P. MOORE,  
Queen-breeder Route 1, MORGAN, KY.

### Please Notice Change of Prices of Leininger's Strain of Italians

We will sell untested Italian queens at 75 cts. each; six, \$4.50; tested, one year old, at 80 cts. each; six, \$4.80; tested, young, \$1.25; six, \$6.50. Breeders, \$10 each. We guarantee that all queens will reach you in good condition, to be purely mated, and give satisfaction

Fred S. Leininger & Son . . . Delphos, Ohio

### Three-band ITALIAN QUEENS ....

bred from imported mothers, the best in the world; good honey-gatherers and very gentle. One for 50 cts., \$6.00 per dozen. Pure mating, safe delivery, and perfect satisfaction guaranteed. L. L. FOREHAND, FORT DEPOSIT, ALA.

### Queens--Queens--Queens.

We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

W. J. FOREHAND & SONS . . . FORT DEPOSIT, ALABAMA

## WARDELL'S ITALIANS

Descendents from the Famous Root \$200 Queen

I was head queen-breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

|                           |                               |                         |                               |

| Untested . . . . .        | September and October, \$1.00 | Tested . . . . .        | September and October, \$2.00 |
| Select Untested . . . . . | " " " " 1.25                  | Select Tested . . . . . | " " " " 3.00                  |

Our supply of untested and select untested is likely to be small after October.

Prompt delivery assured. Address all orders to F. J. Wardell, Uhrichsville, Ohio

## Classified Advertisements

Notices will be inserted in these classified columns for 25 cts. per line. Advertisements intended for this department cannot be less than two lines, and should not exceed five lines; and you must say you want your advertisement in the classified columns or we will not be responsible for errors.

### HONEY AND WAX FOR SALE

A No. 1 clover in 120-lb. cases at 8 cts. Sample 10 cts. H. C. LEE, Brooksville, Ky.

FOR SALE.—White-clover honey, both comb and extracted. W. M. PEACOCK, Mapleton, Ia.

FOR SALE.—White-clover comb honey; extracted in 60-lb. cans. HENRY HETTEL, Marine, Ill.

In new 60-lb. cans, clover honey, 8 cts.; buckwheat, 7. G. H. ADAMS, box 184, Schenectady, N. Y.

A1 clover—amber-blend honey in new 60-lb. cans, at 8 cts. VAN WYNGARDEN BROS., Hebron, Ind.

FOR SALE.—Fine extracted buckwheat honey, \$3 per case of 118 lbs. net. LEROY LLOYD, Caywood, N. Y.

Buckwheat honey, comb and extracted; also clover extracted, 60-lb. cans. E. L. LANE, Trumansburg, N. Y.

FOR SALE.—White-clover extracted honey in 60-lb. cans, two cans to a case. ARTHUR NORBERG, Spring Valley, Ill.

Well-ripened clover and buckwheat honey in new 60-lb. cans—two cans to the case. B. B. COGSWELL, Groton, N. Y.

Light-amber extracted honey, 60-lb. cans, at 6 cts. per lb., f. o. b. cars. Sample, 10 cts. C. R. ALLEN, Vicksburg, Miss.

Choice new-crop white-clover extracted honey in new 60-lb. tin cans, the bargain of the season; sample, 10 cts. D. R. TOWNSEND, Northstar, Mich.

FOR SALE.—A1 sweet-clover honey in 60-lb. cans, two cans to a case, 7½ cts. per lb., f. o. b. cars. JOE C. WEAVER, Cochrane, Ala.

FOR SALE.—Clover honey of finest quality in new 60-lb. cans at 8½ cts. per lb. Also fancy and No. 1 clover comb honey, 4¼ x 1½ sections. MARTIN CARSMOE, Ruthven, Iowa.

FOR SALE.—Fancy white-clover honey; extracted, 8 cts. by the case of 120 lbs. Also same in 2-lb. friction-top cans, 24 cans to the case, 10 cts. f. o. b. Falmouth, Ky. VIRGIL WEAVER.

FOR SALE.—Extra quality white-clover honey, 8½ cts. by the case of two 60-lb. cans. Ten or more cases, 8 cts. Six-pound can, postpaid, in second zone \$1.00. EARL KULISON, Rt. 1, Amsterdam, N. Y.

FOR SALE.—Raspberry, basswood, No. 1 white comb, \$3.00 per case; fancy, \$3.25; 24 Danz. sections to case; extracted, 120-lb. cases, 9 cts. per lb. W. A. LATSHAW Co., Clarion, Mich.

No. 1 white comb, \$3.50 per case; No. 2, \$3.00; No. 1, fall comb, \$3.00; No. 2, \$2.50; 24 sections to case; extracted in 60-lb. cans; clover, 9 cts.; amber, 8 cts. Amber in pails, 6 ten-pound or 12 five-pound to case at \$6.00 per case. H. G. QUIRIN, Bellevue, O.

RASPBERRY HONEY.—Thick, rich, and delicious. Put up for sale in 60-lb. tin cans. Price \$6.00 a can. Sample by mail for 10 cts., which may be applied on any order sent for honey. Write for price on large lots. ELMER HUTCHINSON, Rt. 2, Lake City, Mich.

FOR SALE.—5000 lbs. fancy extracted white-clover honey; also a quantity of extracted heartsease and Spanish-needle blend, put up in barrels of about 550 lbs. net, and new 60-lb. cans. Honey is thoroly ripened, and there is none better on the market. Prices reasonable. Sample, 10 cts.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

### HONEY AND WAX WANTED

WANTED.—Fancy clover honey in 4 x 5 sections. L. E. FRENIER Co., Rutland, Vt.

WANTED.—Comb, extracted honey, honey-dew, and beeswax. W. A. LATSHAW Co., Clarion, Mich.

WANTED.—Extracted honey in any lots. Send sample. THE HONEY KING, Mahanomen, Minn.—54982

WANTED.—Comb and extracted honey, in car lots and less carlots. J. E. HARRIS, Morristown, Tenn.

Beeswax bought and sold. STROHMEYER & ARPE Co., 139 Franklin St., New York.

WANTED.—Comb honey. What have you to offer? R. V. STROUT, 325 11th St., S. W., Washington, D. C.

WANTED.—Comb honey, fancy and No. 1 white clover; also buckwheat comb; glassed sections preferred. HOFFMAN & HAUCK, Richmond Hill, N. Y.

BEEWAX WANTED.—For manufacture into Weed Process Foundation on shares. SUPERIOR HONEY Co., Ogden, Utah.

### FOR SALE

White-blooming sweet clover, only 9 cts. per lb. GEORGE M. CALLEN, Selma, Ala.

Get our new Rubber Stamp and Label Catalog. ACME PRINTING Co., Medina, Ohio.

HONEY LABELS.—Most attractive designs. Catalog free. EASTERN LABEL Co., Clintonville, Ct.

SEND TODAY for samples of latest Honey Labels. LIBERTY PUB. Co., Sta. D, box 4-E, Cleveland, Ohio.

All in 8-frame hive bodies in winter-cases, standard full-depth self-spacing Hoffman frames, 8 to each hive. All combs straight; colonies strong and healthy with stores for winter. Would bunch the lot for \$3.25 per colony. A few untested Italian queens, 60 cts. each.

WILMER CLARKE, Earlville, Madison Co., N. Y.

**Convention Notice**

**MICHIGAN BEEKEEPERS EAT THANKSGIVING DINNER IN LANSING.**

On November 30, December 1 and 2, Michigan beekeepers will gather at Lansing for the fifty-first meeting of the State Association. The opening day coming on Thanksgiving will enable beemen to renew acquaintance one with the other over the festive board, and will be an auspicious day on which to unite and discuss the summer's work, and to make plans for a more successful season in 1917. The holiday will also enable beekeepers to bring their wives along, so that we expect this meeting to be largely a family affair. Many ladies have already intimated that they would be present to help swell the attendance and enjoy a good time.

We are preparing an interesting and profitable program, which will be published in the November issue, and we can assure all those planning to attend that we are going to have the best meeting that the Michigan Beekeepers' Association has ever had.

There are many beekeepers who do not yet fully realize the value of these conventions. A beekeepers' convention is an investment for the beekeeper, and it remains with him to secure as many shares as possible, because every share should, and in many cases does, return a fine profit the next season.

Many of our most successful beekeepers will be in attendance—beemen who count their crops in tons rather than in pounds; and a few minutes' conversation with these men will be worth all the expense and trouble of coming to the meeting. If you are looking forward to making beekeeping a profitable part of your work in the future, by all means take in these meetings in Lansing.

We do not want the beekeepers to forget the exhibit side of the convention. We shall have plenty of room to display honey and other exhibits; and as we are planning to give diplomas and medals to be won outright, besides the challenge medals, we are expecting a nice showing of honey that will add to the general interest of the convention.

We hope to include other features which will tend to enliven the proceedings; and with the banquet which Messrs. Root and Hunt are providing all beekeepers present, we should easily have a convention that will rank among the largest and most enjoyable ever staged by a state association. We will do our part, and hope and expect you to join with us in making this coming meeting a hummer, and eat your Thanksgiving dinner in Lansing.

East Lansing. F. ERIC MILLEN, Sec.

**Be Efficient in BEE CULTURE**

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

**THE DEVELOPMENT OF THE APPLE FROM THE FLOWER.** By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.

**MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE.** By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.

**CATALOG OF BEEKEEPERS' SUPPLIES.** Our new complete catalog, mailed free to any address on request.

## TRADE NOTES

### SECOND-HAND 60 LB. CANS.

Our supply of second-hand cans at New York has been disposed of; but we still have a good supply both at Medina and Philadelphia of choice cans suitable for use again in shipping honey. These we are selling at \$4.00 for 10 cases; \$8.50 for 25 cases; \$30.00 for 100 cases.

### CHIPPED TUMBLERS CHEAP.

We again have a supply of two or three hundred cases of 2 dozen each of tin-top tumblers holding 6½ oz. of honey, or ¼ lb. of jelly. They have the edges slightly chipped so they cannot be sealed airtight for shipping, but will serve as a cheap container for some uses. We offer them, while they last, at \$2.00 for ten cases of 2 dozen each, including the tin tops.

### MASON FRUIT-JARS.

We have a surplus stock of choice Atlas Mason fruit-jars which we offer, to reduce stock, at the following prices which are good only while this stock lasts, and for shipment from Medina, Ohio, only. Pint Mason jars, 45 cts. per doz.; \$5.25 per gross. Quart Mason jars, 48 cts. per doz.; \$5.50 per gross. Two-quart Mason jars, 75c per doz.; \$8.50 per gross.

These are packed in paper cartons of one dozen each. Pint size would stand reshipping short distances filled with honey, altho we would not recommend it.

### BUSHEL BOXES.

We have on hand, ready for immediate shipment, a good stock of these boxes, packed as shown in cut. They are made with oak corner posts and bottom end slats to receive the nails, the remainder of the box being basswood. They are very convenient, and popular for handling potatoes, apples, onions, and other farm crops. They hold a heaped bushel level full, so they can be stacked any height desired. To reduce stock we offer them for a short time at the following special prices:

All-slatted bushel boxes, per crate of 14, \$2.25.  
Slatted bushel boxes, per crate of 12, \$2.10.  
Galvanized bound boxes, per crate of 12, \$2.75.

In lots of 10 crates or more, 5 per cent discount. The all-slatted is the cheapest, and the most popular style. Two are nailed in each package, and sufficient nails are included for the remainder.

### FURTHER CHANGES IN PRICE.

Advancing costs have made necessary some further changes in price of several articles listed in our catalog.

Enamel cloth is raised 5 cts. per yard to 35 cts. or \$3.60 per piece.

Metal frame-spaces are raised 5 cts. per 100 to 40 cts. or \$3.50 per 1000.

Tin rabbets are raised 5 cts. per 100 to \$1.25; also T tins the same.

Glass for shipping-cases is advanced to \$2.00 per 100 for 2 x 16, or \$3.60 per box of 220 pieces.

Novice honey-knives are advanced 10 cts. each to 90 cts.

Section boxes in quantities above 1000 are marked up 15 cents per 1000, no change being made in the small-quantity rate except that B grade plain are advanced to a difference of 50 cts. below A grade instead of 75 cts., the rate in effect the past year.

### REVISED PRICES ON COMB FOUNDATION.

Because the cost of paper has more than doubled, and labor has advanced, we have found it necessary to revise prices on comb foundation and rates for working wax into foundation. The new scale of prices on foundation packed in assorted paper boxes of 1 to 5 lbs. is 2 cts. per pound higher than those which have been in effect the past year, and, effective Oct. 1, are as follows:

|                        | Price per pound in lots of |       |        |        |        |
|------------------------|----------------------------|-------|--------|--------|--------|
|                        | 1 lb.                      | 5 lb. | 10 lb. | 25 lb. | 50 lb. |
| Medium brood . . . .   | .62                        | .60   | .58    | .56    | .55    |
| Light brood . . . . .  | .64                        | .62   | .60    | .58    | .57    |
| Thin super . . . . .   | .70                        | .67   | .65    | .63    | .62    |
| Extra thin super . . . | .75                        | .70   | .68    | .66    | .65    |

Packed in 25-lb. wood boxes, 1 ct. per lb. less.

Packed in all 5-lb. paper boxes, ½ ct. per lb. less.

Packed all in 2-lb. paper boxes, 1 ct. per lb. more.

Packed all in 1-lb. paper boxes, 2 cts. per lb. more.

Wholesale and jobbing prices are marked up on the same basis.

Rates for making wax into foundation are advanced 2 cts. per lb. in 25 and 50 pound lots, and 1 ct. in larger lots, with a like advance for paper packing.

THE A. I. ROOT CO., Medina, O.

## Special Notices by A. I. Root

### THE LADY EGLANTINE CHICKENS.

On page 379 of our last issue I told you of a pullet that laid her first egg when 4 months and 8 days old, and that she was at that date laying an egg every day. I am glad to tell you she has continued to lay an egg every day up till today, Sept. 26—that is, so far as I can tell without trapnesting. As her comb is so different from any of the others I almost invariably find her on the nest some time in the forenoon. Furthermore, I put her in a cage and took her over to our county fair where she stayed two days and laid an egg each day on the fair-ground, and one the day after she got home. (About a week ago a sitting hen came off with eight chicks from the little pullet's eggs; and they are as lively as crickets at this date.) Not only has this one pullet shown herself to be such a persistent layer at so early an age, but we are getting five or six little eggs (they are steadily getting bigger) from the seven pullets every day; and yesterday we got six. All of them laid an egg but one. Now, already we are having applications for eggs; but, bless your heart, my good friends, it would not do for the writer of the Home papers to go to selling eggs unless he sells them to the grocer at grocery prices. If you want some of the Lady Eglantine stock write to the Lady Eglantine Farms, Greensboro, Md. The little book they send out will be valuable, even if you do not make a purchase.

### "CONVERSATIONS WITH CHRIST," ETC.

The little tract containing the title above, given on page 747, Aug. 15, can be had free of charge by addressing L. B. Worcester, Tabor, Iowa. In ordering you had better send a stamp or stamps to pay postage.

The Hephzibah Faith Missionary Association, Tabor, Iowa, also publishes a beautiful little Christian and temperance paper twice a month, called *Good Tidings*, at only 50 cents a year, now in its sixteenth year; also a very pretty and wholesome weekly for young people, entitled *John Three Sixteen*, at only 30 cents a year. Both periodicals are specially designed for mission Sunday-schools, and large numbers are used by Christian workers for free distribution at railroad stations, jails, etc. Samples free. Address Faith Missionary Association, Tabor, Iowa.

# A Wonderful Book . . . .

This is the judgment of every thinking man who has read

“The Story of the Soil” By Prof. Cyril G. Hopkins

It covers the whole field of life on the farm, soil fertility, and permanent agriculture.

---

## What They Say About It

“Holds the intense interest of the reader.”  
—Ohio Farmer.

“The farmers owe Mr. Hopkins a debt of gratitude.”  
—Chicago Tribune.

“Worth millions to the farmers of America.”  
—Prairie Farmer.

“Ought to be in the hands of every farmer in the world.”  
—Farmer and Breeder.

“I enjoyed every word of it. A fascinating novel about the soil.”  
—Editor American Agriculturist.

“A wealth of information.”  
—Editor Wallace’s Farmer.

“The book is destined to do more good and stir more thought among the farmers of this country than any other publication that has yet appeared.”  
—Ex-Gov. W. D. Hoard.

---

## Don’t Wait Till They are Gone

This book formerly sold for \$1.62 in cloth binding. A few days ago we secured from the publishers the entire remaining stock of this great book in paper binding and can offer it with “Gleanings in Bee Culture” for one year at \$1.15. When this consignment of these books is exhausted we shall be unable to furnish more.

DON’T WAIT. Get in your order today.

Gleanings in Bee Culture, Medina, Ohio

# Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

### June and July

Select Tested Queens, . . . 1 for \$1.75; 12 for \$19.25  
 Tested Queens, . . . . . 1 for \$1.05; 12 for \$12.00  
 Untested Queens, . . . . . 1 for 60 cts.; 12 for \$ 7.00

### August and later

1 for \$1.65; 12 for \$18.00  
 1 for \$1.00; 12 for \$10.75  
 1 for 55 cts.; 12 for \$ 6.00

Very best queens for breeding, \$3.00. 1 lb. bees in package, \$1.25; 2 lbs. in package, \$2.00.

Add price of queen. If any of our untested queens should prove to be misnamed we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

W. D. ACHORD, FITZPATRICK, ALABAMA.

## Before Winter Sets in

And while winter shuts us in is a good time to learn all about that Ford car--especially do you want to know how to put it away in good shape for the winter months and overhaul it.

## "The Model T Ford Car"

Tells you all about it. Written especially for Ford drivers and owners by that recognized authority on gasoline power, Victor W. Page, and written so that any man or woman can understand it. More than 100 illustrations, 300 pages, handsomely printed and bound. Worth many times its cost to any Ford owner. Price \$1.00 postpaid, or

# Special Bargains in Shipping-cases

With the bountiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

- 2 crates of 50 each, 9½-inch, 2-row, at \$4.00 per crate.
- 19 crates of 50 each, 10-inch, 2-row, at \$4.00 per crate
- 13 crates of 50 each, 6¼-in. 3-row, at \$4.00 per crate.
- 56 crates of 50 each, 12-pound cases, at \$4.00 per crate.

All of the above have either 2 or 3 inch glass, and take 12 sections 4¼x4¼x1½ plain.

There are also for the same size section, packed 10 in a crate:

- 10 crates of 10 each, 9½-in. 2-row at 85 cts. per crate.
- 3 crates of 10 each, 6¼-inch, 2-row, at 85 cts. per crate.
- 4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.

For the 4¼x1½ beeway section we have:

- 4 crates of 50 each, 15¼-inch, 2-row, for 15 sections, at \$4.50 per crate.
- 6 crates of 10 each, 15¼-inch, 2-row, for 15 sections, at 95 cts. per crate.
- 10 crates of 50 each, 11¾-inch, 2-row, for 12 sections, at \$4.00 per crate.
- 6 crates of 10 each, 12-lb. safety cases with cartons at \$1.20 per crate.
- 2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate.

For 24 sections, 4¼x1½ plain:

- 2 crates of 10 each, 9½-inch, 4-row, at \$1.75 per crate.
- 3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.

For 12 sections 4x5x1¾:

- 15 crates of 50 each 3-row cases, at \$4.00 per crate.

## ADDITIONAL SHIPPING-CASES AT BRANCH OFFICES.

### At Washington, D. C.

- 3 cases, 10 each, 12-lb. cases for 4¼x1¾ sections, at 85 cts. each.
- 7 cases, 10 each, 12-lb. cases for 4¼x1½ sections, at 85 cts. each.
- 3 crates, 50 each, 12-lb. cases for 3¾x5x1½-inch sections at \$4.00 per crate.

### At Mechanic Falls, Me.

- 5 packages, 10 each, 12-lb. safety-cases for 4¼x1¾ sections, including safety carton, at \$1.20 per crate.
- 2 crates, 10 each, 12-lb. cases for 4¼x1½ sections at 85 cts. per crate.
- 3 crates, 10 each, 12-lb. cases for 3¾x5x1½ sections at 85 cts. per crate.
- 1 crate, 10 each, 12-lb. cases for 4x5x1¾ sections at 85 cts. per crate.
- 2 crates of 10 each, 12-lb. safety cases for 4x5x1¾ sections, including safety cartons \$1.20 per crate.

### At New York Branch.

- 20 cases, 12-lb., 3-row, sliding covers, 4x5x1¾.
- 85 cases, 9½-inch, 2-row, sliding covers, 4¼x½.
- 1 crate 50 2-row and 1 crate of 50 3-row 12-lb. cases for 4¼x1¾ sections at \$4.00 per crate.

### At Philadelphia Branch.

- 8 crates, 50 each, 12-lb. cases for 4¼x1¾ sections at \$4.00 per crate.
- 10 crates of 10 each, same, at 85 cts. each.
- 13 crates, 50 each, 12-lb. cases for 4¼x1½ sections at \$4.00 per crate.
- 9 crates, 10 each, same, at 85 cts. per crate.
- 4 crates, 50 each, 24-lb. cases for 4¼x1½ sections at \$8.00 per crate.
- 4 crates, 10 each, same, at \$1.70 per crate.
- 4 crates, 50 each, 16-lb. cases for 4¼x1¾ sections at \$4.50 per crate.
- 7 crates, 50 each, 12-lb. cases for 3¾x5x1½ sections, at \$4.00 per crate.
- 2 crates, 10 each, same, at 85 cts. per crate.

We also offer the following glass jars, to close out at special prices, subject to previous sale.

### At Mechanic Falls, Me.

- 5 gross ½-lb. square jars, with corks, at \$4.00 per gross.
- 29 cases of 2 dozen each, Simplex or Federal 1-lb. jars at \$1.10 per case.

### At Philadelphia Branch.

- 9 cases of 1 dozen each, 1-pt. Premium jars, 50 cts. per case; \$4.00 for the lot.
- 10 cases ¼-lb. square jars with cork, 75 cts. case of 2 dozen.
- 1 gross ½-lb. square jars with cork, at \$4.00.
- 8 cases ½-lb. square jars with cork, 90 cts. case of 2 dozen.
- 4 gross 1-lb. square jars with cork, \$5.00.
- 3 cases 1-lb. square jars with cork, \$1.10 case of 2 dozen.
- 5 gross 2-lb. square jars with cork, at \$7.50.
- 37 cases 1-lb. Simplex jars, 2 dozen per case, at \$1.30.

### At New York Branch.

- 4 bbls. of 7-oz. tumblers, 24 doz. to barrel, at \$5.00 per barrel.
- 11 gross of 2-lb. square jars with cork, 6 dozen to case at \$7.50 per gross, \$4.00 per case.
- 13 cases of 2 dozen each ½-lb. square jars with cork, at 90 cts. per case.

### At Washington, D. C.

- 3 bbl. 12 dozen 1-lb. Simplex jars at \$5.25 per bbl.
- 1 bbl. 12 dozen 1-lb. No. 25 jars at \$5.00 per bbl.
- 2 crates 12 dozen 1-lb. Simplex jars at \$5.00 per crate.
- 1 case 2 dozen 1-lb. Simplex jars at \$1.10 per case.

These are fine for exhibition purposes.

- 4 dozen ½-lb. Hershiser jars with nickel tops at 50 cts. a dozen.
- 11 doz. 1-lb. square Hershiser jars with nickel tops at 65 cts. a dozen.

THE A. I. ROOT COMPANY, Medina, Ohio

# SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

### Shipping-cases in Flat, without Glass.

|              |                                                   |                               |
|--------------|---------------------------------------------------|-------------------------------|
| No. 1...     | holding 24 sections, 4 1/4 x 1 3/8, showing 4     | .....10, \$2.00; 100, \$18.00 |
| No. 3...     | holding 12 sections, 4 1/4 x 1 3/8, showing 3     | .....10, \$2.00; 100, \$18.00 |
| No. 1 1/2... | holding 24 sections, 4 1/4 x 1 1/2, showing 4     | .....10, \$1.90; 100, \$17.00 |
| No. 6...     | holding 24 sections, 3 3/8 x 5 x 1 1/2, showing 4 | .....10, \$1.80; 100, \$16.00 |
| No. 8...     | holding 24 sections, 4 x 5 x 1 3/8, showing 4     | .....10, \$1.80; 100, \$16.00 |

### Shipping-cases with Glass.

|               |                                                                             |                   |                   |

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

**Extra Fancy.**—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

**Fancy.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

**No. 1.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

**No. 2.**—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY 6, 1915.

#### COMB HONEY.

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross, also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

#### *Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.  
Honey in badly stained or mildewed sections.  
Honey showing signs of granulation.  
Leaking, injured, or patched-up sections.  
Sections containing honey-dew.  
Sections with more than 50 uncapped cells, or a less number of empty cells.  
Sections weighing less than the minimum weight.  
All such honey should be disposed of in the home market.

#### EXTRACTED HONEY.

This must be thoroughly ripened, weighing not less than 12 pounds per gallon. It must be well strained and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L. A.," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

#### STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

#### *Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.  
Unripe or fermenting honey weighing less than 12 lbs. per gallon.  
Honey contaminated by excessive use of smoke.  
Honey contaminated by honey-dew.  
Honey not properly strained.

## YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

**THE FRED. W. MUTH CO.**  
"THE BUSY BEE MEN"

204 Walnut Street.

CINCINNATI, O.

## HONEY MARKETS

### BASIS OF PRICE QUOTATIONS.

The prices listed below, unless otherwise stated, are those at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

**MATANZAS.**—We are now paying for light-amber honey from 46 to 47 cts. a gallon.  
Matanzas, Cuba, Oct. 7. ADOLFO MARZOL.

**DETROIT.**—Very little demand at present. We quote extra fancy comb at 15; fancy, 14; extracted, white, 9; amber, 8.  
Detroit, Oct. 10. F. P. REYNOLDS & Co.

**PITTSBURG.**—Demand is opening up fairly well. We look for good business from now on. We quote fancy comb honey, per case, \$4.80; No. 1 or choice, \$4.00.  
Pittsburg, Oct. 10. W. E. OSBORN Co.

**CLEVELAND.**—Both supply and demand for honey continue extremely light, but we look for a much better demand as soon as local fall fruits are out of market. We quote new comb honey, fancy, per case, \$3.75 to \$4.00.  
Cleveland, Oct. 3. C. CHANDLER'S SONS.

**BUFFALO.**—Receipts are light; no surplus stock in our market; demand also light; quality of honey arriving is very fine—the best we have had in several years, grading mostly No. 1 white and fancy white. No dark honey is arriving; honey in our markets is sold by net weight only. We quote comb honey, extra fancy, per lb., 16; fancy, 15 to 15½; No. 1, 14 to 14½; No. 2, 13 to 13½. Clean average yellow beeswax brings 32 to 33.  
Buffalo, Sept. 30. GLEASON & LANSING.

**PHILADELPHIA.**—We have about cleaned up our holdings of last season's honey, and are now in good shape for new stock. The outlook seems favorable for the sale of fine comb honey at fair prices. We quote below the outlook at present in our market. Extra fancy comb honey, per pound, 15 to 16; fancy, 14 to 15; No. 1, 12 to 13; No. 2, 9 to 10. White extracted honey in cans brings 8 to 8½; light amber, in cans, 6 to 6½; amber, in cans, 5½ to 6. Clean average yellow beeswax brings 28 to 30 cts.  
Philadelphia, Oct. 10. CHARLES MUNDER.

**CINCINNATI.**—The demand for honey is good, especially for extracted honey. We are selling white-clover extracted honey from 7½ to 10 in 60-lb. cans; amber extracted honey from 5½ to 8, according to quantity and quality. The demand for comb honey is showing life, altho the big buyers are leary lest the western men "bust the market to smithereens." We are selling comb honey from \$3.40 to \$3.75 a case, and now have calls for No. 2 and No. 3 grades, but have none in stock. For choice bright yellow beeswax we are paying 28 cts. delivered here.  
Cincinnati, Oct. 11. THE FRED W. MUTH Co.

**NEW YORK.**—Honey is beginning to arrive in good-sized shipments now, both comb and extracted. As to comb honey, there is a fair demand, especially for No. 1 and fancy white, which are selling around 14 to 15; lower grades at 12 to 13; mixed and dark, 10 to 11. Extracted is arriving freely, and white clover is selling around 7½; amber, 6½ to 7; buckwheat, 6½. Shipments from the South are not very large at this time, but large shipments are arriving from the West Indies, and will increase next month, when the new crop is ready for market. These goods are selling around 60 to 65 cts. per gallon, according to quality.  
New York, Oct. 9. HILBRETH & SEGELEN.

**KANSAS CITY.**—The demand for comb honey is light on account of a big local crop. Car of Colorado here this week; jobbing, around \$2.90 to \$3.00. Demand for extracted is light; supplies not very heavy. Fancy and No. 1 comb brings \$3.00; D in No. 2, \$2.75; extracted, white, 8½; light amber, cans, 8; amber, 6 to 7. Clean average yellow beeswax brings 25.  
C. C. CLEMONS PRODUCE Co.  
Kansas City, Oct. 6.

**CHICAGO.**—The supply is abundant and is, as usual, in excess of demand during this month. Sales are fair, but large; supply keeps down price. We quote extra fancy comb honey, per case, 15 to 16; fancy, 15; No. 1, 14; No. 2, 12 to 13. White extracted honey brings 7 to 8; light amber, in cans, 6 to 7; amber, 6. Clean average yellow beeswax brings 30 to 32.  
Chicago, Oct. 10. R. A. BURNETT & Co.

**ST. LOUIS.**—The demand for both comb and extracted honey is improving right along, and stocks are quite ample. We quote extra fancy comb honey, per case, \$3.75; fancy, \$3.50; No. 1, \$3.00 to \$3.25; No. 2, \$2.50 to \$2.75. White extracted honey brings per pound 9 cts.; light amber, in cans, 7½ to 8; amber, in cans, 6½ to 7; in barrels, 5½ to 6. Clean average yellow beeswax brings 28½.  
St. Louis, Oct. 9. R. HARTMANN PRODUCE Co.

**TEXAS.**—I note quite an improvement over the latter part of September as compared with the first and previous month. The supply is pretty well exhausted. Honey is light amber, but of good flavor; bees gathering very little at this time. No sections are used here. No. 1 light-amber bulk comb honey is selling at 9 to 10; light amber in cans, 7 to 8. Clean average yellow beeswax brings 25 cts. for common.  
Sabinal, Texas, Oct. 2. J. A. SIMMONS.

**ALBANY.**—Receipts of comb honey are behind hand more than usual this season, especially when there is a good crop as there is this year. We strongly advise shipping promptly to meet this month's demand, which always brings the best prices of the season. We quote extra fancy comb honey, per pound, 16 to 17; fancy, 15 to 16; No. 1, 14 to 15; No. 2, 13 to 14. White extracted honey brings 8; light amber, in cans, 7½; amber, 7. Clean average yellow beeswax brings 30 to 32.  
Albany, Oct. 12. H. R. WRIGHT.

**PORTLAND.**—Demand is light. Comb honey is coming in slowly; quality not up to standard. Tendency is to run to light amber and amber. Prospects for later shipments of comb honey are very fair. Producers seem to be holding for higher prices, which I do not think will materialize. Fancy, per case, brings \$3.60, 14 oz.; No. 1, \$3.50, 12 oz. or over; No. 2, \$3.25, 11 oz. or over. White extracted brings 9; light amber, in cans, 8; amber, in cans, 7. Clean average yellow beeswax brings 28 cts.  
Portland, Oct. 3. PACIFIC HONEY Co.

**INDIANAPOLIS.**—Better demand for extracted than for comb. The quality of both is of the best. We are unable to obtain enough comb and extracted, due to producers holding for a much higher price than the market is offering. We are anticipating that a great amount of extracted will be offered at 6½ to 7 cents in the next two weeks. We quote fancy comb honey, per case, at \$3.75 to \$4.00; No. 1, \$3.50 to \$3.60.  
Indianapolis, Oct. 9. WALTER S. POWDER.

**TORONTO.**—There is no change in the price of honey since our last notice. The demand in this Province seems to be very good and the quality of the honey is very much above the usual grade, a large portion of it being white clover. Owing to the lateness of the buckwheat crop and the dry season, the crop of buckwheat honey will be light.  
Toronto, Oct. 11. EBY-BLAIN, LTD.

**MEDINA.**—No new features of importance have been presented in the honey market the past two weeks. The offerings of a number of large lots of California extracted from producers and dealers have occasioned some surprise. The movement of Eastern comb since Sept. 25 has been steady with prices unchanged.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. Notice is given just before expiration. Subscribers are urged, if unable to make payment at once after expiration, to notify us when they can do so. Any one wishing his subscription *discontinued* should so advise us upon receipt of the expiration notice; otherwise it will be assumed that he wishes GLEANINGS continued and will pay for it soon.

HOW TO REMIT. Remittances should be made by draft on New York, express-order or money-order, payable to the order of The A. I. Root Co., Medina, Ohio. Currency should be sent by registered letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

## FOREIGN SUBSCRIPTION AGENTS.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents at the prices shown:

PARIS, FRANCE.—E. Bondonneau, La Korrigan, Avenue de la Gare, á Juan-les-pins. France. *Per year, post paid, 8 francs.*

GOODNA, QUEENSLAND.—H. L. Jones. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/7 p.*

DUNEDIN, NEW ZEALAND.—Alliance Box Co., 24 Castle St. *Per year, postpaid, 6/7 p.*

# Home Markets for Honey

If you are developing a local market for your honey, you will be interested in the following from a Wisconsin producer, who writes regarding the 64-page book, "The Use of Honey in Cooking." He says:

"We received the honey recipe books O. K. and were more than pleased with them as they were one of the finest boosts for getting honey before the people that we could have procured.

"The people were clamoring for them and our booth was one of the leading attractions at the fair.

"One of the members of the association who was putting out small glass containers sold one to a lady from Minneapolis, who was attending the fair here. This morning he received an order that she had taken among friends at home to ship 25 gallons of extracted honey to Minneapolis. So it pays to advertise, and your recipe books do the work." (Name on request).

We offer these books, "The Use of Honey in Cooking, 64 pages, 115 tested honey recipes, with many facts regarding honey, at 10 cts. each, postpaid. In quantity lots with your advertisement on the back cover (no other address given in the book) as follows:

- 100 copies, printed as above....\$ 4.50
- 250 copies, printed as above.... 9.25
- 500 copies, printed as above.... 17.25
- 1000 copies, printed as above.... 25.00

If sent by mail, postage extra.

Order a quantity and watch your honey go.

C. H. W. Weber & Company, Cincinnati, O.  
2146 Central Avenue

## WHY NOT

### Order Your Supplies for Next Season Now?

---

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 4 per cent discount during October. Send in your order just as soon as you find out just what you require and we will take care of it promptly.

---

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

## HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual one. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

### Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. **PREPARE!** Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

#### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

G. B. Lewis Company, Watertown, Wisconsin, U. S. A.

Send for catalog giving name of distributor nearest you.

## DON'T FUSS

With your old combs and cappings, but send them to us. We will render them into beeswax for you on shares and pay you cash for your share, or we will make it into

### Dadant's Foundation

for you.

If you prefer, we will pay you our best trade price in exchange for BEE SUPPLIES.

Send for our terms. We feel sure that we can save you some money besides saving you a "mussy" job.

**BEESWAX WANTED** at all times.

**Dadant & Sons, Hamilton, Illinois**

## EDITORIAL

### The Cause of Swarming

IN a little discussion between J. E. Hand and J. E. Crane, in this issue, page 969, we believe the majority of our best beekeepers would favor Mr. Crane's viewpoint.

### Amount of Stores Necessary to Winter a Colony

THIS difficult question is answered very satisfactorily by Mr. Doolittle in this issue in his department, page 972. While he admits that a colony can be wintered on one pound of stores a month, this amount is altogether inadequate, because bees, in order to do well in the following spring, must be "rich in stores." He therefore recommends feeding up in the fall with more than will carry them thru. It is pretty well agreed now that fall feeding is much better than scant feeding, and then feeding again in the spring to stimulate.

### Late Fall Feeding; a Precaution

MR. W. C. MOLLETT, in this issue, urges early feeding in the fall. In the main he is correct; but one precaution should be noted. Feeding in early September may start brood-rearing, with the result that a considerable amount of stores will be consumed. While the conversion of syrup into young bees is a splendid thing, the process sometimes leaves the colony short of stores; and it may have to be followed up by later feeding; and certainly all the colonies should have a careful inspection. If one is obliged to feed after cool weather sets in, he should make a syrup  $2\frac{1}{2}$  parts of sugar to one of water. It should be given hot, and all at one feeding.

### Experiment Station Rears Queens

THE Agricultural Experiment Station of the University of Wisconsin in Bulletin 268, May, 1916, gives a brief report of a

new work that they are taking up, recognizing that Italian bees are more resistant to European foul brood. Efforts were made during 1915 to develop queen-rearing in connection with the work of the Economic Entomology Department. Mr. C. A. Aeppler is in charge of this work. One hundred and twenty-six queens were sent out to beekeepers in twelve counties. The queens sold at 50 cts. each. A larger number of queens will be reared this season in order to meet the expected demand.

### Bees Fertilize Coconut Blossoms

IN the journal of the Jamaica Agricultural Society for July, 1916, page 273, is an interesting account of the value of bees to cross-pollinate the coconut blossoms. The coconut bears the two kinds of flowers—the male and the female, altho those on the same stalk do not mature at the same time. Generally, too, there is only one set of flowers open, or ready to fertilize, or to be fertilized, on a coconut at one time, this being one of nature's devices to guard against inbreeding or self-fertilization.

It has been noted that, on coconut estates where bees are kept, the yield is phenomenally high. Palms of five and six years bear heavy crops, and the bunches are well filled.

### Beekeeping on the Indian River, Fla.

IN this issue Mr. L. K. Smith gives a rather discouraging view of the out-apiary business on the Indian River in Florida. But if one were going to keep bees for pleasure and profit, putting the main emphasis on *pleasure*, we do not know of any place in the United States where one could get more solid enjoyment than operating a series of yards up and down the Indian River. We have been there. In fact, the editor, three years ago, got back his health in making a cruise on that same river, an

account of which was given in GLEANINGS for April 1 and May 1, 1914, February 15 and March 15, 1915.

Mr. Smith mentions having very small yards. He might with profit have had larger ones; nor was it necessary for them to have been so far apart, unless there was difficulty in finding a suitable location. Mr. O. O. Poppleton made a success of the out-yard business on this river some years ago. He secured health and pleasure both.

### Distance Bees Fly in Quest of Stores

THE two Millers, page 966, on the question of how far bees fly in quest of stores, are at loggerheads. While we must admit that bees will fly from three to five miles for nectar when conditions are favorable, it is our opinion, from considerable observation, that they very often do not go much over a quarter of a mile. Very recently we had occasion to move the Waterworks yard scarcely a mile in an airline to the Blakeslee yard.

Our man was asked to see whether any bees returned to the Waterworks location next day. Not a one. Apparently the bees of the moved yard had not been in the habit of going more than half a mile, and they might have been going less. This was in the aster bloom.

We shall have to conclude that there is no invariable rule. It is wide of the truth to say that bees will not fly five miles sometimes; and it is equally erroneous to say they will not go more than a quarter of a mile. That they will generally not go more than a mile in average localities and seasons we believe is not far from the truth.

### Outdoor vs. Indoor Wintered Colonies

THERE is a general belief among our best beekeepers that, while colonies wintered indoors consume less stores, colonies of equal strength wintered outdoors will be in better condition for the harvest. This belief is founded on the fact that outdoor-wintered bees will begin rearing brood earlier than those indoors. Breeding causes consumption of stores. Young bees in the spring are a big asset. If so, the greater consumption of stores has been a good investment.

In this issue, in his department of Stray Straws, Dr. Miller says that, since he has put a furnace in his cellar, and allowed the door to be open much of the time, he thinks his bees are just as vigorous in the

spring as those wintered outdoors, and he is probably right. Since he put in the furnace he has better ventilation and a uniformly higher temperature.

Outdoor air, it is said, has a tendency to favor breeding. Some years ago one authority on indoor wintering made the statement that he did not want too much fresh air in the cellar because it started breeding; that such breeding would cause a larger consumption of stores, and dysentery.

There may be something in this; but we believe that Dr. Miller is on the right track in giving an abundance of ventilation, and with it a higher temperature. If the outdoor colonies have any more vigor than indoor colonies it is because they have young bees; and young bees, of course, mean early brood-rearing. We are perfectly well aware that early breeding in the cellar is attended with some risk, especially to beginners; but this is not saying that an expert cannot avert dysentery.

### Honey-crop Conditions and Prices

IT is clearly evident that there was a shortage in the yield of honey in the Imperial Valley and clear up thru California. There was also a shortage in Idaho, where such a large crop of comb honey was produced last year. There was likewise something of a shrinkage in Colorado and other mountain states.

However, the big crop of honey, both comb and extracted, in the East at this writing, will in all probability more than offset the shortage in the West. The honey-market quotations given in our last issue and in this issue, confirm this in that they show a slightly easier market than last year. Taking everything into consideration, it is quite remarkable that the market is as firm as it is.

While the quotations over the country generally would seem to indicate a better demand for both comb and extracted, the demand at Medina is certainly brisk, and prices are holding fairly firm. We do not understand why this is so unless it is because of our publicity campaign in the shape of some full-page advertisements in the *Ladies' Home Journal* and *Good House-keeping*. Our readers will notice that these put strong emphasis on honey as a food and condiment and on our own brand in particular.

It is evident that producers are beginning to unload their crops, and they are doing it at their convenience. Too much unloading at one time demoralizes the market.

It is well to bear in mind that the market on *comb* honey will ease up as soon as freezing weather comes on. The trade is afraid to get it in cold weather, and more afraid of its granulating afterward. The experience of last year has been an expensive object lesson to many. Comb honey should if possible be shipped before the holidays; for after that time the demand will be sluggish, if experience means anything, until the next year's crop is in sight.

Honey-producers as usual are making the mistake of extracting their honey too green. The result will be that some of it will sour in the open market. Such practices will have a strong tendency to disgust the trade and depress prices.

### Exportation of American Honey into Germany.

In the "Daily Commerce Reports" issued by the Department of Commerce, Washington, D. C., is a report from Vice-consul Ernest L. Ives, Breslau, Germany, under date of August 28, on the subject of the German bee industry. Among other things, he says that the present yearly production of honey and wax in Germany is between five and seven million dollars' worth.

He refers to the migratory beekeeping practiced by the Germans, or how bees are moved around on "wandering carts." These carry from 25 to 30 hives, such carts being moved from one place to another. They are in reality portable house-apiaries. Besides these special moving apiaries on wheels, something over 375,000 hives are transported on special trains to the heaths near Luneberg and Oldenburg.

Under the heading of "Imports of Honey and Artificial Honey" he furnishes a table of the amounts of honey from the United States and other countries sent into Germany. With the exception of Cuba the United States stands at the top of the list.

The price of German honey is 65 cts. per lb.; and this extraordinary increase in price, the vice-consul says, is mainly due to the very poor harvest in the spring and summer of 1915 and of this year, and also to a falling off of imports. Why he makes no mention of the great war in Europe in this connection is not easily understood. In ordinary peace times 65 cents is an extraordinary price.

Under the head of "Criticisms of Methods of Collecting Honey" he has this to say:

As previously mentioned, large quantities of honey have been imported from America.

Beekeepers complain of the competition of this honey, which is sold at very low prices on account, as is claimed, of its "inferior quality." It is stated that honey in wooden tubs is imported by wholesale dealers at a price of \$3.80 to \$4.75 per 110 pounds. Adding the costs of packing and transportation, it can be retailed at \$0.10 to \$0.13 per pound. This low price is said to be due to the methods of collecting the honey in the countries of origin, the swarm being killed by sulphuric acid; this affects the aroma of the honey, which is also contaminated by the corpses of bees, chrysalises, and other impurities, whereas German honey is won by the centrifugal process. Further, the German product is usually packed in glass jars and cans. Recently tubes containing one-eighth to one-half a pound have been much in use. Wooden tubs are not considered practical for the transportation of honey, since wood is said to spoil the flavor.

The best honey imported from the United States is packed in tin canisters containing about 55 pounds, two canisters being usually packed together in a wooden box. Honey from South America is imported in tubs of 165 to 220 pounds.

Evidently the vice-consul, Mr. Ives, has got some things a little mixed. In the first place, honey is not shipped from America, or at least from the United States, in tubs;\* and in the second place, the quality is not affected by the methods of killing bees. Honey from log gums and box hives is not exported; and even when such honey is taken in the old-fashioned way, "sulphuric acid" is not the agent for killing the bees. He evidently means the fumes of sulphur.

It would be quite interesting to learn where the vice-consul gets his information about American honey coming in tubs of 110 lbs., and the poor quality of it being due to the carcasses of dead bees and to the use of "sulphuric acid" when killing the bees. He possibly meant sulphurous acid or vapor of burning sulphur. As a matter of fact, sulphur dioxide is the agent used; *i. e.*, the gas of burning brimstone.

When he speaks about artificial honey he is probably taking hearsay. While it is presumably true that adulterated honey might be shipped to foreign countries and sold as honey, it is evident that the writer has got things a little mixed.

Probably some of our German correspondents can enlighten us; for the German beekeepers themselves, who know anything about American methods, know that our box hives or old log gums do not produce any honey that goes beyond the locality itself.

\* Possibly he means "kegs."

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

JAN GREVE, of Bergen, Norway, writes that the statement in GLEANINGS that "The demoralization of the beekeeping fraternity of all Europe seems to be complete," greatly overstates the case.

Outside the direct theater of the war, beekeepers are going along as usual, except that they have to pay a high price for sugar.

YEARS ago, when I wintered in a cellar so cold that it had to be kept always closed, I always had an uncomfortable feeling that in spring the bees were not so vigorous as those wintered outdoors. But since a furnace is in the same cellar, allowing the door to be open much of the time, with pure air always, I think the bees are just as vigorous in spring as those wintered outdoors—possibly more so.

ARTHUR C. MILLER hints at skepticism as to the need of having apiaries 3 miles apart, reporting crops utterly different at a distance of  $\frac{1}{4}$  mile, p. 866. Please play fair, Arthur. In ordinary cases, with somewhat level ground, there has been plenty of proof that bees will go several quarter miles, and it's ordinary cases we're talking about when we mention 3 miles. Now will some one (say from near Providence) make out a list of the exceptional cases, and tell us the proper distances for each?

LET me warn the beginner not to take too seriously what is said by Gerstung, page 869, against trying to breed toward non-swarming. We are told, "The reader must bear in mind that the writer had in mind only conditions prevailing in Germany." So it may be that we are to think only of Germany when told that, if we could eliminate the swarming impulse, "the bees would become degenerate, and slowly, yet surely, would go toward extinction." Certainly it hardly appears so in this country. If the Dadants, with only 2 to 5 per cent of their colonies swarming, find their bees going toward extinction, they have kept very quiet about it. For more than half a century I've been trying all I could to prevent swarming, breeding from colonies that never offered to swarm; and the fact that the average yield per colony has doubled is not very strong proof of degeneration.

MR. EDITOR, you ask, p. 837, whether I'm not attaching too much importance to iron in honey. You will hardly think so if you realize how much importance physicians attach to administering iron, even tho "in

very minute quantities," in readily assimilable forms. Please recall that, altho iron is present in the human body in minute quantity, that minute quantity is necessary for health, and even life; that that minute quantity is present in honey in the very best form for direct assimilation; that in sugar it is found not at all; and then figure out for yourself how much importance should be attached to it. "Talking about it for bee-food," were you? Well, don't you believe the all-wise Creator knew just about the right amount of iron to put in for bee-food? And if he put a very minute quantity of iron in it, do you believe you can have first-class bee-food without any iron at all?

[But the amount of iron is a very small part of one per cent. Along with it are other elements in small quantities, like lime, sodium, sulphur, magnesia, and phosphoric acid. Why should not these be considered with iron? After all, is it not the pollen, the dextrose, and the levulose which are present in larger quantities—particularly the last two—that are the elements that make honey better than syrup that is only saccharose?—Ed.]

MR. EDITOR, I understand, p. 776, Sept. 1, you can tell by the flight at entrance when bees need more super room. But you don't say how. I can't tell by watching the entrance whether another super is needed or bees have double the room they need. Please tell me how. [Neither can we determine, by watching the entrance only, whether another super is needed, or whether bees have double the room they need, and we do not believe that any one else can. If you will put on your specs and read over again what we have said, you will see that we stated that the condition of each colony, in the incident referred to, was determined by a combination of three different ways: Watching the flights of the bees going into the entrances; tilting up the supers at the back and looking under; and by hefting or lifting the back end of the whole hive. Of course, if you pick out the sentence at the head of the first column, page 776, you might infer that the diagnosis was made solely on the indications at the entrance; but the next sentence and all the rest of the article shows that we used every means available without resorting to lifting out the individual frames. It takes but a small fraction of a minute to heft a hive or to tilt up a super, the entire diagnosis not taking up much more than the fraction of a minute.—Ed.]

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The first general rain of the season is falling today (Sept. 30).

\*\*\*

I was glad to have Mr. Frank E. Cliff, page 614, July 15, verify my comments as to the handling of honey by the employes of the Postoffice Department. The reading of Mr. Cliff's article will be well worth the time.

\*\*\*

Mr. Doolittle's article on the middlemen, page 782, Sept. 1, is timely and to the point. The fact of the matter is that there must be a middleman, and if the beekeeper thru the medium of organization is not ready to fill the gap it will continue to be filled by one who exacts a profit for his labor.

\*\*\*

Our annual weather records are computed from July 1 and all rain is figured from that date. Up to this date (Sept. 27) we have had in this city an inch as measured by official records, yet the value to the beekeepers of this amount, falling as it has during the summer months, amounts to practically nothing as a factor on next year's crop.

\*\*\*

J. L. Byer says, page 780, Sept. 1, "If there is anything to be made in any business, the man who stays with the job is the one who will win out in the end"—and he is right. My father spoke those words to me twenty-five years ago and he won out. However he was later nearly ruined financially by the great Kaw Valley flood of 1903.

\*\*\*

It seems I owe Mr. M. J. Meeker, our county inspector, an apology, in that I quoted him as favoring the caging of queens in the treatment of black or European foul brood. Instead he informs me he is opposed to the caging of queens in the treatment of this disease, giving as his reason that a queen not showing sufficient strength of stock to resist the disease in the start is not worth any future trials against the disease. His reasoning is backed by experiments, and to most of us must seem logical. I am pleased to make this correction as I confused his conversation with that of another party.

\*\*\*

## IMPERIAL VALLEY'S PECULIAR SEASON.

I am handed some notes taken by a friend during a conversation with Mr. J. W. George relative to conditions in the Imperial

Valley, which I herewith present with a few remarks of my own. According to Mr. George there are several conditions that have worked against the success of the beekeepers of that section during the past season. A change of climate is given as one cause, but I am of the opinion it should not be termed a change of climate so much as a peculiar season, which has been the case on this side of the range. There was an increase in the acreage of cotton and consequently a decrease in the acreage of alfalfa; a shortage of water for irrigation purposes, causing a lighter secretion of nectar; grasshoppers; a warm early season with a short flow, followed by cold, reducing the bee force greatly. Mr. George says that the average per colony will not exceed 60 pounds, the normal yield being from 120 to 180.

\*\*\*

## THE END OF THE SEASON.

With the close of this month (September) the season of 1916 may be said to have closed. It is possible there may be a few localities where a light flow of surplus may be gathered, but they are few and far between. In southern California as a rule the season has been a sad disappointment, and this is also true of the central and northern valleys to a large extent. Inyo County seems to have been favored by a good crop if all reports are true, while the Imperial country is by far below its usual output. In this part of the state the early prospects were never better up to the first of March, but at this time the rain stopped short, and we were the victims of warm dry weather that shortened our crop materially. So we now start thru another winter with high hopes that only a beekeeper can possess. When a beekeeper loses hope it is equivalent to an apiary for sale or the beginning of a run-down yard that no one would pay much for.

[Early in the season, the prospects for a big yield in California were never better. The rains had been coming on just right; and had it not been for the hot dry winds there is every probability that there would have been a big yield. The shortage of the crop in California and other parts of the West has offset the big crop in the East in the clover region. Had there been a large yield in the West as well as in the East, prices certainly would have taken a tumble. As it is, they are nearly holding their own in the East, and are more than holding their own in the West.—Ed.]

J. E. Crane

## SIFTINGS

Middlebury, Vt.

A good-looking lot is that class in beekeeping at the Ontario Agricultural College summer school, page 800, Sept. 1. I notice nearly half of them are women.

\*\*\*

Very little surplus honey was gathered here in Vermont in August. Honey crop is rather poor except in one county, where it is very good.

\*\*\*

I have heard, at one time or another, a good deal about the "king-bee," but never expected to see one. But here is the next thing to it, on p. 795, Sept. 1, a real "Bee King." Glad to make his acquaintance.

\*\*\*

The method employed by A. E. Ault, of Brantown, Fla., as given on page 807, Sept. 1, for making increase, is a most excellent one, as it leaves few or no weak colonies to be built up later. It also helps in keeping down swarming.

\*\*\*

Dr. Miller, I am interested in the advice you give Wesley Foster, page 677, Sept. 1, in regard to the use of honey. You say, "I would like to have you live longer." Are we to understand that the moderate use of sugar will shorten a man's life, or that the use of honey will lengthen it?

\*\*\*

That is an important point made by the editor, page 468, that honey kept at a temperature of 130° for two or three days is much less liable to granulate than when raised to 160° for a short time. Is it not also true that honey is much less liable to granulate if it is warmed and bottled before it has first granulated?

\*\*\*

Mr. H. H. Kollister's method of securing straight combs by the use of a sharp triangular top-bar, page 737, Aug. 15, takes one back thirty-five or forty years, when we used them, and we found it was a great help if the rear of the hive was raised a few inches. There was less danger of their jumping from one frame to another.

\*\*\*

Page 719, Aug. 15, Mr. Doolittle says, "I am sure that every beginner will do well if he removes the largest patches of drone comb in all his hives, replacing them with worker comb except in such colonies as are set apart as breeders." Few persons have

any very pronounced ideas on this subject. I am often surprised at the large amount of drone comb I find in the hives of those thought to be pretty good beekeepers, and sometimes almost in the center of the brood-chamber.

\*\*\*

We are reminded these days of that beautiful parable of our Lord on preparedness. He said that ten virgins went to attend a wedding. All took lamps or torches with them, for the wedding was to be at night. Five were thoughtful, and took a supply of oil as well as lamps. The others did not think they would need any oil. "How foolish!" we say; but how like a multitude of beekeepers! So we have at this season requests for a little foundation. Another wants a few hundred or a few thousand sections, and perhaps another a hive at once for their one lone colony has just swarmed. How foolish to keep bees, and not be prepared to supply them with what is needful for success!

\*\*\*

Prof. Baldwin, in his department for July 1, relates his experience in introducing queens by that old plan called the "honey method." It seems really surprising that he should be able by this method to remove an old queen and introduce a virgin at once successfully. If this can be done, and not fail more than one time in ten, it will prove of great value in superseding old queens during spring or early summer. If one has the conveniences for introducing in this way it need not be very fussy nor take a great amount of time. I find in trying to introduce again in this way that it is a little difficult to roll a queen in thick honey. Perhaps the temperature of Florida would make it thin enough, but I suspect a little thinning would be better for our climate if we try to work rapidly.

\*\*\*

## SUPERS ENOUGH FOR A WHOLE YARD.

That auto truck as pictured on page 733, Aug. 15, certainly looks pretty good. As we have been using one for six or eight weeks I can give my testimony that it is a good thing for out-apiaries. Where yards are ten or twelve miles away it saves lots of time. How nice to take supers enough for a whole yard and all the help needed at one load, and then to get there in a quarter of the time required by a horse! and then to be able to take off a ton or more of honey and bring it all home the same day!

## SELECTING THE BREEDER.

P. C. Chadwick, page 718, Aug. 15, gives some rules for selecting a breeding queen. This is a matter of more importance than we have been accustomed to think—of more importance, I believe, than is the breeding of domestic animals or birds. Years are required to change a herd of dairy cows, while a yard of one hundred colonies of bees may be changed in a single season.

\* \* \*

## THE SHAKEN SWARM IN THIS LOCALITY.

"Here is what happens in this locality when the shaken-swarm plan is practiced," says Wm. Beucus, page 736, Aug. 15. "If shaken on to starters, almost certain absconding; if shaken on to full sheets, very much less absconding; if shaken on to a set of clean, sweet-smelling worker combs, no absconding whatever." Now, this is doubtless true to some extent in most places, tho not as bad as in his "locality." Bees seem especially inclined to abscond when shaken on to a full set of frames of foundation. We found, the past season, that if one or two frames of drawn combs are given with a hive full of foundation it will usually hold them; in fact, I think it answers about as well as a hive full of combs.

\* \* \*

## PUT THE BLAME IN THE RIGHT PLACE.

We sometimes wonder why the flowers do not yield more honey—why the bees should often find it necessary to visit many hundreds of flowers to secure a load of nectar. Too often we forget that the object of the secretion of nectar is to secure cross-fertilization; and if the amount were large a load would be found in a few flowers; but if only a small amount is found in each flower a large number must be visited, and thus the pollen scattered over a wide area. A bee finding a scanty yield of nectar in the flowers of one apple-tree naturally flies to another; and by so doing it gives us the best kind of cross-fertilization.

\* \* \*

## CARROT HONEY!

Long ago an old pessimistic preacher declared there was "nothing new under the sun." We can excuse him, perhaps, for he did live in a rather slow age. Had he lived in this age of steam and electricity, of automobiles and flying-machines, I think he would have thought there were many new things under the sun. Even in beekeeping there is something new to learn each year; and I have seen something new recently. One of our helpers reported in August see-

ing bees working on wild carrot, gathering honey. "Impossible!" I said. "Bees do not work on that plant. It isn't in the catalog of honey-plants in the A B C and X Y Z." Then another reported seeing bees at work on it. I had noticed the bees in our home yard were storing a little in brood-chambers. Then I went and looked myself, and, sure enough, there were the bees walking around on the great flat umbels of this plant, lapping up the atoms of nectar.

\* \* \*

## JUST WHAT IS THE CAUSE OF SWARMING?

There are few things we would more like to know positively and accurately than the cause of swarming. Mr. J. E. Hand, page 599, July 15, gives his views, some of which do not seem to correspond with our experience among the bees. He says, "Give me a queen of undiminished fecundity and I will show you a non-swarming colony." This year we have had many colonies swarm with young queens that have been laying but a short time. Indeed, a young vigorous queen seemed but poor protection against swarming.

Mr. Hand further says, "Queen-cells are inseparably associated with swarming." We have found colonies repeatedly swarming without a trace of queen-cells upon the combs of their hives. He gives us to understand that queen-cells are started largely for the purpose of superseding the queen; that the queen cares little for them until they are sealed, and then she is so put out that there is a sort of insurrection in the hive, and out go the bees. And yet we often find the queen among the last to leave the hive. More, we often find them swarming before the oldest queen-cell is sealed. If sealed queen-cells were the cause of the trouble we should only have to see that there were no sealed cells until the queen had regained her fecundity to prevent all swarming, yet this is no sure method of prevention.

He also tells us that the queen "cannot control egg production," and that a queen will scatter her eggs over the combs of a small hive and become exhausted sooner than in a large hive. This does not harmonize with my experience.

If Mr. Hand's theories are correct, why is it that bees swarm less in hives well ventilated than in hot poorly ventilated hives? Is the fecundity of the queen greater in such hives, so that she can keep right on thru the season? Is the fecundity of the queen greater in seasons of scarcity when few swarms issue than in seasons of abundance? We know the amount of brood in such seasons is far less.

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

Bees seem to be in unusually fine condition this fall all over Florida. Rains have been plentiful but not severe, encouraging vegetation, but still allowing bees fair weather for gathering.

\* \* \*

How many in our land of sunshine have ever planted or grown to flowering size either or both the *Bigonnia venusta* and the *Antigonon leptopus* or Mexican pinkvine? They will pay well for the beauty, and the bees are "crazy" over them. The latter blooms from May to frost, the former only in early spring, but both are a riot of color.

\* \* \*

## SWEET CLOVER AND ALFALFA IN FLORIDA.

Several inquiries have come in regard to sweet clover in Florida. So far as I know, sweet clover has not been acclimated in this state. I can only hope that it may be at some future date. If the government experts can succeed in discovering a species or variety of sweet clover that will grow in a warm moist climate in sandy soils, it is *sure* that Florida will be doubly valuable as a honey or forage state. They sent the alfalfa line north from about Denver to Canada, and into Canada; and why may they not sweep the hand of the floral dial away to the Southland, for both sweet and alfalfa clovers? Alfalfa is growing to a slight degree already along the drainage canals of the east coast in St. John's Co. But it is as yet very limited in area, and lives only three years. Then it dies and must be replanted. Probably it gets "wet feet" by its roots reaching water level.

\* \* \*

## FINAL NOTES ON THE HONEY CROP.

Honey-crop reports for the state are now pretty well in. Orange was poor in quantity and quality; saw palmetto only about a third of a crop; mangrove the same; but cabbage palmetto was a surprise. It not unusually ends by July 20; but this year bees were gathering from it as late as Aug. 14. In most locations the honey from the cabbage palmetto is mixed by the bees with other honeys—for instance, on the east coast with mangrove. But it is secured in almost its original and pristine purity on the west coast between Bradentown and Fort Myers. Pennyroyal will soon begin blooming in the southern portions of the peninsula. Partridge-pea honey is quite abundant in the high pine sections; but it is always dark-red, strong in flavor, and unde-

sirable as a table honey. In the tupelo sections our correspondents indicate a good flow from the tupelo, but poor from the ti-ti. Taking the state as a whole, I should say the season of 1916 has been about an *average*, perhaps slightly below.

Apropos of the honey from the cabbage palmetto (*Sabal palmetto*) referred to above, we might mention a letter received from a beekeeper in the southern half of the state. He writes of that honey: "The less I have of it the better I like it. It may be some other tree, flower, or shrub that blooms at the same time that yields the worst honey I get. It is so thin it runs like water; and, when first uncapped, often bubbles like gas in all the cells. It is acid and very acid, tho nice-colored." I am sure our correspondent is "getting *his* mixed." The clear color, the thinness, the bubbles, all prove cabbage palmetto. These three qualities inhere in no other one honey in Florida, so far as I can determine. But the acidity and acridness—no! No honey has less of both qualities than cabbage palmetto. In fact, it is, when pure, the purest and mildest honey in the state; and, tho thin, it is delicious in every way. The bubbling when first uncapped is very characteristic of this honey; but it is not due to fermentation, and all bubbles disappear on extracting the honey. They show only in the cells just after they are uncapped. Therefore our correspondent's bees *must* be gathering some other clear but pungent honey at the same time that they gather from the cabbage palmetto. What it is I have no data for determining.

\* \* \*

## NECTAR FROM COW PEAS.

Another apiarist, writing from Fort Ogdon, Fla., wishes to know what it is that his bees gather from cow peas. He says he never sees the bees on the blossoms, but only at the base of the pod where it joins the stem. In the case of certain plants the bees gather nectar, not from the blossoms, but from the stem bases. For example, the *Cassia chammachrista*, or sensitive pea, this year the bees seemed to work on the blossoms in the early morning, on only the stem bases and leaf bases of the stalks later in the day. Usually they work not at all on the blossoms. But I have not heard it said or noticed personally that they do not work on the blossoms of the cow peas. It may be that our correspondent's bees are gathering the secretions of certain aphides or plant-lice, tho it is possible that the cow pea also secretes nectar at the pod-bases.

# BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

The gasoline age is beginning to benefit the beekeeper more and more. Altho a number of beekeepers have taken advantage of the use of motor vehicles of some type or other for a number of years past it has been during only the last two years that they were more abundantly adopted for apiary work. Inquiries have been coming from quite a number of beekeepers contemplating the purchase of an automobile or truck for beework, and desiring certain information regarding them before making the purchase. This indicates a still greater use of the auto during the coming years.

For the small beekeeper the larger, heavier, and more expensive auto trucks do not seem to be as practical as some of the lighter machines. There are some who differ with me on this question; but after a trial with both kinds, together with a thoro study of the two in my own apiary work, my conclusion is that more can be accomplished with two half-ton trucks than with a one-ton truck. This is especially true where a large number of apiaries must be visited frequently. In fact, a great deal of the running around to the apiaries can be done far more economically than with a larger and more expensive machine. I still favor two Fords over any other kind of machines for our work.

\*\*\*

## CO-OPERATION IN TEXAS.

Co-operation and organization have been uppermost in my mind for many years, and the readers will remember that I have called attention to this important question quite frequently in these columns. I believe thoro in a united effort of the beekeepers toward a better marketing of their products. It not only helps them but everybody else who is dependent upon them. Let the beekeepers get a good price for their product, and not only they will thrive, but the supply-dealer, the manufacturer, and everybody else who trades with the beekeepers will thrive. For this reason all these interests should lend a helping hand where beekeepers are endeavoring to band themselves together for the purpose of making their vocation a more profitable one, not only to themselves but for all concerned. We are trying to do this very thing in Texas today,

and it is my sincere wish that the efforts on the part of the Texas beekeepers in this direction may be crowned with success.

While Texas honey prices were anything but satisfactory a little over a month ago, we are getting better prices now. The market is much more steady, and the demand is keener. All this occurred in spite of the information that there were still great quantities of honey in the hands of numerous large producers, together with the approach of the autumn months and cool weather during which the sale of honey is usually curtailed. Extracted honey, too, is on a firmer basis at this time than it has been for a number of years, and the supply has been rapidly decreasing.

Information about the cause that has brought this condition about is lacking. Perhaps none of us have thought about it seriously enough to ascertain the real cause. Perhaps it may be attributed to the general spell of prosperity that has spread over the country. Even if this be true I cannot help but feel that our efforts to organize ourselves for better marketing of our honey and other products has already had its effect in that the beekeepers were awakened and just simply quit throwing their honey away at low prices. They are all asking more for their honey now than before the agitation of organizing began. Let's keep the good work going.

\*\*\*

## SOME DIFFERENCES BETWEEN THE NORTH AND SOUTH.

It sounds rather strange to read on page 838, under "Honey Crop Conditions and Prices," the following sentence: "As soon as the crop begins to pour into the market we shall be able to get more definite information"—strange because here in the South we have been pouring our honey into the market ever since April and May, and at this time are just about "winding up the season" with what scattering lots of honey there may still be left unsold. There does not seem to be any large quantity of this, and the demand is keener than it has been for some time. It is doubtful whether any honey will have to be carried over the winter, and the usual winter and very early spring trade in honey that has been created during the last few years will have to go begging for want of a supply.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

BE SURE TO HAVE ENOUGH.

"What is the quantity of stores needed by a colony of bees during the winter?"

There have been various estimates at different times by different writers, the amounts ranging from 7 to 35 pounds. This question is surely of some importance to beekeepers, for, if an average colony of bees may be wintered safely on 7 lbs. of honey, it is of no use to let them consume any more, and we might as well save the 28 lbs. of the higher estimate. But from past experience I have found that scanty stores often prove a nuisance, in that it is better to have more stores than the bees consume than to be obliged to feed in early spring.

"But suppose we call the amount 18 lbs., or half of the higher estimate—how would that do?"

I am not sure but that it might be a mistake to set down any stated amount as absolutely and exactly sufficient, for the reasons that colonies not only differ in numbers, age of bees, etc., but winters also differ in duration, in suddenness of changes, high winds, etc., and the number of sunshiny days or stormy days even have some influence on the question.

Colonies which are wintered in the cellar consume less honey than those wintered out of doors; but in localities where the winters are comparatively mild, if the bees are strong in the fall the difference between outdoor and indoor wintering is not so great as some would have us think. Most beekeepers agree that comparatively weak colonies will consume more stores according to their numbers than the more powerful ones, owing to the necessity of producing heat thru the consumption of stores. For this reason some contend that it is undoubtedly better to winter the weak colonies in the cellar and the populous ones out of doors. I have had colonies which would consume in the cellar only a pound of stores a month, and come thru in the best condition, while another colony in the same row, and apparently having the same number of bees and in the same condition, would consume from three to four pounds a month. To have limited all to a winter's store of one pound a month would show the shortsightedness of any apiarist.

"But, all things being equal, is it best to leave a strong average colony a large amount of honey, say 30 to 35 lbs.?"

I hold to the larger supply, even tho the

quantity left in excess after wintering might constitute a sufficient amount to cause some to think if it had been sold it would have paid for an ordinary season's management. Those advocating a small amount of winter stores depend upon feeding in early spring to keep the colony along; but from years of experience along this early spring feeding I have found that we are quite likely to be caught in March or early April with a spell of a week or ten days of real winter weather, during which the bees will often fail to go after the feed; and the result is starved colonies or colonies greatly injured by the loss of brood thru a fear of starvation from a too scanty supply. Those advocating the short supply of stores for winter seem to think that brood-rearing can be made to forge ahead much faster by feeding the bees half a pint of thin sweet every day than by any other method; but from experiments along this line for many years I can only think that such is a mistaken idea. By setting apart 20 or 40 colonies and feeding half of them while the other half were left rich in stores from the previous season, but without feeding, and then comparing notes regarding each half the unbiased mind can prove the real truth in this matter. And if we stint our bees without any feeding we compel them to reduce brood-rearing. Any colony which has not enough stores to make the bees feel "rich," or to feel that there is a great plenty ahead, will be much less prone to breed the latter part of March or in April, just at the time an abundance of brood should be started if we are to secure the best results in the early clover harvest. The apiarist who is so fond of his bees that he is willing to go thru with the buying of the feed and the labor of feeding every day, or who will not pass three days without examining them, may be able to remedy any shortage in good time and feed when he sees it necessary; but to those who make bee culture a matter of earnings, and who have also other things to occupy their minds, it seems far preferable to leave the supply largely sufficient in October, and trust in the wisdom of our pets as to the use of that more than sufficient supply.

Of one thing I am sure: None of the honey will be wasted if the colony winters successfully; and an abundant supply, as a rule, tends toward successful wintering. Successful wintering of a colony rich in stores will give a "stronger army" for the honey season than if their stores are controlled and scantily supplied.

# GENERAL CORRESPONDENCE

## THE RELATION OF TEMPERATURE TO BEE ACTIVITY

BY ALLEN LATHAM

It is doubtful if any form of life is more sensitive to temperature and temperature changes than is the honeybee. This is shown in comb-building, honey-gathering, and in brood-rearing. Only at the most favorable temperature do we see these activities carried on at their best.

It is almost impossible for comb-building to go on with the temperature below 90 or so. Comb built at a lower temperature is not the well-formed and delicate structure constructed under the higher temperature. It is irregular, and heavier. Likewise a temperature above 100 interrupts comb-building. Thus we see the bees when comb-building is in progress striving to keep the hive, or at least that portion where the building is going on, at the desired temperature—carrying on a vigorous ventilation if the hive is too warm, and crowding together to furnish heat when more heat is desired. Few of us but have welcomed the glad sight of hosts of young bees migrating into the supers.

Many of us like to diagnose the condition of the colony from the outside. The flight of the bees tells us much but not all. Lifting the cushion and running the hand over the inner cover or over the mat, as the case may be, will tell much more. It will render a very close estimate of the size of the brood-nest if the super be not yet in place; and if super is in place it will tell to what extent it is occupied. It will not, of course, tell to what extent the super is filled with honey.

This explains why it is so essential to have a large force of bees in comb-honey production. At the present date, Sept. 22, I am enjoying the most remarkable fall flow I have ever known. Goldenrod and asters are profusely abundant, and are holding out unusually long. Yet with this tremendous flow of honey the work in the supers is very slow. Had the bees their July numbers, work would be going on in three and four supers at full blast, instead of slowly in one super. Under present conditions the brood-nest is rapidly disappearing, and the brood-combs are becoming solid slabs of honey. The chief factor to bring this about is temperature, the cold nights sending the bees away from the supers and outer portions of the hive and bringing on a more and more restricted area where the temperature is kept up to the point for

wax-working. As the season comes to a close there will be considerable comb left unsealed, the last honey gathered being left in open cells, the bees not being stimulated to raising the temperature to the necessary point for that work.

We are all familiar with the effect of temperature changes upon honey-gathering. The bees may be booming when the thermometer suddenly registers a fall of ten degrees. The boom is off. Frequently this is because the flowers cease to secrete the nectar; but if the temperature was already rather low, and some flowers like goldenrod secreted at a rather low temperature, the fall in temperature simply stiffens up the bee. She will no longer go to the field, even tho there is nectar to gather.

Brood-rearing progresses only as the force of bees can warm up more comb and keep it warm. Queens will sometimes lay in comb not up to the desired temperature; but the brood will not mature. Whenever a cold night causes the bees to draw away from the outer portions of their extended brood-nest it is a serious setback, for the bees are slow in warming up that comb again.

Warmth attracts bees. Combs attract bees. Warm combs are doubly attractive to bees. I have not investigated to what extent it would be worth while to warm up frames of comb before giving them to a colony, but years ago I discovered the vast advantage of feeding warm syrup over feeding cold syrup. It will be noted at this point why failure so often attends the spreading of brood in the spring. The difficulty is often that the increased comb surface is too much for the force of bees to keep warm, but more often the difficulty is the failure of the bees ever to warm the new comb. Hence the brood-nest becomes two separate units instead of one. Then the one which does not contain the queen rapidly deteriorates, with the result that the brood-nest, after a week or so is actually smaller than it was before the spreading. Breaking the cap-pings of what sealed honey is in the comb will help much; but it would be far better to put that comb in a very warm room and let it stay there till warmed thru before giving to the bees. If one wishes to force his bees in spring let him warm up a number of combs of honey. Remove an outer comb of a colony; move over the combs till

the brood-nest is split, then insert a warm comb. Proceed thus till the warmed combs are used up, then take the combs that have been removed into the warm room, and, after they are thoroly warmed, give them to other colonies in like manner. This is a safe and sane procedure, but must not be done recklessly. If the cappings are broken these inserted combs will almost always show freshly laid eggs the following day.

Too high a temperature is not conducive to good results in brood-rearing. That side of the hive exposed to the sunshine will show a comb well stocked with brood in the spring months; but, likely as not, in July it will show little or no brood. The spring sunshine attracted, but the summer sunshine repelled. The double-walled hive has the advantage here. The newly hived swarm is likely to desert its hive if it is summer, and that hive stands exposed to sunshine. On the other hand, if the day is cool a swarm will run pellmell into a warm hive, while it will almost refuse to go into a cold one. If a swarm has stayed out over night and

is sluggish with cold, try hiving it in a hive which has been well warmed. The rule works both ways, and so we like a cool hive for the hot swarm of the sunny mid-day.

The queen-breeder, too, does well to bear the matter of temperature in mind. Cell cups which have been allowed to become cold are less likely to be accepted, and the queens are likely to be second rate in quality. See that the grafted cups are well warmed before they are returned to the hive. It is my practice to fold a newspaper about the prepared frame before exposing it to the outer air while carrying it to the hive. It is my belief that many failures to get good queens are due to lack of care in this respect. It is true that bees will rear queens under adverse conditions, and so will cows give milk, and hens lay eggs. But profitable queen-rearing, like profitable milk and egg production, calls for thoughtful methods. It will not be time wasted for many of the readers of this paper to put much thought upon the matter of temperature and bee activity.

Norwich, Ct.

## WESTERN NEW YORK FIELD MEETING

BY "ONE WHO WAS THERE."

The basket picnic and field meeting of the Western New York Honey-producers' Association, which was held at the home and apiary of Mr. Roy Wisterman, at Dysinger's Corners, N. Y., was a decided success. While Mr. Wisterman does not claim to be a professional beekeeper, he finds it a profitable addition to his extensive farming operations. He says he does not know very much; but one has only to look at some of the fine queens which he reared by the grafting process to know that he is no backlotter at the beekeeping industry.

Lunch was served on tables erected on the spacious lawn by the wives of the beekeepers. The word "lunch" does not do justice, tho, to the "cats" that were served.

After lunch several subjects were taken up. Mr. J. Roy Lincoln, of Niagara Falls, spoke on "The Management of Bees in an Out-apiary." Shortly before fruit-bloom he unpacks his bees and clips his queens. He also gives a super which in reality is another body, as he uses full-depth bodies all thru. Shortly after fruit-bloom, or while it is still on, he places a frame of brood from the lower story in this super. He leaves them thus until the fore part of June, or until clover starts, when he takes one frame of brood and two frames containing

the most honey, and places them in another body—the brood in the center and the honey on the outside, and the rest of the hive filled with empty combs or foundation. This body is now placed on the bottom-board with an excluder over it, and the brood placed on top. The bees are brushed off the combs with a Cogshall bee-brush in order to find the queen. (This is the easier way when there is such an army of bees.) The queen is placed in the lower story with the one frame of brood, and the remaining brood is placed over the excluder to hatch out. The combs are then store combs. If more supers are needed they are added under the brood-combs or directly over the excluder. Ten days later any queen-cells that may have been started are removed; or if increase is desired they are set on a new stand; or an upper entrance is given for the queens to mate.

In this way swarming is entirely controlled. The secret is to get the queen to lay in both stories, and so use up any dark honey that may be left from the preceding season. As these combs are used for store comb after the brood hatches, it is desirable to get rid of all dark honey.

The drones are also controlled. Being over the excluder they cannot escape, and

Western New York field meeting at Dysinger's Corners, August 12.

are killed by the bees. They fall down on the excluder, but never plug the openings by so doing. Plenty of drone comb is placed in desirable colonies to rear the drones to make sure of having good ones.

Mr. Lincoln says that he can manipulate 50 colonies a day by the foregoing method. He uses eight frames in a ten-frame super, and extracts at the end of the flow.

Mr. William Vollmer, of Akron, N. Y., told of his varied experience in buying bees in combless packages from the South. In case of the one-pound package with queen, he thinks it is advisable to put the bees on empty combs with a frame of brood, if they are received early in May, in order to make them a remunerative proposition. With the two-pound package it is also advisable to give a frame of brood, but the combs are not quite so essential. The two-pound package generally makes sufficient honey the first season to pay for itself; and as far as honey is concerned, therefore, is a better investment. Of course, if increase only is desired the first season, the smaller package is better.

Mr. Vollmer prefers a roomy package and a good candy to ship well. Combs of honey are not satisfactory. They melt down and daub the bees, making them worthless.

Cheap queens are usually dear at any price. The bees are not so important, except they should be young. If blacks or hybrids they should be forced thru an excluder to get rid of the undesirable drones.

Some beekeepers make a practice of buying young swarms for increase. This is also a good plan if the stock is desirable; but if one takes into consideration the extra time and labor involved in getting one, two,

or more at a time, instead of having all come at once, as is the case when packages of bees are shipped in, there is not much difference, tho the young swarms are usually the cheaper.

Mr. John DeMuth, of Pembroke, N. Y., told of his experience with European foul brood. The beekeeper must first eliminate the black bees or the disease will do it for him. A good strain of Italians is a great help in holding it in check; but some strains are almost as susceptible as blacks. Caging queens for a period sometimes effects a cure. Killing old queens and giving young vigorous ones is another method. Where foul brood prevails it is hard to rear queens, so they had better be bought from some reliable breeder whose stock has shown good resistant qualities.

Mr. DeMuth does not think it necessary to melt up combs that have contained European foul brood. He merely puts them above an excluder over a strong colony to be cleaned up. This disease is like other diseases. It seems to diminish after being in a locality two or three years, and gradually wears itself down somewhat. Mr. DeMuth has visited a large number of beekeepers in the western end of the state, and they all report a small amount of disease, especially where it is in the locality. Most of them treat it by one of the foregoing methods, and consider it the same as a weed in the garden. Eradicate it this year and you may not have any next, or you may. With a little help it can be held in check so as not to be as serious as might otherwise be expected.

When selling honey at home to the neighbors Mr. Vollmer recommended asking the

C. L. Hill's house-apiary. Light and ventilation are provided by the 12-inch opening on three sides covered with screen. There are two tiers of hives, the entrances being painted in different colors.

full price. If one feels inclined to give away any, give it outright. In this way if any one asks the price of honey only one price is given, and the beekeeper will not

be accused of having two prices, a thing which will not do if one intends to do any amount of business.

Akron, N. Y.

## MY HOUSE APIARY

BY C. L. HILL

---

From my experience of the last three years with a house apiary I consider this plan of keeping bees far superior to the individual stands out of doors.

On three sides of my building, just under the eaves, is an opening 12 inches wide covered with rustless screen. The hives are located on the floor, and there is also another tier of hives three feet above the lower tier, all having entrances thru the wall. The entrances outside are painted different colors.

The hives are formed by partitioning off the space into compartments like bins long enough to take frames lengthwise. The "bins" are deep enough to hold eleven frames.

The floor boards may be withdrawn for cleaning. There is enough space between the upper and lower tiers of hives to permit

Two glass-fronted supers in position over the brood-chamber. In a house apiary supers may be made of thin material as there is no exposure to the weather.

two supers over the lower brood-chambers. I have it so arranged that the upper supers are held by supports so that the lower supers may be removed without disturbing the upper ones.

The colonies winter excellently with nothing over the hives except very thin covers and blankets to retain the heat. The combs are always dry, and there is never any mold nor dampness whatever.

Later on we expect to start a number of outapiaries with these buildings which permit us to handle bees at any time, rain or shine.

May's Landing, N. J.

The supers are independently supported. The under one may be withdrawn if desired.

## HOLLAND HONEY AND HONEY CROPS

BY J. H. J. HAMELBERG

The majority of our beekeepers still using the skep, it is not to be wondered that extractors are not very often found in this country. The combs, cut out of skeps, not being in frames, could be extracted only by improvising some device to hold them in position in the extractor. This would entail a considerable amount of labor, to say nothing of the time it would take to uncap these combs of all shapes and forms. Consequently our beekeepers use other ways to get the honey out of their combs; and the products obtained by these methods are distinguished by "leak" and "press" honey, the former being the honey which drains (leaks) from the combs while stored in some vessel, the latter being obtained by putting the combs under a press very similar to a wax-press. This press honey is, of course, much inferior to the drained honey, as it always contains pollen, and, unless the beekeeper has been very careful, the juice of brood and dead bees as well. But it is excellent for feeding purposes, and it also seems to answer very well for making cakes, as our bakers buy it readily. A good many beekeepers, however, sell their honey in bulk as chunk honey.

The comb honey and the extracted honey on our markets are furnished by our modern apiaries. It has been contended that there

are a few beekeepers in this country who import American or West Indian extracted honey by the barrel, selling it afterward for "pure inland;" but for the truth of this I cannot vouch. When looking over the shipping-lists of vessels having entered from American or West Indian ports, one often finds an item of so many barrels of honey, but no one ever seems to have taken the trouble to trace the destination of such imported honey, for which reason it would be unfair to charge our beekeepers with the above implied fraud.

It cannot be said that we are a honey-eating people, as, for instance, are the Swiss. As yet very little honey is consumed by the laboring and middle classes, it still being considered somewhat as a luxury for the table of the rich. But then, very little has been done until now to point out to the people the value of honey as a food.

Our extracted honey is put up in glass jars of  $\frac{1}{4}$ ,  $\frac{1}{2}$ , or 1 kilogram, and of late fancy jars have also come in use, as, for instance, in the shape and color of a straw skep. The half-kilogram jars (1.1 lb.) are most popular, and are sold by retail for 30 to 40 cts. each.

Chunk honey is better appreciated by our honey-consumers than comb honey in sections; but a good many people prefer the

A location for an apiary chosen by C. L. Hill, of May's Landing, N. J. Bees here are in reach of the cranberry-bogs.

extracted honey for table use. Very likely our national feeling for cleanliness has something to do with these preferences. Chunk honey is mostly produced by our skep-keepers, and they can readily sell it to buyers in their neighborhood, once they have a good reputation for cleanliness and honesty. Our modern apiaries advertise their product, and fill the orders they get, but they don't peddle their honey. One may buy it at a grocery; but it does not appeal to our feelings to see sections, however beautifully filled, exposed to the dust and the flies before a grocer's windows.

As to our honey crops, they remain far below those obtained by some apiarists in the United States—for example, Dr. Miller. I have his very valuable work in which he describes his forty years' experience, and I have studied it rather closely. But there never has been any question about my obtaining the crop that this American veteran gets from even weak colonies or what he considers as such.

We have good seasons and bad ones, although more of the latter. But even in a very good season I would be very well satisfied if my bees gave me an average of 75 lbs. per colony, and, as to an average of 150 lbs. or more, I don't even dream of it.

Altho we have the linden, white clover, buckwheat, and some other good honey-plants, one does not see in this country acres and acres of them, as seems to be the case in the United States. On our poorer soils one may encounter patches of a few acres of buckwheat; but of the hundreds of acres of this grain on a stretch, by which, for instance, the late Mr. Alexander was surrounded, we cannot form an idea. Such stretches of land with only *one* honey-giving plant are to be found here only on the heaths; but then, heather honey is a rather ill-flavored and very dark-colored product which is disliked by many.

Alfalfa and sweet clovers are not cultivated in this country, and we thus miss two great honey sources. But still I think our bad seasons are not caused so much by the want of bee-pasture as by our changeable climate. When I read sometimes in GLEANINGS of complaints of beekeepers about bad crops on account of the temperature some nights going below 60 degrees, I wonder how these beekeepers would feel here, where the thermometer, even during our warmest summer months, seldom registers as high as 60 degrees at night; where night frosts kill the buckwheat bloom, and where the heather often does not secrete any nectar on ac-

count of the cold nights! And the long spells of rain we have but too often! rain for days on a stretch, washing all the nectar out of the flowers! One can fancy the state of mind of the beekeeper when the lindens around his apiary are in full bloom and his

bees have to remain at home on account of the pouring rain; when, morning after morning, his hope is frustrated on seeing the sun breaking thru the clouds! And such seasons are not the exception here. Soest, Holland.

## TWO VARIETIES OF THE EUCALYPTUS

### *Eucalyptus Mellidora* (Yellow Box Gum)

BY LESLIE BURR

The name *Mellidora* is from the Latin, and means "honey scented." The common name is yellow box gum. The trunks of these trees are often crooked and gnarled. The branches have a spreading or sprawling habit. In Australia the tree is said to grow to a height of 250 feet, and obtain a diameter of from six to eight feet. The outer bark is of a brownish-gray color, and is persistent. The inner bark is yellow. It is because of this yellow inner bark that the tree is called "yellow box." The branches are smooth. The leaves on the young trees are apt to be oval; but when the tree obtains a few years' growth the leaves are lance-shaped. There is very little difference in

the sides of the leaves, both sides being of a dull-green color.

The botanical name, *E. mellidora*, was given this particular eucalyptus by reason of the fragrance of the blossoms.

As to its habits, its period of bloom is during the winter and early spring, the period of bloom continuing over several months. The tree will do well near the coast, on low mountains, in hot valleys, and will also resist considerable frost. It is one of the most profuse bloomers, and probably yields a greater amount of honey than any of the other varieties. The flowers grow in compact clusters. The seed-pods are about  $\frac{1}{4}$  inch in diameter, and are egg-shaped,

Leaves and blossoms of the yellow box gum, *Eucalyptus mellidora*.

with the small end of the egg cut away. The wood is very durable under ground, and is valuable for fence-posts. The tree makes a rapid growth, but is not as rapid a grower as the *E. globulus*, or blue gum, but the wood is more valuable.

#### EUCALYPTUS CORYNOCALYX, THE SUGAR GUM.

Taking all things into consideration, the *Eucalyptus corynocalyx*, commonly called the "sugar gum," will in the future probably be the most important to beekeepers of all the various species of eucalyptus. The tree in the matter of bark, leaves, and general appearance is similar in many respects to various other species; but it is in fact one of the easiest to identify. The average person who is at all familiar with eucalyptus should have no difficulty in identifying it.

The bark of the tree, after it has attained some size, is smooth, and continuously flakes off in patches. The main trunk is of a cream color, the patches where the bark has recently been shed being of a lighter color. The color of the bark of the very young twigs is reddish. The young leaves are nearly round or slightly oval, those of the mature tree being the usual lance shape, similar to those of the red or blue gum, the average length of the leaf being some five or

six inches. In the color of the leaves there is some variation in different trees. On some trees the foliage is quite light, generally, tho the leaves on the upper surface are a dark shiny green, the lower surface being dull and of a lighter green. There are a considerable number of these trees in Balboa Park, the 1400-acre city park of San Diego, Cal. The period of bloom lasts for several months, beginning about May 1. Some authorities state that the tree comes into bloom in the fall, but such is not the case in this locality, altho there is considerable bloom during the late summer and fall months.

The principal distinguishing feature of the sugar gum is the form of the buds and of the mature fruits, the unopened bud being club-shaped, from which it derives the name, "corynocalyx," meaning "club-shaped calyx." The cover which tips the end of the bud is the largest in diameter of any part of the bud and is very abruptly pointed, very much resembling the club which used to repose near the Giant Bugaboo Bill in the story-books of our childhood days. The buds grow in clusters, there being usually from eight to twelve buds in a cluster. On some trees, however, there may be double the foregoing numbers. The fruit

is urn-shaped, and the opening of the end is very small, the seed-valves being deeply enclosed. Quite often there are also longitudinal grooves on the outer surface.

In the matter of localities where it will grow, a few trees in southern California were injured by the heat on the well-remembered 17th day of September, 1913, when most of the thermometers in southern California were not long enough to register the temperature, and so broke in the attempt. The various authorities on the subject of eucalyptus, however, recommend it as being one of the species adapted to hot dry regions. The tree also seems to stand about as much frost as any of the eucalyptus family.

In the matter of growth, it is generally conceded to be but little behind the blue gum; and in some few instances it has out-grown that tree. In the last year or two considerable numbers of this gum have been planted, altho in years prior such was not the case.

As to usefulness, it makes a fair shade-tree and has been planted to a considerable

extent as an avenue shade-tree. When planted comparatively close, as in the case of timber culture, the trunks are very straight with but little taper. Various authors on the subject of eucalyptus agree that the timber is more useful than that of the blue gum, for the reason that the trunk is straighter and the wood has the added quality that it will not rot when placed in contact with the earth, so is useful for fence-posts, railroad-ties, etc.

As a honey-producer, in the amount of nectar secretion it is one of the best. It has white blossoms, and is quite a profuse bloomer. The honey is amber. Taking everything into consideration, this species is not only one of the most valuable to bee-keepers, but also thoroly deserves that reputation for general purposes, and should be one of the most widely planted of trees thruout the Southwest. Every beekeeper, wherever eucalyptus will grow, should boost the sugar gum, for the benefit of himself and his neighbors.

San Diego, Cal.

## THE VICTORIAN APIARISTS' ANNUAL CONFERENCE

BY E. B. MACPHERSON

The meeting was held in Melbourne at the Flinders Building. There were present bee-farmers from Great Britain and Denmark; also members from distant states of this great commonwealth, all of whom took a keen interest in the different papers which were read by live and practical beemen. Bee talk and good fellowship reigned supreme.

Mr. D. Morgan, the president, read a good paper on shifting bees to better fields. He finds that, the darker the bees are kept,

the better they will travel, and also recommends good strong factory-made hives for migratory beekeeping. He uses loose frames, and says he can put a small nail in each end of the frames before shifting the bees, and says he can put them in and draw the nails out as fast as he can pack bees with Hoffman frames. Mr. Morgan has shifted his apiaries many times.

The members brought samples of their own honey. Which was the best? Well, you know every one thinks his own honey

The Victorian (Australia) annual convention.

is the best; but next year there is to be a prize of ten shillings (given by Mr. Pender, of New South Wales) for the best one-pound pot of honey. Mr. S. George Rich is giving a prize of ten shillings to the one who gets the most new members during the year for the Victorian Apia-ri-ists' Association. As is well known, some large honey-producers are not in this association. If all "honey-grubbers" would link up with us we might be a power to reckon with. The photographs are some that I took at the Botanical Gardens in Melbourne, where we spent a very pleasant day at the close of the convention.

Snapped in the Melbourne Botanical Gardens.

Mr. F. R. Beuhne gave us proof that he is a bee expert. He answered all questions from the question-box in short order. He also had some very interesting specimens of pressed-gum leaves and blossoms.

Port Fairy, Vic., Aus.

## MY OUTYARDS EXIST IN MEMORY ONLY

BY L. K. SMITH

Imagine, if you can, a straight lagoon, one and one-half miles wide and seventy long, and you have an idea of the Indian River on the east coast of Florida. Now locate your home apiary; put a dozen colo-

nies across this river in a neighbor's yard; another dozen  $2\frac{1}{2}$  miles south; another dozen 2 miles north, a dozen 3 miles further on, and another 7 miles, and then try to care for the 7 colonies of a friend, and you have my situation.

Now for the ways and means to care for this string of small apiaries. I had a sail-boat, row-boat, wheelbarrow, extracting-tent, and a wife and daughter. Right here I must say that my wife was the bee-master, and chief conspirator, while I was master mechanic and sailing master, my daughter being an able assistant.

For some years we worked along this way; then it fell to my lot to do the work alone, and for a time I hammered at it faithfully. But at last came doubts of the advantages obtained by this out-apiary system, and today those out-apiaries are memories only—memories of the hives either over full of honey or full of moth—memories of postal cards received, which told of swarming, of finding covers partly off the hives, and finally of two colonies being stolen from one of these yards.

When I believed in swarm control I believed in the out-apiary, and was willing to do the work necessary. I had to load up my boats with extracting equipment, sail and pole to the landing nearest the outyard to be extracted, unload on the shore, wheel

Mr. Blackburn, of England, one of the speakers at the Victorian convention.

and carry the cans, tent, hive-bodies, tent-poles, and extractor, from 50 yards at one apiary to 250 at another. Then I would set up the outfit, get out the combs, extract the honey, and replace the empty combs. Sometimes a shower would mix up my plans a little, but more often it was the robbing. At times I would leave the extractor in the boat anchored some distance from shore, and bring the combs to the boat and extract without screens of any kind. This worked nicely until the robbers got a line on me, and then the shop had to close.

After a time I carried empty combs to these outyards, and brought home the full ones. This made heavier lifting to load and unload in getting the honey home, but it was much the best plan.

A motor finally took the place of the sail; and, while it had many points in its favor, it did not solve the problem, but served to convince me of the errors into which we had fallen years before regarding the out-apiary, the greatest of them all being in the enforced neglect of the bees at home while trying to care for those at an outyard.

To sun up, I will say that, when I start another outyard, I will take in a partner.

Grant, Fla.

[There are thousands of beekeepers who are able to manage out-apiaries successfully. We believe our correspondent does not mean to denounce the out-apiary in general, but to point out some of the disadvantages when there is a lack of the proper facilities. Many a man having been successful with one apiary meets with failure when he attempts the out-apiaries, frequently because of his lack of suitable equipment.]

Fundamentally, a convenient location must be sought that will profitably support a good number of colonies—not too far

A sail-boat is too slow a means for transportation from one outyard to another.

away from other apiaries, for travel costs both time and money. There is no question but that the automobile is solving the out-apiary problem in instances too numerous to mention.—Ed.]

## EARLY FEEDING ADVISABLE

BY W. C. MOLLETT

About every other autumn we usually have a light honey-flow or too much wet weather, so that it is necessary to feed more or less in order to carry the bees thru the winter. I usually feed during September or October unless I have no time to attend to it then, so that I may happen to be compelled to feed at different times thru the winter, as the weather will permit. I usually make the syrup about 2 to 1, or equal parts sugar and water, according to whether it is in the fall or winter, as it should be made thicker if the feeding is to be done late in the season.

I notice that it is very much better to feed early than late, as I have much better success when I feed in September than

when I put it off till later. At this time there is usually a light flow of nectar and plenty of pollen. This seems to make feeding more successful than later, as it does not excite the bees so much, and they can secure pollen, which seems to be very necessary for bees when fed sugar syrup. Last fall I did not get the bees fed up in time, and so was compelled to feed several times during the winter when the weather was warm enough. This did not give the bees time enough to get the syrup properly ripened or sealed, as the warm spells lasted only two or three days at a time. As a result either of this or of the weather they did not winter very well, and in spring were much weaker than usual. Further-

Comb of eggs and unsealed brood given to a queenless colony. Nine queen cells were built. One on the lower right-hand corner, not visible, hatched first. Photographed by R. L. Leland, Belding, Mich:

more, when fed at different times it seems as if bees consume much more than when the feeding is all done at once. I think that, if we are required to feed sugar, we should do all our feeding early, at the same time giving each colony enough to carry it thru the winter so that they can properly evaporate the dampness, and also get it mostly sealed before cold weather.

#### COLD-WEATHER UNITING.

Sometimes in the fall or early winter we find it is necessary to unite a few colonies that are too weak to go thru the winter. It is not a very difficult matter to unite bees late in the season; but in warm weather it is often impossible to unite them with any degree of success, especially if the honey-flow is over. A few times I have tried to unite two colonies into one and succeeded only in making two colonies into nothing, for, after the bees had fought and practically exterminated each other, the remaining bees were so weakened that they were worthless.

One autumn, as the result of a failure in the honey crop, I had several colonies that were too weak to winter successfully. I did not attempt to unite them till the weather became very cold—about January. Then, just as a severe cold snap was commencing, I went around and loosened the bottom-boards, so that the hives could be lifted without disturbing the bees when I was ready to unite them. The next morning I removed the covers as carefully as I could and lifted the colonies to be united on to the other colonies without making very much

disturbance, and only a few bees flew out. As the weather was very cold the bees made no attempt to fight, and I did not place a newspaper between the two stories. By the time the weather warmed up a little they had become so much accustomed to the change that there was no trouble. Of course, in cold weather it is necessary to be as careful as possible, so that the bees do not fly out, as all the bees that escape will probably be lost, for, on account of the change of location, and the cold, the bees from the hive that is removed will be lost. Generally the bees will unite readily without any disturbance in cold weather, as they are so intent upon keeping up the heat of the colony that they do not take much notice of the change.

When two hives are placed together, the upper one is warmer than the lower, and the bees from the lower one will go up into the upper one and remain there most of the time till spring. In the spring one of the hives can be removed and used later for hiving a swarm.

It is better to unite colonies that have inferior queens or that lack vigor as honey-gatherers or that have any other defect, and thus get rid of undesirable stock. It would not be advisable to unite a colony having an inferior queen with one having a good queen, as it might happen that the bees would kill the better queen. This would not be so apt to happen if the one having the undesirable queen were weaker than the other one.

Stonocoal, W. Va.

# Heads of Grain From Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

*The bees that lay in their winter stores while the sun shines don't have to pay the butcher for his hand every time he weighs a soup-bone.*

## OCTOBER

BY GRACE ALLEN

When Autumn bows to Summer  
 (Who then steals quite away),  
 And spreads her gold and scarlet round  
 In such a royal way,  
 And chills the nights and mornings,  
 But sets the day afire  
 With gypsy flame and brilliant sun  
 And vagabond desire;

When smartweed takes the meadow,  
 And bitterweed's in bloom,  
 And aster opens on the hills—  
 Ah, then I leave my room,  
 And loiter in the beeyard  
 Where every hive's a-hum,  
 And vagrant thought, like flying bees,  
 Come and go and come.

### Fall Feeding for Stimulation.

Fall feeding of bees is advisable especially in case of weak colonies. It pays to feed at any time after the honey-flow is over, for the reason that the queen will regulate her laying by the amount of stores coming in to the hive. This is especially true during the fall months when there is little honey to be gathered.

By feeding a little syrup every day or

several times a day one can keep the queen laying very late in the fall so there will be a large force of young bees with which to start in the winter.

This in turn means strong colonies in the spring. Many times colonies that appear to be very strong in the fall dwindle down during the winter so that they come out very weak in the spring. This is due to too many old bees in the hive, caused by the queen failing to continue her work late in the season.

The syrup that is stored with the late honey that is gathered improves the quality of the winter food, and this is excellent for brood-rearing in early spring.

It does not matter if the hive is full of honey; the queen will stop laying at any time in the fall when there is nothing coming in, whether it be early or late; but by feeding a very little at a time, and often, they will continue as long as the weather will permit the hatching of brood.

The hive should be kept as close and warm as possible; in fact, double-walled hives should be used, and packed as warm as for winter. Heat is more essential in September, October, and November than in December and January.

Bees will stand almost any kind of treatment except in early spring and late fall. These are the more vital periods at the time when young bees are most valuable.

Hartford, Ct.

Geo. T. Whitten.

[When feeding for stimulation it is always best to err on the safe side, and proceed with the idea of eliminating every possible chance for robbing. We advise giving half a pint of syrup very late in the afternoon only, so that by morning the excitement caused by the feed will have subsided. If the syrup were given several times a day, especially to weak colonies, robbing might be started. The latter part of October is usually too late for stimulative feeding except in the south-central and southern locations.—Ed.]

### Another Successful User of the Honey Method of Introducing.

Since receiving the Sept. 15th issue of *Gleanings* I have been searching my files of bee literature of all sorts for items relating to queen-introducing. As I have not completed my research I am not ready to give specifically any data, but I wish to say the practice of sprinkling the bees and daubing the queen for introducing is decidedly not new as a whole nor in detail.

Just why I or any other beekeeper who has known of it right along has not given it thought or trial until now is a puzzle to me.

I used the method last season (1915) with perfect satisfaction and no failure, and this season more with the same success. Furthermore, I talked the "sousing" method, as I

like to describe it, before our summer meetings at Mount Holly and Elizabeth, and I have within the week received the word from the largest beekeeper in the state (about 400 colonies), "I have tried the 'souse' method—success every time."

My way of doing it is to use dilute honey, a good teaspoonful to a teacupful of water, which I souse over and between the frames from a flour or powdered-sugar dredger, and distribute it well. Use more or less according to the strength of the colony; anyhow, don't be stingy with the souse; give the queen a souse (so she looks like a wet hen), and run her down between the wettest frames.

This dilute honey is less likely to result in injury to the queen; is more quickly cleaned up, and less likely to start robbing; takes far less honey, and can be handled more rapidly; if any of it gets on the hands or clothes there is less of a mess, and it answers every purpose.

I will not take space now to discuss the ethics of this method; but I must say it looks like the simplest, least injurious, most nearly natural, quickest, and most logical method which can be devised. I will venture the prediction that, by the end of five years, everybody will be using the "sousing method," thereby saving hundreds of dollars and oceans of time.

Hoboken, N. J.

C. D. Cheney.

#### Fooled 'Em, Sure.

One day in August I was surprised to find a case of genuine robbing in full swing. The weather being very warm, and white clover still plentiful, and the bees gathering nectar from it, I little dreamed of any robbing likely to occur, so had left all entrances wide open—a circumstance that gave the robbers their opportunity.

I at once smoked away the bees and closed the entrance, then narrowed down the entrances to the near-by hives to about an inch opening. Having a supply of half-cured hay near by, I brought a few forkfuls near the hive. After about half an hour I again smoked away the cloud of robbers seeking to enter, and opened up the hive to a very torrent of well-filled robbers. The most of the thieves having made their exit I hastily closed the entrance again, leaving an opening sufficient for only one bee to pass at a time, and quickly covered the hive and accumulating bees deeply with the hay at hand. Near nightfall I cleared away the hay and opened the hive, allowing the marauders to go home. After dark I removed the hives to a dark corner in a cool cellar and covered it up, but with the entrance open.

I immediately put a dummy hive in its place on the stand, but with empty combs and a feeder in the bottom in which I put about a quart of very thin sugar syrup. The next morning I was pleased to see the robbers returning to the feast and crowding the narrow entrance of the dummy. They

were kept busy several hours before the syrup supply was exhausted, when, finding no more sweets around, they very quietly took their departure, thinking, no doubt, that they had effected a complete job.

Two days later I took the bees from the cellar and replaced them on the stand, where they were not again molested, and are doing as well as ever, apparently not any the worse for their experience.

#### A Connecticut Report.

This is not a good location for the beekeeper, not being a natural clover location, and little interest is taken in trying to raise it. However, there has never been a time in the last twenty years when bees have had to be fed to keep them alive from May to October. On the other hand, there has not been a heavy honey-flow in the same period. From May till early July honey comes in a slow flow which booms brood-rearing and swarming; but with no heavy flow to check brood-rearing the problem becomes a big one if a surplus is to be secured. I had several queens laying in the outside combs of ten-frame hives May 5, 1914.

In trying to avoid increase and get the much-desired surplus I built a few ten-frame Jumbo hives, chaff packed them as the regular chaff hive, but the big hive sent out a swarm as early as any. A modification of the Aspinwall hive was tried, with slatted dummies and ten frames in two stories. This gave the same result as the Jumbo. Cutting queen-cells has been practiced, but I am not delighted to see a big swarm pile out of a colony which had the cells cut only a day or two previous.

I find that good queens can be reared here up to July 15 without feeding or trouble from robbers, but after that it is not very pleasant. I have forty colonies, which is enough for this location. My highest average yield of comb honey per colony has not exceeded fifteen pounds. The fall flow is very light, usually not being sufficient for wintering.

Delos O. Hart.

Barkhamsted, Ct., Feb. 29.

#### Smoker Chips.

Dry locust bark makes the best of smoker fuel.

If you do not want your smoker to go out while you are at lunch, fill it, get it going, then place it in a box twice the height of the smoker and leave the top of the box open.

A 60d spike nail and a tin tobacco-box for matches will be found convenient where you fill and light your smoker.

A piece of old enamel cloth stuffed in the top of your smoker will prevent its burning the fuel too fast, and will increase the volume of your smoke.

High noon on a hot day is the best time to examine a cross colony of bees.

Morgan, Ky.

J. E. Jordan.

**Pollen Stored above an Excluder.**

My bees persist in putting pollen in the shallow extracting-frames, not in solid patches, but in scattering cells enough to spoil the appearance. The hives are ten-frame, with queen-excluder under the supers. What is the cause and cure?

Mt. Vernon, Ill. T. E. Brown.

Dr. Miller replies:

It is unusual for pollen to be stored above an excluder unless it be that the brood-combs are shallower than those in Langstroth frames, said frames being  $9\frac{1}{2}$  inches deep. In any case I don't know of any remedy unless it be to have deeper frames below. There is just a possibility that you have a strain of bees unusually given to storing pollen in the surplus apartment, in which case introducing a queen of different stock would be indicated.

I don't see any great harm, however, in having pollen in extracting-combs. You speak of its spoiling the appearance; but those who buy extracted honey never see the combs from which it is extracted, and so care nothing for their appearance.

**Do Bees Work the Second Crop of Red Clover?**

In this locality I have never seen a honey-bee on the second crop of red clover; but I have never failed to see them on the first crop. The reason is this: The second crop yields nothing but pollen. In this locality the first crop is loaded with nectar; and since I have had Italian bees, the first crop has more seed than the second. This would be a good location for bees if the second crop of red clover would yield nectar, as the second crop is much shorter, and the bees could reach the nectar much easier. Again, the second crop blooms at a time when the bees have little to do.

Velpen, Ind. W. T. Davidson.

[The reports from most localities indicate more bees on the second crop.—Ed.]

**Bill-board Advertising Sold the Crop at Home.**

About the time I began to take off my honey I went down town and bought some boards and painted them white. I had a man letter an advertisement on three large bill-boards that I made with my white lumber.

In the meantime I had told quite a good many that I had some nice honey, both comb and extracted, the price to be 15 cts. for the comb and 10 for the extracted in 10-lb. tin pails. I took a little to one of the editors of our village papers and he gave me quite a nice send-off about my honey.

The result was, the first thing I knew my extracted was all sold, and nearly all the comb honey. My crop was 2800 lbs. of extracted and 800 of comb honey. I could have sold as much more extracted if I had had it. Nearly all the honey was sold right

at the house. I had to deliver only a very little of it.

Aitkin, Minn.

Wm. Craig.

**75 Per Cent Purely Mated.**

I have bought quite a lot of untested queens from various breeders thruout the United States, and also in Italy. I had a few lots some years ago that ran pretty dark, nearly or quite fifty per cent, and the most that I have bought would run from 75 to 100 per cent pure so far as mating was concerned.

I have occasionally had a few old queens tucked in with dozen lots, and once, some years ago, I received a virgin when I sent for and paid for a warranted queen. This was from one of the good breeders too.

Union Center, Wis. Elias Fox.

**Carbolic Acid for the Colony that Does the Robbing.**

The first of August I passed near my apiary one morning and noticed the bees were very cross. I went out to see what was the trouble, and they were robbing from several colonies. I soon found the colony which was doing the robbing, and I was at a loss what to do, but happened to think of my bottle of carbolic acid. I got that and smeared the entrance of the colony which was doing the robbing. In about two hours I used the carbolic acid again, and by mid day everything was quiet as usual, and has been ever since.

Stockton, Va. Francis W. Gravely.

**Bees that Worked for Nothing and More than Paid for Themselves.**

I put a swarm in a home-made hive upstairs in my winter home, Auburndale, Fla., on Feb. 25, last year, and by April 1 the surplus part at the top of the hive, containing 56 1-lb. sections, was completely filled with the finest honey. In February of this year I raised the lid to see what was there, and, to my surprise, it was again completely filled with palmetto honey, making 112 lbs. in less than one year. What do you think of that?

Auburndale, Fla. I. G. Tolerton.

**B's**

A little girl who is but six years of age was asked to make a sentence, each word of which began with B. The outcome of it was this:

Big bees buzz.  
Bright bees bite.  
Beautiful bees bring bank bills.  
Big bees bring bother.  
Bumble bees bother bears.  
Both bother boys.  
Bees bear bee bread.  
Bee bread brings bees.

Ethel M. Comyn Chesig.  
Okanagan Center, B. C.

# GLEANINGS FROM QUESTIONINGS

F. A. C., Nevada.—What causes brood to be wrong end up in cells?

A. We cannot explain to you why pupæ sometimes get in a cell wrong side up. We can only surmise that nature has made a mistake in some way. Of course the young bee dies, because it cannot get out.

F. P. H., Los Angeles, Cal.—In rearing queens how many mated queens can one get per month from each mating hive or nucleus? What per cent of virgins are lost in mating?

A. We get an average of two laying queens per month from each nucleus. Eighty per cent successful mating for the season is a good average.

W. E. K., Missouri.—Would it be all right to put net weight of sections on top of cartons instead of on the sections.

A. Yes, it is entirely permissible; in fact, it is the only thing to do when sections are put in cartons. The actual net weight of the honey inside of the section must go somewhere on the outside of the package. Where the sections are not put in cartons, then of course the net weight must show on the section itself.

J. A. C., Wisconsin.—My queens stopped laying in August. What was the trouble?

A. A queen when one or two years old will often and generally let up on egg-laying thru August and into September, and will not begin again to any extent until the fall flow, or when colonies are given stimulative feeding. On the other hand, queens three weeks or three months old will lay right thru the season, and their colonies must be supplied with stores to take care of the brood to prevent winter starvation.

E. J. E., Transfer, Pa.—Should supers be left on the hive during the winter in order to provide winter stores?

A. Ordinarily a super should not be left on the hive during the winter. There are some exceptions to this rule, as for instance in the case of exceptionally strong colonies, or colonies that are short of stores when it is too late to feed. In such case a super may be left on containing honey. The better plan, however, is to make sure that there is plenty of honey in the brood-combs so that the super would not be needed unless for holding packing material.

M. C. W., Bethel, Ct.—How can I disinfect a honey-extractor which has been used to extract honey from combs that contained foul brood?

A. If you have access to steam it would be a good plan to fill your extractor can with water and then introduce steam until the water boils. Let it boil for a few minutes and then it will be perfectly safe to use. If you have no steam you will have to rely

on using a large quantity of boiling water, heating several wash-boilers of water at a time, so that the can will be filled with scalding water.

F. A. C., Golconda, Nev.—I wish to winter my bees on candy. What is the best recipe for making it?

A. We do not advise feeding candy except when the discovery that the bees are short of stores is made too late for feeding sugar syrup. We regard candy as a substitute to be relied upon in case syrup feeding is impossible, as in cold weather, for instance. If there is a chance to feed syrup, do so by all means, rather than to rely upon candy.

It is not too late to feed syrup. We recommend a syrup made by mixing two parts of sugar to one of water and feed until each colony has at least twenty-five pounds of sealed stores—stronger colonies thirty to thirty-five. The candy is an unnatural winter food, but it can be relied upon in emergencies.

C. G. M., Ohio.—I am a beginner with five colonies. Will you tell me how to winter them?

A. Assuming that the bees are in single-walled hives your first undertaking will be to make sure that each colony has enough stores. An average-sized colony in a ten-frame hive ought to have not less than twenty-five pounds of sealed stores, and thirty is safer. If there is not enough in the combs to make up about this weight, feed thick sugar syrup not later than October 20, made by mixing two parts of sugar and one of water.

The next important requisite is a sheltered location. A spot sheltered by buildings, trees, or artificial windbreaks should always be selected. Such a place is better in summer as well as in winter.

In your locality additional protection is necessary if you winter out of doors. Contract the entrances down to a space of  $\frac{1}{4}$  by 3 to 5 inches, and be sure that each hive is well protected. If you like you can place empty boxes over each hive and fill in all around with leaves or shavings, or other good packing material, covering up everything on top with a cover that will not leak. Of course the entrance must be left open all the time. If you prefer you can pack the five hives in a row, or place three in one group and two in another.

If you have a cellar where the temperature does not vary much below 40 nor above 50, where the ventilation is good, you could winter in the cellar without any packing. Less stores would be consumed also, altho you would have the labor of carrying them in and setting them out again. Ideal beecellars are rather hard to find. Too much dampness or cold air makes trouble every time.

A. I. Root

## OUR HOMES

Editor

Except a man be born again he cannot see the kingdom of God.—JOHN 3:3.

He which converteth the sinner from the error of his way shall save a soul from death, and shall hide a multitude of sins.—JAMES 5:20.

During our pastor's recent vacation there was one Sunday when there were no services in our Congregational church; but he enjoined us, each and every one, to take the opportunity to attend the neighboring churches. Said he, "Do not any of you stay at home just because there are no services in our own church." I accordingly went to the Baptist church. On this occasion the leader of the Bible class had occasion to remark that the Jews were Jews by birth. They prided themselves on the fact of their being sons of Abraham, and seemed to claim there was no other way of belonging to God's elect than by birth. Well, our leader suggested right here that the new birth that is open to each and every child of humanity opens the way to every sinner, no matter what his past life may have been.

If I am correct about it, there has been a great deal of difficulty in comprehending or explaining this matter of the new birth. Even Nicodemus, a "master of Israel," expressed a difficulty in comprehending it away back in oriental times.

Well, my purpose in this Home paper is to try to make it plain to you what this new birth means, and how it is brought about. The story I am going to quote comes from Frances E. Willard. And, by way of introduction to you as to who Miss Willard was, I clip the following from the *Appeal to Reason*:

Frances E. Willard was recognized as one of the greatest women this country has produced. Her entire lifetime was spent in the advocacy of reforms, particularly temperance. The state of New York has honored her memory by putting a statue of her in Statuary Hall at the United States capitol in Washington. Miss Willard's statue is the first one of a woman found in that famous hall.

Now, friends, here is the tract that I have read over and over, and I hope it may appeal to you as it has done to me every time I have read it:

## WHITE SHOES AND WHITE DRESS.

Miss Willard always enjoyed telling this true experience of one of the leaders of the Temperance Crusade:

One morning during the crusade a drunkard's wife came to my door. She carried in her arms a baby six weeks old. Her pale, pinched face was sad to see, and she told me this sorrowful story: "My husband is drinking himself to death; he is lost to all human feeling; our rent is unpaid, and we are liable to be put out into the street; and there is no food in the house for me and the children. He has a good trade, but his earnings all go into the saloon on the corner near us; he is becom-

ing more and more brutal and abusive. We seem to be on the verge of ruin. How can I, feeble as I am, with a babe in my arms, earn bread for myself and children?"

Quick as thought the question came to me, and I asked it: "Why not have that husband of yours converted?"

But she answered hopelessly, "Oh! there's no hope of such a thing. He cares for nothing but strong drink."

"Ill come and see him this afternoon," said I.

"He'll insult you," she replied.

"No matter," said I. "My Savior was insulted, and the servant is not above his Lord."

That very afternoon I called at the little tenement house. The husband was at work at his trade in a back room, and his little girl was sent to tell him that a lady wished to see him. The child, however, soon returned with the message, "My father says he won't see any one."

But I sent him a message proving that I was indeed in earnest. I said, "Go back and tell your father that a lady wishes to see him on very important business, and she must see him, even if she has to stay till after supper."

I knew very well that there was nothing in the house to eat. A moment afterward a poor, bloated, besotted wreck of a man stood before me.

"What do you want?" he demanded, as he came shuffling into the room.

"Please be seated, and look at this paper," I answered, pointing to a vacant chair at the end of the table where I was sitting and handing a printed pledge to him.

He read it slowly, and then, throwing it down upon the table, broke out violently:

"Do you think I'm a fool? I drink when I please, and let it alone when I please. I'm not going to sign away my personal liberty."

"Do you think you can stop drinking?"

"Yes, I could if I wanted to."

"On the contrary, I think you're a slave to the rum-shop down on the corner."

"No, I ain't any such thing."

"I think, too, that you love the saloon-keeper's daughter better than you do your own little girl."

"No, I don't, either."

"Well, let us see about that. When I passed the saloon-keeper's house, I saw his little girl coming down the steps, and she had on white shoes, and a white dress, and a blue sash. Your money helped to buy them. I come here, and your little girl, more beautiful than she, has on a faded, ragged dress, and her feet are bare."

"That's so, madam."

"And you love the saloon-keeper's wife better than you love your own wife?"

"Never, no, never!"

"When I passed the saloon-keeper's house I saw his wife come out with a little girl, and she was dressed in silk and laces, and a carriage waited for her. Your money helped to buy all the silks and laces, and the horses and the carriage. I come here and find your wife in a faded calico gown, doing her own work; if she goes anywhere she must walk."

"You speak the truth, madam."

"You love the saloon-keeper better than you love yourself. You say you can keep from drinking if you choose; but you helped the saloon-keeper to build himself a fine brick house, and you live in this poor tumble-down old house yourself."

"I never saw it in that light before." Then, holding out his hand, that shook like an aspen leaf, he continued, "You speak the truth, madam—I am a slave. Do you see that hand? I've got a piece

of work to finish, and I must have a mug of beer to steady my nerves, or I cannot do it; but tomorrow, if you'll call, I'll sign the pledge."

"That's a temptation of the devil. I do not ask you to sign the pledge; you are a slave, and can't help it; but I do want to tell you this. There is one who can break your chains and set you free."

"I want to be free."

"Well, Christ can set you free, if you'll submit to him, and let him break the chains of sin and appetite that bind you."

"It's been many a long year since I prayed."

"No matter; the sooner you begin, the better for you." He threw himself at once upon his knees, and while I prayed I heard him sobbing out the cry of his soul to God. His wife knelt beside me, and followed me in earnest prayer. The words were simple and broken with sobs, but somehow they went straight up from her heart to God, and the poor man began to cry in earnest for mercy.

"O God! break these chains that are burning into my soul! Pity me, and pity my wife and children, and break the chains that are dragging me down to hell! O God! Be merciful to me a sinner." And thus out of the depths he cried to God, and he heard him and had compassion upon him, and broke every chain and lifted every burden, and he arose a free, redeemed man.

When he arose from his knees, he said: "Now I will sign the pledge, and keep it."

And he did. A family altar was established. The comforts of life were soon secured—for he had a good trade—and two weeks after this scene his little girl came into my husband's Sunday-school with white shoes, white dress, and blue sash on, as a token that her father's money no longer went into the saloon-keeper's till.

But what struck me most of all was, that it took less than two hours of my time thus to be an ambassador for Christ in declaring the terms of heaven's great treaty whereby a soul was saved from death, a multitude of sins were covered, and a home restored to purity and peace.

The above tracts are furnished at five cents per

dozen; 30 cents per 100, postpaid. M. E. MUNSON, publisher, 77 Bible House, New York.

Some of you may urge that the above is only fiction; but the first paragraph tells us that it is a true experience; and it is very much such an experience as I have had again and again, as you may recognize if you recall what I have written in these Home papers. This intemperate man was a sample of those that the world considers beyond help. It required quite a little faith on the part of the good Christian worker to insist on seeing him when he refused to be seen. Then it required a considerable amount of tact as well as faith to *get hold* of such a man. The white shoes and the white dress belonging to the saloon-keeper's daughter touched the vulnerable spot in the heart of the poor besotted inebriate. Then the suggestion in regard to the saloon-keeper's *wife* drove another nail, until the poor slave of drink got to the point where he could say, "O God! have mercy on me, a sinner."

Now for the moral of this tract, and may God grant that it may be scattered far and wide. There are such poor helpless slaves of drink in almost every community; and you too, my friend, whether man or woman, can do just such work if you will. Get down on your knees first, and ask God to give you faith and courage, and then turn in and help in this glorious work of "rescuing the perishing."

## TEMPERANCE

Visiting the iniquity of the fathers upon the children unto the third and fourth generation.—Ex. 20:5.

Ever since infantile paralysis commenced its terrible work I have been impressed with the idea that sooner or later we shall find the trouble comes, perhaps indirectly, from the use of intoxicants; and I have feared, too, that some of our great cities might be reluctant to admit or have it come out in print that our open saloons are more or less responsible for this terrible malady. It has already been remarked that it is confined mostly to our great cities, and to those portions of these cities where there is a congestion of population and a lack of sanitary measures; and I wish somebody could tell me whether its ravages are not confined mostly to our wet cities. Has infantile paralysis started or made any headway in our dry cities and towns? We have had just one case here in Medina County, and it occurred right close by the only spot where

there are two saloons put in by the famous (or infamous) home rule a year ago. Below is a clipping from the Cleveland *Leader*, which, while it does not hit exactly where I expected, contains a suggestion that may well be pondered. The Bible tells us that when Pharaoh said, "Who is the Lord that I should obey him?" when nothing else would subdue that proud monarch the Almighty struck a blow at the first-born in all the land; and is it not possible that the loving Father has seen fit to strike a blow at the babies when nothing else would rouse up and bring to their senses the fathers and mothers? Now read the clipping and look out all around you, as far as you are able, and see if nicotine is not at the bottom of the whole matter.

"TOBACCO PLAGUE CAUSE;" INFANTILE DISEASE IS FORM OF NICOTINE POISONING, CLAIM.

NEW YORK, Sept. 29.—If you are a smoker you probably have heard of Dr. Pease, president of the Non-smokers' League, and arch enemy of the cigarette. Well, then, Dr. Pease and his favorite

author, Miss Annette Hazelton, have a little news for you.

Infantile paralysis, says Dr. Pease, is simply a form of tobacco poisoning. Infants in arms become infected thru their tobacco-using parents, he has informed the health department.

Our poultry friends will remember that, a short time ago, a sort of paralysis started among the poultry; and when the searchlight of science was turned on the matter they declared the whole trouble was because the chickens had gotten hold of some dead carcass; and poultrymen everywhere are exhorted to see that everything of this sort is either burned up or buried so deep that no enterprising scratchers can ever resurrect it. Is it possible we have fathers and mothers in this land of ours who would keep on using tobacco when it might kill or cripple for life the baby in the cradle, or, worse still, the *unborn* babies?

#### "THOU CHILD OF THE DEVIL."

The above expression that I used in these pages recently it seems has called forth the following from friend Doolittle. Read it very carefully and see if you don't think he is about right:

##### THE DEVIL DRESSED IN WHITE.

*Bro. Root:*—I note what you have to say in the Temperance department of GLEANINGS for September 1, p. 817, under the quotation of scripture, "Thou child of the devil; thou enemy of all righteousness; wilt thou not cease to pervert the right ways of the Lord?" You think that Paul, if he were alive upon the earth now, would say this of the liquor people and their business, even tho it sounds a little rough. And in this I agree with you exactly, and I have so said many times in print and otherwise. But allow me to ask, "Who are the liquor people?" Sixty years ago, when I was a boy, the man who made a business of selling liquor was called a "black devil," and was so considered, as is the liquor traffic of today by many of the people of the United States; but in 1862 the government at Washington took this devil in as partner, clothed him up in white, and gave him next to the highest place in the affairs of the nation. By that act Congress never gave such a gift to anybody else—not even in its land grants to the railroads—as it gave to the liquor interests, when, in 1862, it passed the internal-revenue bill. The modern liquor-traffic is the product of that bill. It created organization, it established monopoly, it gave an air of respectability to what had before been disreputable in the eyes of all decent people. It enabled the liquor maker and seller to shake his dirty fist in the face of the American government and say: "You cannot do without me!" and, while robbing the American people of billions of dollars annually, to trample on their necks with the insulting assertion, "I pay your public expenses;" and, strange to say, this devil is still wearing his white apparel, because 498 sovereign citizens of these United States, out of every 500, say at every national election, "We love to have it so," by casting their ballots with political parties who are pledged to the continuance of this very same state of affairs. Every thinking man knows that the party in power at Washington is the government; and every voting citizen of these United States should know that, when he gives his ballot for the election of *pro-license* parties, he is voting for the

continuance of this "devilish" state of affairs for another four years, to the very utmost borders of our fair land. The man who wants the liquor traffic, this "child of the devil" (according to the apostle Paul, A. I. Root, and Doolittle), to go right on destroying "50,000,000 children and young people under 25 years of age" (as given on page 817 of GLEANINGS), the value of each of which is "\$8000," or "\$400,000,000,000" for the whole, can vote the Republican ticket or the Democratic ticket or the Socialist ticket; whichever of these he votes, his ballot will say to the gin-miller, the brewer, the distiller, the saloon-keeper, "Go right on destroying the boys and girls of the nation." But the citizen who wants to make his vote say that he wants the liquor-traffic to stop robbing the people, to stop disturbing our nation's life, to stop killing men and women and children, will have to vote the Prohibition ticket to have his ballot say that. It is useless to attempt to stop the sale until we stop the manufacture. And before we can do that, we have got to *break the partnership* of the national government at Washington with the traffic. And before we can do that we have got to have a party that isn't taking the lion's share of the profits and taxing and licensing it. We have got to go to Washington and adopt "one standard of morals" on the liquor question, the same as we did on the slavery question and the Louisiana lottery question.

Borodino, N. Y., Sept. 6. G. M. DOOLITTLE.

I think I can give a hearty amen to the above unless it is where it includes the Socialist ticket with the Republican and Democratic tickets. Quite a few Socialists have written me lately to the effect that socialism was "out and out" for prohibition. I have not seen the Socialist platform; but if that platform gives any more encouragement than does the Democratic and Republican, I have not been informed.

#### RAISING REVENUE FOR OUR GREAT CITIES BY TAXING THE SALOON-KEEPERS.

There is much discussion going on just now as to how it came about, and where the trouble is, that so many of our great cities are not only short of funds but are threatened with bankruptcy. There have been all sorts of discussion in regard to the cause; but yet few periodicals, unless we except temperance papers, come right out and admit that liquor revenue costs in the end *ever so much more* than it comes to. Below is a clipping from the *New Republic*:

##### OHIO'S BIG BOOZE BILL

COLUMBUS, Sept. 23.—At the present time there are 6000 saloons in Ohio, each of which pays yearly license fees of \$1000. In spite of this enormous income from wet sources, the city of Akron is bankrupt, while Toledo, Columbus, Cleveland, Cincinnati, and other large wet cities, are in serious financial straits and are practicing rigid economy. The saloon revenue is insufficient to pay the saloon cost. It is estimated that the enormous sum of \$110,000,000 is wasted annually in Ohio alone for liquor.

Of course, the above is from a temperance periodical; but here is another one, clipped from the *Youngstown Telegram*, that does

not pose, so far as I can learn, as a temperance publication:

#### LIQUOR AND TAXES.

While the local Chamber of Commerce is discussing the sad financial condition of the larger Ohio municipalities, and recommending concerted action toward obtaining relief, it might inquire into the ancient claim that it is the revenue from the liquor-traffic that keeps cities solvent. It would be an interesting inquiry just now when 6200 licenses are to be distributed in Ohio among 7000 applicants.

If the saloon makes lower tax rates, and breeds prosperity, then Cleveland, Youngstown, Akron, and Toledo should have comfortable municipal bank balances, for their license quotas are filled up. Columbus, Cincinnati, and Canton should be almost as prosperous, for their saloons approach in number the limit allowed by law. Instead they are harassed with debts. Topeka, Des Moines, Denver, Portland, Seattle, Spokane, Birmingham, Atlanta, Memphis, Nashville, Wheeling, Charleston, Richmond, and Oklahoma City are not crying bankruptcy. Yet they derive no revenue from the liquor-traffic. They range in population from 50,000 to 300,000, and they have not the wealth of Ohio cities.

In view of the above, is it not about time that our city fathers should begin to "sit up and take notice"?

#### THE LARGEST DRY CITY IN THE WORLD.

The clipping below comes from the *New Republic*:

TORONTO, LARGEST DRY CITY; CANADIAN CITY WITH FOUR HUNDRED THOUSAND BECOMES WORLD'S LARGEST DRY CITY.

TORONTO, Sept. 16.—Today this city enters the dry column under the provincial act, and becomes the largest dry city in the world. This act, which puts the entire province of Ontario dry, cannot be contested for at least three years.

The provincial legislature in passing the act first voted absolute prohibition, and then asked the people of the province to ratify the vote. This popular vote will not be taken until after the war, however.

I am not sure the above is correct in saying that Toronto is the largest dry city in the world; but if it is *not* true we shall be "gladder yet." Below is something further, from the *American Issue*. Is it not worth a careful and *prayerful* consideration?

#### HOW IS THIS FOR A RECORD?

The city of Toronto, Canada, together with the entire province of Ontario, became dry Saturday, September 16. On the last day saloons were open, there was the usual drunken orgy attending the final closing of the liquor-joints. The following Monday morning there were 142 drunks in police court. Tuesday morning there were six such cases, and on Wednesday there was not a drunk before the court. That is some record for a city of more than 400,000 population, the largest prohibition city in America.

#### WHY CALIFORNIA FAILED A YEAR AGO.

There were at the last election for governor 250,000 voters who did not vote on the question of wet or dry, and 80,000 who *never voted at all*—a total of 330,000 voters that never voted yes or no, and you can rest assured the *wets* were *all out*. We were beaten 160,000. We are organizing to see that every one votes, so you see there are 330,000 votes to be counted one way or another.

There are only 2100 saloons in San Francisco Co. I have been in business for several years in serving the public, and I can vouch for all of the above. May the good Lord bless you in the good work you are doing.

Modesto, Cal.

F. F. TURNER.

Are there not other states, where *thousands*, "never voted at all?"

#### FLORIDA AND ITS PRESENT PROGRESS.

I have been for some time hungering and thirsting for some good news from Florida. The following is clipped from the *New Republic*:

#### FLORIDA'S LEGISLATURE IS DRY.

Last year the submission of the prohibition amendment was defeated in the legislature of Florida by one vote. Now Mr. Pendleton, Superintendent of the Florida Anti-saloon League, announces that 24 of the 32 members of the State Senate and 60 of the 75 members of the House have pledged themselves to vote for a resolution submitting the question of a state-wide prohibition amendment to the voters in the 1916 general election.

#### PROHIBITION SENTIMENT GROWS IN FLORIDA.

By a vote of 3 to 1 the important county of Brevard has voted for prohibition.—*American Issue*.

"STRAWS SHOW WHICH WAY THE WIND BLOWS."

We clip the following from the *Weekly Bulletin* of the Methodist Temperance Board. Have they not got it about right?

THE AIR IS FULL OF STRAWS, AND THEY ARE ALL THE SAME COLOR.

The rousing verdict of the voters of Maine in favor of the prohibition law, the sweeping victories of the "drys" in the primaries of Montana, South Carolina, and other states, simply marked a continuing tendency which has been evident for several years.

In Kansas all political parties in convention this year declared for prohibition. In Iowa the Republican and Democratic parties boarded the water-wagon. In Colorado the Republican and Democratic parties endorsed the present dry law and declared against allowing brewers to make beer and sell it in unbroken packages. In West Virginia both Republicans and Democrats in convention put an O. K. on state-wide prohibition and declared for strict enforcement of it. In New Mexico, a wet state, the Republican party in state convention declared in favor of submitting a prohibition law to a vote of the people thru the legislature, and it is practically certain that the Democratic party will take similar action. The Republican convention of Utah nominated a dry candidate for Governor, defeating Governor Spry, who vetoed the prohibition act passed by the last legislature. The state administrations of Washington and Oregon are in favor of prohibition and a strict enforcement of it.

Here is something else from the same sheet:

#### WHISKY NOT EVEN GOOD FOR SNAKEBITE.

Dr. Evans, the medical editor of the *Chicago Tribune*, recently discussed the question of snakebite.

"Should whisky be given?" he asks, and answers "No. All authorities agree on that."

Dr. Evans quotes McFarland, an authority, as follows:

"The usual recommendation is to load up with whisky. In reality nothing could be worse. The use of whisky for snakebite does much harm."

Just think of it, friends. For ages past the man who was near death because of a snakebite has been deluged with whisky. If he died, they declared he was so far gone that even *whisky* would not save him. If he recovered, in like manner they would declare he would have died sure had it not been for the booze; whereas the real truth is, the whisky did harm and *hindered* recovery, *always and every time*.

Here is another straw, which I copy from Mr. Bryan's *Commoner*:

Straws, they say, show the direction of the wind. The fact that the railroads are taking liquor off the diners is a good-sized straw. The sentiment against alcohol is growing.

#### DRINKING WHISKY TO ENABLE ONE TO STAND SEVERE COLD.

It seems almost impossible to get many people over the notion that whisky is good for snakebites, good for enduring severe cold, etc. Our good friend F. E. Porster, of Morrill, Kansas, sends us the following, by Dr. Charles Lerrigo, and which appears in the *Farmers' Mail and Breeze*.

"Many people are quite sure that when the weather is biting cold they really need some one of these alcoholic drinks to keep them warm.

"A company of strong men thought so when they were traveling across the western plains several years ago. There were 20 of these men. It was winter, and they had to spend a terribly cold night in their camp without any fire. They had food enough and plenty of whisky; but one of the men knew more than the others; and, while they were talking about what they should do to keep warm, he said that for one thing it was not safe for any of them to drink whisky that night. He even went so far as to say that they were far more likely to freeze if they drank it.

"Two of his friends believed him, and the three took no whisky before going to sleep; they were cold in the night, but they were not very uncomfortable. Three of the other men drank a little. They were much colder than the first men, but they did not freeze. Seven men drank more, and their fingers and toes were frostbitten by morning. Six drank a good deal, and they were so badly frozen that they never really got well again. Four drank until they were foolish, and one after the other they all died three or four weeks afterward. The last three men were drunk when they went to bed, and by morning they were frozen to death.

"Each one of these men was strong the day before, and each had the same number of blankets that night. It seemed to be just the whisky and nothing else that made the difference."

#### HOW COULD IT BE OTHERWISE?

We clip the following from the *Farm, Stock, and Home*:

##### A LEFT-HANDED "DISASTER."

Prior to January 1, 1916, Breckenridge, Minnesota, was a "wet" town, enjoying all the business advantages that go with the free dispensing of liquors. Since that time the blight of prohibition has struck the little city on the Red River, and this

is how the disaster prophesied has affected the situation: A representative of this paper recently spent a couple of hours looking around the town for evidences of business demoralization. He found a man who had been looking in vain for a suitable house to rent. He found one vacant business place on the main street, and was told that there had been three others, but that they were now occupied, and in each instance by lines of business that provide comfort and well-being for the family. Most disappointing of all to the believer in the theory that local prohibition is bad for a town was the report from the business men. The merchants said their accounts were being better taken care of than before the saloons went, and a banker reported that it was impossible for him to say just how greatly the business of the saloons had injured the town, because of the unusual business conditions prevailing during the past few months, causing an increase in bank deposits since January 1 of something to exceed \$100,000. He had observed no increase in the number of small depositors as yet, but understood that working men's bills were being paid up, and looked for a marked increase in the number of small depositors soon.

This cold businesslike analysis of the effects of prohibition is worth whole reams of hysterical argument either for or against.

#### "IF PROHIBITION IS ADOPTED, THESE VINEYARDS WILL BE DESTROYED," ETC.

As an illustration of the way the liquor party tries to deceive the people, we clip the following from the *American Issue*:

The liquor interests have posted signs along the line of railroads in vineyards which read: "If prohibition is adopted these vineyards will be destroyed." In some instances their sign posters have done absurd things, for in scores of places the signs are placed in vineyards which do not as a rule ship a ton of grapes to wineries. In one place the proprietor admitted that he had not sold a pound of grapes from his vineyard for wine-making purposes for some years.

I have seen the statement elsewhere that the liquor party were putting up these notices without even asking permission of the owner of the vineyards or other lands where they are sticking them up.

*Mr. Root*:—I have been riding thru a large grape-growing district, and I noticed large signs posted in every vineyard reading thus: "Prohibition will ruin this fine vineyard. Vote No on both propositions." These vineyard lands will grow almost any cereal crop, and produce great wealth. Can't you say something along dry lines that will help out the dry side of the question? I have come to the conclusion that red liquor and religion will not stay in the same hide. As one goes in, the other comes out.

Rialto, Cal., Sept. 17.

E. J. ATCHLEY.

#### BOOZE AND HEAT PROSTRATION.

I clip the following from *The Farming Business*:

##### DOCTORS BLAME ALCOHOL.

As a result of a study into the cases of heat prostration, Dr. Karl Meyer, medical warden of the County Hospital in Chicago, and Dr. Harry Gauss, an interne, have found that ninety-eight per cent of the heat strokes are traceable to alcoholism or the use of alcohol. Their opinion is based on an examination of 155 cases of heat prostration taken to the County Hospital during three days of the extraordinary hot spell in July. The mortality in these

cases was 44 per cent. Dr. Gauss questioned twenty-five patients suffering from heat stroke. All but two had drunk some alcoholic beverage during the day. The twenty-three confessed to libations extending from one bottle to one gallon of beer, besides stronger drinks. Most of the victims admitted the habitual use of intoxicants.

"It was hardly necessary to question many of them," Dr. Meyer said, "because the external evidence of the use of alcohol was so plain. A case of heat prostration without an alcoholic breath seemed a rarity. In fatal cases the use of a stomach pump commonly revealed the fact that the victim had been drinking. Ninety-eight per cent of the cases were due to alcohol."

From the above it transpires that these sad cases are not the result of extremely hot weather, but mostly the effect of intoxicants. For some time I have been watching to see if the dreaded infantile paralysis were not in some similar way connected with intemperate habits on the part of one or both of the parents. It seems that the whole wide world is just now, for the first time, waking up to the direct and indirect consequences of the drink habit.

Right on the heels of the above comes the following kind word:

*Mr. Root:*—As my heart goes out in sympathy with your kind and loving words for humanity, and against this terrible demon rum, I cannot help sending you the enclosed clipping.

Chicago, Aug. 24.

W. F. COLEMAN.

The inclosure referred to by the brother is nearly a column from the *Chicago Tribune*, repeating at greater length with terrible emphasis the fact that it is *booze* and *not* the hot weather nor hot sun that causes sunstroke. May God be praised that our leading physicians are waking up, and beginning to call things by their right name.

#### MINNIE ELLET VERSUS A CITY OF 135,000.

During the recent heated period something was said in the great city dailies about policemen being obliged to stand out in the sun without any shelter. Just recently in the city of Akron (only 20 miles from where I sit dictating this), no protest was made when a *liquor concern* proposed giving one of the members of the police force a big umbrella for protection. Now, when said umbrella was decorated with a liquor advertisement, it seems no one felt like taking the responsibility of protesting (among the 135,000 inhabitants) except this one little woman, who has before this had something to say in our pages in regard to temperance matters. With the above explanation read the following, clipped from the *Cleveland Plain Dealer* of Sept. 8:

WATER CONQUERS RUM; CITY CAN'T AFFORD POLICE SHELTER, SO TEMPERANCE STEPS IN.

Akron, financially embarrassed, was unable to buy a big stationary umbrella to shelter its traffic police-

men, so accepted one from a local liquor concern. The umbrella carried a liquor advertisement.

Naturally this riled Miss Minnie Ellet, temperance leader. City officials explained that the city was broke.

This noon Miss Ellet marched into the city hall with an umbrella of the same size, carrying an advertisement of the virtues of pure water. Chief Durkin accepted it and turned it over to Safety Director Morgan, who installed it at the corner of Main and Quarry streets in the presence of 500 people who watched the performance.

#### DRUNKS, JAILS, AND UMBRELLAS.

*Editor Beacon Journal:*—A few weeks ago the newspapers printed the mayor's reason for the many "drunks" that infest our streets—"City prison too small to hold any but the 'disorderlies,' a new city building imperative." Well! The next day another paper told of Belmont County's jail being overflowed and Hancock County's being completely empty. Belmont County is wet; Hancock County is dry. Yesterday I noticed that a brand-new umbrella covered the traffic cop at the flatiron corner. The ad, upon it is "Grossvater." And then I wondered if our great, prosperous, bankrupt city was advertising for more "drunks," or whether she was too poor to buy her own umbrellas, or whether the "Grossvater" and his kin completely "cover" the city. And I wonder why "strong masculine minds" advocate increased jail facilities as a cure for drunkenness. No government arrests a man for buying more groceries or drygoods than he can carry. Why arrest, imprison, and fine him for buying an over-supply of licensed and protected wet goods? If license does away with speakasies and makes all saloon-keepers law-abiding, where do "drunks" get the where-with-all that makes 'em stagger and blear-eyed even if they're not disorderly?

Aug. 22.

MINNIE J. ELLET.

"AN UNSPEAKABLE CURSE, WITHOUT ONE REDEEMING QUALITY."

We clip the following from the *Methodist Temperance Bulletin*. It seems as if it contains more boiled-down common sense than I ever saw before in regard to the liquor business. Reader, if it is possible, pass it around to your friends who may be likely to vote wet, or, perhaps, not vote at all.

#### GREAT BUSINESS JOURNAL EXPRESSES ATTITUDE OF AMERICAN INDUSTRY TOWARD DRINK.

*The Manufacturers' Journal*, of Baltimore, is in some particulars the leading industrial publication of the country. Its influence, especially in the South and East, is very strong. Here is what it says of the "liquor business:—"

"We are absolutely, teetotally, and in every way possible, opposed to the whisky industry, not only because of its immoral influence, but from the economic standpoint. It is a curse to the country, of such gigantic proportions that, the sooner it is blotted out, the better it will be for mankind. The billions of dollars that are annually spent in this country constitute one of the most fearful curses ever brought upon the land, and every dollar thus expended is an economic waste and a drain upon the physical, mental, moral, and financial stamina of the country. Moreover, the alliance of the saloon interests with the politics of the country is another curse, and to this influence is due much of the rottenness in American politics. \* \* \* \* Whisky and the saloon business are an unspeakable curse, without one single solitary redeeming quality."

# HIGH-PRESSURE GARDENING

## PLANTING A PEACH-TREE.

When we built our little bungalow three years ago there was a peach-tree perhaps two feet tall standing out near the walk in front of the house. Mrs. Root wanted it pulled up, for, she said, "Who wants a peach-tree out in the front yard close to the walk?" But I told her we would let it alone, and then if it did not bear we would dig it up. In grading the lawn the surface was raised nearly a foot; but I put some bricks around the tree in a circle so as to be about a foot away from the stem. Well, last year it bore perhaps a dozen peaches—great big yellow "Rareripes," as we used to call them; and on this 22d day of September I have just picked a bushel of great beauties, and there are nearly as many more left on the tree. After eating something like half a dozen that were dead ripe I said to Mrs. Root, "Sue, these are the finest peaches I ever tasted." She replied, "Oh! you say that of everything."

I leave it to you, my good friends, is it not a pretty good habit to get into, to be pleased with things—especially things that God sends us without labor or expense? for I might almost say this beautiful peach-tree with its luscious load never cost us a copper. We never dug around it nor fertilized it, nor did anything to it, and yet there are all these luscious peaches. For many years it has been said that peaches do not succeed in Medina Co. They grow them by the car-load along the shores of Lake Erie, but very few are grown in this locality. If you urge that this was an exception, and probably just happened so, I have another story to tell.

On the dividing line between our place and that of our daughter Carrie Belle, her folks planted a barberry hedge; in fact, they planted it before we moved in. Well, right close to my garage, on the dividing line, three peach-trees sprang up of their own accord, like the other one, and two of them are not six feet apart. Now, these three seedlings have quite a good crop of great big handsome peaches. They are a little later than our yellow Rareripes. But if four peach-trees grew without any care or cultivation, and bore fine luscious fruit, why could not somebody plant an orchard in that locality and grow peaches? I think there are a few scattered about the town and over the country; but there is no peach-orchard now very near us. While talking about peaches, here is something else: I guess I had better head it—

## A SHORT CUT BETWEEN PRODUCER AND CONSUMER.

You know it has been one of my hobbies to have the producer make the shortest cut possible to the consumer, thus leaving out the middleman and a number of profits. I clip the following from the *Cleveland Plain Dealer*:

**MOTORISTS BUY PEACHES; OTTAWA COUNTY GROWERS CUT OUT MIDDLEMAN BY FRONT-DOOR SALES.**

PORT CLINTON, Sept. 18.—Hundreds of bushels of peaches were taken out of Ottawa County yesterday by automobile traffic alone. Nearly all touring-cars which came thru Port Clinton during the day visited the peach belt and came back with bushel baskets tied to the running boards or strapped to the car in any possible manner.

Growers of this section have learned the best way to dispose of ripe fruit is to pack it in bushel baskets and have it ready along the road to hand to buyers when they drive thru the country.

Buyers are given choice fruit which is just right for immediate use, and relieve the grower of fruit which he would be unable to ship to a distant market. Many automobiles lined up at fish-houses, but were unable to get any fish yesterday.

Just now our nation is full of automobiles, and they are making them, more and more every day; and lots of people use these automobiles to run around over the country just for pleasure, without any special errand. Let me now suggest that, when you take your pleasure-ride, you hunt up the producer of something you need—something in the way of daily food, for instance. See what you are getting—get it fresh; and encourage the producer by paying him spot cash, as illustrated in the above clipping.

By the way, I almost forgot the moral connected with that peach-tree close by a sidewalk. Its great luscious peaches have been slowly ripening so near the public walk that one could reach out and pick a peach without even stepping over on the grass, and yet not a peach has been pilfered so far. Don't you think that speaks well for our town of 3000 population? May God be praised for the privilege of living in a community where they respect the property of another even where no fence protects fruit when one is passing along the walk. Is not such a state of morals far better than "stone walls" or "barbed-wire" fences?

## "FROM PRODUCER TO CONSUMER"—MORE ABOUT IT.

Just after the above was dictated I found something in the *Rural New-Yorker* in regard to long range and short range between producer and consumer. See below:

### EXPENSIVE BREAKFAST FOODS.

Not long ago we had breakfast at a farmhouse back some miles in the country. We were offered a choice of six different kinds of "breakfast food."

Entire wheat boiled soft and served with cream and sugar would have been better than any of the half dozen, and much cheaper. The South Dakota Experiment Station has analyzed 26 different breakfast foods, and finds that they cost all the way from 7 to 44 cents a pound. One sample of "puffed" grain cost 43 cents a pound, while the same grain boiled soft would have been more nutritious, and cost about two cents. When we come to consider this 35-cent dollar let us figure on the breakfast food value of corn, oats, and wheat. We sell wheat at two cents a pound, and buy it back at from 12 to 40 cents!

Just think of it, friends—buying one of the staple daily foods, if not the most staple, for 2 cents a pound instead of paying 40 or even 43 cents! We have been using quite a little oatmeal lately with that nice thick Idaho honey I have been telling you about. Well, without thinking much about it we got it in fancy pasteboard boxes. I do not know how much a pound it cost that way; but you can easily figure it out. Well, we were using so much of it that it occurred to me to ask our grocer if he did not have the flaked oats in bulk. "Oh, yes," he replied; and the price was only 5 cents per lb., whereas if we bought it in pasteboard boxes it would be away up.

Now once more about that automobile. Potatoes are just now at the grocery 45 cents a peck—almost \$2.00 a bushel. Take your automobile and go out where the farmer is digging potatoes, and get enough to last you all winter. Get some potatoes that suit you, and get them for about what the farmer gets by the wagonload. Do the same with winter apples, wheat, eggs, butter, and ever so many other things, and you will save enough in a very short time to help greatly *in paying for the automobile*.

After the above was put in type, when the peaches were almost gone I sent some specimens to our Ohio Experiment Station, and below is a reply from my long-time friend W. J. Green:

*Dear Mr. Root:*—The peaches which you sent came in good order, altho one or two of them were slightly decayed. The quality is excellent—much better than the average. I have no doubt the size will be sufficient under cultivation. It is too late now to propagate the tree for budding. If the tree should prove to be hardy in bud it would be a very valuable variety.

W. J. GREEN, Horticulturist.

Wooster, O., October 5.

In the above there is something said about the size, as you will notice. Perhaps I should explain that the largest and best had all been used before I thought of sending any to our Experiment Station. The first year the tree bore a dozen or so which were, some of them, extra large.

By the way, I have before mentioned that this peach-tree has never had any pruning; and as now it has a great dense

bushy top, I asked Mr. Green about when to prune it and how to prune it. He replied as follows:

Regarding the time to prune peach-trees I will say that early in the spring is the right season of the year. If you will cut off the tips of the branches at that time, removing nearly half of the growth made this season, the crop of peaches will be improved in size, and the number of bushels not reduced. This cutting-back of the trees every year makes them more stocky and better able to support the crop of fruit. There need not be much thinning-out of branches except in case the branches are, without doubt, too close together.

Wooster, O., Oct. 10.

W. J. GREEN.

#### SWEET CLOVER; DOES IT GROW BETTER ON HARD SOIL?

I notice in your last booklet you still retain some unfair comparisons in regard to sweet clover growing better on hard soil. The error is made by drawing conclusions from two soils that are different. I nowhere find anything in my experience (which is extensive enough to settle the point), nor in the experience of others, that hard soil is best for sweet clover. It may often be better, but it is not due to its density. It is due to the one fact that it has been for a long time out of cultivation or never cultivated, and the comparison is made with soils worn out by cultivation. The comparison is, therefore, unfair. While sweet clover sprouts better in a firm soil, I have never seen a testimonial that it grew better in a hard soil unless the observation was taken with entirely different soils. I do not think there can be any contradiction on this point. Soils can never be too loose for the best growth of sweet clover, and it germinates better on loose soil than other clover. For very early spring sowing, soils are never too loose for sweet clover. You evidently have no evidence that hard soil is best for sweet clover. Growth of sweet clover can be increased 200 to 300 per cent by cultivation like that given other crops.

Tompson Station, Tenn.

W. H. ARNOLD.

My good friend, you may be right in regard to the matter; but I believe it is the common experience to find tremendous growths of sweet clover where there has been a brickyard or stone quarry where the surface soil has been all removed, etc. I have already cited railway embankments. Here in Ohio we have miles of road made of crushed limestone; and when sweet clover gets started the seed seems to be carried on the wheels of vehicles, and sweet clover springs up all along the roadside close up to the wagon-track. A few days ago I attempted to make some repairs on the limestone road in front of our home. It is so hard that I could hardly move it or loosen it up with heavy blows with a mason's pick; but where sweet clover had gotten a foothold in that hard crushed limestone it was growing up higher than my head.

A year ago I pictured and wrote up my sweet-clover sport, and sent seeds to a great number of the friends from this one plant. Of course I sowed some of the seed myself, and gave the young plants careful cultivation. But a good many of them were thrown out by the frost during winter. The best

plant on the lot is now (July 21) in full bloom, higher than my head, and covered with bees. This plant was on the edge of a strawberry-bed, and had no cultivation, because I wanted to save the strawberries. The hard uncultivated clay seems to have saved it from being thrown out by the frost. I think I shall have to confess that the seedlings of my pet plant are but little if any different from the common white sweet clover. If anything they bloom a little earlier; and for some reason or other the plant is larger, and there seem to be more bees on this plant than on the common sweet clover all around it. One reason may be that it has a place all by itself, whereas the other plants are close together. As I have said, it has had no cultivation whatever. We should be glad to hear from others to whom we sent seed a year ago; and we shall also be glad to get the experience of all along the line of giving sweet clover cultivation and loose soil like other crops.

#### "A GOLD-MINE ON EVERY FARM."

We clip the following from the *Florida Grower*:

There is a gold-mine on every farm. From the ground now occupied by stumps sufficient food could be grown in a year to equal in value a good-sized gold nugget. Rarely, if ever before, have food products sold for so high a price. Never before have our farmers had so great an opportunity to make

themselves comfortably wealthy from one crop, and at the same time perform a great service to all the world by feeding the hungry.

From what experience I have had I should say the above is about right—not only down in Florida but here in Ohio. All that is wanted is a man who knows how and is not afraid to work. Our boys and girls in the corn and canning elubs will show us how if we are willing to be taught.

#### FRUIT-TREES.

Inasmuch as there has been considerable discussion in regard to the best remedy for San Jose scale, I wrote to Prof. Gossard, of the Ohio Experiment Station, and below is his reply:

*Mr. A. I. Root*:—You need have no hesitation at all in running an advertisement in your journal for scalecide. This is one of the very best of all our scale remedies, and is possibly excelled by none. We constantly make use of it in our work, and for a number of scale species get better results with it than with any other remedy. Scalecide rightly divides with lime-sulphur solution first place among remedies for control of San Jose scale. It is particularly useful on old rough-barked apple and pear trees. I enclose a paper by Mr. Houser on the more recent tests of remedies for San Jose scale.

H. A. GOSSARD, Entomologist.

Wooster, O., Oct. 2.

All of you who are interested in better fruit should get right about it and send for the little book by the scalecide people. See their advertisement.

## HEALTH NOTES

### "MILK AND HONEY;" GOATS' MILK INSTEAD OF COWS' MILK.

With all the good things that get into GLEANINGS I wonder that milk goats have never been written up. The wisest of men said, "And thou shalt have goats' milk enough for thy food, for the food of thy household, and for the maintenance of thy maidens."—PROVERBS 27:27.

The Bible has much to say about milk, and often speaks of honey. When the Israelites were taken from Egypt the Lord promised them "A good land and a large, unto a land flowing with milk and honey."—Ex. 3:8; and it is well known that the Syrian (or they are now called Nubian) goats of Palestine are the finest goats and best milkers of the goat family. Seventeen times in the Bible is "milk and honey" mentioned. It is well known by every Bible student that goats' milk was used by God's ancient people much more than cows' milk, and I assure you that "milk and honey" will have a new meaning to those who use goats' milk and honey. As so many beekeepers are "little landers," it strikes me that they should keep goats, not only to have "milk and honey" but to have the very best, cleanest, easiest digested, most healthful, as well as the cheapest milk, and to be sure that the blessed babies do not get the dread tuberculosis that is destroying its thousands of innocents. "Innoxious, uninfected, sanitary nourishment for the infant,

the child, the invalid, and the aged, has been until recently a reflective problem for the medical man as well as the layman;" but goats' milk is solving the problem.

"The fourth annual report of the District of Columbia Association for the prevention of tuberculosis, and this is from the most reliable and highest source of information in the United States, tells us that one-fourth of all cases of tuberculosis among children under 16 years of age, and one-eighth of all fatal cases under 5 years of age, are due to bovine tuberculosis. And among children fed exclusively on cows' milk, nine out of ten cases of fatal tuberculosis revealed that five, or 55 per cent, were due to bovine infection. The most noted authorities of Europe and America agree that the qualities of goats' milk lie in its chemical composition, its immunity from danger of carrying the germs of tuberculosis, and make it the *ne plus ultra* of all foods. As a prophecy, remember that the goat will be the foster-mother and wet-nurse of generations yet unborn."—LOUIS G. KNOX, M. D., D. V. S.

Most people have an idea that goats' milk has some strong, pungent, bitter, or unpleasant taste. I assure you that if you like milk you would drink goats' milk and never know the difference unless you detected that it was exceptionally good.

My wife objected to my getting goats, because I am so "finicky" about the milk I drink. Now that I have goats, I am so "finicky" about my milk that

I am very touchy about the cows' milk I sometimes get in some places. Do you like a cow smell? Well, do you like the cow smell in your milk? How often do you see a really clean milk cow? They are usually smeared with their droppings, and their filthy tail is everlastingly on the swing. My goats are white, and you will never see them unclean. I can sweep their droppings away with a broom. Their tail is short, and never in the way, nor filthy. They are as clean about their food as the ordinary person. They prefer weeds, leaves, shrubs, etc., to grass, but it must all be clean. They are the most docile and lovable of pets; can be kept on one-eighth of a cow's keep; will eat the scraps of bread, fruit, and potato parings from the kitchen (if they are perfectly clean), and will cost for keep but little over one dollar per month if you buy all the feed, and will give from one to four quarts of milk per day that is twice as rich as cows' milk, and absolutely immune to tuberculosis. Thorobred Swiss milch goats are expensive; but their crosses on the common goat are cheaper, and sometimes nearly as good. I should like to see more beekeepers and little landers enjoying real "milk and honey," the best milk, the only safe milk. I have nothing for sale.

Noosack, Wash.

REV. ALSON W. STEERS.

We have already had several suggestions that goats' milk be recommended in place of cows' milk; and one writer sent us a number of clippings telling where babies' lives have been saved by substituting goats' milk for cows' milk. But I have always had a prejudice against goats because of the smell that I supposed pertained to all goats. As the writer makes no mention of a disagreeable smell of the animal I have been wondering if there is any particular strain of goats that is devoid of this smell. And besides the smell they have always seemed to me to be very uncouth-looking animals—more so than our other domestic animals. Is it not true that a certain kind of rather expensive cheese is made from goats' milk? If what the writer claims in the above is true, perhaps it may be well to have the matter discussed a little more in GLEANINGS. We have had several sample copies of a periodical devoted exclusively, or nearly so, to the breeding and care of goats.

*Later.*—Recently while traveling in the northern part of Michigan the train stopped at a junction for some little time. Close by the train a man came up with a little wagon drawn by a goat. It had horns, and was almost as large as a Jersey cow. In fact, I did not know before that goats ever grew to such a size. This big goat seemed to be a novelty to the passengers, for they all began to push their heads out of the window, and finally they gathered around the man and his cart. He was selling peanuts and popcorn. The goat was evidently used to attract attention; and his owner by means of it gathered in quite a lot of dimes and nickels. Was this big goat a large kind of goat, or was he a giant among his own species?

ANIMALS, 95 PER CENT NORMAL AT BIRTH;  
HUMANITY ONLY 20 PER CENT; WHY?

I have before made frequent mention of Prof. W. T. Shannon, of Delaware, Ohio. His lifework is not only for better babies but better men and women, "lifting up the fallen," etc. We give below the first page of a six-page leaflet. If you want to help, send for a sample copy of his journal, *Practical Eugenics*, or, better still, send 50 cents and get it a whole year. Address as above.

#### PRACTICAL EUGENICS.

We have more than eight hundred weekly and monthly publications devoted to better fruit, vegetables, cereals, bees, chickens, and stock. Largely thru their agency we have doubled the variety, size, and quality of our vegetables and fruits, and produced our popular varieties of poultry and breeds of domestic animals. Nearly every man at the head of a family, whether he owns an acre of land or not, subscribes for one or more of these papers. Their wisdom has our commendation.

Not one family in twenty takes a magazine or reads a book devoted to the teaching of sane and practical methods of improving the race of mankind. We have turned the advent of childhood over to ignorance and selfishness. Prudery and ignorance prevail, instead of intelligent child culture. The double standard of morals, so largely responsible for the degenerating habits of tobacco, alcohol, and immorality, goes unchallenged. Young people are teased about sweethearts, marriage is a joke, divorce is an ever increasing reality, and degeneracy threatens the race.

#### "SMOKING AND FIRE LOSS OF LIFE AND PROPERTY."

The above heading I clipped from a little pamphlet of eight pages and from the eight pages I clip as follows:

This article was prepared by Mr. Williams, at the request of Mr. Rolla V. Watt, Manager of the Royal Insurance Company, San Francisco, California, specially for Manfred P. Welcher, Field Secretary Anti-cigarette League of America, Eastern Division.

Copies of this folder will be sent by Mr. Welcher at 5 cts. for 10 copies; 50 cts. for 100; \$5.00 for 1000. General delivery, Los Angeles, California.

The pamphlet contains a vast amount of important matter in regard to fires caused by smoking, particularly from cigarettes; and at the close we read as follows:

The great Baltimore fire, costing the insurance companies fifty million dollars, was caused by a cigarette thrown into rubbish, where it smoldered and finally created the conflagration which looked for a time as if it would sweep the entire city.

Every time a cigar, pipe, or cigarette is lighted, a fire is started; and whether it will become a conflagration that will destroy a block or a whole city depends upon the care or carelessness of the smoker.

There is not an hour of the day that some fire is not being caused by a careless smoker, either with matches or by throwing away his stub of a cigar or cigarette, and some drastic nation-wide action must be taken to prevent it.

The state of Washington passed a law prohibiting the use and sale of cigarettes, and almost instantly the number of preventable fires was reduced.

# Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER. By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE. By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES. Our new complete catalog, mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER. Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES. The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING. Just the thing for the up-to-date housewife. Price 10 cents.
- BEES AND POULTRY, how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES. A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE. A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES. A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.
- THE BUCKEYE HIVE, or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET CLOVER, the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE. A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth. \$1.00 postpaid.

Be sure that the following coupon is carefully filled out.

HOLLOPETER, Pentic, Pa.

## HELP WANTED

WANTED.—Experienced young man for our beekeeping supply department; one who has a knowledge of beekeeping and is not afraid to work. Give reference, and state salary expected. THE FRED W. MUTH CO., "The Busy Bee Men," 204 Walnut St., Cincinnati, Ohio.

## TRADE NOTES

### SECOND-HAND 60-LB. CANS.

Our supply of second-hand cans at New York has been disposed of; but we still have a good supply both at Medina and Philadelphia of choice cans suitable for use again in shipping honey. These we are selling at \$4.00 for 10 cases; \$8.50 for 25 cases; \$30.00 for 100 cases.

### CHIPPED TUMBLERS CHEAP.

We again have a supply of two or three hundred cases of 2 dozen each of tin-top tumblers holding 6½ oz. of honey, or ¼ lb. of jelly. They have the edges slightly chipped so they cannot be sealed airtight for shipping, but will serve as a cheap container for some uses. We offer them, while they last, at \$2.00 for ten cases of 2 dozen each, including the tin tops.

### NO. 4 EXTRACTOR FOR SHORT FRAMES CHEAP.

One of our dealers has an overstock of No. 4 Novice extractors which he offers to return at a price that permits us to offer them at \$6.50 each. If among our readers there is any one who uses short frames not over 13¼ inches wide under top-bar, or 13 inches deep or less than these dimensions here is a bargain for him. Just half present list price of this size of machine.

### MASON FRUIT-JARS.

We have a surplus stock of choice Atlas Mason fruit-jars which we offer, to reduce stock, at the following prices which are good only while this stock lasts, and for shipment from Medina, Ohio, only. Pint Mason jars, 45 cts. per doz.; \$5.25 per gross. Quart Mason jars, 48 cts. per doz.; \$5.50 per gross. Two-quart Mason jars, 75 cts. per doz.; \$8.50 per gross.

These are packed in paper cartons of one dozen each. Pint size would stand reshipping short distances filled with honey, altho we would not recommend it.

### SPECIAL BARGAIN IN WINTER HIVES.

The time for putting bees into winter quarters is at hand. There may be some who would try out the double-walled hives if they could buy them at bargain prices. We have available for shipment from St. Louis, Mo., if ordered this month, fifty each of eight-frame and ten-frame Dovetailed chaff hives of old-style with tight bottom and wood cover. We offer these, to close them out quick, at just half price.

They are one-story with telescope cover and Hoffman frames, put up in crates of 5 each. We offer the eight-frame at \$7.00 per crate of 5, or \$60.00 for the lot of 50 hives. The ten-frame at \$7.50 per

crate of 5, or \$65.00 for the lot of 50 hives. This is as low as our wholesale price on single-walled hives, and surely is a bargain to any one who can use them. Here is a chance to test the advantage of a double-walled hive over a single-wall without the hives costing you any more. Stock must be moved at once, therefore we are placing the price at a figure that should find a buyer quickly.

### BUSHEL BOXES.

We have on hand, ready for immediate shipment, a good stock of these boxes, packed as shown in cut. They are made with oak corner posts and bottom end slats to receive the nails, the remainder of the box being basswood. They are very convenient, and popular for handling potatoes, apples, onions, and other farm crops. They hold a heaped bushel level full, so they can be stacked any height desired. To reduce stock we offer them for a short time at the following special prices:

All-slatted bushel boxes, per crate of 14, \$2.25.  
Slatted bushel boxes, per crate of 12, \$2.10.  
Galvanized bound boxes, per crate of 12, \$2.75.  
In lots of 10 crates or more, 5 per cent discount.  
The all-slatted is the cheapest, and the most popular style. Two are nailed in each package, and sufficient nails are included for the remainder.

THE A. I. ROOT CO., Medina, O.

## Special Notices by A. I. Root

### T. B. TERRY AND "THE STORY OF THE SOIL."

Some of our readers may wonder that I have had so little to say about my long-time friend T. B. Terry since his death on the first day of this year. Well, it is not because I have forgotten him. There is hardly a day but that I think of him, and feel lonesome without his counsel. The matter was brought to mind by looking over the book, "The Story of the Soil," which our people have been offering to the readers of GLEANINGS at a ridiculously low price. Well, in this book there is a report of one of Terry's happy talks, given at a farmers' institute, that covers about 20 pages. That talk alone is, in my mind, worth the price of the book; yes, and GLEANINGS thrown in; and yet you are offered both the book and GLEANINGS for only \$1.15. Well, even if the 15 cents does not come anywhere near the cost of the book to us, the book will do a lot of good to the readers of GLEANINGS. See advertisement on the back cover of this issue.

## Convention Notices

The twenty-sixth annual meeting of the Illinois State Beekeepers' Association will be held in Springfield on Wednesday and Thursday, November 15 and 16, 1916. Further notice will be given in the dailies and individual notices with program sent to all the members of the association.

Springfield, Ill., Oct. 9. JAS. A. STONE, Sec.

# A Wonderful Book . . . .

This is the judgment of  
every thinking man  
who has read

“The Story of  
the Soil” By Prof. ;  
Cyril G. Hopkins

It covers the whole field of life on the  
farm, soil fertility, and perman-  
ent agriculture.

---

## What They Say About It

“Holds the intense interest of the read-  
er.”  
—Ohio Farmer.

“The farmers owe Mr. Hopkins a debt  
of gratitude.”  
—Chicago Tribune.

“Worth millions to the farmers of  
America.”  
—Prairie Farmer.

“Ought to be in the hands of every  
farmer in the world.”  
—Farmer and Breeder.

“I enjoyed every word of it. A fasci-  
nating novel about the soil.”  
—Editor American Agriculturist.

“A wealth of information.”  
—Editor Wallace's Farmer.

“The book is destined to do more good  
and stir more thought among the farmers  
of this country than any other publication  
that has yet appeared.”  
—Ex-Gov. W. D. Hoard.

## Don't Wait Till They are Gone

This book formerly sold for \$1.62 in cloth binding. A few days ago we secured from the publishers the entire remaining stock of this great book in paper binding and can offer it with “Gleanings in Bee Culture” for one year at \$1.15. When this consignment of these books is exhausted we shall be unable to furnish more.

**DON'T WAIT.** Get in your order today.

---

Gleanings in Bee Culture, Medina, Ohio

# Best and a Bargain

"The Busy Bee," 1 1-2 H. P. Gasoline Engine

**W**ILL you be wanting a gasoline engine during the next year? If so, there is a sure-enough bargain awaiting you now that may not be waiting next spring or summer. It is the chance (while they last) to buy one of our famous "Busy Bee" 1 1-2-horse-power engines for only \$36, if ordered of The A. I. Root Co., Medina, O. The Root Company unqualifiedly recommends this engine, especially for extracting power. They say that it is always satisfactory. Ask them.

These engines in the stock of the Root Company can be sold today at the low cost of \$36 only because they were purchased before January 1 last. When this stock of the Root Company is exhausted, this engine cannot be purchased at \$36 of anybody anywhere. It's a great chance for anybody needing an engine now or soon.

Fruitman and Gardener, 106 Main St. Mt. Vernon, Ia.

## WHY NOT

### Order Your Supplies for Next Season Now?

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 4 per cent discount during October. Send in your order just as soon as you find out just what you require and we will take care of it promptly.

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

# SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

## Shipping-cases in Flat, without Glass.

|                                                                |                          |

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT COMPANY, MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

**Extra Fancy.**—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

**Fancy.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

**No. 1.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

**No. 2.**—Combs not projecting beyond the box, attached to the side not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY 6, 1915.

**COMB HONEY.**

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades.*

Honey packed in second-hand cases.  
Honey in badly stained or mildewed sections.  
Honey showing signs of granulation.  
Leaking, injured, or patched-up sections.  
Sections containing honey-dew.  
Sections with more than 50 uncapped cells, or a less number of empty cells.  
Sections weighing less than the minimum weight.  
All such honey should be disposed of in the home market.

**EXTRACTED HONEY.**

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

**STRAINED HONEY.**

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.  
Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.  
Honey contaminated by honey-dew.  
Honey not properly strained.

## YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

"THE BUSY BEE MEN"

204 Walnut Street.

CINCINNATI, O.

## HONEY MARKETS

### BASIS OF PRICE QUOTATIONS.

The prices listed below, unless otherwise stated, are those at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

PHOENIX.—There is a marked increase in prices as well as inquiry for our amber honey. Amber in tin five-gallon cans, 2 to the case, offered at 6 cts. f. o. b. Phoenix for what seems to be the last car lot unsold as practically all of our season's crop has been sold. Wax is firm at 25 to 26.

Phoenix, Oct. 21. WM. LOSSING.

KANSAS CITY.—The demand for honey is not improving. However, we look for a better market with colder weather. We quote fancy comb honey, per case, \$3.00; No. 1, \$2.90; No. 2, \$2.75. White extracted honey brings 8½ to 9; light amber in cans, 7½; amber in cans, 8. Clean average yellow beeswax brings 25.

C. C. CLEMONS PRODUCE CO.  
Kansas City, Oct. 21.

BUFFALO.—We report a better demand for comb honey and all available stock on the market is clearing in good shape. Stocks on hand are light, and receipts continue small. We quote extra fancy comb honey, per lb., 16; fancy, 15½; No. 1, 15; No. 2, 13 to 14; white extracted honey, 8; light amber, in cans, 7 to 7½. Clean average yellow beeswax brings about 32.

Buffalo, Oct. 25. GLEASON & LANSING.

LOS ANGELES.—Only small lots of extracted are in the hands of producers. Dealers have about enough for local use. A large stock of comb honey is looking for a fair market, mostly in hands of producers; quality fair. We quote extra fancy comb honey, per case, \$4.25; fancy, \$3.85; No. 2, \$2.50. White extracted honey brings 8½; light amber, in cans, 8; amber, 7. Clean average yellow beeswax brings 35.

Los Angeles, Oct. 23. GEO. L. EMERSON.

ALBANY.—There is a good demand for straight grades of clover and buckwheat, while mixed quality sells at buyer's prices. We quote fancy white, 15; No. 1 14; mixed, 13; buckwheat, 13; mixed, 12. The crop is large, and we don't refuse reasonable offers rather than lose sale. Fancy comb honey brings 15; No. 1, 14; No. 2, 12 to 13. White extracted honey brings 8 cts.; light amber, in cans, 7 to 7½; amber, in cans, 7. Clean average yellow beeswax brings 30 to 32.

Albany, Oct. 25. H. R. WRIGHT.

TEXAS.—The long-protracted drouth has been broken in most sections of the state, which will, if we have late frost, give the bees a chance to replenish some much-needed stores. There is but little change in market since our last quotations. Beekeepers who did not have an established market for their honey, and for some time feared that they would not be able to dispose of their crop, are now finding ready sale, and most of them are pretty well sold out. We quote No. 1, bulk, in two 60-lb. cans, 10 and 10½; No. 2 ditto, 8 to 9, or light amber. Light-amber, in cans, brings 6 to 8. Clean average yellow beeswax brings 27 to 28.

Texas, Oct. 19. J. A. SIMMONS.

PITTSBURG.—Receipts are liberal, demand fair, and with continued heavy receipts any change will be lower. Extra fancy, per case, brings \$4.25; fancy, \$3.75; No. 1, \$3.25; buckwheat, \$3.00 to \$3.25. Pittsburg, Oct. 25. W. E. OSBORN CO.

CHICAGO.—Prices are ranging from 15 cts. to 16 cts. per lb. for the fancy to extra fancy, and 14 to 15 cts. per lb. for the No. 1 grade. Amber grades from 1 to 3 cts. per lb. less. Extracted—the best grades of white are bringing 8 cts. per lb., light ambers about 7 cts. per lb., and the dark ambers at 5 to 6 cts. per lb. Beeswax 30 to 32 cts. per lb.

Chicago, Ill., Oct. 18. R. A. BURNETT & CO.

ST. LOUIS.—Prices are unchanged since our last quotation. The demand for extracted honey is good, and comb honey is moving fairly well, with prospects of a better demand soon. Our market is not overstocked, but supplies are ample for the demand. We quote extra fancy, per case, \$3.75; fancy, \$3.50; No. 1, \$3.00 to \$3.25; No. 2, \$2.50 to \$2.75. White extracted honey brings 9; light amber, in cans, 7½ to 8; amber, in cans, 6½ to 7; in barrels, 5½ to 6. Clean, average yellow beeswax brings 28½.

R. HARTMANN PRODUCE CO.

St. Louis, Oct. 25.

PHILADELPHIA.—There is no special change in our market since last quotations. Market is in good shape for shipments of new honey. We have an outlet for fancy stock; can also move under grades at the right price. Let us know what you have. We quote extra fancy comb honey, per pound, 15 to 16; fancy, 14 to 15; No. 1, 12 to 13; No. 2, 9 to 10. White extracted honey brings 8 to 8½; light amber, in cans, 6 to 6½; amber, 5½ to 6. Clean average yellow beeswax brings 28 to 30.

Philadelphia, Oct. 25. CHAS. MUNDER.

BOSTON.—Demand for honey is good. Fancy comb brings \$3.75 per 20 frames; No. 1, \$3.25 to \$3.50; No. 2, \$2.25 to \$2.50. Extracted white, 60-lb. cans, eastern, brings 9½ to 12.

Boston, Oct. 24. BLAKE, LEE CO.

NEW YORK.—Nothing new to report. Conditions continue the same. HILDRETH & SEGELKEN.  
New York, Oct. 25.

HAMILTON.—Demand is good; quality is the best we have had in years. We quote extra fancy, per case, \$2.50; No. 1, \$2.25; No. 2, \$1.70; white extracted in 60-lb. tins, 12; light amber in cans, 10.

McNab Street Branch, F. W. FEARMAN CO., Ltd.  
Hamilton, Ont., Oct. 24.

TORONTO.—The situation since our last report of October 10 is unchanged, and prices ruling are the same as before. We quote white extracted, in 60-lb. tins, 12½.

Toronto, Oct. 24. EBY-BLAIN, Ltd.

LIVERPOOL.—We quote for salable parcels on this market as follows: Owing to very large arrivals of Chilean the market is quiet. Recent values on the basis of pile 3 are \$8.80, CIF; Hayti white is worth \$11.04 ex store. Californian in cases brings \$11.52 to \$14.40 per cwt. ex store, as in quality. Chilean beeswax brings \$34.25 per cwt.; Oto, \$39.00.

Liverpool, Oct. 9. TAYLOR & CO.

MATANZAS.—Light amber extracted in barrels brings 46 cts.; amber, 46 cts.

Matanzas, Cuba, Oct. 15. ADOLFO MARZOL.

MEDINA.—Somewhat contrary to our opinion, comb-honey offers have appeared from the West in greater numbers the past two weeks than usual at this time of the year, and the tendency in some localities is toward lower prices. We confidently expect, however, a stronger market soon. Extracted honey is firm.

Medina, Oct. 25. THE A. I. ROOT CO.

## Home Markets for Honey

If you are developing a local market for your honey, you will be interested in the following from a Wisconsin producer, who writes regarding the 64-page book, "The Use of Honey in Cooking." He says:

"We received the honey-recipe books O. K. and were more than pleased with them as they were one of the finest boosts for getting honey before the people that we could have procured.

"The people were clamoring for them and our booth was one of the leading attractions at the fair.

"One of the members of the association who was putting out small glass containers sold one to a lady from Minneapolis, who was attending the fair here. This morning he received an order that she had taken among friends at home to ship 25 gallons of extracted honey to Minneapolis. So it pays to advertise, and your recipe books do the work." (Name on request.)

We offer these books, "The Use of Honey in Cooking, 64 pages, 115 tested honey recipes, with many facts regarding honey, at 10 cts. each, postpaid. In quantity lots with your advertisement on the back cover (no other address given in the book) as follows:

- 100 copies, printed as above... \$ 4.50
- 250 copies, printed as above.... 9.25
- 500 copies, printed as above.... 17.25
- 1000 copies, printed as above.... 25.00

If sent by mail, postage extra.

Order a quantity and watch your honey go.

### HONEY-JARS

No. 25 one-pound screw-cap, \$4.75 a gross. Discount on quantity. Light honey, clover flavor, two 60-lb. cans, 9 cts. per lb. Sage honey, 9 1/2 cts. Catalog of apianary supplies and bees free.

I. J. STRINGHAM, 105 PARK PLACE, N. Y.  
Apiaries: Glen Cove, L. I.

### 3 Garden Tools in 1

**The BARKER** Weeder, Mulcher and Cultivator

The only garden tool that successfully, in one operation, kills weeds, and forms a complete soil mulch to hold moisture. "Best Weed Killer Ever Used." A boy with a Barker beats ten men with hoes. Has shovels for deeper cultivation. Self adjusting. Costs little. Write for illustrated folder and special Factory-to-User offer.

**Barker Mfg. Co.**  
Box 117 David City, Neb.

Established 1885

Send for our 64-page free catalog of Beekeepers' Supplies—full of information regarding bee fixtures, etc. Beeswax wanted for supplies or cash.

John Nebel & Son Supply Co., High Hill, Mo.  
Montgomery County

**BEE SUPPLIES** Send your name for new 1916 catalog.  
Dept. T, CLEMONS BEE SUPPLY CO.,  
128 Grand Avenue, Kansas City, Mo.

### CANDY

Bees sometimes starve with plenty of honey in the hive. Why not avoid this risk by placing a plate or two of candy on the frames when you pack for winter. It is a good life insurance. Send for circular also catalog of supplies.

H. H. Jepson, 182 Friend St., Boston, Mass.

**PATENTS** Practice in Patent Office and Courts  
Patent Counsel of The A. I. Root Co.  
Chas. J. Williamson, McLachlan Building  
WASHINGTON, D. C.

## HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual one. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

### Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. **PREPARE!** Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

#### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

**G. B. Lewis Company, Watertown, Wisconsin, U. S. A.**

Send for catalog giving name of distributor nearest you.

## DON'T FUSS

With your old combs and cappings, but send them to us. We will render them into beeswax for you on shares and pay you cash for your share, or we will make it into

### Dadant's Foundation

for you.

If you prefer, we will pay you our best trade price in exchange for BEE SUPPLIES.

Send for our terms. We feel sure that we can save you some money besides saving you a "mussy" job.

**BEESWAX WANTED** at all times.

**Dadant & Sons, Hamilton, Illinois**

# GLEANINGS IN BEE CULTURE

Published by The A. I. Root Co., Medina, Ohio.

E. R. Root, Editor  
A. I. Root, Editor Home Department

H. H. Root, Managing Editor  
J. T. CALVERT, Business Manager

Entered at the Postoffice, Medina, Ohio, as second-class matter.

VOL. XLIV.

NOVEMBER 1, 1916

NO. 21

## EDITORIAL

### GLEANINGS A MONTHLY AFTER JANUARY 1

WE have long cherished the hope of making GLEANINGS a monthly publication—one that might compare favorably with the standard magazines that now grace our tables. The time now seems auspicious for starting an improvement in this direction, and we feel sure that our readers, when they see what we are going to give them during the next year, will be delighted.

The first and foremost purpose of the change from a semi-monthly to a monthly is to give the editors of GLEANINGS the needed time to make a better and handsomer journal; for the financial fact is that the cost of the new monthly for a year will exceed the present yearly cost of the semi-monthly. While some economies will be effected in the amount of paper used and in mailing, this saving will be put into a better quality of paper, better printing, better engravings, better subject-matter, and a larger journal.

Practically all the magazines in the country are now either in the weekly or monthly class. There is no need of a weekly bee publication, and no good reason for continuing a semi-monthly if it stands in the way of an improved monthly publication of a higher class.

If, at the end of the year 1917, there should be a subscriber to GLEANINGS (now paid in advance for the next year) who feels that he has not had his full money's worth in the new and better monthly journal, we will then refund to him the amount of his subscription upon his request to do so.

A. I. Root will continue to give the readers of GLEANINGS nearly if not quite as much of his matter in the new monthly as in the present semi-monthly for two issues.

We are looking forward to a bigger and better GLEANINGS with enthusiasm, and hope and trust that every reader will share this enthusiasm with us.

### Asters Yielding Better after Frost

OUR Mr. Mel Pritchard, who has charge of our queen-rearing yards at the bass-woods, reports that bees worked well this fall on asters, but while the flow was at no time heavy it was continuous.

When we asked him if the frosts had not pretty well cleaned them out—"Cleaned them out?" he said; "why, I have always noticed that the asters yield better *after* frost than *before*."

A few days ago we had a very severe frost—so severe that we naturally concluded that even the asters that would stand ordinary frost would go down with all other vegetation; but they did not. Even at this date, Oct. 21, the asters are looking well;

and if warm weather is coming on they will yield something yet, according to Mr. Pritchard.

### Death of Prof. A. J. Cook

WE have known for some time that Dr. Cook, State Horticultural Commissioner of California, was in ill health; and we also knew that he was obliged to drop his work; but we were not aware that death was so near. We see by the *Western Honey Bee* for October that he died September 29 last.

Dear old Prof. Cook was one of the pioneers in modern beekeeping in this country in the early '70's and '80's. He was not only a prominent writer but one of the most

influential beekeepers in the country. A full sketch of his life will be given in our next issue.

### Our Cover Picture

THE picture on the cover shows one of the big irrigation ditches in southern California that has transformed what was formerly one of the great American deserts into one of the most productive localities in the world. Imperial Valley now contains four million acres under cultivation, with two million more that will be made available as soon as some of these big ditches can be built thru them.

It is one of the most fertile spots in the United States. The soil is deep and rich, and irrigation has supplied the one thing lacking—water. As alfalfa is one of the main crops it follows that beekeeping is an important industry. Usually bees follow where irrigation is opened up.

Unfortunately there have been two poor seasons in Imperial Valley; and, unfortunately, it is already overstocked with bees and beekeepers; but when those two million acres are opened with some of these big ditches there will be more room for beekeepers.

### Wintering Bees in Cheap Cases

AT our Strongsville yard, we have wintered bees very nicely by putting the hives about four inches apart in long rows, and crowding straw between the hives around them and on top. No straw was placed *in front* of the hives. Boards or roofing paper placed on top and at the back keep the packing dry. The plan answers very well in lieu of more expensive and (we may say) better winter cases.

The objection to it (and it is quite a serious one some open winters) is the drifting of the bees. The strongest colonies are apt to draw from the weaker. When the entrances are so close together, bees do not properly mark their locations. When the weather outside warms up, and the sun shines, and bees are out flying, they are apt to join the entrance of the strongest flyers. This makes the weak weaker and the strong stronger. We have observed the same tendency with the quadruple winter cases, but not to the same degree.

### Size of Entrances During Winter

THIS question is frequently asked. According to Dr. Phillips they should be contracted down during chilly weather, and still more during very cold weather. When

we raised the question as to whether these smaller entrances will not clog up with dead bees he came back by saying that, if the packing was ample, bees would not die on the bottom and lie there; that the hive would be warm enough so that the others could carry the dead out and dump them in front.

It has been our practice to contract the entrances at our outyards, which we do not visit except at long intervals, to 6 by  $\frac{1}{4}$  inch. Then once and sometimes twice during the winter we send a man to the yards to rake out any dead bees at the entrance passageways. While we have been wintering in these large winter cases with six inches of packing all around, and ten inches on top, we find a good many dead bees in the entrance passageways.

### Are Your Bees Packed for Winter?

IT will not be many days hence in the northern states when there will be snow with cold and piercing weather. The question is often put, "Have you put your bees away for winter?" The cold raw winds in November sometimes do a colony more harm than zero weather later on. Dr. Phillips, of the Bureau of Entomology, reports that a high wind of moderate cold will cool off the interior of a hive more than a still air considerably below freezing. We have found the same thing true in our own yards. Colonies that are wintered outdoors, and are not packed, suffer considerably; and if there is any brood in the hive when the temperature suddenly drops, it may become chilled. Wherever it is practicable, colonies should be packed in the fall as early as possible. As long as any asters or other fall flowers are in bloom, bees that are to be placed indoors should be left out till all bloom is gone.

Right here, colonies packed outdoors in October, or, better yet, in September, will fare much better than those in single-walked hives, subject to frequent changes of temperature and high piercing winds—especially winds that blow up into the entrances.

### Less and Not Less

THERE are fewer pages in this number of GLEANINGS than in former numbers, but not less reading matter. By restricting the advertising space as much as possible we are able to give GLEANINGS readers as much bee lore as usual in fewer pages. We do not expect this size of GLEANINGS to be permanent; but in the exigency of a very much overworked printing-plant we shall

contract advertising space and diminish the bulk of GLEANINGS, providing this can be done without injustice to our readers. So it happens that there is "less and not less" in GLEANINGS this number, and the same condition is likely to prevail in the next several numbers of our magazine.

### Honey-market Conditions and Prices

THERE is not much new to report except that the market seems to be improving some. In some localities, it seems to be fully as high as last year. In other localities the price is a little easier. The reader is referred to our honey-market quotations in this and previous issues.

While in the extreme West the season was far below expectations, and while the yield was a low average in Colorado in the early part of the year, conditions improved later on. The shortage of honey in Montana, Idaho, California, and particularly in the Imperial Valley, was enough to pull down the general average of the West. Had there not been a large yield of honey in the East, particularly in the clover regions, prices would have materially stiffened over those of last year.

As is usual, beekeepers are making the mistake of shipping their honey late. Carloads of comb honey are yet to be sent by rail. The danger of breakage when the weather is cold or freezing, the danger of starting initial granulation, the danger of breaking the market when all of these shipments are unloaded at once, and unexpected, are things that cannot be and should not be overlooked. Buyers remembering past years' experience, particularly that of last year, become disgusted when these late shipments pour in when they should have come in soon after the crop was taken off the hives.

### Importance of Windbreaks for Good Wintering

WE have already, in times past, spoken of the importance of windbreaks for protecting bees wintered outdoors. If we had to choose between windbreaks and single-walled hives or double-walled hives out in the open, we would unhesitatingly choose the former. We have learned here and about Medina that unless we have a screen of woods, hills, or farm buildings, we are likely to have some heavy losses, even tho the bees are packed in double-walled hives. Time and time again we have noticed that colonies that are exposed to a sweeping wind will suffer very much more than colo-

nies in the same yard that are protected by bushes, trees, buildings, or anything that shuts off piercing winds.

Those who are expecting to winter their bees outdoors should not forget the importance of a good location for the beeyard. A windbreak is almost as important in early spring and late fall as during winter. In the spring, colonies well protected will fly out to gather some pollen or nectar, while those exposed to high winds will not venture out. We have seen many instances of this in several of our yards. One year in particular the bees of the out-apiary on the side hill, screened on the north, would work on apple-bloom while those on top of the bluff, exposed to the winds, stayed indoors. Those protected built up faster than those exposed.

### Quadruple Winter Cases vs. Cellars

THERE seems to be quite a strong movement in Canada toward wintering colonies in quadruple winter cases with a liberal amount of packing rather than to put the bees in a cellar. It is claimed that the outdoor bees are ready for a harvest before those wintered in a cellar. This is because bees outdoors start brood-rearing earlier; and early breeding is important providing the brood-nest is well protected by packing.

The time was when cellar wintering in Canada was almost universal. While there are some who still prefer to winter indoors, the beemen of Canada now seem to be working over toward the outdoor plan.

What is good for Canada may be equally good for those of us who are located south of the Great Lakes. While cellar wintering has never been practiced to any great extent in most localities in Ohio, Indiana, Illinois, yet the tendency today is more and more toward the outdoor plan. The ideal beecellars are few and far between. If the temperature in a cellar can be uniform at about 45 or 50, and the atmosphere pure, bees will winter well; but if the temperature is variable, going down to freezing and at other times going up to 60 or 70, as it does in many cellars, the bees will become uneasy, and half or two-thirds of them will have dysentery before spring. On the other hand, when bees are well housed outdoors, variations in temperature do not affect them so adversely. Even if they do start brood-rearing, the very fact that they are able to get a flight every now and then enables them to keep themselves clean. If celled bees become uneasy, they will worry themselves to death or contract dysentery.

The fact that the tendency is toward

outdoor wintering in very cold climates as well as in the milder climates is rather interesting, going to show that beginners and sometimes experienced beekeepers will do well to follow the example of the large producer.

### How Far South Should Winter Packing be Used?

For the last thirty years it has not been considered necessary to use double-walled hives or winter packing for colonies located on or below the Ohio River. Dr. Phillips, of the Bureau of Entomology, made the remark this summer that the winter experiments conducted by the Bureau had led him to believe that some beekeepers in the South might with profit use winter packing. From some experiments with our Virginia bees, it is apparent that colonies that were packed were in better condition than the same-sized colonies in single-walled hives.

When we say "packed" we do not mean that the colonies must be in factory-made double-walled hives. Bees can be packed in straw or leaves, with a roof of boards or roofing paper, very cheaply.

If there is any advantage in packing colonies early in October and November in the northern states, would there not be some gain in protecting bees in the Southland where the temperature goes down to freezing and below, and where it is chilly and damp off and on for at least two or three months? While it is true that bees *can* fly in many of these localities every day, that very flying wears them out, and if they are not taken care of properly they will soon die. In a warmly packed hive, on the other hand, they will consume less stores and the brood will be protected when chilly bad weather comes on.

We are well aware that some of our friends in the South will poke fun both at us and Dr. Phillips; but if they will try out winter packing they may find occasion to change their minds.

### Spraying vs. Beekeeping

PROBABLY we may look for an ever increasing array of parasites and diseases, not only on our fruit-trees but on the shade-trees. The forces in nature that tend to tear down are always on the increase, and constant vigilance is necessary to combat them. This means that the beekeeper must realize that spraying of shade-trees as well as of fruit-trees is bound to increase, and the probabilities are that bee-poisoning resulting from spraying is likely to become

some day a serious matter in many localities just as it is now in a few localities.

Dr. Burton N. Gates, in charge of apiculture at the Massachusetts Agricultural College, and state inspector of bees for Massachusetts, has made a compilation of the known instances of alleged poisoning, with some recommendations for relief, in a bulletin on the subject, No. 10A, under the Massachusetts State Board of Agriculture. We believe this is the best and most authoritative statement on the spraying situation that has yet appeared.

Dr. Gates gives numerous instances of poisoning that have come under his own observation, and also takes from GLEANINGS and other bee-journals similar reports from other states. A report from West Newton, under date of June 16, 1915, is as follows: "Each morning there are many bees, sometimes 200 or more, on the ground, unable to fly, but trembling around until they die." Another from Middleboro: "The bees come home with white lead on their backs. In the morning you can see a quart of bees on the ground in front of their hives."

The poison is not only in the nectar, but in the pollen. Some peculiar features of the situation, as pointed out on page 18, is that certain colonies in an apiary may be affected, while others, apparently, are not. One beekeeper reporting for his locality says perhaps one apiary in ten is doing well.

The remedial measures mentioned on pages 18 and 19 are as follows:

"1. Legislation, which shall control spraying practices, overcome the spraying of blossoming trees, license contracting sprayers, and limit the indiscriminate, injudicious, and unnecessary use of poisons; the correction of mistaken state and municipal spraying practices.

"2. Educational campaign, which shall correctly inform users of spray poisons and reveal the errors and fallacies in current spraying practices; which shall promote the welfare of beekeepers.

"3. Co-operation of the manufacturer and distributor of spraying materials, compounds, and apparatus might be enlisted, to the end of furthering the educational campaign for sane spraying practices and the protection of bees.

"4. Development of spraying compounds which shall be repellant to bees. This, at the writer's suggestion several years ago, attracted the attention of scientists. It is hoped that benefits will result, yet it must be remembered that such experimentation is necessarily of slow progress."

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

*The British Bee Journal*, p. 256, suggests as a proper wholesale price for honey of first quality, 24 cents per section, and 16 to 17 cents a pound for extracted. Doesn't that compensate for the smaller yield they get in England?

J. L. BYER considers ridiculous the large entrance advocated by many, p. 909. Now that's ridiculous of you, J. L., to talk that way without telling what harm comes from it. I don't know whether you would class my entrance of 24 square inches as too large; but, honest Injun, wouldn't you rather have that than the  $1\frac{1}{2}$  square inches you tell about?

M. S. PHILLIPS says if you want to find out whether a nucleus has a virgin, don't give it unsealed brood, for then it will kill the virgin and start cells. Take a frame of *sealed* brood, pin on the middle a *sealed* queen-cell, and put it in the middle of the brood-nest. If any kind of queen is present, you will find the cell destroyed in a few hours. This looks like a valuable hint. [Yes; but if one doesn't have a sealed queen-cell what is he to do?—ED.]

JAMES A. STONE says he has no trouble in cleaning out the groove when combs have been cut out of a frame with groove and wedge in top-bar. Take an old-time three-pronged table-fork; cut one of the outside prongs off about  $\frac{1}{4}$ -inch; turn both outside prongs up like sled-runners, then you can plow the comb or whatever is in the groove clean out; remove the wedge and place it in the groove to push the tongue back, and let it remain a few minutes, when you can insert the foundation as easily as at first.

"IN supering, it is rare that a season is so favorable that lifting supers and placing empties beneath is advisable," says Wesley Foster, Sept. 1, p. 781. Locality, again? If there were no other objection, here, to giving supers above only, a sufficient objection is that such supers may have sealed sections in center with raw foundation surrounding, while, placed, below, all but the corner sections will be sealed alike. In a big flow here, if we don't find it advisable to add an empty *both* above and below, we think there's something wrong with the colony.

A DUMMY in order to get the first frame out of a hive more easily I earnestly advocated for years. A few months ago I went to figuring on it, and it wasn't long before I was convinced I had been wrong. With a dummy the outside layer of bees was less

than any of the inside layers, and surely the outside comb needed the greater protection. The outside comb sometimes had less brood than the others; with more bees to keep it warm, that might be bettered. I decided to test the matter fully, and, against the earnest protest of my assistant, left dummies out of a third of my hives during the season of 1916. For some reason the bees couldn't see the force of my figures and arguments. There was no increase in brood in outside combs. Unless extra time was taken to shove all the frames to the opposite side, taking out the first frame had to be done slowly to avoid killing bees—possibly a queen—and the bees were stirred up by it so it was hard to find the queen. When the frames were returned it took extra time to equalize the space at each side. Brace-combs made some trouble. Leave dummies off if you want to, but never again for me.

A. I. ROOT, you show good taste in liking milk out of the refrigerator with oatmeal and honey. I think I take a little more comfort by having in the evening *hot* milk with extracted clover honey, sometimes having in it bread made from whole-wheat flour that I ground myself. [My good friend, the above makes me glad several times. First, I am glad to know that you, like myself, are prolonging your life, probably because of simple living—milk and honey. In regard to the hot milk, whenever my digestion gets a little out of shape, say by being tempted to eat between meals or something like that, I too use hot milk. Sometimes I say to Mrs. Root, "Please let me have scalded milk, and have it hot, instead of cold milk, until I give further notice." The hot milk with toast soon gets me right again. And then, again, I am glad once more to find that you are cutting out a great lot of middlemen by making your whole-wheat flour yourself, and getting better flour than you can probably buy, even if you pay a big price for it in paper packages. By the way, doctor, I am going to feel awful lonesome if you die before I do; so please do not die just yet. A few days ago I had occasion to look over your book where it tells about how cheaply you lived on wheat away back in your schooldays. May God be praised that you are still with us, not only to live on wheat (and grind it *yourself*), but because you are able to give wise counsel to a great lot of "kids" who sadly need it.

P. S.—Say, doctor, do you still sing that grand old hymn, "The Rock that is higher than I"?—A. I. R.]

# BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

## THE HONEY MARKET.

Local retailers are selling comb honey at 10 to 20 cts. per section. The higher price is secured for the fancy and No. 1 grades, and the lower price for the cull honey, of which the beekeepers have quite a supply that is dumped upon the local market. The culls bring from \$1.50 to \$2.25 per case, according to weight and amount of finish, the weight running from nine ounces up. The average weight is probably fifteen to seventeen pounds per case, with the weight of the case subtracted.

There is a growing demand for comb honey in bulk, and some beekeepers are disposing of their cull comb honey in that form. The 5-lb. and 10-lb. pails, and 5-gallon cans are the favorite packages. This bulk comb honey brings 10 to 11 cents per pound according to package in which it is packed.

The market on extracted honey is good, and the price is higher than one year ago. Alfalfa extracted honey brings 7 cents in small lots, and a little less where a carload is taken. This is the price paid producers. At some points where freight rates are high, sales have been made on the basis of 6 to 6½ cents per lb. The extracted honey is very fine in color and body this year, and the flavor is all that can be desired in alfalfa and sweet-clover honey.

The comb-honey market has been rather slow, and sales have not been made as rapidly as the honey was prepared for shipment by the beekeepers. Western-slope comb honey has been sold for \$2.20 and \$2.40 per case. Cars of eastern-slope honey have brought from \$2.75 to \$3.00 for the fancy grade so far.

Honey-crop conditions have improved in Colorado during the late flow, as this has been good in some parts of the state that had a poor summer honey-flow. During September considerable honey was stored in supers in the Arkansas Valley and portions of the western slope in Colorado. The comb-honey crop has not been sold; but considering the crop in the East, sales have been better than could be ordinarily expected. The middle West has taken large amounts of honey, cities of 15,000 population taking comb honey in car lots. Of course, some of this honey is distributed in surrounding territory; but the fact that honey has not increased in price as have other foods has made a great difference in demand.

The local sales of honey have been much larger than common, partially owing to the very large tourist trade. Parties visiting Colorado by auto from states to the east and south have bought honey freely to take home with them. Our county produced at least fifteen cars of honey, and half or more of it has been shipped out, and there is not to exceed five cars left at this date, Oct. 11.

## WHY RETAIL AT SO LOW A PRICE?

Beekeepers are doing this more and more, and the practice is to be encouraged; but many beekeepers do not consider that it is advisable to charge a price high enough so that one can get paid for the additional work necessary. One beekeeper has been putting extracted honey up in 10-lb. friction-top pails, hauling it by auto for a hundred miles, and peddling it out from house to house at 75 cents per pail.

Another beekeeper advertises in his local paper to sell extracted honey at five cents a pound.

Now, this first beekeeper who is selling extracted honey at retail at 75 cts. for 10 lbs., has nice honey, and I have sold and am selling in the same territory cases of six 10-lb. pails to the grocers at \$7.50; and wholesale grocers are charging the retail grocers about \$8.00 for six 10-pound pails. It is not necessary, nor good business, to retail honey at less than carlot prices.

The retail grocers are the ones who sell the bulk of our honey crop; and if it were not for them we should have a hard time selling our crop. If we retail honey, and compete with them, let us hold up the price any way; and when we sell to retailers, sell at a price sufficient to give a fair profit to them and ourselves also.

Suppose extracted honey is worth 7 cents wholesale in 60-lb. cans. When retailed in smaller packages it ought to bring not less than the following prices:

Six 10-lb. pails, \$7.00; one for \$1.60; 12 5-lb. pails, \$7.40; one for 90 cts.; 24 2½-lb. cans, \$8.00; one for 35 cts.; 12 pints (glass), \$2.40; one for 25 cts.

Some Colorado dealers are selling for more than these prices, and a few for less.

\*\*\*

Colonies slow about entering the supers, and strong on clustering out, may be driven into the supers by raising the hive from the bottom-board with small blocks. This cools off the lower part of the hive, gives ventilation, and forces the bees to seek the warmer part of the hive to store honey and build comb.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

## CONNIVINGS OF HONEY-BUYERS.

In the *Western Honey Bee* for October appears what purports to be a confidential conversation with a buyer representing a Los Angeles firm. The conversation was given to show how the buyers connived to fix the price on honey for the season, and to describe the method used. Let me quote: "As the honey season advances, and some honey begins to be reported in the apiaries, our firm, or one of the others, selects a certain beekeeper, not one of the large producers, but one who usually has from two to five tons to sell, and always one who *has* to sell." Continuing, the writer says the buyer drives the sharpest bargain possible, and in twenty-four hours every buyer on the coast knows of the sale and the price paid, thus establishing a precedent. I will not comment on the plausibility of the story, or how such confidential matter has found its way into print; but it seems to me the buyer, instead of going to all of this trouble, could find a better lead by using one of their contracts in which the beekeeper contracts a crop that is only in prospect, at a figure too small to display good judgment. I know of at least two beekeepers who contracted their honey this year, before one drop of it was gathered, at 5 cts. a pound. The first offers for the 1916 crop were around six cents. Who was to blame?

## THAT FULL-PAGE HONEY AD.

When I saw the full-page "Airline" ad. in the *Ladies' Home Journal* for October, I meditated over its influence on the readers, millions of them. It occurred to me that we get just about what we pay for. Here is an advertisement that surpasses anything of its kind that has ever been undertaken. Such extensive advertising will bring results; and while the advertisers will reap a benefit, a demand will be created for honey thru such advertising that will find its way to the producer for a supply to fill the demand. The entire beekeeping fraternity will be benefited directly or indirectly, while the bill will be paid by one firm. But, as I was saying, we get just what we pay for; so if we pay one and a half dollars into an association we shall not get to exceed that amount in return. If it were possible for beekeepers to form an organization that could establish a brand and keep a stock on hand to fill a demand created by extensive advertising, such as the one just mentioned, we would get returns in propor-

tion. But that will never be done by the beekeepers, for they will furnish neither cash nor honey for such an enterprise. So let us take off our hats to "Airline" and wish it all the success possible, for I predict it will be one of the greatest factors in the honey market of the country in a few years. In it there is offered a continual supply, of a definite color and average flavor, which, in time, will make it a table watchword.

## SHALL WE SAVE THE LAYING-WORKER COLONIES?

On pages 865, Sept. 15, Mr. E. S. Miles advises saving layer-worker colonies. Like Dr. Miller, I believe the best cure is to break up the colony. To my mind it is impractical to save such a colony. We may add brood and bees, eventually getting a queen to laying, but this is done at the expense of other colonies, and virtually amounts to building a new colony. The best way I know to relieve a laying-worker condition is to give such a colony a frame of brood containing eggs, then exchange stands with a strong colony. The bees from the strong colony will soon put an end to the laying workers, and raise a queen.

This fall I had about fifteen colonies that went queenless by not having close enough attention after extensive requeening operations. There was a good supply of bees; but all except two had degenerated into laying-worker colonies. It was to my advantage to save them at this time of the year if possible. Ordinarily I would have doubled them up with other colonies; but as it happened this time I had a number of two or three frame nucleus colonies, containing a queen and a small amount of bees that could not possibly winter without the addition of brood. In trying to introduce the queens into the laying-worker colonies by the bee method I found the supply of bees was too small to protect the queen, so I lost several queens where the entire nuclei were set into the laying-worker colony. I finally succeeded by taking the laying-worker colony off a distance and shaking the bees off the combs on to the ground. I then set my nucleus into the fertile-worker hive which was given the place of a strong colony, while the strong colony was given the place of the laying-worker colony. The results were entirely satisfactory, and, thanks to the bluecurl flow that followed for three or four weeks, all came up to winter with a good force of bees. But in this process I do not figure that I saved the laying-worker colonies.

# NOTES FROM CANADA

J. L. Byer, Markham, Ont.

## THE HONEY MARKET.

The honey market in Ontario is still better than when I wrote for the October issue. The big crop seems to have disappeared, and at this early date, October 13, I find it impossible to buy any honey at a price that would let me out, unless I sold it locally at a figure higher than I obtained for my own crop. High prices of other food products, good wages among the masses, and an unusually fine quality of honey, seem to be the factors that have brought about such conditions. At any rate, contrary to the usual state of affairs, the late market will this year be just as good as or better than the early, and I have not the least fear but that all the honey will be cleaned up before next year's crop comes on the market; in fact, I have my doubts as to much of the crop being available in a wholesale way after the first of the year.

## WHY WE FEED SUGAR.

On page 932, Oct. 1, A. C. Miller chaffs Mr. Crane for admitting that he has fed "tons and tons of sugar syrup," and incidentally claims that such practice is not necessary if "improved methods" are used. Being in the same boat, so to speak, as Mr. Crane, so far as the feeding question is concerned, we naturally would welcome some good plan that would help us to do away with the feeding problem, and at the same time give us good results in wintering. With this desire in my mind, let me briefly outline conditions as we find them here in our home district. Our main flow is from alsike clover; and at the conclusion of that flow, in about four years out of five we find brood-nests with but little honey in them, the most of the combs being filled with brood. After taking off the clover honey, super combs are returned to the hives, if for no other reason than to protect them from the moths; for with thousands of such combs it surely is a job to keep them from being ruined if not given to the bees to be cared for. About Aug. 1 our buckwheat flow starts; and while one super would as a rule take care of all the surplus we get from that source in our district, yet we hesitate to reduce them to that number by reason of the moth nuisance as before outlined. Even with two or more supers on a hive, with hives as large as the ten-frame Jumbo, sufficient honey will go into brood-nests at this time for winter stores *if the flow is not heavy*. With a hive of the eight-frame L. capacity run for extracted honey,

feeding will nearly always be necessary. With a good flow from buckwheat—say 40 to 60 pounds in our locality—even the Jumbo hives will need feeding after supers are off.

This year has been an exception to much of the foregoing; for during the last ten days of our clover flow, which lasted longer than usual, queens, whether young or old, let up in brood-rearing, and the majority of the hives were jammed with clover honey, even when abundant super room was still present. With a very light buckwheat flow, brood-rearing was not increased to the same extent as in other years, and this clover honey was left in the brood-nests so that little feeding is necessary. This is one year out of the five referred to, and in no way clears up the question as to what to do to avoid feeding in the other four years.

Would Mr. Miller advise keeping sealed combs of clover honey when honey is the price it is here in Ontario? In some seasons the keeping of such honey would mean the whole crop. Would he take off the supers during the buckwheat flow? and if so, what would he do with, say, some 15 or 20 thousand such combs, in order to protect them from the moths? In any locality where there is a fall flow as late as the middle of September the feeding problem is solved at once; for, no matter whether supers are on hives or not, honey coming in at that date will, to a great extent, go into brood-nests, as queens always slack up brood-rearing at that season. We have learned this much by establishing the yard up north, as there we have aster and golden-rod in September, and feeding is never such a big job as we often run up against here in York Co., where August sees the last of our honey-flow.

## THE CONDITION OF THE CLOVERS.

Since sending in my last batch of Notes, refreshing showers have visited many sections of Ontario, and once more the grass is looking green. But conditions as to the crop of clover for next year have changed but little, as alsike grown for seed is our main source of honey here in York Co.; and the long-continued drouth, coupled with the extreme heat of late July and early August, played havoc with the freshly seeded areas, and the acreage of alsike for next year will be very small. Judging by conditions at our north yard in Simcoe Co., where more white clover grows than here in our home section, the white clover seems to have stood the drouth better than expected.

Grace Allen

# THE DIXIE BEE

Nashville, Tenn.

The Tennessee State Fair came very near having the State Guard as the main attraction this year, for we had two regiments camped on the fairgrounds nearly all summer. Thousands of visitors went out there every week, especially on Sundays, when the soldiers were reviewed and paraded around the race-track, with regimental bands playing, flags flying, lots of saluting, and a general thrilly, military atmosphere. One of the Drane brothers, of Memphis, and Mr. Wyant (beekeeping soldiers all) took us down into a wonderful trench built out on the grounds by Company B, 1st Regiment. The bomb-proof part was cosy enough to play house in; but one turns sick thinking of trenches these days. They also escorted us to, *not into*, the barb-wire entanglements beyond. Orders from Washington sent the troops down to the border just two or three days before the fair opened. The bee and honey exhibits were in the building formerly containing the guard-house where the prisoners were kept.

While there were not many exhibitors, there were some right good-looking and interesting exhibits. Of course people passing by are always attracted by the live bees, and eager to find the queen (or, about as often, the king). Mr. Buchanan's "Home, Sweet Home," made by a clever arrangement of comb honey in sections and full-size frames, made quite a hit.

\*\*\*

From Forsythe County, North Carolina, come reports of very poor crops this year. Some yards yielded no surplus at all, others averaging twenty or thirty pounds. "Weak colonies," one correspondent writes, "have died and hunger-swarmed practically all the year. A light flow is now coming in from several plants of the *Composite* family. Unless aster yields well, our winter loss will be 50 per cent." Judging from present conditions here in Tennessee, I suspect aster has come nobly to the rescue.

\*\*\*

## THE GREAT VARIATIONS IN TEMPERATURE.

It seems to me as tho these fall months, with their wide variation between the maximum and minimum daily temperature, must be rather hard on the bees. They have not yet formed into compact winter cluster, and to a great extent even have eggs and young brood, so they are maintaining high temperatures in the brood-nest, around 93 and 95 degrees, as I understand. In the daytime

it gets warm enough so they are flying, working on aster and goldenrod or some other fall flow, then at night down drops the outer temperature so low that it surely must require a considerable expenditure of energy to maintain the necessary warmth. One day in September I noticed the temperature in places in Utah, Montana, and British Columbia, varying 34 degrees between maximum and minimum, and one report from Colorado showed a variation of 36 degrees, from 74 down to 38. Even Nashville that day slid from 73 to 50, a difference of 23 degrees. And none of these are anything rare or unusual. In the summer there is a daily variation, yet it is always fairly warm. In the winter there is a variation, yet it is always fairly cold; but in these transitional months it seesaws up and down from summer temperature to winter temperature in a way that would seem to be rather disconcerting to the bees.

\*\*\*

Mr. J. F. Archdekin, urging co-operation for beekeepers, especially in the matter of selling honey, says, page 658, "Co-operation has always been a distinguishing feature of the human race." And so it has, in limited times and places. But it is certain that, so far as we know, co-operation has *always* been a distinguishing feature of the hive. And some day (slowly, perhaps, but surely) beekeepers are going to show themselves as capable of intelligent co-operation as the bees with which they work.

Of course the reason a great many beekeepers seem indifferent to such suggestions is the simple fact that the marketing of their crop has not yet become a problem for them. They have good local markets and not much competition, and so do not feel the necessity of working hand in hand with other producers.

\*\*\*

## Instinct.

I wonder when these bees of ours  
 Learned the things they know.  
 Some countless ages back perhaps?  
 Or just some weeks ago?

I wonder where they learned them all.  
 In far-off, ancient dells  
 Of fig and olive? Or right here  
 Within their waxen cells?

I wonder, yet I cannot tell,  
 As back and forth they go,  
 When or where or how they learned—  
 I only know they know.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

## DISTURBING BEES IN WINTER.

A correspondent writes that it will soon be time for the bees to go into winter quarters, and wishes to know if it will do any harm for him to look at them occasionally during their winter nap. He says an old beekeeper told him that he examined the bees at all times of the year, and in all kinds of weather, and that it did no harm.

I am well aware from past experience how any one having a bad case of the "bee fever" can be amused by looking at them during winter; but from that same past experience I think it far better to amuse ourselves in some other way. During the spring and summer, when the bees are able to fly, a little disturbance is not injurious, and at certain times a manipulation of the hives and combs may be made very profitable, especially if it can be done when there are no robber bees prowling about to pounce upon their stores. If the apiarist is thoroly informed on the condition of each colony of bees as to their needs he can better supply them, in time to be of the most service. But in cold weather the novice cannot be too much warned against the ill effects of a disturbance of colonies, whether they are in the cellar or in the open air. Bees at such times are closely clustered together in as compact a shape as the combs allow.

If a hive is carefully opened it will be noticed that the bees' heads, so far as may be, are all turned toward the center, and that they move but little, all their efforts seemingly tending to gain access to the warmest spot. If outdoors the disturbance causes them to "break the cluster" to ascertain and drive off the danger. If the weather is around the zero mark many will become numb, and perish before the cluster can be properly formed again. If in the cellar, the disturbance may cause more trouble, as the bees will become more alert to drive off intruders, and many fly out and get lost on the cellar bottom. And if the disturbance is long continued, the bees will fill themselves with honey, and in turn feed the queen, which will result in premature breeding, bee diarrhea, and death. Thus quietude is almost indispensable.

If the novice must satisfy his curiosity he must do it at the peril of the bees. If food for each colony has not been supplied before the bees go into winter quarters, it is a difficult thing to supply this now without risk. The proper time to feed is as soon as the last flowers which give a sur-

plus have gone out of bloom—during the last half of September and the first half of October, here in the northern states. Then frequent disturbance causes the bees to become fearful that they may be driven from their stores, consequently they fill themselves with honey to overloading, and then, when the disturbance ceases, they unload it back into the cells again. But this filling with honey and putting it back in the cells brings on an excitement which has caused them to consume more than they otherwise would, and there is consequently overloading of the intestines. And as bees are so cleanly that they will not discharge the feces in the hive unless they are positively obliged to, their anxiety for a chance to get into the open air causes them to break the cluster and raise the temperature in the hive to summer heat, which makes brood-rearing almost a necessity, even in mid-winter, the result of which is a worn-out vitality, which gives what is called "spring dwindling," so that the old bees nearly all perish before the bees emerging from the brood become plentiful and strong enough to build up.

There are times in winter when it will well pay to look after the bees that are on their summer stands. It is when a warm day comes, in which the temperature rises to from 45 to 60 degrees in the shade, with no wind, or nothing stronger than a breeze. If the hives are surrounded with snow, it should be shoveled away and the entrances to the hive cleared of dead bees so that the bees can have a flight and empty themselves of their feces. Some even recommend that, if the bees are slow about coming out, or if the hive is in the shade, the hive be pounded on gently, so that the bees may become aware of the warm atmosphere outside. But I have found more trouble from the bees coming out and becoming chilled on the snow with the mercury standing at from 35 to 40 degrees in the shade, when the sun is shining brightly, than in their staying inactive when it was warm enough for them to fly safely. At times when bees come out and are lost on the snow it is best to shade the entrances by setting up a board in front of each hive, or by sweeping snow against the front.

If any colonies are known to be lacking in stores, such warm days in winter are just the time to supply them by putting in the number of combs of sealed honey which will be required. This is far better than to try to feed syrup or honey in cold weather.

# GENERAL CORRESPONDENCE

## AS GLIMPSED THROUGH THE CAMERA

### A New Wrinkle in Wax Rendering

BY H. H. ROOT

In rendering wax with what is often called the unheated press the idea suggested itself to me of introducing a small jet of steam into the can holding the water and wax and the refuse under pressure somewhat after the scheme described by E. F. Atwater, p. 138, March 1, 1909, but I decided that it would not be feasible without access to a good head of steam from a large boiler. Later on I thought of it again, and, as before, finally came to the conclusion

the vertical cleats around the side of the can and extends over toward the center between two of the horizontal cleats.

I dipped a couple of gallons of melted comb and water into the press, and immediately I heard a great gurgling and sputtering as the hot water and wax surrounded the end of the pipe from which steam was blowing. While the pressure was being applied the water and wax kept up a gentle boiling—an ideal condition. This was some-

FIG. 1.—Steam from a small boiler introduced between the slats in a wax-press can. The water and wax keep up a continual slow boiling, insuring constant circulation.

that, even if it did work, having an extra stove around to bother with would hardly pay for any advantage that the plan might present. One day, however, I resolved to try it, still having but little faith.

I took a steam-knife outfit, disconnected the knife, and put on the end of the hose a piece of  $\frac{1}{4}$ -inch copper tubing, about 14 inches long, with a right-angle bend 5 or 6 inches from the bottom, and a long curve at the other end. This I applied to the wax-press can, as shown in Fig. 1. As will be noted, the pipe goes down between two of

thing I had not thought of, my idea having been only to prevent the water and wax from chilling. The gentle circulation of the contents of the can is really the principal point of advantage; for, no matter how long the pressure is kept on the slumgum, nor how many times the screw is raised to allow the hot water to saturate the refuse again, the water keeps up this gentle boiling, so to speak, and the wax on top shows no tendency at all to cool off. The introduction of the steam adds so much to the efficiency of the method that I think there

F. G. 2.—Complete outfit for rendering wax. The two hoilers on the stoves are for making the combs in water. The water and wax in the press are kept hot and constantly circulating by a small jet of steam generated over the small stove.

FIG. 3.—The press can be pulled forward ready for filling.

is no need for running the refuse thru a second time. Some wax is left, I know; but a very small amount after all if the work is carefully done. In fact, I think the refuse is cleaner than I have ever seen it before, even after it has been run thru a press twice; and there is no hop-skip-and-jump, nor any need of covers or any other special precautions to prevent chilling of the wax in the press, so long as there is water in the boiler and gasoline in the tank of the single-burner stove.

#### SOME OF THE DETAILS OF RENDERING WAX.

It is some time since we gave in GLEANINGS the process that we recommend for rendering wax. No doubt there are other plans just as good or better; but this plan, except for a very large production of wax, requires the least expenditure for equipment of any with which we are familiar.

Fig. 2 shows the complete outfit, including stove, press, steam-boiler, unmelted combs, the pressed refuse, etc.

A large cookstove with a top big enough to hold two good-sized wash-boilers is ideal; but frequently it is inconvenient to provide such a stove in a basement or outbuilding where the wax-rendering would be done. Two double-burner gasoline-stoves, one for each boiler, will do just as well therefore. Oil-stoves would answer the purpose all right for melting the combs, but would not be as satisfactory for generating steam in the small boiler as a gasoline-stove, owing to the difficulty usually in turning down the blue-flame oil-burner. The wash-boilers cannot be cleaned very easily; hence they

should be kept for this purpose only. Many prefer to use a large square tank of galvanized iron. Or a "feed cooker" may be used, costing anywhere from three to fifteen dollars.

The press should stand on a good solid box that is firmly anchored to the floor. It should be hinged in front so that it may be tipped over to run the hot water and wax into the can beneath. A large box or basket should be provided for the refuse after it is pressed.

When ready to begin work, one of the stoves should be lighted and a boiler of soft water put on to heat. If the water is very hard add a little vinegar. When the water is boiling throw in the old comb. It is astonishing the amount of comb that can be put into one boiler. Thirty-five to forty combs (half barrel) may be put in gradually, provided they are carefully pushed down with a paddle and stirred as they melt. When all the comb is in that the boiler will hold conveniently the cover should be put on and the mass allowed to cook thoroly. About this time the other stove should be lighted and another boiler of water put on. The burner under the steam-boiler should also be set going. It makes the "cheeses" more porous and really facilitates the work if a quantity of straw, preferably rye straw, cut up in two-inch lengths, is stirred in with the melted comb.

It is a mistake to begin pressing as soon as the comb is all melted up. The cooking process must be continued with frequent

FIG. 4.—A large piece of stout burlap is the best material to use for holding the melted comb.

FIG. 5.—Applying the pressure. The wax rises to the top of the water. As much time may be given to the pressing as desired—no danger of chilling, because of the jet of steam.

stirrings until the contents of the boiler is reduced to a steaming mushy mass. There must be no lumps or hard chunks.

When the contents of the first boiler is ready for pressing and the steam begins to issue from the pipe in the bottom of the press-can, pull the can forward on the platform, holding it in position by means of the spider on the lower end of the screw resting on the top of the can, as in Fig. 3. Have ready a few pieces of good strong burlap, at least 40 inches square. Place one of these in the press-can; put the follower on top of it and throw a few dipperfuls of hot water from the other boiler into the can to heat thoroly all the parts. Pour this off and spread the burlap down into the can as in Fig. 4. Dip about two gallons of the melted comb and water into the press and fold the burlap neatly over it, as carefully as tho you were tying up a package. This is very important; for if there are thick rolls of the cloth in any one part of the "cheese," other parts of the refuse will not receive as much pressure as needed. To fold the burlap over, fold the back edge over toward the front, being careful to get the sides straight; then push the front edge over on top of it; lastly, fold in the sides neatly. Place the cleated circular follower in position (down of course); push the can back exactly in the center of the platform, and run the screw down very slowly—Fig. 5.

At this time it may be necessary to turn

down the gasoline-burners under the first boiler in order that the contents may not get too hot; or, if it is on a stove, pull it over to the edge. Always use the utmost care to prevent the wax from slopping over. If it does, there is danger of having a serious fire. As soon as the water in the second boiler begins to boil, begin filling that with combs.

Always turn the screw down slowly. If it is run down rapidly before the liquid in the mass inside the burlap has time to squeeze out, the burlap and the contents inside are likely to squash up around the follower, interfering seriously with the escape of the water and wax. Turn the screw only when it turns easily. Of course, when it is clear down it may be turned tight; but there is really more danger in applying too much pressure than in not applying enough.

Sufficient water should have been dipped in with the comb so that the water and wax when the screw is clear down will just about submerge the iron spider on the end of the screw. It ought to take two or three minutes to get the screw clear down. When it is down about as far as it will go, release the pressure until the cast-iron follower is nearly out of the liquid; pull up on the rope handle of the wooden follower until it is free from the burlap, thus allowing the hot water to saturate the refuse again. After a minute or so apply the pressure slowly once more. This process should be repeated two or three times.

When the screw is finally down as far as it will go, place a wash-tub or a large can on the floor in front of the press and tip the

FIG. 6.—When the pressing process is completed the whole outfit is tipped up on its hinges to pour off the hot water and wax.

latter over, pouring all the water and wax out. Leave the press tipped over a few moments until all the wax drains out—Fig. 6.

When no more wax will drain out, tip the press back into its regular position and pour the hot water and wax into an empty can or barrel having a faucet at the bottom. If a barrel is used which is smaller at the top, the hot water must first be drawn off after the work is over, and the wax run into previously soaped molds to harden. It is more convenient to use an oval-shaped can or round can that is larger at the top, so that the wax may be left right in it to harden in one large cake. There is no difficulty in lifting the cake out, even tho it be 8 or 10 inches thick.

The idea of the faucet at the bottom is to permit drawing off the hot water, so that it may be used over and over again. There is no object in using fresh water each time; therefore when the first boiler is empty enough hot water may be drawn off from the supply-can to fill it half full again for a fresh lot of combs. When first starting out, it is a good plan to fill the boilers a little more than half full so that there will always be enough water for subsequent meltings.

If the work has been carefully done, when the screw is raised after the water and wax have been drained off, and the follower taken out, the "cheese" will be dry, comparatively speaking; and when it is dumped out into the box or basket, if a handful is taken up and pressed momentarily between the fingers, no great amount of wax will show. If only a very fine line of wax appears in the ridges between the fingers you can depend on it that you have done your work thoroly. It is hardly necessary

to say that it is convenient, if not absolutely necessary, to wear a pair of canvas gloves during the whole process; for when the burlap is shaken out the refuse is exceedingly hot—very much hotter than when a jet of steam is not introduced into the press-can. When shaking out the burlap, if the refuse does not shake out clean, lay the cloth over the box, inside down, and quickly rub it between the hands. This will dislodge the refuse still clinging. Now place the burlap over the press again and repeat the process. The same burlap should last for a dozen pressings. Each time you shake it out, however, look it over quickly to see if there is any sign of a weak spot or the beginning of a tear. If there is, discard it and use a new cloth.

A heavy rug or old sack should be thrown over the unheated can containing the supply of hot water and wax, poured in from the can under the press; for the more this heat can be saved the shorter time it will take to start a new boilerful of combs.

The final waste of wax by this process need not be over 3 per cent. There is no process that we know of that secures *all* the wax. The quality of wax from this press is the every best, needing only a little scraping on the bottom to be ready for market. The color is good, and there is no need of refining it afterward.

When diseased combs are rendered, especially those containing some honey, every precaution should be taken to prevent the bees from robbing. If the buildings can not be made bee-tight, the work must be done at night, and every tool and utensil used thoroly scalded. The refuse from the diseased combs should be burned, and the water which was used poured where the bees cannot possibly get access to it.

---

## SOME OF THE THINGS I HAVE LEARNED IN THIRTY YEARS

BY N. SCHNETTLER

In 1885 I bought a colony of bees in the trunk of a tree; but having no success with them I bought two more colonies in Langstroth hives. I had three swarms that summer, and later on increased to 25 colonies.

After that I moved to Nebraska, and worked at the mason trade. I bought some bees and started in again, but without success, for there was so much wind, and in this particular locality where I was there was no white clover nor linden. In 1899 I decided to come back to the old Badger state.

In the spring of that year I bought a colony in a Langstroth hive for \$7.00.

Within seven years I had increased to 100 colonies. Now I have 225 colonies, and that is my limit; for during the last few years I have made only enough increase to atone for winter losses.

### MY EQUIPMENT.

It is easy enough to control swarming if the bees are given sufficient room in time. I use the sectional or divisible-brood-chamber live, so that I can interchange the upper and lower story. I use a flat cover overlaid with single-ply roofing-paper, which makes a waterproof cover that is inexpensive.

The bottom-board is made of matched

N. Schnettler's 225-colony apiary at Valders, Wis. Mr. Schnettler allows only enough increase to make up for winter losses.

Mr. Schnettler allows only enough increase to make up for winter losses.

lumber with  $\frac{3}{4}$ -inch strip on the sides and back for the hive to rest on, so that there is a  $\frac{3}{4}$ -inch entrance. I have contracting-cleats to close this space to  $\frac{3}{8} \times 7$ , or  $\frac{3}{8} \times 2$ .

I use ten-frame hives because the brood-chambers will then always have some honey in the outside combs. When a super is taken off from an eight-frame hive, sometimes there is not a pound of honey left in the brood-chamber. This is why I prefer the large hive.

#### MY CELLAR.

I keep all of my bees in a cellar during the winter, the dimensions of which are  $13 \times 41$ , and 7 feet high. The walls are stone, 2 ft. thick;  $2 \times 4$ 's laid flat are spiked to the wall, the wall is then lathed and plastered, as is also the ceiling.

The floor is made of small cement tiles laid close together on ground made perfectly level. A one-inch coat of concrete over the tile makes the driest floor possible, and that is what the bees want—a dry and well-ventilated cellar.

For ventilation I have a six-inch galvanized pipe at each end of the cellar, the one on the east side coming down to within one foot from the floor, and the one on the west side about two feet from the ceiling. Each pipe runs up thru two elbows and on thru the roof, the one on the east side hav-

ing a half-cover that always turns with the wind, and the one on the west side with a windcatch that always faces the wind. I have the inlet pipe on the west side, because we have the most wind from that direction. By this plan the foul air is forced out on the east. I have a line 180 feet long running east and west that I use to carry the bees in and out of the cellar. I usually put them in during the latter part of November and take them out in the first part of April. I always bring them out in the night.

I produce extracted honey mostly. I have a power extractor, and it is fun to watch it run instead of being obliged to run it by hand.

The little Ford shown in the picture is my honey-peddler. There is nothing handier about an apiary than a little car for delivering honey. I made a platform that fits on top of the rear seat when the cushion is removed, extending over to the front seat. Two screws hold it in place. I can carry fifty 10-lb. pails or even the large cases of honey. When I receive a telephone order for honey I can deliver it very often inside of twenty minutes. I bought the car in 1913, and it runs better than when I first got it.

Valders, Wis.

## NOTES FROM GERMANY

BY J. A. HEBERLE, B. S.

### THE QUEEN-EXCLUDER.

The advance beekeeping has made in less than a century—in fact, the difference between ancient and up-to-date methods—is

chiefly due to four inventions—the movable frame, the extractor, comb foundation, and the queen-excluding board. The value and the merit of the three first inventions have

never been doubted; but the queen-excluder, from time to time in articles published in the German bee-journals, has been adversely criticised. Of course, such articles have always been answered by some who recognized the great benefit of its proper use.

#### THE QUEEN-EXCLUDER.

Some beekeepers called it a nuisance to the bees; others, an instrument of torture. This was said especially of the perforated zinc sheet excluder. Perhaps such criticism has stimulated the inventive genius. The list of bee-supplies was increased by a queen-excluder of "papier-maché" of any size, and by excluders entirely of wood. The wooden excluders are certainly handy for the bees where they are of suitable size; however, these are mostly very small, about 3 x 10 inches. I consider an excluding-board the size of the brood-nest just right.

We have now on the market two kinds of wire excluders. I consider them preferable to the zinc sheet excluders, altho I have only the latter in use.

#### SHEET ZINC EXCLUDERS.

These, after they are stamped, have on one side very sharp edges. Even a treatment with wire brushes does not remove all of them. It is these sharp edges that abrade the natural hair dress, and may inconvenience and injure the bees, some of which have to pass them heavily loaded. These sharp edges may easily be beveled off and made smooth by passing a suitable tool over the edge of each perforation. A few minutes suffices to bevel the edges of an eight or ten frame excluder.

#### DIPPING EXCLUDERS IN WAX.

After the perforations have been made smooth, the excluder might be further improved by dipping it in hot wax and hanging it up with a wire to let the surplus wax

drain off. The hotter the wax the thinner the coating. Such a wax-coated excluder pleases the bees much better than the bare metal. The coat of wax reduces the heat-conducting quality, and offers a better foothold for the bees.

#### ANOTHER WAY.

Besides using excluders there is still another way practiced among beekeepers here to prevent the queen from going into the super. This method is based on the assumption that the queen will not pass thru a long dark channel. The construction of some of the hives in use here can be readily adapted to this system. The brood-nest, by a permanent partition, is separated from the super. On the side of the entrance a long dark channel leads up to the upper story. It is said that the queen very rarely finds her way thru into the super. I have never used the plan; but know of a practical beekeeper who used it successfully for many years, and was pleased with it.

Quite a number of beekeepers have a hole only 3 to 4 inches in diameter; others, an opening about 4 by 10, covered with an excluder to communicate with the super. I am satisfied with an excluder nothing less than the size of the brood-nest.

#### IMPORTANCE OF THE EXCLUDER.

The weather and bee-pasture here are such that, without the excluder, the surplus would be so small (many seasons nothing), I would not keep bees for the honey they might bring, but would keep only a few colonies for the pleasure they would afford. The excluder for me serves not only to keep the queen from going up into the super, but also to limit the brood-rearing at the right time. This I consider essential to success in this locality.

Kempten, Bavaria, Germany.

## ODDITIES OF CHINESE BEES

BY BRO. ROMAIN

The readers of GLEANINGS will be pleased to know that their esteemed paper is read in a country so far distant as China; they may also appreciate the good will of a remote subscriber who comes bringing his note of variety, talking of the Chinese bees, which may, perhaps, share in the oddity of their masters, the citizens of the newest republic.

In China we find the same bees as in Europe—the pure races excepted. They are nearly half yellow, but a little smaller than those in Europe—so much so that they rear "drones" in worker-cells of European

foundation. They show a great reluctance to build on that foundation and to go into the section. Like their masters, they don't trust innovations.

In the southeast of China (Foo-kien) there exists another kind of bees—black, hairy, and much bigger than common bees. The workers are as large as black European drones. I nearly succeeded in getting a colony of those dragon bees. Unfortunately the Chinaman killed them by smoking the box over the chimney of his hut. It was a great pity, for I believe those bees able to gather nectar from the kidney beans

In some parts of the United States this would be a rare sight—a field of sweet clover tied in bundles. The seed was sown here in Medina, last year, between the rows of corn, at the last cultivating in July.

(feves, phaselus), very abundant here in springtime. Common bees do not visit them; but humblebees and pseudo-bees are foraging upon them all day.

The Chinese bees are very mild, and easy to manipulate. A big hive may be visited, frame by frame, without smoke and without getting a sting. One of their most interesting qualities is that they completely ignore the "propolis." Not a bit is to be found in their hives. This has, perhaps, a tendency to attract the moth which is, in fact, a terrible enemy of bees in China. But the manipulation of hives is thus very much simplified. Our spacers being staple-screws fixed in the top-bar, a single pull or push can move five or six frames at a time (39 cm. x20), (15¾x8 inches), somewhat like the English frame. There are no squares at the bottom, our hives not being intended to be moved. Of course the Chinese peasants do not know the modern frame hive. They make hives of whatever vessel comes into their hands—box, bamboo basket, old barrel,

earthen pot, old petroleum-box, bucket, pail. The preferred hive is the one with drawers without bottom, these being added underneath, and taken off from the top. By this ingenious system they sometimes obtain a very strong population, but with a large number of drones. The boxes are usually placed in front of the house, high up under the projecting roof. Often, also, they are placed inside the rooms with a bamboo tunnel across the wall, or the entrance is made by simply removing a brick. This last mode of location has the immense advantage of preserving bees during the winter, which is rather severe in the north of China, where a temperature of  $-25^{\circ}$  Centigrade ( $7^{\circ}$  Fabr.) is often registered during three months—December, January, February. Another but no less real advantage of this indoor location is to save boxes from thieves. Hives in the open field, as in Europe, would have 9 chances out of 10 not to see the end of their first season, the Chinese being robbers or marauders by instinct or necessity.

Hives are rather thinly scattered throughout China—a few here and there, except in certain districts in the West, where they are pretty numerous. In a wild state bees are found in trees, old walls, in the tombs, or, rather, in the space between the coffin and the masonry surrounding it. I must remark that in China the coffin, made of thick planks (sometimes 5 in.), is simply laid on the ground, and a brick wall constructed around it.

Many attempts have been made by Europeans and Japanese to introduce Italians in China, but, up to the present, with little success. A friend beekeeper, Mr. B., has bought more than 20 queens from America and Australia, but all were dead on arrival except three, which the bees quickly dispatched to their ancestors—out the foreigners!

Lately the Chinese government has manifested the intention of improving beekeeping; but years may pass before anything is done in practice. However, that culture or

industry would give very satisfactory results in many places.

In Shanghai, where, as a rule, the winters are very mild,  $-5^{\circ}$  C. about ( $27^{\circ}$  F.), strong colonies rear brood during the whole winter—a fact I have ascertained myself during the last two seasons. Wax scales are very abundant on the bottom-board. During the calm sunny days of November, December, and January, the bees gather a good deal of honey and pollen from the loquat-tree, just blooming in winter. The consequence is that many colonies may swarm even in March.

Unfortunately our flora is very poor, China having no meadows and no woods. Here are our best honey-plants: the colza, or rape; the coronilla; some fruit-trees; the vistaria, the Virginia creeper, the *cucurbitaceae*, the sunflower, cotton, the locust. Of these the first only is abundant. The honey (very inferior in flavor to European or American honey) is used only as a remedy, and the quantity obtained from a box

Harvesting sweet clover at Medina

is only a few pounds. Ten pounds would be a rich harvest. Foreign honey is sold at 85 cts. to \$1.00 per pound.

The *British Bee Journal*, the *American Bee Journal*, *Gleanings*, and *Apiculture*, of Paris, are read and circulated in Shanghai,

where the beekeepers (a dozen already) seem to take a keen interest in beekeeping, and, no doubt, will improve that ever interesting branch of agriculture.

S. Francis Xavier College,  
Shanghai, China.

## SOME OF THE REASONS WHY BEEKEEPING IN CHINA IS DIFFICULT

BY C. A. PIERRON

The study of beekeeping is most certainly an interesting one. Practice is more attractive than a mere book knowledge of the subject; but both are what every beekeeper must aim at to be really worthy of the appellation. Some of the numerous things relating to a hive or to a colony of bees would be better understood by the opening of a bar-frame hive and by examining the contents of it in detail, while some other facts given in a book must be accepted in good faith. They are the result of the patient studies and researches of other people, and with little trouble these good points can be learned. Yet many passages are understood only at a second or third or further reading. But, notwithstanding the good will of the author, a book cannot solve all the difficulties arising before a beginner. Even that "king" of books on beekeeping, the A B C and X Y Z of Bee Culture, cannot enter into the fullest details of the subject; for if it did it would cease to be the most popular book among beekeepers on account of the superabundance of generally unnecessary explanations, or of facts applying to too few cases to be given in a book made for the greatest benefit of the brotherhood. It is, therefore, important for every bee-

keeper to set his brain to work to solve for himself a number of questions that may arise in his mind.

Here in China a beekeeping enthusiast with a "classic" on the subject at his disposal may be thrown into utter confusion capable of leading him to discouragement. One of the great drawbacks of beekeeping in this country arises from the fact that Chinese bees are smaller in size than the common bees. Accurate measurements taken from a certain number of native hives that had been cut thru gave the following measures which I compare with those found in books.

| America or Europe                             | China                                  |
|-----------------------------------------------|----------------------------------------|
| Thickness of worker combs, $\frac{7}{8}$ in.; | almost 13-16 in.                       |
| <i>Worker-cells</i> —                         |                                        |
| Almost 5 to the inch;                         | about 5 $\frac{3}{4}$ cells to an inch |
| <i>Drone-cells</i> —                          |                                        |
| About 4 to the inch;                          | about 4 $\frac{1}{2}$ cells to an inch |
| <i>Space between midribs</i> —                |                                        |
| 1 $\frac{1}{8}$ in. to 1 $\frac{1}{4}$ in.;   | 1 3-16 in. to 1 $\frac{1}{8}$ in.      |

With such dimensions it is quite natural that a lot of statements asserted in books on beekeeping are found faulty for this country.

When starting the keeping of bees, the finding these insects rather small we thought that what was true for Europe or America

could just as well be right for China, and acted on that principle. For example, wishing to transfer the combs from a native hive to a frame hive we fixed in frames some bits of combs that had been used for rearing drones, and which, when compared to the bases of cells on foundation, did not appear extraordinarily large. Of course the following year we had a fine crop of drones instead of honey.

Foundation when given to bees in spring-time was readily accepted; but was with difficulty taken to later in the year. The explanation of this is easy. In spring the bees working as always for the development of the race, and therefore requiring drones as well as workers, were willing to draw out foundation which allowed the rearing of drone brood preparatory to the rearing of queens at the approach of swarming time. Later the swarming impulse leaves them as the honey season nears its end, and the bees do not want drones any longer, but workers only, for they feel that the existence of the colony depends on the number of workers. At such a time foundation with bases too large for them to build worker cells on was hardly drawn out, tho inserted in the middle of the brood-nest, and the remainder of the hive was quite filled with brood and honey.

This having been considered, certain facts which at first seemed to me almost incredible became easy problems to solve. In 1912 we had given some foundation to draw out to a swarm whose queen was removed some time afterward; and tho to us the cells appeared like fine worker-cells, and

that worker brood was reared in them the remainder of the year, yet the following spring we had frames perfectly filled with drone brood. We thought that, on account of the period of queenlessness, the bees had built drone-cells, and gave them some other foundation to draw out; but the result was the same—viz., worker brood that year and drones in the same cells the following spring. We had a like success every time we tried the experiment.

To rear worker brood the bees partly closed the openings of the cells, leaving only a small round opening about the size of one of their own worker-cells. In a neighbor's hive I saw another thing which interested me much. In summer time, during the spell of rest forced upon the bees by the absence of nectar-secreting flowers, his bees busied themselves conscientiously by biting off almost to the top-bars the beautiful combs they had built some time before on comb foundation, and set to work to afford their future sisters quarters better adapted to their requirements. A pretty common thing, will veterans say? When the bee has nothing to do outside it keeps inside doing some mischief. Yes, I know bees do sometimes bite off the bottom of an old comb, and, may be, at the approach of winter, of a new one too; but that is nothing compared to a regular pulling-down of the house to build new lodgings.

Another beekeeper, who had ordered foundation and frame hives from France, complained bitterly to one of my acquaintances that Chinese bees were not willing to accept European civilization. "They won't

Thrashing the sweet clover.

build on foundation," he said, "and won't keep to the frames, but must also build between them."

This last fault was not an attraction for him. His frames were spaced  $1\frac{1}{2}$  in. apart from center to center. No wonder, then, that additional combs are built, since, with frames only  $1\frac{3}{8}$  in. from center to center, I saw additional combs being built. It would be still worse with frames spaced  $1\frac{1}{2}$  in., as is given sometimes in books. It is true that this large spacing is for wintering; but it happens that bees build combs even at the end of October and in the beginning of March. The result of this spacing, too wide for the bees of this country, is what can be expected. In some hives the combs cannot be separated any more than if built across. In others, by taking good care the frames can be taken out; but some combs, being fixed to the edges of the frames, can fall easily, to the great danger of the operator and of the neighbors. Moreover, some frames supporting two combs are liable to break under the weight. We had to correct our comb-spacing to adapt it to the requirements of the bees of this country. It was an easy matter, as we use screws as spacers. A few turns gave us the distance of 1.9-32 in. from center to center, which we adopted.

Another great drawback of the small size of our pets comes from the want of proper excluders. Those which we received from Europe will not work properly. Many times I have known queens to pass thru the perforations of the excluder so that the manipulations made became failures. Likewise the drone-traps allow all but two or three of the largest drones to escape.

When all this is considered one thought

comes to mind—viz., to construct implements and make foundation for China. That would remedy the evil; but the Chinese are not for European or American methods of beekeeping for the present, and there would not be a sufficient demand to incur such a cost at the present time. A second solution would be to Italianize our colonies; but here, again, a great difficulty arises—the danger of mismating. For a time I thought we could have Italian bees, for I had heard some one say that in Japan the native drones would not mate with Italian queens. I found it hard to believe, and conjectured this was to be attributed to the difference in size or to some other unknown reason. Last year all my thoughts on the subject vanished when a Chinese who had studied beekeeping in Japan told me that the Japanese cannot keep pure Italian bees, because of mismating.

Now, it may interest my readers to know how I managed to have my combs built and wired at the same time. I prepared frames with wires as if foundation were to be set in. A small starter with only two or three rows of cells was fixed to the top-bar. The frames thus made ready were put in the hive, which was perfectly level from side to side. I thus obtained beautiful worker combs when those frames were inserted between two brood-combs toward the end of the season in strong hives, or at any time of the year in rather weak ones. This process for obtaining worker combs is slow, far from being perfect, and cannot be compared to the regular and thoro work obtained from comb foundation. I would gladly receive suggestions as to the best way to have combs built when no foundation can be used.

Shanghai, China.

## THE BEE IN COURT

BY C. O. TARBOX

---

A recent decision in the City Court of Yonkers, N. Y., determines the ownership of a swarm of bees that have come out of the owner's hive and alighted upon another's premises. Judge Beall, in deciding the case, wrote a very exhaustive opinion in which he cites authorities dating back to the time of Justinian. He says that Blackstone classifies bees as wild animals; that he takes his law from the Greeks and Romans, and that there has been practically no change in the law from the days of Plato, and that an uninterrupted line of decisions thru Greek, Roman, English, French, the Netherlands, and the English common law,

down to late decisions in Iowa are to the same effect, and suggests "the probable reason for this set policy being the danger of touching the subject." The court holds that, where a swarm of bees left its owner's premises, his title to them was not destroyed by their alighting on another's land, even tho he would be a trespasser in going upon that land to retake them; and that if another than the original owner takes them into his possession while on another's land he gets no title which vests in him or in the owner of the land upon which they are, but is liable to the original owner of the bees for conversion. This, however, seems

to be qualified by the fact that the owner must have kept the bees in sight, or have some special means of identifying the bees as his, and that, when he has lost sight of them, and so lost the means of identifying them, they are then the property of any one who lawfully secures possession of them. This seems to be the first reported case in the New York courts where this

question has been decided; and, unless reversed upon appeal, it will stand as the settled law of New York upon the questions decided. The title of this case is *Brown vs. Eekes, et al.*, reported in Vol. 160 N. Y. Supp., at page 489. The complainant, a beekeeper, was also a lawyer, and the court suggests that no lawyer needs bees to assist him in stinging.

Fredonia, N. Y.

## AN OLD SOLDIER WHO IS BOTH A BEEKEEPER AND FRUITGROWER

BY S. E. O'NEEL.

I am an old soldier, 75 years of age, but still able to look after 40 colonies of bees, a large lawn and flowers, and a good fruit and vegetable garden. I get far more profit and pleasure from the bees than from anything else I have.

take flight again. Since the picture was taken, a honey-house has been built near the apiary, and the young grapevines are old enough to shade the hives nicely.

There is lots of pleasure and health in the combination of bees, flowers, and fruit.

S. E. O'Neel's apiary of 40 colonies at the rear of his residence, Dupont, Ind. Mr. O'Neel is an old soldier who finds health, pleasure, and profit from his bees and fruit.

I have each colony standing on a sloping concrete slab, which forms an alighting-board down to the ground, so the heavily laden bees can crawl in when too tired to

I dislike a disorderly back yard. Everything here is kept as nice as is the front lawn.

Dupont, Ind.

## TAKING OFF HONEY RAPIDLY

BY LOUIS H. SCHOLL

Two comments on a recent discussion of the above subject by me that have appeared in *GLEANINGS* will bear a few words of explanation so that the readers will not feel that they may be misled by the experience

that I gave. The first of the comments, by P. C. Chadwick, appears on page 587, July 15.

Mr. Scholl says, page 471, June 15, that by his method it is possible to take off more

than a thousand pounds of honey in half an hour! Then he adds, "The writer holds an actual record of 1140 pounds of honey removed in exactly 28 minutes." I figure that to be just a fraction under 41 pounds per minute. No, thanks; I do not care to have any one slamming around among my pets like that.

In the August 1st issue, page 650, Mrs. Allen comments in this manner:

Mr. Scholl says, page 471, "It is possible to take off more than a thousand pounds of honey in half an hour." My marginal comment, in the light of our own recent experiences, reads merely "Whew;" May I repeat it here "Whe—ew!"

Let me explain that we are just as careful about "slamming around among my pets"

as is friend Chadwick, and that the trick of taking off the quantities of honey does not harm the bees in the least. The truth of the matter is that, when a hive is approached and the cover raised, the bees are simply told by the "smoke language" to move down and out of the finished super or supers that are to come off that hive. Then the cover is removed entirely, thrown on the ground in front of the hive, and more smoke is blown over the top of the open super. While the bees are making their way down, the next hive is treated in the same manner, then another, until we have four or five hives open and the bees going down. Rapidly returning to the first hive we smoke them all again in the same rotation. Next we set down the smoker, and, with hive-tool in

hand, pry loose and lift off quickly the topmost super from each of the four or five open hives. Grasping the smoker again we go over the smoking operation with each hive that has more honey to come off, in a rapid manner. Thus the supers are rapidly freed of the bees and removed from the hives.

The illustration given herewith shows the manner in which the foregoing is done. The few remaining bees, still in some of the supers, will find their way out and back to the hive from which they came by the time the supers are loaded on the wagon or truck, or they are shaken or "jostled" out of supers not entirely free of them by gently "jouncing" the lower part of the supers against some object. All of this is done so quickly, and yet in so gentle a manner, that there is no room for argument on the subject of "slamming around."

New Braunfels, Tex.

Scholl's method of taking off honey in a hurry.

## THE ROCK HONEY OF INDIA

BY N. TOURNEUR

Many are the honeys of India; but most singular of them all is the rock honey of the Madras Presidency. It is one of the various items of the forest products collected in the Satyamangalam Hills and bulks large in the revenue list.

Rock honey is produced by a very large brown bee, and stored in holes and under ledges of rock. Coarse and dark, the wax of it very dark in color, it is in great demand among the natives.

The first season's products are collected in August, when the rocks are dry, and the harvest of the second season as soon as the hot dry weather begins. Thus the danger of slipping off the rocks is lessened very much; but on the whole it is perilous work, often bringing disaster and death to the collectors.

In the Satyamangalam Ranges the work is done by natives of the Kurumbar hill tribe. When the proper season comes for gathering the honey a party of from fourteen to fifteen start out up into the wooded ranges which the bees frequent. The expedition always sets out on Monday, which day of the week the superstitious natives look upon as lucky. The party take with them coconuts, camphor, plantains, and other offerings to their tribal deity, also their implements for gathering the honey, consisting of a long ladder made of fiber with a strong rope of the same material, a bowl made of basketwork smeared over with clay till it is water-tight; a sharp-pointed staff, and a bundle of torches made of green and dry grasses. Of the party, only two are collectors of honey, the rest being employed to carry goods and chattels, put up sheds, light fires, cook, and to do the odd jobs for the two collecting Kurumbar. These two alone climb the rocks and gather the honey, and, invariably, are brothers-in-law. That is, to be more explicit, each man's wife is the sister of the other man, and each Kurumbar is responsible for the life and safety of the other.

When the collectors reach a suitable ledge of rock, which is easily enough picked out, their quick eyes tracing the flight of the busy bees, the rope is attached to the ladder, and tied firmly to a handy tree. The ladder is then thrown off the top of the rocky ledge. One of the Kurumbar holds on to it, and the other climbs down the ladder till he finds himself on a level with the great clusters of honey-combs which are on the slippery sides of the rock. Arrived there, he puts his right foot firmly on one

rung of the ladder, and his left over the rung above till the rung is in the crook of his leg. Thus firmly fixed he swings himself to and fro, having in one hand a burning torch and in the other the pointed staff; and as he swings into the rock he applies the torch to the combs, drives away the bees, and gathers the luscious combs.

At the end of each day's work the Kurumbar climbs up to the summit of the rock. The operations go on for several days, the collector having a singular immunity from stings. On the last day, when all the honey and wax have been obtained, the rope is untied and the ladder dropped down to the bottom. From ten to eleven cents a pound is given for this honey by the native dealers.

### HONEY IN COMMERCE.

Another famous honey of India is that which forms a popular article of commerce up in the Himalayan provinces. In most of the villages of the northern ranges of the Himalayas bees are kept, and the honey, whether the produce of the wild or the domesticated bees, adds to the income of many a native household.

It is usually sold in the local bazaars at an eighth of a rupee, or two annas—that is, six cents a pound; and altho not much thicker than syrup, and of a brownish color, it has a flavor equal to the finest honey of Narbonne—the honey par excellence of all Europe, and is, moreover, much less cloying.

The domesticated bee of these regions is known by the name of "mohru," "mohri," or "mori," according to the particular province. It is not much more than half the size of ours, but is very industrious and mild-tempered, and in this respect gives even more pleasure in working with them than pure Ligurians. Straw hives, with tapering conical roofs of reed, are in use. The fine quality of the honey is ascribed to the most common source of the bee's honey-gathering—the prangos. It is a bushy growth which grows very freely in the Himalayan provinces, and consists of long feathering leaves of dark green, crowned by a profusion of large tufts of yellow flowers, which have a rather pleasant aromatic fragrance, and are covered with a glistening, viscid, sugary juice that attracts the bees in such numbers that the flowers are often blackened by them.

### A TRULY WILD HONEY.

The wild bee or "bhaonra" of these mountainous regions, and larger than our

domestic bee, also provides a large quantity of honey and wax. It is almost black in color, and has wings longer and broader than the bee of the hive. Its temper is fiery, and its sting very venomous. It usually builds its nest under the projecting ledges of rock, and steep overhanging precipices, in a situation usually inaccessible except to the most daring native.

Advantage is taken by the collectors to rifle the nests when the prangos is fully in flower, when the bees have plenty of honey, and are in their most amiable mood. When the hot season or time of dearth comes, then the wild bees are very irritable, and difficult to approach, their honey-sacs being but partly filled.

It is interesting to note, too, that the honey of the wild bee of the Himalayas, if

gathered before the month of March, is fully equal to that of the domestic bee; but if in the following month it is said to produce intoxication followed by insensibility. This effect is due, probably, to the wild bees feeding on the flower of a species of aconite which is then in bloom, and very plentifully, high up the mountains, beyond the range of flight of the domestic bee.

Both the honey and the wax of both kinds of bees form valuable articles of export down to the plains, and help to swell the revenues of the little states or kingdoms. There is a great demand for the wax, which is run down and treated for the composition of candles, in particular for those burning before the many different shrines of the many various gods of India.

Thundersley, Raleigh, Essex, England.

## A TELEGRAPH OPERATOR AND HIS BEES

BY CURTIS C. GROOMS

While in my apiary the afternoon of October 11 I found aster honey coming in very briskly. At one time I noticed seventeen bees in the grass in front of one hive so heavily loaded that they had failed to reach the entrance. I do not know when I have felt so good over anything, for I had extracted from two to six combs from each of my brood-chambers during September, fully expecting some flow from aster; but up to the 28th of September none had come in. Toward the end of the month there was a good rain, altho it was cold. Soon, however, the weather warmed up, and the honey has been coming in nicely ever since. Most of my colonies had plenty of stores to last thru the winter.

Last spring I purchased 50 colonies of bees in ten-frame hives with five empty hives for \$200. I increased them to 85. Three colonies were almost destroyed by European foul brood, and four were queenless. Treating the diseased colonies and doubling up the queenless ones leaves me with 78 good strong colonies. Two of them that had the disease last spring I transferred and cleaned the hives out after charring the inside and the frames, and placed new swarms in them. These I examined a few days ago and could not find a cell of disease anywhere, nor in the colonies that I took out of these hives and put in other hives.

I sold \$237 worth of honey from the bees this year, and have a small amount left, which is selling rapidly. I sold the comb honey at 18 $\frac{2}{3}$  cts. per section in lots of six; in smaller lots for 20 cts. straight. I sold the extracted for ten cents a pound if the

customer furnished the cans. Several asked me how I could afford to sell it at that price. One man came back the second time; and when I told him the honey was all gone he said, "Why don't you charge more for it?" I think I shall charge 12 $\frac{1}{2}$  cts. for the extracted honey another year. I had a little over 770 pounds, and sold it in one month's time. I did not have to go out to sell it, for my customers all came to me and asked for it.

### VALUE OF FULL SHEETS OF FOUNDATION.

Referring to the trap for destroying drones on page 743, August 15, this cannot help being a detriment to the worker bees going in and out. I believe in preventing drones from being reared in such large quantities by using full sheets of comb foundation. If a swarm is put in a hive having only starters there may be fully half drone comb built if there is a good honey-flow on. The drone-cells are likely to be in the lower half of the combs; and as the honey is stored in the upper half the queen does not have enough room to lay worker eggs, therefore there is nothing but a small force of old worker bees left in the fall. It costs only about 60 cts. to put full sheets of foundation in a ten-frame hive, and it takes only three to five days for a swarm to fill such a hive with brood, eggs, and honey. A swarm hived the latter part of June on full sheets of foundation gave me a surplus of 56 sections (four of these at 15 cts. each would pay for the foundation used), while a swarm I hived at the same time on starters never so much as entered the super at all.

Bradford, Ohio.

# Heads of Grain From Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

*Aunt Miranda Catnip says Doolittle is right. When a colony decides to walk out there's no use in resorting to arbitration. She says, jes let 'em swarm.*

## Moving Bees Without Ventilation.

That it is not always necessary to give ventilation in moving bees may sound unorthodox, but I have found it practical and convenient.

When the time taken in moving is not too long, and the weather is fairly cool, the entrances may merely be plugged with wet rags. The rags must be soaking wet, however, and should be applied without wringing any of the water out. I have moved bees in this way when they had to be confined four or five hours, and they came thru in good condition. The colonies were of ordinary strength, and the weather was warm at first, but later a cold wind came up. In this case the moving was done on spring wagons, in the daytime; but the plan is not to be recommended when horses are used in daylight. At another time I moved some very strong colonies by automobile over three miles of rough road, using this plan with entire success.

The explanation seems to be that the bees get what water they need from the rags; and the entrance being dark they lie quietly on the combs instead of continually trying to get out, as they otherwise would.

### A SAFETY CARRIER FOR COMB HONEY

Here is a method of packing comb honey for shipment by express or parcel post that

seems to meet the requirements of safety and economy very well. The principle involved is that, if you want men to do things right, make the right way the natural way; make it so obvious and easy that they will follow it unconsciously.

My crate is simply a tray four or five inches deep, a little larger than the case containing the honey, and having an upright piece at each end—on the outside—and fastened between these uprights a cross-piece which holds the case of honey firmly in place, and which may also be made to serve as a handle. There should be packing enough in the bottom so that the case will set only an inch or two into the crate.

When so arranged the package will not be placed on its side, because the weight of the honey would overbalance it; it will not be placed on its end for the same reason, and also because of the upright pieces; and it will not be placed on its top on account of the cross-piece and the very evident fact that it was not meant to be so placed. Clearly the only way it will set is firmly on its bottom, in which position it has three inches of packing under the honey to take up the shock. The honey will be visible thru the glass, if glass is used, and this will serve as a further warning against carelessness, while at the same time both glass and honey are protected by the projecting crate.

Doubtless the details may be improved, but a limited experience has convinced me that the principle is sound when applied to single-case shipments.

Torrington, Ct.

Walter H. Hull

## Are All Workers of One Class?

Among the workers of one and the same colony there seems to me to be a difference, not only in color but in shape as well. Some appear to have a much more slender abdomen than others, and, especially with Italians, the end of their abdomen seems to be of a much darker hue of brown. Little importance is, perhaps, to be paid to this last fact, as it can be attributed to atavism. But the difference in shape is less easily accounted for, I believe.

Often for hours I have watched bees carrying in pollen, but I have never seen one of these slender workers come in with any, altho I believe they bring in honey. I have also noticed that, after a swarm is hived and has settled quietly in the hive, the guards at the entrance are mainly or exclusively composed of these slender bees, and, when disturbing a colony, these bees are the ones to fly out first and attack the intruder.

Is this accidental, or do I see wrong? I don't know. I don't possess the required instruments to make out whether or not there is any anatomical difference between these slender bees and the rest of the workers' force, neither do I have the training for such delicate work.

Can it be possible that, like the ants, the bees have their soldiers which have nothing to do with the rearing of brood?

J. H. J. Hamelberg.

Soest, Holland, Aug. 21, 1915.

Dr. Miller replies:

There is no such thing as classes among the workers of a colony, and at the same time they are divided into distinct classes. That is, each worker in the course of its life has the same duties to perform as every other worker, so that no worker is in a different class for life from any other worker. But the work of a worker is by no means the same each day of its life. When a week old its occupation is not the same as when a month old. So it is not in the same class when a month old as when a week old, and in that respect workers may be said to be in different classes according to age and occupation.

The two classes into which workers are commonly divided are nurses and fielders, a worker being a nurse until something like 16 days old, when it changes into the other class and becomes a fielder. Of course this varies according to circumstances. At the close of winter the nurses are many weeks old; and if there are no older workers in the hive to do field work a worker may become a fielder at five days old.

The abdomen of a bee may vary greatly in size, the parts telescoping into each other. Take a bee that has been confined in winter four or five months, and its abdomen will be three times as large as that of a bee that has died of starvation. A nurse bee stays mostly in the hive so that it is not important that it should be of light weight. It fills up with honey and pollen so as to prepare food for the babies, and its abdomen is well distended. When it turns to field work, it gets down to flying trim, with no excess weight. Perhaps that may account for the slenderness of the bees you have seen. C. C. M.

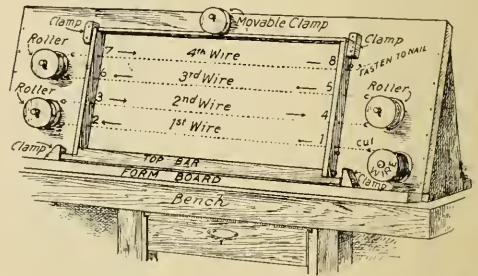

### Simplex Wiring-device.

My wiring-board is a few inches wider and longer than the frame to be wired. It is fastened to a base at an angle for convenience in working. Stationary blocks or clamps are fastened in the right position as shown in the illustration, for holding the frames square, and in position while wiring. An oval-shaped movable clamp at the upper edge of the board turns down on the bottom-bar, and holds the frame in place. The whole board should be screwed or clamped to the thing so as to be perfectly rigid.

The spool of wire runs on a rod projecting out from the board. The wire as it leaves the spool is threaded thru several staples driven in the board so that when it is slack it will not unwind or kink. The wire after it leaves the staple runs thru hole No. 1, then across thru No. 2, around the lower left-hand roller, back to hole No. 3 and 4, around the roller at the right end of the board, then thru holes 5 and 6, around the upper left-

hand roller, and finally back to holes 7 and 8. At this last hole it is fastened with a nail.

The wire is easily tightened with the right hand on the spool, twisting the spool to the right, thus taking up the slack. The wire is first tightened while still on the rollers, then the spool is turned to the right after the wire has been slipped first from the upper left-hand roller, then the right-hand roller, and finally the lower left-hand roller. When the wire is at the right tension it is wrapped around a previously driven nail, the nail driven in and the wire cut.

The three rollers are of such diameter, and placed in such a position with reference to the holes in the end-bars that the wire passes around them in a direct line with the holes. The rollers are supposed to be only about an inch from the frame.

With this wiring device the frame is held rigidly, absolutely square. The wire is easily drawn to any tension desired, and cut only as used, so that there is no waste and no odds and ends. I think this is the easiest and best plan that has yet been devised. It makes wiring pleasant as well as profitable.

Oklahoma City, Okla. N. S. Gladish.

### Honey Method of Introducing Simpler than Any Other.

During all of 1915 one of my colonies had a heap of dead bees before the hive continually. The symptoms resembled bee paralysis. I had a young queen ready to introduce; but when I looked for the old queen I found comb after comb solid with brood which showed that the queen was doing her part well, and I hadn't the heart to kill her.

This queen was still on the job July 15, 1916; and, strange to say, none of last season's trouble has been seen about that colony this season. However, the colony second in line from the one mentioned has had the same affliction ever since the opening of this season. There were positively no robbers, but there yet appeared to be a continual fight, the result being a heap of dead bees before the hive daily. Seeing no prospect of improvement I decided to requeen, which I did on July 15, pinching the old queen's head, then sousing the bees between the frames in the hive with honey-water, also giving the new queen a generous baptism, and running her down between the wettest frames. The whole operation (having every-

thing ready beforehand) did not take two minutes from pinching the old queen's head until the supers were back on the hive; and there have been since not enough dead before the hive to be noticed. I have not been able to figure the answer, but these are the facts.

The colony first mentioned having stored but little last season, and not promising much for this, was requested at the same time and in the same way.

This plan of introducing seems to promise well, is practicable for anybody, and as simple as can be. There is no "psychological moment," nor is there any necessity for any special experience or facility of judgment.

Lyndhurst, N. J.

B. Keep.

### Why Did They Do It?

Bees sometimes do queer things. I discovered, on going thru hive No. 19 that it was hopelessly queenless, with not a cell of brood in any stage, and thinking it might have a virgin queen (which is not likely with no brood) I gave a frame of brood in all stages from the egg up, and within a few days there were 22 queen-cells well under way.

I at once sent for an untested Italian queen, which came by return mail in fine condition. I opened the hive, lifted out the frame of brood, shook about all the bees off, then cut out all queen-cells visible, replaced the frame of brood with the brood about all sealed, placed the cage with the queen and attendants on top of the frames, and closed the hive.

In 24 hours I examined the cage, thinking possibly they would have the pasteboard eaten away; but they had not done so. I removed it as per instructions, and as formerly done, and closed the hive for one week. I then removed the cage and found the queen laying well.

About one week after she commenced to lay I found in front of the hive for three consecutive mornings an aggregate of five virgin queens. This satisfied me of two things: That I had overlooked queen-cells, and that the introduced queen had been accepted.

Now listen: Just 14 days after I placed this queen in the hive I found her dead in front of the hive; and upon examination I found that she had almost filled two frames with eggs which were in about all stages of development. There was an inferior virgin queen running on the combs. Why in the name of common sense would they destroy this beautiful laying queen and accept an inferior virgin that might never lay? and where did this virgin come from so late? The old brood was too old to make a queen from, even an inferior one, and the new queen had not been in the hive long enough for a virgin to have been raised from the brood.

So I say bees do queer things. This has

broken me from giving a colony a comb with eggs when I am introducing a queen unless I introduce by some other way than the cage method, and immediately after the hive has become queenless.

Indianapolis, Ind.

J. F. Kight.

### A Systematic Advertising Campaign.

The following editorial is a sample of what I furnish each of the local papers weekly. Each week during the year I get out a news item in different form. The cost of this is trifling, for I furnish each editor with honey free, and in return they put in my clippings or notices. Under this system of advertising, my sales run about four times greater than they were before.

The busy little honeybee is about the only mundane creature that hasn't taken advantage of the war in Europe to loaf on the job and thus cause an advance in price of its product. Beef and pork are almost out of sight, and never in history has the price of eggs been the case this year. Few people realize the food value of honey or it would be more extensively used on the table. It is the most important and healthful food product known to mankind, and is the only thing that has not kept pace with the high cost of living on account of an abundant local crop. Just think of a full gallon of twelve pounds for only \$1.25, and this will provide the system with more nourishment than twice the amount of any other diet, it being a digested sweet. Everybody should take a swat at the high cost of living by buying honey.

I also furnish the ministers of the city with honey free, and they help to boost sales among the country people.

Three to six girls, twelve to fourteen years old, canvass the small rural towns. I pay them a commission of 15 per cent.

I have already sold 600 gallons of honey, besides about 1000 pounds of comb honey.

Humboldt, Neb.

J. L. Gandy.

### Yes, Furnish the Papers the Truth.

Enclosed is a clipping from the Cincinnati Post. On account of various explanations given, I sent in a more definite statement. When the daily papers once become interested in bees I think it a good idea to get a lot of free advertising by giving a beekeeper's views.

#### WHAT DO YOU KNOW ABOUT BEES?

An argument has been raised regarding the habits of the bee. We were asked whether it ever sought honey from red clover. A farmer assured us that it did not, the honey in red clover being out of its reach. A subscriber writes that the Italian bees are able to penetrate the red clover for honey, but that the black bees do not. Has any one else any information to give about this?

In many ways honey is now used in place of sugar. As a small producer I have now more orders than at this time any other year. It seems that people are becoming more interested; but we must produce a good ripe article. This counts. If people are once misled it will take a long time to convince them to the contrary.

Cincinnati, O.

Henry Reddert.

### West Virginia vs. Southern California for Bees.

I should like to get information about West Virginia as a place to live in. How much land in sweet clover would keep profitably 40 to 50 hives of bees?

Burbank, Cal.

A. H. Nash.

[The climate of West Virginia, of course, is a good deal milder than in the northern part of the United States next to and above the Great Lakes, but not as mild as it is in Burbank, Cal. For the keeping of bees or for a general mild climate you will not find any place in West Virginia probably equal to where you are. A good deal of territory in West Virginia is mountainous.

We are not able to give you a definite estimate as to the number of bees you could keep in a given area of sweet clover. Something would depend upon the locality—that is, the character of the soil and the climate. Ordinarily we should say that an acre of sweet clover would support a colony of bees. In other words, it would take about fifty acres of sweet clover to make very much of a showing in the hives, and really a hundred acres would give better results.—Ed.]

### Martin and Bee-martin Very Different.

Page 717, E. G. Baldwin says "the pretty bee-martins are housed by my neighbors." Surely he must be mixing up martins and bee-martins. A bee-martin can't be made to live in a martin-house. It makes its nest out on the end of a branch. A martin and a bee-martin are no more the same thing than a chestnut and a horse-chestnut, or wheat and buckwheat. So far as I know, authorities all agree that the bee-martin does not ordinarily eat worker-bees, but eats drones, queens, and rosebugs, and drives away the enemies of small birds in general; so that it is a good neighbor except where there is queen-rearing, but a bad neighbor there.

If we could all agree not to call it bee-martin, but use the name by which I believe it is better known to the general public, "kingbird," there would be less danger of getting it confused with martins in our talk.

Steven T. Byington.

Ballard Vale, Mass., Sept. 7.

### Bee or Purple Martin.

Some inquiry has been made in regard to martins eating bees. The so-called bee-martin, or king-bird (*Tyrannus tyrannus*) is known to catch bees, and I have seen them take them on the wing, but have never thought they did as much harm as good. They are easily recognized, as all of their tail feathers are tipped with white. They never nest in houses or boxes of any kind, as they always build their own nest, generally in a bush or low tree. Their eggs are cream-colored, with brown spots.

The purple martin (*Progne subis*) builds its nest in box or house, often several in one house, if it is divided into rooms. Their eggs are white. The adult male is a deep

shining blue-black all over. Females and younger males, probably including all under two years old, are of a dull purplish black above, and grayish beneath. I have never known or heard of their catching bees, and they are very useful.

### THE YIELD FROM ALFALFA AT HIGH ALTITUDES

I have made some inquiry here, and conclude that the yield is at best uncertain above 5000 feet. Here in the valley, at an altitude of 4300 feet, the yield is excellent. Within twenty miles east of us the Sacramento mountains reach a height of 10,000 feet. I am told that the bees up toward the summit starved to death last summer.

### THE LONG-IDEA HIVE.

I should like to say a few words in favor of the Poppleton "Long-idea hive." I did not know Mr. Poppleton, tho I lived within about forty miles of him for many years in Iowa. A near neighbor of mine, Mr. G. W. Webster, who also went to Florida later, knew Mr. P., and adopted his hive and system, extracting most of his honey. From him I learned the principle and adapted it to my own use, building hives to take L. frames, and using wide frames with separators to hold sections. I think queen-excluding division-boards would make success complete. In that climate we used these hives with double walls, the outer wall extending several inches higher, to admit of using a large chaff cushion in winter. I also used ordinary section-cases on top of frames.

Burdett Hassett.

Alamagordo, N. M.

### White of Egg with the Syrup.

Some years ago a friend in Italy sent me by mail to North Germany 1½ lbs. of bees with queen, the first of March, not considering that at that time, as a rule, winter weather prevails there. I had an empty hive on hand and put in it five or six pieces of old comb (about an inch wide), as starters in the brood-frames, and gave sugar syrup—how thin it was I do not now remember; but at all events, the bees used no water. If I am not wrong, I fed up to the month of May, and gave every evening from two to six teaspoonfuls of milk and the white of an egg. It was very seldom that a bee left the hive. In June and July it was a very strong colony, and I had a rich crop from white clover and basswood.

Altho I have thought a good deal about this matter since coming to this country, I have not as yet had an opportunity to test this matter fully. The bees found, however, in this food all they required; and I think that in any case the plan should be tried out fully. For the small beekeeper it is too costly and requires too much time. But the professional queen-breeder will assuredly find this scheme of great value. The milk and egg should be renewed fresh every evening. I have at times myself drank or eaten what the bees left.

Gustav Kohnke.

Clio, Mich., Sept. 26.

### A New Insecticide.

When I was able to obtain bisulphide of carbon at reasonable price (\$1.00 a gallon) I used it freely, altho there were some objectionable features connected with its use. When prices went soaring I went back to using sulphur, which is effective and quite inexpensive. We are now informed by the Department in Washington that this new insecticide, para-dichlorobenzene, is a compound deadly to insects, harmless to human beings, and has no pronounced odor which clings to fabrics like other insecticides. It is not very expensive. It may be bought in barrel lots at 15 cents a pound. Its use is very simple. It need not be sprinkled about in corners, etc., but just placed on top of the articles to be fumigated in an open can or other vessel. Para-dichlorobenzene is a colorless crystalline substance which evaporates quickly when exposed.

The new bulletin, No. 167, tells more about it, and may be had for five cents. The bee-keeping fraternity ought to make use of this new insecticide for the purpose of killing the wax moth and larvæ.

Naples, N. Y.

F. Greiner.

### English Sparrows Catch Bees.

I have a swarm which a friend of mine in Ft. Smith, Ark., caught late in the summer. It has had rather hard luck in the last few weeks. The hive was in an open space on the lawn in the Union Station grounds. When the bees would come out on the alighting-board English sparrows would swoop down in droves and pick them off. In the A B C and X Y Z reference is made to bee-martins and butcher-birds catching bees, and I wondered if any one else had found that English sparrows do this. The colony was so depleted that only about a pint of bees were left.

R. G. Lowry.

Pittsburg, Kan.

[We have had one or two reports of English sparrows catching bees, but did not think the trouble serious. It would seem from your experience that at times they can be considered as an enemy of the honeybee.—Ed.]

### Use Honey from the Same Hive.

On July 6 I transferred a colony from an old-style hive to a standard hive; and in making the change I lost the queen. I kept a sharp lookout for her, but failed to see her.

I filled four frames about half full with sealed brood-comb, and put half-sheets of foundation in the rest, and placed the new hive on the old stand. The bees did not all go inside the hive until the third day. On the sixth day I opened the hive, and, on lifting out the first frame, discovered the hive was queenless.

I ordered a queen right away, and on the evening of the eighth day it arrived. I introduced it on the ninth by the "honey method" described by Mr. Baldwin, and I must confess I was not on "easy street."

On examination the next day I found her on the very first comb, all cleaned up, and a half larger than when introduced the day before. On the third day, when I took a peep in the hive I found her laying.

I would advise those trying the honey method to use honey from the same queenless hive so the queen will have the scent of the colony. I used lots of honey, smearing her all over, and pouring some after her as she tumbled down between the frames.

East Butler, Pa.

W. E. Kiser.

### The Daily Gain of a Hive on Scales.

The following is the daily gain of an average colony on scales. The weights were taken at night, about sundown. It is only the net gain for the day. The evaporation of the night before is not accounted for. The scales were not touched except at night. Of course in taking off supers the scales had to be changed. The first day of the record is May 24. It includes perhaps two to four days' gain—so small an amount I did not record it. The colony did not swarm. I have had a colony on scales many years, but this is exceptional in the heavy flow.

The first white-clover gain recorded May 24, 4 lbs. The following are the gains on consecutive days: 6, 5, 9, 5, 10, 13, 3, 6, 8, 7, 12, 10, 9, 7, 6, 3, 4, 9, 9, 7, 3, 12, 23, 0, 10, 16, 9, 8, 5, 13, 26, 16, 8, 8, 2, 16, 14, 10, 7, 4, 6, 4, 8, 16, 5, 2, 4, 1, 2. There probably were two or more days not accounted for. In rainy weather there was no gain. Several times it rained in the night, and was very wet until about noon. But the bees would make up in the afternoon all the night loss, and 5 or 6 lbs. net gain. The total gain was about 410 lbs. The honey is exceptionally fine—very white and clear, of heavy body.

The very heaviest gains were recorded after an empty super of extracting-combs was given. If the combs were given Monday, Wednesday would be the heavy day. The colony drew about four supers from foundation. The rest were empty combs.

Marecline, Mo.

Irving E. Long.

### Honey in the Bread.

I saw something in a recent issue of *Gleanings* where a man who does his own cooking says he puts honey in his bread. Well, he has not got the "start" of me; for when I want the bread to be unusually good I take the trouble to put some honey in it; and when people praise my bread and say, "How good it is," I say, "I put honey in it this time."

Beekeeper.

### Paste to Stick Labels to Tin or Glass.

The following formula will do it:

Half an ounce silicate of soda; one ounce corn starch; one and one-half pints of water. Add the starch and silicate of soda to the water, and stir until uniform; then place the dish in another vessel of water and heat until the starch is gelatinized.

Bridgewater, Vt.

W. C. Raymond.

# GLEANINGS FROM QUESTIONINGS

G. W. H., California.—I have seen several toads hanging around the hives in my apiary. I killed one and found sixteen bees in its stomach. I then killed another and found forty-one bees. Is there any remedy, aside from killing the toads?

A. In a good many places toads eat many bees by sitting at the hive entrance and licking them up as they do flies. If you find a number of them about your apiary you will probably find it necessary to place your hives on stands high enough so that the toads cannot reach the entrance.

J. F. A., Cleveland, O.—What makes comb in the lower part of the hive turn dark in the center?

A. The dark color is caused by stain from the various layers of cocoons left after the bees have been rearing brood. A comb will remain light-colored except for the deposit of propolis as long as no brood-rearing is going on; but the part of the comb containing brood always turns dark and finally the whole comb will be practically black. This does no harm, however, and the comb may be used year after year with absolutely no bad effects.

F. B., Bensenville, Ill.—Which is better for wintering bees—a cellar or a woodshed?

A. A building above ground is not suitable for wintering bees in confinement, owing to the fact that the temperature changes considerably. In a cellar the temperature is more uniform; but for best results it should not go below 40 nor above 50, for any length of time, and there should be good ventilation without excessive moisture.

The shed would answer all right provided you had openings cut in the side so that the bees could have an open entrance to the outside at all times. It would be well to provide packing around the hives inside the shed in order to confine the heat.

W. F. M., Glenwood, Mo.—What makes the bees attach the combs in my sections to the separators? When I remove the sections from the super it tears a hole in the cappings where I separate them from the separator.

A. Certain strains of bees are worse in this respect than others, but the building of brace-combs is quite apt to be indicative of an overcrowded condition of the hive. It is true that you cannot always supply extra room by way of comb-honey supers at exactly the right time; but at the same time, by being careful to supply additional room before the first super is entirely finished, you can overcome at least some of this nuisance.

If full sheets of foundation are used and the hive is not absolutely level from left to right, sometimes a sheet will sag over until

it touches the separator. Under such circumstances the bees will always attach the comb to the separator.

J. S., Bandon, Oregon.—In order to have less wax in a section of comb honey, and just that much more honey, why not use drone foundation instead of worker?

A. A few beekeepers use this in sections; but it produces a rather peculiar effect, making the honey look coarse. It is for this reason that so few use it.

As a matter of fact, it is a question whether any one would notice the difference in the amount of wax in the comb when eating the honey, for counting the midrib and the cappings there is nearly the same amount of wax in a section of drone comb as in a section of worker comb.

H. B. Y., Buffalo, N. Y.—What would be a fair price for a full ten-frame colony in first-class condition in a double-walled hive well supplied with winter stores—good combs built from full sheets of wired foundation?

A. It is difficult to give a definite answer to this question, for the price that the seller gets is not so much what the equipment is actually worth but what the buyer will pay. In the fall of the year one has to consider that the buyer runs some risk in losing the colony thru the winter.

A good deal depends also on the queen. With a good young queen of a vigorous strain the colony ought to be worth around \$10.00 or \$11.00, or possibly even more. Whether a buyer would pay this is another proposition.

Good straight combs built from full sheets of wired foundation ought to be worth from 25 to 35 cts. apiece, sold separately.

O. C. E., Steubenville, Ohio.—What is the best way to move an apiary fifty yards?

A. A very safe way to accomplish the move that you refer to is to carry the bees a couple of miles into the country, leave them for a week or so, and then bring them back, placing them wherever you desire. There is then very little danger that the bees will mix up badly or get into the wrong hive.

Another plan, which is somewhat less work, but which is a little more risky, is to move the whole apiary in the late evening, placing the hives wherever you want them. Take away everything that looks like a hive on the old location. Stand boards in front of each hive in the new location; and the next morning, before the bees begin to fly, pound on each hive vigorously and smoke the bees considerably so they will fill up with honey. Then when they come out to fly they will be more likely to notice that a change has been made, and they will mark their location. We have moved apiaries short distances in this way with very little loss.

A. I. Root

## OUR HOMES

Editor

Can the Ethiopian change his skin, or the leopard his spots?—*JER.* 13:23.

Then Paul answered, What mean ye to weep and to break my heart? for I am ready not to be bound only, but also to die at Jerusalem for the name of the Lord Jesus.—*ACTS* 21:13.

Let us not be weary in well doing; for in due season we shall reap if we faint not.—*GAL.* 6:9.

I have before remarked that I was one of a family of seven. My older brother was of a rambling disposition. When he was in his teens he would go off and be gone for days and even for weeks. He wanted to see more of the world, and, as a consequence, he found employment with ungodly men—some of whom, it seems, took pains to destroy the faith that a good mother worked and prayed to implant. Even after he was married and was the father of grown-up children he was restless and uneasy. He was all over the United States and even away down in Mexico; and later he bought a ranch near San Diego, Cal. After the death of his first wife he married the second time, and died not long after the birth of two children; and when these two children were of only tender years their mother died also, and for some time they were left only partly cared for in the city of San Diego.

When the civil war broke out, my brother, in accordance with his nature and disposition, enlisted, and became an officer in the army. After the death of both father and mother it was deemed advisable to have the children go to the Soldiers' Home in Xenia, Ohio. I have before mentioned the buildings, extensive parks, and other arrangements made for the best care of the children, especially orphans of the soldiers. In fact, it has been for years called "the Children's Home."

Well, the boy, Homer Root, seems to have inherited his father's disposition. He could not stay contented very long in one place. I am sorry to say that, while in California, without father or mother, he learned to smoke cigarettes, to use bad language, and to be untruthful. By the way, some good authority has said that, as soon as any boy begins the use of cigarettes, he becomes untruthful. It is a part of the cigarette business. Well, this nephew of mine did not seem to get along very well at the Soldiers' Orphans' Home, and then came here to work for us in our factory. Perhaps I have been unfair in not speaking of the boy's good qualities. He had a love for mechanics, and especially for electricity; but, like his father, he did not seem to like being shut up in any shop,

office, or factory. He took for a time a particular liking for the machine-shop; but soon became uneasy, and wanted to go off on the railroad where he could be outdoors, and work as an assistant to their electrician. I think he did fairly well on the railroad; but he soon wanted another change, and the first thing I knew he had enlisted in the navy and was on board of the warship *Arkansas* for a cruise of three years. The strictness in the navy seemed to do him good, and he made a pretty fair record. I have mentioned him frequently in these Home papers, and have given place to one or two letters from him, especially those pertaining to the gyro compass. Well, neither this boy Homer nor his father before him seemed to take much of a liking for church or Sunday-school, *Christian Endeavor*, nor the Y. M. C. A. They did not seem to come much along his line. During the past years I have kept more or less in touch with him, and not only wrote him letters but prayed for him; but I am afraid that much of the time I prayed without very much faith. I am afraid, also, I had given up thinking that he would ever have much to do with *Christian* work in any form.

Dear friends, in years past I have several times spoken of my "happy surprises;" and I think I have said that a Christian who does his duty, and holds unswervingly to the straight and narrow path, will, at least occasionally, meet with "happy surprises." Well, one of these came some time last winter. It was a letter from my nephew of whom I have been speaking. Perhaps I should mention first that he wrote me, perhaps a year before, saying that he was thinking of getting married to a young lady he had known at the Home in Xenia. After getting the particulars I advised him to get married, even tho some of his relatives advised otherwise. Well, now for the surprise. While in my Florida home, as I have said, I received a letter reading something as follows:

*Dear Uncle*:—I would give almost anything in the world to have you hear a minister preach here in Springfield," etc.

It was a surprise to me to know that the boy was attending church at all; and the idea that he should ask *me* to go to church with him was almost a huge joke. I gave a shout of surprise, and forwarded the letter to the good minister whose name he gave. I took it that he must be an evangelist, something like Billy Sunday; and so I addressed my letter to the "Reverend Mr.

Rourke, Evangelist, Springfield, Ohio." I received a prompt reply; but brother Rourke told me he was not an evangelist, but just a regular Presbyterian preacher; and he said, furthermore, that Homer was bringing more recruits into their men's Bible class than any other member. Did you ever? Just think of it—this boy whom I was worrying about was in regular attendance at a men's Bible class, and bringing in others. Of course I urged my nephew to follow the leadership of the good minister of whom he thought so much, and become a member of that Presbyterian church; and I furthermore added that, when I should hear the good news that he was an enrolled member, I would go and hear the minister he had learned to think so much of. By the way, this good pastor said something like this in his letter to me:

"Mr. Root, you cannot think how much good it does the pastor of a church to get such a letter as yours containing the one from Homer. When defeat and disappointment seem at times to be almost the only result of a clergyman's labor such letters as yours and *his* are like an oasis in the desert. It gives me an inspiration to go on."

One Saturday morning in September I started on my trip to Springfield. It had been some time since I had seen my nephew; and the more I talked with him and became acquainted with the family of his good wife, the more I was impressed with the transformation in the wild and careless boy of a short time before. He looked different and acted differently, for he is now a bright, manly *Christian gentleman*. When he introduced me to the different members of that great Presbyterian church, and seemed to be recognized on all sides as *one of them*, I could not help saying mentally, "Thank God, thank God." It brought to my mind vividly a verse in a familiar hymn that comes in something like this:

His power, and his alone,  
Can change the leopard's spots  
And melt a heart of stone.

I questioned a good deal about Homer's wonderful change. If I am correct about it, the good young wife urged him repeatedly to go to church with her just once. Perhaps his first attendance was at the men's Bible class. He became interested. This devoted minister seemed to have a faculty, not only for *getting* hold of young men but of *holding* them; and in a little time Homer was inviting his shopmates to go to the class. Now here is the point, friends. When you get a man or boy to work *bringing in recruits* you will very soon have him "born into the kingdom."

Away out west there is a town or city

(it may be a *city* now) called Anacortes. It was built up, or at least was started, in one year, and, as a matter of course, saloons were galore on both sides of the street. One of the prime movers in starting the town had the good sense to recognize that something *besides* saloons is needed to build up a community. Then this man commenced to talk about a church; but on all sides they considered it a big joke, and again and again his friends would say, "*You* scheming for a church? Why, what has got into you? Turned pious?"

He said he had not particularly turned pious, but in his opinion they could not have a nice and enterprising town without a church. Then the next thing was to get a preacher. So this man commenced hunting for one. He finally met a minister on board a steamer, and told him he would have to stop at Anacortes and preach a sermon. The minister demurred, saying, "How about an audience?" Our real-estate man said he would guarantee an audience if the minister would stop over one trip; and then he went about going thru the town, inviting everybody to come and hear this minister *preach*. They had some trouble in finding a room big enough and in getting seats. But our vehement friend carried the day, and all of them heard a sermon. Do I need tell you the outcome? Altho he had not planned in the outset anything of the sort, he soon became a devoted Christian worker. How could he invite people when he himself was outside the fold? And, my good friends, it will work so every time. Get to work; get these boys and girls at work doing something good and useful. Get them interested in building up churches and Sunday-schools, and in doing away with saloons and brothels, and *God* will take care of the harvest.

Well, of course I was greatly interested to see this man of whom I had heard so much conduct the Bible class. The lesson was somewhere in the book of Acts; and the incident referred to in our second text, where Paul said he was ready not only to go to prison, but he was ready to die for the Master. Our leader, in commenting on the incident, asked how many there were ready to go to jail for righteousness' sake. He said that he himself was ready to go to jail any minute rather than to compromise with the powers of darkness. I could honestly say amen to this, and I did come near saying it; but in a minute more I was glad I did not. By the way, friends, I have heard a good many different preachers of the gospel in the past thirty or forty years; and it is rare that I hear a sermon where I do not find occasion to give some point in it, somewhere, a hearty indorsement by

some sort of amen. In fact, I do not remember that I have ever, with few exceptions, heard anything from any minister that I was not ready to indorse and follow the speaker; but on this occasion I "met my match." After the good pastor had said he was not only ready to go to jail but to go to death he added something like this:

"Yes, friends, I am ready to go to jail, and stay there, and *rot*, rather than compromise with the powers of darkness."

I did not dare say *amen* to that last sentence. It frightened me. I have for years past felt that I was ready to die as a martyr, if need be; but I am afraid I was a good deal like poor Peter, who was ready to fight and ready to be killed, if need be; and he struck out with his sword in order to give the Master to understand that *he* was not afraid; but when the command came to put up his sword and do nothing his courage failed; and when just a girl suggested that he was one of that fanatical crowd his courage all oozed out, and he suddenly turned a cowardly coat and enlisted in the service of the Devil. It is very hard for me to sit still and wait for *anything* or for *anybody*. I want to be *doing* something; and when the suggestion came that I might be called upon to "lie still and rot," perhaps as many a devoted soul in ages past has been required to do, I backed down like Peter.

Again, in the sermon later the minister said something like this:

"You may be aware, friends, that there has been a good deal of talk of having moving-picture shows in our great cities looked after. A committee has been appointed in the city of New York, and they report that 80 per cent of the films in common use were demoralizing. Their tendency is to lead our boys and girls down to shame and crime instead of lifting them up or building them up."

Let me pause a moment right here. In a recent daily, mention is made of a boy who set a building on fire; and the only reason given for doing so was that he saw the same thing done in a picture show; and the show gave the whole thing in a way that would make the boy think it is a great thing to make a stir in the neighborhood by such an act. Let us now get back to the sermon.

The speaker said that, rather than be engaged, directly or indirectly, in anything that would lead our boys and girls down to crime and ruin he would be willing to be nailed up in his coffin; and then I was ready again to say "amen." I would rather die than to live having the guilt rest

on my conscience that I had been instrumental in the spiritual death of any boy or girl. But the speaker in his next sentence took me right off my feet as before. The sentence was this:

"I had rather be nailed up in my coffin, and be *buried alive*."

Let us now go back to Peter once more. When the Master said to his little crowd of followers that every one of them would desert him in time of trial, Peter boldly declared, "Tho I should die with thee, yet will I not deny thee." Poor Peter! Little did he know the power of Satan. And somewhat in like manner little did I know or realize what a coward I am, after all. I had been thinking I could consent to death—that is, a speedy death, or such a death as we ordinarily witness—for the dear Master's sake; but, oh dear me! I did not contemplate "being nailed up, and buried *alive*."

Just one more illustration in closing, about our transformed young relative. In a shop where he works (electrical works, of course) there is a young man who had been following Ingersoll and Tom Paine, and taking some periodical that ridicules the Bible, Christian religion, etc. Homer invited this young man to come to their Bible class. The reply was something like this:

"Bible class? Do you mean you want me to go to 'Sunday-school'? Not much." But Homer was not to be put out, and so he invited him again, only to meet with sarcasm and ridicule; but after he followed it up Sunday after Sunday this friend of his finally consented to go *once*. Homer told him if he would go just once and listen to Mr. Rourke, and then did not feel inclined, he need not go any more; and then Homer added, "Now, uncle, what do you suppose happened? Why, the time he went first was away along last spring; and he has been there every Sunday since."

Oh, yes! there is still one more thing I must tell. Before the class opened, the pastor said, "Who is absent today whom we have a right to expect to be here?"

A bright young man stood up and mentioned a name.

"Can any one tell why our friend is away this morning?"

Somebody answered, "He is out of town," and so on with several names. Finally somebody was mentioned, but no person could give any reason for his absence. Then came the question, "Who will volunteer to hunt up our friend and ask why he is not with us today?"

Some one replied very promptly, "He and I are quite well acquainted, and I will

find out and report the reason of his absence."

There, friends, is a suggestion for Bible classes, men's brotherhoods, Y. M. C. A. associations, etc. Whenever a pupil finds he has been missed and is inquired after, he will be pretty sure to come next time. Now a word in closing.

If you, my dear reader, have any young friends or relatives, a boy or girl who seems to be getting out of the straight and narrow way, do not be wearied in pleading or praying for that one. "Be not weary in well doing, for in due time we shall reap if we faint not."

---

#### REPORTS ENCOURAGING AND REPORTS DISCOURAGING.

Our older readers will remember that years ago I used to have two departments headed as above. Objection has been made to giving these great yields of honey because it tends to give beginners the idea that keeping bees is a ready means of "getting rich quick." But if we go to the opposite extreme, and give only reports *discouraging*, this would be manifestly unfair. Well, several times lately I have urged that our journal give a little more space to reports *encouraging*. Of course I do not as a rule have much to do just now with the department of bee culture. Well, only yesterday, Sept. 8, I was getting ready for my after-dinner nap when one of my sons-in-law called out, "Say, father! Don't you want to come over to the honey-room and see them unload a car of extra-fine honey?"

Of course, I went over. The first thing that pleased me was that there was not a trace of a leaky package in the whole carload. There was not a drop of honey on the bottom of the car, nor anything sticky anywhere. A screw cap was loosened from one of the cans, and some slips of pine wood passed around for the different members of the firm to sample the 20,000 pounds. Just as soon as I tasted it I uttered an exclamation of delight. In answer to my question as to who produced that big lot of extra-fine honey, Mr. Calvert replied, "Mr. Sowinski." Well, I was pleased again to be told that a foreigner (at least his name would indicate such) was the successful beekeeper, instead of some old downeast Yankee whose name has, perhaps, been before the beekeeping world for years past. I was also told that this was only about half of his crop of 40,000 lbs., and that the whole yield was from between 300 and 400

colonies. When I wanted to give the full name and address with particulars one of our men who makes it his business to hunt up and buy honey said our good friend who produced the crop would object to any report being made that would give his locality.\* This matter has come up many times before, where somebody gets a great yield, and a great lot of beekeepers begin to camp all around him, very likely to discover later that the *man* and not the locality gets the honey by the carload. Let me digress a little.

A few days ago at one of our board meetings the question came up as to the purchase of a new printing-press to print honey-labels. By the way, I think we are having more orders for honey-labels just now than ever before since GLEANINGS was started toward fifty years ago. While I write, the new press is running off beautiful labels in colors at the rate of 2800 sheets an hour—the number of labels on each sheet depending on their size, of course. As usual I objected a little to the purchase of a new printing-press. I thought we had presses enough, and some that were not running. But this new press takes care of the label work largely. It is a *self-feeder*, and has already run off 2900 sheets without a stop or a failure.† As I write, it is printing 29 labels at once, or 81,200 an hour. My impression is that when people get a taste of this fine honey I have been speaking about it will keep that new press pretty busy printing labels to put on the bottles. Just a few days ago I got a glimpse of a nice little bottle of honey for only *five cents*, and I was delighted to think one could get about all the honey that is good for him, perhaps at a restaurant or a lunch-counter for "only a nickel." Mr. Calvert threw cold water on my speculation, however, by saying that the way glass bottles are advancing (on account of the war) he was a little afraid "the more we sold the worse off we would be."

Well, friends, it rejoices my heart to know that my prediction to the worrying friends (when I first got crazy about the possibilities of bee culture) toward fifty years ago, is coming to pass. At that time I said, "Now don't you worry, my good friends and relatives. The time is coming, and I expect to live to see it, when honey, like butter and eggs, will not only be on sale at every corner grocery thruout our

\* This beautiful honey is supposed to have come largely from the wild red raspberry.

† By the way, I forgot to mention the fact that if any accident happens, say when a sheet gets in wrong, the press stops promptly of its own accord until somebody sets the matter right.

land, but it will also be on sale *every day in the year.*" My prediction has not yet been quite fulfilled, but it is "coming, coming, coming." Milk and honey ("uncooked

food") straight from the loving hand of the great Father, is going to take the place of intoxicants and stimulants; and may God hasten the day.

# TEMPERANCE

## SOME WORDS OF WISDOM FROM AWAY OVER IN SWITZERLAND.

I take it for granted that the readers of GLEANINGS, or at least the greater part of them, are going to vote dry in the coming election, or at least they will vote to put men into office who are not afraid to stand up before the world for prohibition. With this in view I wish you would not only read the little clipping below from the *Union Signal*, but get every voter, as far as possible, to read it and ponder on it before they cast their vote on Nov. 7.

### THE TOLL OF THE BREWERY.

Such horrors as a great modern joint-stock brewery perpetrates are unrivaled in the whole world's history. Men in past centuries were made chattel slaves. But the slaves kept their health. Men have been killed by thousands; but the children of the murdered remained strong. Now they make slaves of them and murder them at the same time. They kill them together with their children and *children's children*. They kill them slowly; they torture them slowly to death.—*Dr. Von Bunge*, University of Basel, Switzerland.

## GOUT, SCROFULA, SOFTENING OF THE TISSUES, AND TOO MANY OF OUR CRIMINALS COME FROM BOOZE.

See the following, which we clip from the *Kansas City Star*; and it comes from so good an authority as President Poincare:

### WILL FRANCE GO DRY?

The leading men of France, headed by the president of the French republic, are engaged in a campaign against alcoholism. Soon after the war began, the French government prohibited the sale of absinthe. Now in every postoffice in France the following poster appears, by order of the minister of commerce and posts:

### THE ALARM!

FRENCH SOCIETY FOR ACTION AGAINST ALCOHOLISM  
Honorary President, M. Raymond Poincare.

Drink is as much your enemy as Germany.

Drink since 1870 has cost France much more than the present war.

The cordials of your parents reappear in their offspring as great hereditary evils. France owes to wines a great many consumptives, without counting sufferers from gout, scrofula, rickets, premature softening of the tissues and too many of our criminals.

Drink decimates France.

Mothers, young men, wives! Up and act against drink, in memory of those who have gloriously died for the fatherland. Thus you will accomplish a mission as great as that of our heroic soldiers.

It looks as though the several of the older nations of Europe may be freed from the curse of drink, notably France and Russia, and possibly England, long before the United States joins the list of dry countries.

From the above it would appear that if France gets rid of drink as a result of the war she is going to be the gainer in the end; and is it not about time that the whole wide world wake up and do likewise?

### "A LOT OF MONEY WASTED."

We clip the following from Bryan's *Commoner*:

The *American Grocer* recently estimated that the drink bill of America now exceeds one billion and seven hundred millions annually. As only about one person in four uses liquor, this means \$90 for each. That's a lot of money to waste, especially as poor men are the chief sufferers.

### CROOKS SHUN A DRY TOWN AND A DRY STATE.

Morden Ward, in the *Detroit Times*, declares that crooks have been flocking from dry states into wet ones, and that self-defense will force Michigan to adopt prohibition. "A crook hates a dry town, for there is no place to hide," he says. "Closing the saloon naturally drives out all of the professionals." —Methodist Temperance Board.

### "IT WERE BETTER FOR HIM THAT A MILLSTONE WERE HANGED ABOUT HIS NECK."

*Mr. Root*:—I am enclosing a clipping concerning a king who is setting an example that will destroy others, and it seems to me as if it might have been better if he had been drowned. Surely the influence for wrong is very great.

Chrisman, Ill., Aug. 1.

GEO. W. FAIR.

The clipping referred to above comes from the *Terre Haute Star*. It reads as follows:

### KING THANKS SCHOOL BOYS WHO HELPED RESCUE HIM.

COPENHAGEN, July 30.—King Christian received at the castle today two school boys who helped to rescue him last week when a boat he was sailing was upset near Aarhus, and presented them with cigarette-cases.

After expressing his thanks to the boys, the king and queen drove to a restaurant to thank the proprietor, who discovered the king's perilous position and gave the alarm. The king presented him with a diamond ring.

Just as soon as I got hold of the above it occurred to me that our Lord and Master *did* say of a certain class of people, "It were better for him that a millstone were hanged about his neck and that he were drowned in the depth of the sea." Now the question arises, "What class of people does the above severe arraignment refer to?" The fore part of the verse I have already quoted tells what it is as follows: "But whosoever shall offend one of these

little ones which believe in me." Perhaps some of the friends will think that our good brother who sends the clipping, and myself, are pretty severe. But when we take into consideration what cigarettes are doing for the youth of our land, are we not right about it? It is true the conditions laid down by our Lord are in regard to offending "little ones which believe in me." I suppose it refers particularly to those who go out of their way to spoil the faith of some child who has already started to serve the Master. Suppose, for instance, some wicked man should stop a group of boys who are on the way to Sunday-school and tell them that their religion is only a superstition, etc., and turn them away. I can recall instances in my own life where this thing has been done, where a grown man stopped his work just in order to *poison* the minds of children.

Where does the cigarette come in here? Ask our teachers or any one who has charge of children, and I think they will all say that no other one thing will lead a boy astray more quickly than encouraging him in the cigarette habit. May God speed the day when *the whole wide world* shall be awakened to the real harm the cigarette is threatening to do to the *boys* of the world.

#### TOBACCO AND TUBERCULOSIS.

The following, from the good doctor who answers questions in the Health Department of the Cleveland *Plain Dealer*, is suggestive:

##### HAVE HIM STOP SMOKING.

J. S. B. writes: "My son, who is 20 years old, has tuberculosis. He likes to smoke a little. Is it harmful, and would you advise him to stop?"

##### ANSWER.

A youth with tuberculosis has enough to combat without adding the poisons from tobacco smoked even in moderation. Have him stop.

Please notice that this good doctor suggests, if he does not say so right out, that every tobacco-user is handicapped more or less. He has got to scrape up sufficient vitality to overcome the poison, even when used "in moderation," as suggested in the above. Please notice also that the tobacco-user is not only handicapped in his ability to resist disease, but he is also handicapped more or less in "efficiency." If you want to be at your very best, for yourself or for humanity, and for the children who are coming along after you, cut out all sorts of stimulants, and even "tobacco" in "moderation."

#### "HOBOES"—A NEW TRICK.

Just a few days ago a fairly well-dressed man came limping up to the door as if he could hardly walk; and the expression on

his face indicated that it gave him great pain even to hobble along. He piteously asked Mrs. Root if she could not give a poor lame man a little lunch to enable him to get to his friends. Now, Mrs. Root has for some time past (perhaps because I insisted on it) offered these fellows work but no lunch. This man, however, was unable to work, and so she spent quite a little time in picking up for him a good meal. But imagine her surprise to see him start off with his lunch at a very good gait without a trace of his former lameness. This aroused her curiosity, and so she watched him until she saw him (when he supposed he was fairly out of sight) throw away the greater part of the food she had given him. It probably was not *good enough* to suit him.

I give this bit of experience because I know there are a good lot of women among the readers of GLEANINGS who as a rule have enough to do without encouraging tramps; and I hope that, after they have read this, they will not be humbugged as Mrs. Root was. The incident seems to indicate that tramps are getting poor encouragement, and that they *usually* get a cold reception unless they put up some new "stunt" like the above.

#### COTTAGE CHEESE—SOMETHING FURTHER IN REGARD TO HOW TO MAKE IT.

The big advertising that has been given to sanotogen has called attention to cottage cheese, especially since Prof. Wiley has told us that cottage cheese is practically the same thing as the much-lauded sanotogen. Well, here is something from a lady who has been for many years a friend of GLEANINGS, in regard to how to make cottage cheese. By the way, we find it in our market for only 10 cts. per lb., and it is also offered at the same price away down in Bradentown, Fla. When I can get hold of it I prefer it with my fruit supper to the regular cheese which costs three times as much or more. Now for the directions as to how to make it.

In GLEANINGS for March 1, p. 214, Mrs. Root should have said more for a new hand, and also some old hands, as to how to make "Dutch cheese," cottage cheese, or "smeared case." It should be stirred often to heat even—just enough for the whey to separate from the clabber, and hang in a jelly-bag until cool. If too hot it will not be healthy. Fanny Field, the old-time poultry woman, would not make it too hot for her chickens. It is best when the clabber first thickens—not old, sour, or bitter. Some use a thermometer to heat, and season with cream, butter, sugar, salt, pepper, cinnamon, or nutmeg. It takes practice to make it perfect, and then it is good without anything. If you pour hot water on, and then stir cold water it answers for small quantity.

Watertown, O., March 10. M. L. DEMING.

# "SCALECIDE"

Fall Spraying Controls Leaf Curl. . . Does the Work; Cleans up the Trees.

Don't put off the dormant spray until the spring rush. The weather may be bad or the ground too soft. Spray this fall and make sure of controlling peach-leaf curl, San Jose scale, pear psylla, apple canker, collar rot, etc. You can save trees now that would die before spring. Use "Scalecide." Better and cheaper than lime sulphur—cuts

the labor cost. Never injures trees, hands, face or pump. Cost of spray materials will advance before spring. Order now and save money. Write today for free booklet, "The Whys and Wherefores of Fall Spraying." B. G. PRATT CO., Manufacturing Chemists, Department 61, 50 Church Street, New York City.

## Jacob Biggle on "Corn"

An absorbing article you will find in the November issue of The Farm Journal. Something about the American Indians, the first corn growers. Also some good New England philosophy.

You should read Jacob Biggle's monthly articles in The Farm Journal. Start your subscription to this biggest and best-of-all farm and family paper with the November issue. 5 years for \$1. Goes into nearly 1,000,000 homes. Ask for free sample and your free copy of the 1917 Poor Richard Almanac. Write today.

## HELP WANTED

WANTED.—Experienced young man for our beekeeping supply department; one who has a knowledge of beekeeping and is not afraid to work. Give reference, and state salary expected. THE FRED W. MUTH CO., "The Busy Bee Men," 204 Walnut St., Cincinnati, Ohio.

## Convention Notices

The annual meeting of the Western New York Honey-producers' Association will be held on Tuesday, November 14, 1916, at the American Hotel Hall, Akron, N. Y. An interesting program will be provided, covering various topics of interest to beekeepers. A good attendance is expected, as this has been a fairly good season. If any one has any new or practical ideas, short cuts or innovations of any kind, pertaining to beekeeping, he is invited to present them with details thereof. Election of officers for the coming year and other business of interest to members will be brought up for discussion. Every one interested in bees or honey is invited to attend.  
Akron, N. Y., Oct. 13. WM. F. VOLLMER.

The twentieth annual meeting of the Chicago Northwestern Beekeepers' Association will be held in the Great Northern Hotel, Room 138, on Monday and Tuesday, December 4 and 5, 1916. The program is not completed, but the following expect to be there and read a paper on the subject following their names: N. E. France, Platteville, Wis., "Marketing Honey;" Edward Hassinger, Jr., Greenville, Wis., "About Heating and Clarifying Honey;" Louis C. Dadant, Hamilton, Ill., subject not announced; Kenneth Hawkins, Plainfield, Ill., "Displaying Live Bees in Chicago Groceries;" Dr. E. F. Phillips, Washington, D. C., "Extension Work in Beekeeping." The question-box will be made a strong feature. Of course many others will have papers.

Valparaiso, Ind. JOHN C. BULL, Sec.-treas.

## ONTARIO BEEKEEPERS TO MEET IN TORONTO IN DECEMBER.

The Ontario Beekeepers' Association will hold its annual convention on Tuesday, Wednesday, and Thursday, December 12, 13, 14, in Toronto. This later date than usual will be welcomed by the beekeepers, as the great rush of fall apitary work will be over.

A very interesting program, extremely practical, has been arranged by the executive committee.

Prominent beekeepers from both Canada and United States will be present. Mr. C. P. Dadant, Hamilton, Illinois, editor of *The American Bee Journal*, will take up the question of "Prevention of Natural Swarming." Mr. Dadant is an extensive honey-producer, and has harvested over 100,000 pounds of honey this past season. The Dominion Apiarist, Mr. F. W. L. Sladen, in charge of the bee-investigation work on the various experimental farms, will speak of some line of his investigations. "Beeswax Production" will be discussed by Mr. W. A. Chrysler, of Chatham; and Mr. G. A. Deadman, Brussels, will deal with "The Use of Shallow Supers in Connection with the Regular Size." Comb honey has been successfully produced by Mr. S. B. Bisbee, Beamsville, and his experiences will be valuable and interesting. Special apianian appliances will be explained by Mr. E. T. Bainard, Lambeth, and Mr. W. J. Craig, of Brantford.

Of special interest from the social side of the convention will be the banquet on Wednesday evening, at which Mr. Couse will speak of the "Past Presidents of the O. B. A." Mr. Couse has been a member continuously since the association was organized, and for many years held prominent positions on the executive committee. His personal acquaintance with the past presidents enables him to handle his subject in a very interesting and able manner.

Programs will be ready for distribution shortly, and may be had by applying to the Secretary-treasurer, Morley Pettit, O. A. College, Guelph.

#### BEESKEEPING COURSE AT RUTGERS.

The need for and the opportunities in honey production are so large in New Jersey that Rutgers College has decided to offer a short course in bee husbandry.

It is believed that nine-tenths of the nectar annually secreted is lost thru lack of properly managed bees to gather it. It is known that tons of honey are annually brought into this state to supply local needs, and that practically no effort is being made to increase the use of honey.

In view of these facts the splendid opportunity for profitable honey production in the state is apparent.

Many have started producing honey without training, and with such a small number of colonies that success was impossible.

The largest honey-producer in the state has but 250 to 300 colonies of bees, representing an investment of not over \$3000, and the net proceeds average \$1500 annually.

One active man should be able to do all the work in handling 300 to 500 colonies, with the help of unskilled labor for two or three weeks during extracting time.

That this splendid resource of the state may be developed, Rutgers College will offer a short course in bee husbandry provided as many as four persons apply for the course. This course is planned to give the student a practical knowledge of profitable bee husbandry. Any one after completing the course, and after having spent one season in a commercial apiary, will be fitted to conduct profitably a honey-producing business.

Full particulars regarding this course can be had by addressing Prof. F. C. Minkler, Director Short Courses in Agriculture, New Brunswick, N. J.

#### TRADE NOTES

We call attention to the decidedly advantageous subscription offer now made on the back cover, giving one year's subscription to GLEANINGS, together with one's year's subscription to *Green's Fruit Grower* and the *American Poultry Advocate* (leaders in their fields) all for \$1.00. This is a rare chance in the subscription line. Take advantage of it while you can.

#### \$3.00 COMBINATION PRICE.

The combination price of a year's subscription to GLEANINGS IN BEE CULTURE and the new forthcoming edition of the A B C and X Y Z of Bee Culture has been fixed at \$3.00 (for the cloth binding). The new A B C and X Y Z will be off the press about Jan. 1 next. Orders for the new edition can be booked now.

#### DON'T SEND MORE.

That advertising in GLEANINGS pays is again proved by the fact that in response to our advertisement in our Oct. 1st issue for certain back numbers of our journal responses poured in from every direction until our need of back numbers was filled times over. Please don't send more; but remember that advertising in GLEANINGS pays.

#### Special Notices by A. I. Root

##### DEATH OF PROF. A. J. COOK.

We note by the *Western Honeybee* for October that our good friend Prof. Cook has gone. We are told that he died at the home of his son in Owosso, Mich., Sept. 29, aged 74 years. The above is the first intimation I have had of his death; and had I known that he was back to his old home in Michigan I would have considered paying him a visit. In our next issue I expect to give a sketch of my good friend of years ago. May God be praised that he died with an abiding faith in a glorious hereafter.

##### OFF TO FLORIDA, AND THAT "ADDRESSED POSTAL CARD."

As usual, Mrs. Root and I expect to start for our Florida home after I get my vote in an election day; and, God helping me, I expect to make that vote for men who, like myself, want to see the whole world dry—men who are not afraid to stand out before the world and declare themselves heart and soul for nation-wide prohibition of the liquor-traffic. Now about the postal card.

Down in my Florida home I cannot very well have a stenographer—that is, I would not have enough writing to keep a stenographer busy; and somehow in my old age I do not take to the dictaphone nor even to the typewriter. I can take my pen and write something on a postal card, and it does not wear on my nerves like these new-fangled inventions. Let me illustrate.

Altho I have for years past begged the friends to inclose an *addressed* postal card when writing to me, a good many seem to forget it or do not understand. One friend last winter asked a lot of questions that necessitated hunting over back volumes and interviewing books and catalogs for half an hour or more. When I was ready to answer him to the best advantage, by writing very small I got a good lot on the postal card he inclosed. When I turned it over I found he had omitted putting his name and address on it. Dear me! I wonder if anybody thinks I cannot afford to keep on hand a stock of one-cent stamps and postal cards. Well, I addressed the card as well as I could. He wrote his letter very well; but when it came to the name and address, he just put it on with a rush. After worrying over it I got it wrong, and in due time the card came back to me from the Dead-letter Office, marked, "No such office." When I went back to my files and found his letter again, and after more careful scrutiny, I found I had spelled the name of his town wrongly.

Now, then, friends, just fire at me as many letters as you choose; but before you write the letter, address a postal card so that Uncle Sam or your postmaster can read it; then write all you like, and I think I can promise to give you an early answer. You see, with an addressed postal card I do not even need to read your name unless I choose.

By the way, friends, why would it not be a splendid idea for every "mother's son" of you to have some postal cards with your address printed in plain black and white? and then when you are writing to anybody, no matter who, inclose a postal and help him to give you a prompt answer of some sort, may be while he is standing in the postoffice, so he can fire it right straight back at you?

ROOT QUALITY is emphasized in these stickers. Printed on high-grade gummed paper with a rich red ink, they reflect the taste of the user and add to the appearance of the stationery. Try 1000 and compare. . . 35c PER 1000 POSTPAID.

THE A. I. ROOT COMPANY, MEDINA, O.

# A Wonderful Book . . . .

This is the judgment of  
every thinking man  
who has read

“The Story of  
the Soil” By Prof.  
Cyril G. Hopkins

It covers the whole field of life on the  
farm, soil fertility, and perma-  
nent agriculture.

---

## What They Say About It

“Holds the intense interest of the read-  
er.” —Ohio Farmer.

“The farmers owe Mr. Hopkins a debt  
of gratitude.” —Chicago Tribune.

“Worth millions to the farmers of  
America.” —Prairie Farmer.

“Ought to be in the hands of every  
farmer in the world.” —Farmer and Breeder.

“I enjoyed every word of it. A fasci-  
nating novel about the soil.”  
—Editor American Agriculturist.

“A wealth of information.”  
—Editor Wallace's Farmer.

“The book is destined to do more good  
and stir more thought among the farmers  
of this country than any other publication  
that has yet appeared.”  
—Ex-Gov. W. D. Hoard.

## Don't Wait Till They are Gone

This book formerly sold for \$1.62 in cloth binding. A few days ago we secured from the publishers the entire remaining stock of this great book in paper binding and can offer it with “Gleanings in Bee Culture” for one year at \$1.15. When this consignment of these books is exhausted we shall be unable to furnish more.

**DON'T WAIT.** Get in your order today.

---

Gleanings in Bee Culture, Medina, Ohio

.. A Great ..  
**Subscription Offer**

**Three Leaders  
Three Kindred Businesses  
Three for \$1.00**

Gleanings in Bee Culture is now able to announce one of the most valuable and most advantageous low-price subscription offers it has ever made, namely: Gleanings in Bee Culture, Green's Fruit Grower and the American Poultry Advocate—all three one year for \$1.00. To the readers of Gleanings, it is not necessary to point out the advantages in the business combination of bees, fruit and poultry—and here are three journals that tell you as much (or more) about bees, fruit and poultry as any three journals published—and only \$1 for the three one year.

### **Green's Fruit Grower**

**Rochester, New York**

With Charles A. Green as Editor, is the oldest fruit journal in America, published at Rochester, the very birthplace of the fruit industry in the United States. It tells in season, all about spraying, how to beautify the home grounds, about ornamental shrubs, vines and trees, small fruits, home gardens, and successful orchards. In fact, it covers all phases of fruit growing, from planting the trees to marketing the fruit. It has a special department where subscribers' questions are answered, and a department devoted to the home and its interests.

Advanced enough for the commercial grower, yet simple enough for the beginner, and always reliable, it deserves a place in the homes of all who are interested in fruit-growing for home use or commercial purposes.

### **American Poultry Advocate**

**Syracuse, New York**

This great poultry authority, established 1892, is devoted to interests of both fanciers and practical poultrymen. It is authoritative and helpful in all branches of poultry work, from hatching and rearing the chicks to maturing fowls for show room and market. Tells how to get eggs at the least cost, how to feed to get best results. No detail left out. It is the second oldest poultry publication in the United States and stands second to none in its value to poultry raisers. It is helpful to the beginner as well as the expert. The newest and best in poultry literature is found between its covers each month. This paper will help you to success in the management of your poultry, and by following the valuable information given you should be thrifty and prosperous.

### **The Three for Only \$1.00**

This combination can be secured only by writing direct to the publishers, and while the offer may be open to our readers for a year it may have to be withdrawn earlier on account of general increased cost of publication. Secure it today.

An Old Book . . . but a Good One

## Winter Care of Horses and Cattle

By T. B. Terry

---

The famous author of this book treats of the most humane and profitable care of both horses and cattle. Among the subjects he deals with are Shelter, Comfort, Feeding, and the Different Kinds of Feed, Watering, Exercise, Kindness, Saving Manure, Feed Crops, Barn Arrangements, etc. It's all valuable. It can be made to mean dollars and dollars to you, if you own a horse or cow.

This book will be sent free to you, postpaid, if you will send us your subscription (\$1.00) to *Gleanings* before Jan. 1 next, and so help us to reduce the volume of work in our subscription department during the January rush season. If you have already subscribed for *Gleanings* for a year in advance, send us 10 cents and we will mail you this famous Terry book—now old but always good. Fifty pages, paper bound, with introduction by A. I. Root.

This offer will hold good so long as our supply of these books lasts. We have now about 1200 of them. The book originally sold at 40 cents. The copies now in stock are a trifle shop worn, but not to a noticeable extent.

kitchen ranges, of the highest quality sold at remarkable money-saving prices. Almost every one has heard of the Kalamazoo Stove Co. This company has sold thousands of stoves and ranges to our readers. They had big exhibits at all the leading state fairs and many county fairs. They have sold goods direct by mail to customers in almost every town and city in this country.

They are known from coast to coast for quality goods and for satisfying their customers. One stove in their catalog that attracts our attention particularly is their new Kalamazoo Crown Heater. It's in Mission design, and has all the elegance and beauty that heretofore has been found only in the big base burners, and its price but a fraction of what most concerns would ask for a stove of this type.

Another new design that attracts great attention is the New Kalamazoo Mission Steel Range with white enamel splasher back and oven-door front. We doubt if any one has ever seen anything more beautiful for the kitchen.

### WRITE NOW—HIGHER PRICES COMING.

Owing to increase in cost of materials every one is advancing prices. The Kalamazoo Stove Co. do not guarantee their present low prices after December 1, 1916. Therefore write at once—get your order in this month and take advantage of low prices.

A dollar saved is as good as a dollar earned; and if you are in the market for a stove, heater, base burner, or kitchen range, get in touch with the Kalamazoo Stove Co., of Kalamazoo, Mich. Write today—get your stove before prices advance. Ask for their catalog No. 416.

### Special Notices by A. I. Root

#### GOATS, GOAT PERIODICALS, AND GOATS FOR SALE.

There have been so many inquiries since our article that we wish to inquire if somebody can tell us about the goat periodicals; and will somebody who has goats for sale put a short notice in our advertising columns to answer inquiries?

#### THE BOOK "GARDENETTE" CLUBBED WITH GLEANINGS.

See what is said about this book on page 1093. We have an arrangement with the publishers whereby we can offer the paper edition together with GLEANINGS for one year for \$1.40. The book sells for 60 cents. The cloth edition is later and much larger, containing 133 pages, while the paper-bound edition has only 64. This larger and later edition will be furnished together with GLEANINGS for \$1.75. The price of the book alone is \$1.25.

### Save Money on Your New Stoves

If you are thinking of getting a new heater or kitchen range this fall, by all means write to the Kalamazoo Stove Co. for their new catalog. To look at the beautiful illustrations of the popular styles of stoves in this book, and to note the low factory-to-you prices, would whet the appetite of any stove-buyer.

Never before have we seen such opportunities for saving money. Here are heaters, base-burners.

## HONEY MARKETS

### BASIS OF PRICE QUOTATIONS.

The prices listed below, unless otherwise stated, are those at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

ST. LOUIS.—Prices are unchanged since our last quotations. The demand for extracted honey has been very good, but comb honey is moving rather slowly owing to warm weather. Our market is plentifully supplied with comb honey, but is in good shape for shipments of southern honey. We quote extra fancy comb honey, per case, \$3.75; fancy, \$3.50; No. 1, \$3.00 to \$3.25; No. 2, \$2.50 to \$2.75. White extracted honey brings 9 cts.; light amber in cans, 7½ to 8 cts.; amber in cans, 6½ to 7 cts.; in barrels, 5½ to 6 cts.; clean average yellow beeswax brings 30 cts.

R. HARTMANN PRODUCE CO.

St. Louis Mo., Nov. 6.

SABINAL.—The honey is just about all in, also out. The last honey was disposed of as fast as could be gotten ready for the market by beekeepers of this section, also at one and two cents better than the prices for earlier honey, notwithstanding the earlier honey was of better grade. We quote No. 1 comb honey, per case, 10 to 11 cts. in two 60-pound cans; No. 2, amber bulk in two 60-lb. cans, 7 to 9 cts. Light-amber extracted honey, in cans, 8 to 9 cts.; amber, in cans, 6 to 8 cts. Clean average yellow beeswax brings 26 to 28.

Sabinal, Texas, Nov. 6. J. A. SIMMONS.

DENVER.—Comb honey in carlots moves slowly, but extracted in carlots is in very active demand. Comb honey graded by Colorado rules is sold in a local way at the following jobbing prices per case: Fancy white, \$2.97; No. 1 white, \$2.84; No. 2, \$2.70. White extracted, 8 to 8½; light amber, 7½ to 8 1/3. For clean yellow beeswax we pay 26 cts. per pound in cash, and 28 in trade, delivered here.

COLORADO HONEY-PRODUCERS' ASS'N.

Denver, Colo., Nov. 8

PORTLAND.—No great demand for comb honey. Conditions are much the same as previously reported. Extracted honey is moving very slowly. Last season's holdings are about cleaned up. We quote extra fancy comb honey, per case, \$3.50; fancy, \$3.25; No. 1, \$3.00; No. 2, \$2.75. White extracted brings 9; light amber, in cans, 8; amber, in cans, 7. Clean average yellow beeswax brings 26.

Portland, Ore., Nov. 6. PACIFIC HONEY CO.

ALBANY.—Demand is very good. Receipts are heavy, and market weak; crop is a large one, especially light and mixed grades. It is not practical or proper to sell comb honey (of necessarily uneven weight) by the case, but by weight, gross and tare. We quote fancy clover comb, 15; No. 1, 13; No. 2, 11 to 12. White extracted, 8; light amber in cans, 7½; amber in cans, 7. Clean average yellow beeswax brings 32 cts. per lb.

Albany, N. Y., Nov. 9. H. A. WRIGHT.

CHICAGO.—There are free offerings of comb honey, yet it sells at fairly steady prices. We quote extra fancy, per lb., 15 to 16 cts.; fancy, 15; No. 1, 14; No. 2 or out of condition, 10 to 13. White extracted honey brings 8 to 9 cts.; light amber, in cans, 7 to 8 cts.; in barrels, 6 to 7 cts.; amber, in cans, 6 to 7 cts.; in barrels, 5 to 6 cts. Clean average yellow beeswax brings 32 cts.

Chicago, Ills., Nov. 9. R. A. BURNETT & CO.

LOS ANGELES.—Our stock of extracted is almost exhausted. There is a large stock of comb looking for a fair market, mostly in hands of producers; quality fair. We quote extra fancy comb honey, per case, \$4.25; fancy, \$3.85; No. 1, \$3.25; No. 2, \$2.50. White extracted honey brings 8½ cts.; light amber, in cans, 8 cts.; amber, in cans, 7 cts. Clean average yellow beeswax brings 35 cts.

Los Angeles, Cal., Nov. 9. GEO. L. EMERSON.

KANSAS CITY.—Demand is limited on account of warm weather, and trade being supplied to a great extent by local beekeepers. With cold weather we look for a better demand. We quote fancy comb honey, per case, \$3.00; No. 1, \$2.90; No. 2, \$2.65 to \$2.75. Light-amber extracted, in cans, brings 8½ cts.; amber, 8 cts. Clean average yellow beeswax brings 25 cts. C. C. CLEMONS PRODUCE CO.

Kansas City, Mo., Nov. 6.

HAMILTON.—Honey of fine quality is still coming in. Some dark honey is still coming in at lower prices. Demand is good. We quote extra fancy comb honey, per case, \$2.50 per dozen; fancy, \$2.25; No. 2, \$1.50. White extracted, per lb., 12 cts.; amber, in cans, 10 cts. F. W. FEARMAN CO., LTD.

MacNab Street Branch.

Hamilton, Ont., Nov. 6.

DETROIT.—Comb honey is in good demand. It is slow coming in. Stocks on hand are light; plenty offered. Extracted also is in good demand. We quote extra fancy, per case, 15 to 16 cts.; fancy, 14 to 15 cts.; 13½ to 14 cts.; white extracted brings 8 to 8½.

F. R. REYNOLDS & CO.

Detroit, Mich., Nov. 7.

PHILADELPHIA.—We have nothing new to report on comb honey. We could move some good extracted honey in 60-lb. tins. We quote white extracted, per lb., 8½ to 9 cts.; light amber, in cans, 7 to 7½ cts.; amber, in cans, 6 to 7 cts. Clean average yellow beeswax brings 28 to 30 cts.

Philadelphia, Pa., Nov. 6. CHAS. MUNDER.

BOSTON.—Demand is good; stock is moving freely. We quote extra fancy comb honey, per case, \$3.75; fancy, \$3.50; No. 1, \$3.00; No. 2, \$2.25 to \$2.50. White extracted, per lb. brings 10½ to 12 cts.; light amber, in cans, 8 to 9 cts. Clean average yellow beeswax brings 28 to 30 cts.

Boston, Mass., Nov. 7. BLAKE, LEE & CO.

BUFFALO.—Receipts are more liberal this week, but still light for the season of year. Stocks are well cleared, and not much accumulation on the market. We quote extra fancy comb honey, per lb., 15½ to 16 cts.; fancy, 15 cts.; No. 1, 14½ to 15 cts.; No. 2, 13 to 14 cts.

Buffalo, N. Y., Nov. 9. GLEASON & LANSING.

CLEVELAND.—Demand fair at quotations. Supply in our market not very heavy. We quote fancy, per case, \$3.85 to \$4.00; No. 1, \$3.65 to \$3.75; No. 2, \$3.00 to \$3.50.

Cleveland, O., Nov. 10. C. CHANDLER & SONS.

PITTSBURG.—Conditions are practically the same as per our report of Oct. 25, with a slightly improved demand, with no change in prices.

Pittsburg, Pa., Nov. 9. W. E. OSBORN CO.

TORONTO.—Prices are unchanged since last issue. Comb honey which is now on the market sells as follows: No. 1, per case, \$2.40 per doz.; No. 2, \$2.25.

EBY-BLAIN LIMITED.

Toronto, Ont., Nov. 6.

MATANZAS.—Light-amber honey in barrels brings 46 to 47 cts.; amber, in barrels, 46 to 47 cts. Matanzas, Cuba, Nov. 4. A. MARZOL.

MEDINA.—Comb-honey offerings continue from unexpected quarters, with prices easy. Extracted honey in the West has passed into the hands of dealers for the most part, and is now offered only at advanced figures. Eastern markets are also improving.

THE A. I. ROOT CO.

Medina, O., Nov. 10.

remember we carry a full stock and sell at the lowest catalog price. Two lines of railroad—Maine Central and Grand Trunk. Prompt service and no trucking bills.

**THE A. I. ROOT CO.,** Mechanic Falls, Maine.  
**J. B. MASON, Manager**

# WHY NOT

## Order Your Supplies for Next Season Now?

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 4 per cent discount during October. Send in your order just as soon as you find out just what you require and we will take care of it promptly.

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

## HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual one. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

### Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. PREPARE! Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

#### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

**G. B. Lewis Company, Watertown, Wisconsin, U. S. A.**

Send for catalog giving name of distributor nearest you.

## DON'T FUSS

With your old combs and cappings, but send them to us. We will render them into beeswax for you on shares and pay you cash for your share, or we will make it into

### Dadant's Foundation

for you.

If you prefer, we will pay you our best trade price in exchange for BEE SUPPLIES.

Send for our terms. We feel sure that we can save you some money besides saving you a "mussy" job.

BEESWAX WANTED at all times.

**Dadant & Sons, Hamilton, Illinois**

# GLEANINGS IN BEE CULTURE

Published by The A. I. Root Co., Medina, Ohio.

A. I. Root, Editor Home Department

H. H. Root, Managing Editor  
J. T. CALVERT, Business Manager

Entered at the Postoffice, Medina, Ohio, as second-class matter.

VOL. XLIV.

NOVEMBER 15, 1916

NO. 22

## EDITORIAL

PROF. FRANCIS JAGER, elected president of the National Beekeepers' Association at the last meeting in Chicago, is a live wire. He outlines some policies that will mean the development not only of the organization itself but of the industry at large.

### Lack of Rains in the Clover Belt

THE United States weather maps which we are getting daily, while they do not indicate a dry soil for clovers, yet show that the rainfall thruout the eastern states has been rather light. It is to be hoped that this will be followed by snows in winter and rain next spring. Clovers are still in good condition in our locality, and the enormous yield of white clover and alsike last year will mean a good seeding for next season.

### Bee Inspection in Connecticut

FROM Part 6 of the annual report of the Connecticut Agricultural Experiment Station for 1915, we learn that, during the year, 494 apiaries were inspected, containing in all 4241 colonies. In 26 per cent of the apiaries European foul brood was found. In 8-10 of 1 per cent American foul brood was found. Pickled or sacbrood was found in ten apiaries. The total cost of inspection was \$1.51 per apiary.

### Our Cover Picture

A VERY enthusiastic backlotter is L. C. Green, Albany, Cal., whose backyard apiary is shown on our cover for this issue. We judge that Mr. Green is also quite a poultry man, tho he prefers the bees. Quoting from his letter he says:

"Talk about your suburbanites having vegetable gardens, chickens, rabbits, etc., to while away their spare time and help out on the high cost of living. Bees exceed them all for pleasure and profit so far as I am concerned, and I have tried them all. I

am as enthusiastic now as my brother from whom I caught the bee fever, and I can talk nothing but bees. My wife says, 'Bugs.'

"I started in the spring of 1914. I made arrangements to purchase one colony; but the party from whom I was to get it telephoned to me saying that this colony had now swarmed and if I wanted them both I would have to pay \$5.00 more. That was making money fast, wasn't it? I said I guessed I would not take the bees at all, but finally I was told to come and get the two at the original price."

### Diagnosing Without Removing Frames

WHILE it is true, as our correspondent, Mr. Chadwick, points out, in this issue, page 1964, that diagnosing colonies without moving frames might be a bid for carelessness, if he will look back to what we said on page 776 he will see that that method of determining the condition of a colony was not recommended for beginners. The exact methods for accomplishing these results are shown in the A B C and X Y Z of Bee Culture under the head of "Frames, to Manipulate."

### How to Get Rid of Cross Pesteering Bees

MR. CARMONA, in this issue, page 1083, gives a kink of the trade that is worth knowing. Every now and then there will be a few cross bees that will follow one about the yard for an hour at a time. They are hard to hit with the hands, and they compel one to be ever on the alert, and always keeping the veil drawn down over the face, no matter how hot the day. Mr. Carmona offers a remedy that we feel sure is quick and effective. Try it.

### Foul-brood Law for New South Wales

SECTION 1 of the foul-brood law for New South Wales, and mentioned on page 1087, shows a feature that should merit the atten-

tion of the beekeepers of this country. If every beekeeper in every state were compelled to make out a report of the conditions of his colonies, and particularly whether they have any bee disease, it would assist the bee inspectors materially in their work. Perhaps such a provision would not be practicable in this country; but if every beekeeper were compelled to make a report whether he had bee disease or not, and failing to make such report would be subject to a fine, it would save the bee inspectors from going over territory that is probably clean, and direct them at once to the diseased spots.

### Government Figures on the Honey Crop for 1916

FROM the Monthly Crop Report published by authority of the Secretary of Agriculture, Washington, D. C., we find on page 91 of the September issue a table of average yields of surplus honey per colony, spring count of 1916, up to September 1, as compared with 1915 to the same time: Connecticut, Virginia, West Virginia, North Carolina, Georgia, Minnesota, North Dakota, Alabama, Montana, Wyoming, Arizona, Idaho, Oregon, and California show a smaller crop than in 1915. All the rest of the states show a larger crop with the exception of Rhode Island and Wisconsin, which show the same average crop both years. The states which show the greatest increase over last year are New Jersey, Maryland, Ohio, Indiana, and Illinois.

### Beekeeping for Pleasure as well as for Profit

IF there is any place in Uncle Sam's domains where bees can be kept for *pleasure* as well as profit it is along the Florida rivers, particularly the Apalachicola, St. John's, and the Indian rivers. It is just fun to run back and forth to the outyards on the river banks in that mild and salubrious climate; and while the keeping of bees along these rivers may not mean a large profit it will mean renewed health and a new life. On the St. John's and Indian rivers, the apiaries will necessarily be small—a few colonies at a place. As we go further south toward the Florida Keys the yards may be larger.

The pictures by C. H. Clute in this issue, pages 1069 and 1070, bring back to the editor pleasant memories of when, three years ago, he was fighting chills and fever, and when he got back his health. There is some-

thing besides dollars in this world; and the biggest asset one can have is good health, no matter what it costs. The editor has not found it necessary, like Ponce de Leon, to *hunt* for the fountain of eternal youth in Florida. He found it on these rivers.

### Outdoor versus Indoor Wintering

WHILE the tendency seems to be decidedly toward outdoor wintering as mentioned in our issue for Nov. 1, page 1011, some figures presented by our old friend Doolittle on page 1066 of this issue would seem to argue very strongly for cellar wintering. According to Doolittle's figures the consumption of stores by colonies indoors is less than half of those outdoors. Other investigators made similar comparisons in former years and discovered about the same ratio. Were it not for the fact that the colonies wintered outdoors are in many cases considered to be an advance over those wintered indoors, every one would use cellars where the climate is severe enough. Canadian beekeepers are inclined to believe that, in spite of the larger consumption of stores, the outdoor bees are enough ahead to make up the difference. Or, to put it another way, the outdoor colonies it is believed will have a larger force of young bees for the harvest. A colony that is strong enough to gather 100 lbs. of honey may be worth the extra stores.

The exact relative difference in honey producing between an outdoor and indoor wintered colony has never been tested out experimentally. We hope some experiment station will try this out on two groups of 25 or 50 colonies so as to get an average.

### A Chain of Bee Conventions

A CHAIN of bee conventions will be held in Kansas Nov. 20 and 21; Indiana, Nov. 27, 28; Ohio, Nov. 29, 30; Michigan, Nov. 30, Dec. 1 and 2; Chicago-Northwestern, Dec. 4, 5; Minnesota, Dec. 5, 6; Iowa, Dec. 5, 6; Wisconsin, Dec. 7, 8; Ontario, Dec. 12, 13, 14; Idaho-Oregon, Dec. 5, 6.

The Kansas meeting will be held at Topeka. Secretary, O. A. Keene.

The meeting in Indiana will be held at the State House, Indianapolis.

The meeting in Michigan will be held at Lansing. A banquet will be given by the A. I. Root Co. and M. H. Hunt & Sons. See Convention Notices.

The meeting of the Chicago-Northwestern will be held in Chicago, Great Northern Hotel, John C. Bull, secretary.

The meeting in Iowa will be held in Des Moines, Hamlin R. Miller secretary.

The convention in Ontario will be held in Toronto, Morley Pettit secretary.

The Michigan beekeepers are making great plans for a big convention—probably the largest bee convention held in this country this year.

The Wisconsin meeting will be held at Madison, Gus Ditmer secretary.

Idaho-Oregon will be held at Ontario, Oregon, P. S. Farrell secretary.

Announcement in regard to the place of the Ohio convention has not yet reached us.

Dr. E. F. Phillips and E. R. Root expect to attend some of these conventions. Unfortunately the dates conflict in some cases, as will be seen. The Editor will not be able to attend the conventions of Kansas and Idaho-Oregon and perhaps those where the dates conflict.

For other convention notices see Convention Notices.

### The Dark Side of Beekeeping

YEARS ago, in the early days of this publication, we used to carry departments known as the Growlery and another as Blasted Hopes, to represent certain gentlemen of the cantankerous or those who suffered from a bad winter, a poor season, or a poor locality. The Blasted Hopes fellows did not see anything very attractive in beekeeping. They were going out of the business, and were anxious to pay their departing respects to their brethren of the craft. The cantankerous didn't like the publicity, and so we discontinued those departments.

Our correspondent, Mr. Closson Scott, page 1074, apparently is not afraid of telling his failures, and he does it with severe frankness. Altho some of our subscribers have done remarkably well during the past season, and have secured big crops, and while a few of our backlot friends have cleaned up \$5.00 and \$10.00 per colony, it may be well for us to consider that there are some others who have not cleaned up anything—in fact, they are out of pocket.

Mr. Scott has correctly diagnosed the cause of his failure or failures—namely, the poor locality. By looking up the map we find that his portion of Ohio is not a good bee country; indeed, one of the best beemen in the state, twenty miles east of him, after securing for a series of years some very low averages, decided to move to a better locality. He moved on a straight line west into the northwest part of the state, and now he is getting good averages. He is well pleased. We might suggest to our correspond-

ent that he move also; for evidently he does not lack in experience; but, no matter how much he may know about the production of honey, he cannot get it if it is not in the fields.

### Honey Crop Conditions and Prices

It is apparent that the general market shows that *extracted* honey is improving everywhere. It is equally apparent that there has been a very large crop of *comb* honey; and as a consequence the market on this commodity is easing up. It has, in fact, been low all this season. See Honey Market.

Our readers will remember that last winter and last spring we cautioned producers not to run so much to comb honey, as there was such a large supply left over. We were severely criticised at the time for doing so; but the logic of events, and low prices on comb honey during the past summer and fall, with prospects that they may go lower, show that if producers had heeded our advice, and run more for extracted, the market on comb honey, at least, would have been better, without any injury to the price of extracted.

We hardly know what advice to give for next year. It is our opinion that the lower prices on comb honey will induce beekeepers to run largely for extracted next season. This will be a mistake. There will be enough producers dropping comb-honey production without every one making a grand rush for the extractor. Here is a case in point. Last year potatoes were comparatively low—so low, indeed, that farmers this year decided to put their land into wheat and corn. What has been the result? A light crop of potatoes, with prices ranging from \$1.80 to \$2.00 a bushel, with every indication that they will go higher before next year's crop will be available.

#### THE BOTTLE TRADE ON THE INCREASE.

Fairly reliable information goes to show that there will be a larger consumption of honey this year than was ever known before in the history of the United States. Honey in bottles is coming more and more into demand. It will soon be time to develop the trade, if it has not already arrived, of honey in tins in 3, 5, and 10 lb. sizes. The bottling trade is stimulating the demand for liquid honey; and the good housewife will see that it will be cheaper to buy in tins than in glass. It will not be many years before the average family will begin to lay in its supply of extracted honey in 60-lb. cans. Many of them are doing it now.

The supply of maple syrup is growing smaller and smaller. The demand for good table sweets in the mean time is growing larger and larger. While the glucose concoctions can supply a certain cheap trade, it is evident that the average family wants something of a higher grade. Honey is the only available article that can be obtained in quantity.

PRICES ANOTHER YEAR.

It is apparent that honey prices are bound to advance another year. GLEANINGS believes that the beekeeper should not only get more for his honey, but that the consumer should pay correspondingly more for it. Our general campaign of advertising is beginning to have its effect; for we are now in possession of reliable information that shows that the trade in bottled honey is beginning to assume enormous proportions. If some of the beekeepers of the country could know the amount sold by the various bottlers they would be surprised. While production is on the increase enormously, it has not kept pace with the demand; and had there not been a very large production in the eastern states this year, honey would have advanced like all other food commodities; and it is almost sure to do so another season.

**Regulations Relating to the Export of Honey from New Zealand**

GLEANINGS is indebted to Mr. Isaac Hopkins, of Auckland, N. Z., for an extract from the *New Zealand Gazette*, for Nov. 25, 1915. The reprint consists of an order in council for some regulations on honey exports, which went into effect the first day of December. In more than one instance American beekeepers have observed that progressive New Zealand is not one whit behind the times.

There are twenty-one regulations in all, but lack of space prevents giving more than a summary of these. The first six regulations define the terms used, specify the six ports from which honey may be exported, and paragraph No. 4 gives the name of the store at each of the six points in question. Honey intended for export has to be forwarded to one of the appointed stores not less than seven days before shipment. Where there is a noticeable difference in the standard of honey the owner is obliged to submit such honey in separate parcels with a distinguishing mark on each. No honey will be graded or allowed to be exported unless it is granulated.

Regulations 7 and 8 have to do with the method of packing the honey and the branding. Honey intended for export has to be packed in clean tins, lacquered or oiled on the outside to prevent rusting, each tin to be provided with a leak-proof lid capable of being easily removed and replaced. The tins have to be packed in clean new cases of well-seasoned lumber, planed on the outside, and bound with metal straps or wire. The weight of the honey must not exceed 120 pounds net.

The owner must indelibly brand with the approved export brand, which contains the words "New Zealand Produce—Pure Honey," name of the owner, etc. The net weight of the honey also has to be branded on the cases.

Regulation 9 has to do with the securing of application for export of the Director, etc.

Most of the remaining regulations have to do with the grading. The honey is divided into four classes according to color: White, light amber, medium amber, and dark. The system of grading is based on the following points:

|                              |     |        |
|------------------------------|-----|--------|
| Flavor .....                 | 40  | points |
| Color .....                  | 10  | "      |
| Condition .....              | 15  | "      |
| Grain .....                  | 12  | "      |
| Aroma .....                  | 8   | "      |
| Freedom from seum and froth. | 10  | "      |
| Packing and finish .....     | 5   | "      |
| <hr/>                        |     |        |
| Total .....                  | 100 | points |

The A, or Special grade, is the honey which grades from 94 to 100 points, inclusive; B, or Prime grade, 88 to 93½ points; C, or Good grade, 80 to 87½ points; D, or Manufacturing grade, 65 to 79½ points. No charge is made for the grading. The grader stamps a grade-mark on the cases and delivers to the owner a certificate of the grade. No honey can be exported which scores less than 65 points, and, of course, any tins showing signs of leaking are barred. The decision of any grader is held final, and no action against any grader is permitted.

New Zealand cannot consume all of the honey produced. That much of it must be exported is, therefore, a foregone conclusion. Under these conditions a uniform system of grading becomes a very real necessity. Honey-producers of this country, however, may profitably take notice of this forward step of the New Zealand members of the craft, for the great drawback to honey-selling in the United States is carelessness in grading and the lack of a uniform system of grading.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

FOR feeding as late as Oct. 15, a syrup of two parts sugar to one of water is recommended, p. 988. Isn't  $2\frac{1}{2}$  to 1, as given p. 963, better? [In your locality, yes; in ours, 2 to 1 would be strong enough.—Ed.]

"A queen not showing sufficient strength to resist European foul brood in the start is not worth any future trials against the disease," p. 967. That may be true in Mr. Meeker's locality; but in my locality the disease may appear in a colony with an excellent queen, and caging her upon first attack is the very best treatment.

LAST Temperance Sunday my Sunday-school class of men thought it might be well to vote the Prohibition ticket, only they couldn't think of losing their votes. "Suppose," said I, "an election were to decide whether Marengo was to have saloons, and you were sure the town would go wet, which way would you vote?" "If I were the only one to vote that way," said one, "I'd vote for a dry town." "How about voting for a dry president?" said I. A surprised look went around the class, and one of them with a sheepish grin said, "You've got us."

You ask, Mr. Editor, p. 966, whether lime, sodium, etc., should not be considered with iron in honey. Sure; and if you will turn to p. 841, the place that I suppose started your query (p. 837) whether I was not attaching too much importance to iron, you will see I said "iron and other matters." I'm entirely with you that *all* the things you mention, in which honey excels sugar, should be kept before the public constantly, and I'm glad of this opportunity again to stress the minerals in honey, not because more important than other things you mention, but because the public—and possibly some editors—don't realize that elements minute in quantity may be greatly important. [We give up. Guess you're right.—Ed.]

I SAID it was a physical impossibility for bees to build comb with worker-cells one side and drone on the other. Now, what does that troublesome Allen Latham do but send me a sample of the "physical impossibility," a plain case of drone on one side and worker on the other? He says: "The explanation is simple. Whenever bees work out only one side of a sheet of foundation and put honey in those cells before the other side is worked out, then the other side will more often than not be more or less

drone. I have seen hundreds of sections where this occurred. It is doubtful if it ever occurs in natural comb-building." That leaves it still unexplained how bees can build drone-cells on a worker-base. Examination of the sample shows that they didn't do so in this case, for the base is neither drone nor worker, but *flat*. Either he uses foundation with a flat septum, or else his bees have the trick of flattening it. I've seen many thousand sections, many of them with one side built out first, but never observed a single case like the sample sent. I shall have to modify my statement by saying it is a physical impossibility for *my* bees to build worker-cells on one side and drone-cells on the other side of a natural base. But I'm not responsible, Allen, for what fool things your bees may do.

ARTHUR C. MILLER, you take sides against me, p. 932, for criticising one who said "there is no need of having a queen a year old to determine if she is a good breeder." Please look again at that Straw, p. 139, and you will see that the thing I was objecting to was making prolificacy the only point in choosing a breeder, the statement having been made "that there was no need to have a queen a year old before deciding whether she would be good to breed from, for we could tell before she is three months old what kind of a layer she would be." You would object to that yourself, for you say "my queens are at least eight months old before I pick the breeders." But you have some right to object to the unqualified statement I made: "I don't see how I can estimate a queen's value until she is more than a year old." For that might be understood to mean that no one in any case could judge a queen under a year old. Here's my ground: I cannot know the value of a queen until she has been in the hive *from the very beginning of the season until the close of the honey-flow*. Likely enough you would agree on that. If your queens are only eight months old at the close of the honey-flow, then eight months is old enough to judge. My honey-flow closes toward the last of September. At that time some of my queens are only a year old, possibly less. But the greater part of those that began the season are more than a year old, and I must know the rating of a queen *in comparison with others*. So I should have said: I don't see how I can estimate the relative standing of a queen until my queens average more than a year old. Say, Arthur, let's be friends again.

J. E. Crane

## SIFTINGS

Middlebury, Vt.

Honey seems to be moving more readily than a year ago, notwithstanding the larger crop.

\* \* \*

"European foul brood is a respecter of persons," says Wesley Foster, page 910, Oct. 1, and he is right.

\* \* \*

An item in a recent number of the *Rural New-Yorker* speaks of the great value of sweet clover in subduing Canada thistles.

\* \* \*

Arthur C. Miller's observation and explanations, pages 931, 932, Oct. 1, are so entertaining and enjoyable that I honestly believe it pays to stir him up occasionally.

\* \* \*

I was glad to learn from GLEANINGS, Oct. 1, page 903, that glass is being eliminated from section honey. It always seemed to me a swindle to sell so much glass for honey.

\* \* \*

That is not a bad idea of Dr. A. F. Bonney on getting schoolchildren to write an essay on honey, and offering a prize for the best. We are certainly getting practical these days.

\* \* \*

Reference is made, page 902, Oct. 1, to wintering bees under snow. Our experience has been that the more snow about gives the better, providing the entrance slopes away from the hive so water will run away from the entrance.

\* \* \*

We have had fairly good success in introducing virgin queens into full colonies at once after removing the old queen, by Mr. Baldwin's method of immersing in honey and pouring down honey with the queen. I believe this method is going to prove of great value where we wish to supersede old queens.

\* \* \*

It has been a lot of work to weigh every section of our honey this fall, and place the different weights in several different grades; but it is something of a pleasure to know that every buyer will get every section in the same case of the same weight and quality. Another thing I notice, 11 and 12 ounce sections of honey look much better when packed by themselves than when packed with heavier honey. Small apples by themselves may be No. 1; but packed

with large apples they are most emphatically *culls*.

## HOW DANGEROUS IS SACBROOD?

Prof. Burton N. Gates calls our attention, page 913, Oct. 1, to the great loss to beekeepers from sacbrood, a subject of more than ordinary importance. The whole subject of sacbrood is usually treated as a small matter, and dismissed as "nothing but a little sacbrood." The facts are, it is always a serious drawback to the prosperity of a colony, and many times nearly as destructive as American foul brood. While it is thought to be of small consequence, we could hardly expect much interest to be taken in any remedy that might be offered. The disease has such an elusive character of appearing and disappearing that any attempt to cure it has seemed like fighting the air. Some years we have not found half a dozen cells of it, and again it has interfered seriously with the success of many colonies. One beekeeper I know destroyed the old combs in one hundred colonies in one season to get rid of foul brood, and very successfully, too; and the next season I believe half of the hives contained sacbrood. Where did it come from? I don't know. I have sometimes thought we were more apt to find it in new combs than in old, so that there would seem to be a poor show of cleaning it out by shaking on to foundation. Where we have had very bad cases of it we have of late sometimes broken them up, destroying the combs.

With this disease, as with European foul brood, I believe we shall find the most satisfactory treatment in removing the queen where there is a serious loss from it, and requeening with more resistant strains.

Sacbrood is often mistaken for foul brood. While writing the above paragraph on sacbrood I received a letter from Mr. Ivan Robinson, of Pembroke, N. H., saying he had found some very suspicious-looking brood in one of his hives that he feared might be foul brood, as the colony had dead brood, and had failed to store much honey. He had destroyed every bee with brimstone, and put the honey in a safe place. Later I received a sample of the brood, which proves to be sacbrood. The sample of brood received was in this year's comb; and if he had destroyed only the queen, and had given another of resistant quality, he might have had a good colony another year, free from disease. I cannot help admiring his thoroughness, however.

# BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

Some good fall rains have already fallen throuth the greater part of Texas. Fall and winter rains assure us better honey crops the following season, hence these are welcomed by the beekeeper.

\* \* \*

An enjoyable and profitable time was spent in a picnic by the members and friends of the Guadalupe Valley Beekeepers' Association on the grounds of the Bathing Beach on the Guadalupe River, near Seguin, Saturday, Oct. 14. It was the first attempt of this kind for this association, and it was so successful that another and much larger picnic of this kind will be held next spring. Besides "bee-talks" by several of the more prominent beekeepers, there were also demonstrations of a varied nature, in which not only the men but the ladies took part.

\* \* \*

Henry Brenner, of Seguin, Texas, has returned to Porto Rico, after a journey to those islands last spring. He reported excellent advantages existing there for extensive queen-rearing, having experimented along this line while there. His report was also that he was far more successful in his attempts there than under the conditions existing here in this part of Texas. The honey, however, was all rather dark in color in those localities visited by him at that time; but a peculiar feature connected with this is that the comb itself is all of the whitest kind. While the comb honey looks beautifully white from outside appearances the honey itself is very dark in these white combs.

## BEEKEEPERS MORE INTERESTED.

There has been a lack of interest on the part of the Texas beekeepers during the last several years that was beginning to fall. The individual beekeepers were plodding along their own narrow path and according to their own good will, little concerned about their fellow-men following the same pursuit. Producing their crops and marketing these without much regard for market and other conditions, there has arisen each season a crisis of low prices and deplorable market conditions.

With this regular annual recurrence, and its effect on the financial condition of the beekeepers there has awakened a deeper interest and a desire to take some steps that may aid in stemming the tide that was doing material harm. There now exists a

greater desire to do that which some of us tried to bring about years ago—co-operate and organize, and use united effort to a better advantage and benefit of every beekeeper and the beekeeping industry as a whole.

## LOSES ONLY TWO PER CENT IN MATING.

While visiting Mr. Henry Brenner, near Seguin, Texas, a few weeks ago, I was astonished at his success in rearing queens this summer. According to his statement he lost only about 2 per cent of queens failing to become mated, or out of a few over one hundred queens only three were not successfully mated. Two of these were drone layers, and one did not lay at all. The writer saw many of the queens after they had all been laying for several weeks, and their nuclei were quite strong with their own offspring. They were all reared from two selected yellow Italian breeding-queens that had shown excellent results as honey-storers and for other qualities.

All of these queens were mated in upper stories and over strong colonies of bees. A solid board partition cut off all communication between brood-chamber and nucleus. One comb of brood and honey and several combs containing more or less honey were placed in this upper story. Then a cupful or two of bees, previously prepared according to the Stachelhausen method, were poured on to the combs after a ripe queen-cell had been placed between two of the central combs. A hole bored thru the rear of the hive, somewhat toward the other wall of the hive from that near which the nucleus is located, provides an entrance for these bees.

An important item explained by Mr. Brenner is that of not using any division-board next to the outside comb of these nuclei to prevent the robbing-out of the nuclei as is so often the case. He states that if a division-board is used it provides a sort of ante-room in the vacant space between this board and the wall of the hive, into which the robbers will enter from the entrance hole; and, once inside this, they find it an easy matter to gain access to the nucleus proper. Without the division-board and the bees of the nucleus guarding the outside comb of the nucleus, the robber bees do not enter thru the entrance hole at all; and, consequently, he does not lose any of his nuclei by being robbed out.

His method of obtaining queen-cells and taking care of them seems rather unique also, and will be mentioned later.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The meeting of the San Bernardino County beekeepers held at Redlands, Oct. 7, was well attended, and was a success in general.

\*\*\*

Rains have continued to fall in rather generous amounts, totaling nearly four inches in some localities. This is very unusual for October. A dry winter is prophesied by many; but past weather records do not bear out the idea.

\*\*\*

The hive standard is pretty well established in the Langstroth size and should be maintained as the standard, but I am convinced that a deeper frame and not so many of them would make a more ideal hive and one better adapted to the needs of the bee.

\*\*\*

Breeding is at a very low ebb in this locality just now. Some colonies opened today, Oct. 30, contained not one cell of brood. This is due to the fact that just now is the period when there is perhaps less inducement to breed than at any other time of the year.

\*\*\*

The greatest objection to bee-escapes is that in hot weather there is danger of combs melting down, and in cold weather the honey gets too cold to uncap and extract readily. I have never found as satisfactory a way as to shake and brush the bees, then extract the combs at once while they are warm.

\*\*\*

Mr. Crane has discovered that bees work on the wild carrot; now if we could get them to work on the cockle burr we would have the most universal honey-plant in the United States, for I have found that old weed growing everywhere I have been thru all my travels, even on the dry foothills of California.

\*\*\*

If a colony of bees begins to "hang out" we may expect them to swarm, not because it is a necessary part of swarming, but because it is a sign that there is a surplus of bees. Swarming is nature's way of relieving the congested condition. Ventilation will retard swarming because it relieves the necessity of the bees moving out.

\*\*\*

Gasoline is excellent to use in smothering a colony. If your hive is tight-bottomed, pour it in the entrance and close it up

tight; all will be dead in a short time. Moths in a mass of webbed comb may be dispensed with quickly by pouring gasoline over it; the slightest bit touching a moth will kill it instantly.

\*\*\*

When hiring a man get one you can trust and then treat him like a human being. Good food and comfortable quarters gives a man self-respect as well as energy. I have little use for the attitude assumed by some men in this state toward their hired help. We are all human; and because a man is out of a job is no sign he is a bum. Even if he were he might be made a better man by kind treatment.

\*\*\*

In the October 15th issue Mr. Crane says: "A bee finding a scanty yield of nectar in the flowers of one apple-tree naturally flies to another, and in so doing it gives the best possible cross-fertilization." In this thought he is getting down to the real cause of swarming. I expect to submit an article on the cause of swarming soon, but that sentence touching this one thought will, in justice to Mr. Crane, be eliminated.

\*\*\*

The editor cites a case in the Oct. 15th issue where he moved bees less than a mile and not one bee returned to the old location. That is possible when moving even less distance, but it may or may not be because the bees have not traversed the territory. By confining bees to the hive, after moving them a short distance, for ten or twelve hours, then giving them an entirely new entrance there will be little trouble.

\*\*\*

The diagnosing of an apiary by simply lifting the hive and looking under, as recommended by the editor and endorsed by Mr. Byer, may be all right in some localities at some times; but some of the requirements necessary are not told, and it seems to me to be a bid for carelessness. Here in the West we have many beekeepers who would be prone to follow this kind of plan, even in some cases failing to lift the hives at all. Here also arises cause for the rapid spreading of disease in many localities. I will not commit myself by precept or example to a plan that will encourage the shiftlessness already far too common in this or any other disease-infested locality. Where there is a reason to suspect the presence of disease, careful inspection is necessary and should be encouraged to the greatest extent.

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

Further inquiries have come regarding bee-martins referred to on p. 716, Aug. 15. The bee-martins are king-birds which are fly-catchers. The scientific name is *Tyrannus tyrannus*, called also *Tyrannus Caroliniensis*, which is the true bee-martin or bee-bird; but several other species of the *Tyrannus* in the West and South are also called bee-martins or bee-birds, and many fly-catching and insect-eating birds are often misnamed bee-birds, tho not king-birds at all.

## MANGROVE AND PALMETTO ON THE EAST COAST.

The finest palmetto-mangrove honey we ever saw has been gathered by our winged friends this summer—not the largest in amount, tho the total is a fair crop, but the quality is about as fine a table honey as a connoisseur could want on his pancakes for breakfast. We use it (honey, not pancakes) for every meal. As before reported, palmetto lasted about twice as long as usual this year. Our own crop will be about four tons. The blending of the mangrove and the palmetto honey by the bees is unavoidable, as one bloom overlaps the other. But no matter. Both are light-colored, both mild-flavored. The mixture is a little finer than either one alone, for the pure mangrove has just the faintest suggestion of a salty taste that disappears in the blending of the two.

## CONDITION OF BEES IN FLORIDA.

Bees are in unusually fine condition all over the state this fall. Not only did the summer keep them stronger than usual, but also in September and October, right up into November, they have been gathering freely and breeding well. At this writing, Oct. 23, the yard sounds like orange-blooming time. Speaking of that, elicits the remark that there will be a good orange-honey crop next spring, weather conditions favoring; for the time to build up for an early orange flow is in the fall, and bees are surely doing that now. See that all hives have at least five frames full of capped stores, or the equivalent, and is full of bees. Then you can sleep nights, or even go away on an automobile trip, and not worry; for you may be sure all will be well when the fragrant white petals of orange again scent the air.

\* \* \*

The editors of bee papers have all along sounded warning notes protesting against rushing the crop off to some large mart,

and have urged producers to sell at home. In the present condition of the honey markets such advice is *appropos* and timely.

The following letter is from a man who has made beekeeping profitable, and home-marketing of honey one of the means toward success. It has such a genuine ring of common sense, and moreover it is so timely just now, that its insertion here will surely appeal. We quote in part:

Dear Sir:—Your letter was received in due time, and greatly appreciated. Honey in the big markets is so low in price I dreaded to ship there. I am, therefore, supplying my old customers and some new ones. I do not expect over 1000 gallons, and I think I can sell it all to my local trade. I am getting from \$1.25 to \$2.00 per gallon, according to quality and methods of packing. The first year I had bees I got 83 gallons from 14 colonies, and could not sell more than half of it. I fed the rest of it back to the bees in spring. So I decided to try my hand in educating the people in this vicinity to eat honey, and thus build up a market at home for my goods. I made quality and fair dealing my motto for seven years, and now I find that there is a steady increase in demand for my products. I think it is safe to say I shall be able to sell 1000 gallons in my local market, and I think that is pretty good when I have a neighbor five miles from me, with 200 colonies, one ten miles away with 100 colonies, and two more eight and ten miles away with from 30 to 40 colonies each. All are selling in the local market. Happily we do not trespass on each other's territory, and no confusion arises. First, I do my own grading, which is not nearly so rigidly done, and in dealing with the consumer I get my share of the sums that transportation companies and commission men and dealers make. To show you, I enclose a few orders I have received. If I had to sell to the Eastern markets, thru commission men, and stand for all losses in shipping, and all other disadvantages, I would go out of the business entirely.

We wish to commend the practice of the correspondent above quoted. It is a remarkable fact, that, while more colonies of bees are kept per square mile of territory in the southern states, more of the product is consumed right in that same territory than in any other portion of the United States. People are surely eating more honey. A high standard of quality, honest and fair methods of dealing, and "hustling" in the advertising, will infallibly bring results. It is not the big cities that need "more honey." It is the smaller towns and the communities.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

## OUTDOOR VS. CELLAR WINTERING.

Which is better—wintering the bees on their summer stands or in the cellar? A beekeeper of considerable experience tells me that bees winter well on the south side of a building where the sun apparently does double duty. Do you advise this?

Well, hardly. Bees have been known to come out fairly well when left during winter on the sunny side of a building, but more often it results in a loss if not in weakened colonies in the spring. Still, this would be better than leaving the colonies on the north side of a building where the sun does not warm up the hives at all. On the sunny side the bees fly at rather frequent intervals during the winter. The heat produced by the sun on the hive and building, together with the bright light shining in at the entrance of the hive, causes the bees to fly when the air is still, even with the mercury in the shade as low as the freezing-point. If the ground is bare about the hives this bright sun makes it possible for the bees to fly with little if any loss, as the dark ground so absorbs the rays of the sun that the bees can rise in a very low temperature. Bright snow on the ground causes them to come out more than the bare ground.

I know it is claimed that bees wintered on their summer stands come out with greater vitality in the spring than those wintered in a cellar; but after an experience covering more than 40 years I have come to the conclusion that the loss in bees wintered out of doors is more than can be compensated by the extra vitality of those which come thru alive. With a loss several years that went above 75 to 80 per cent of the colonies left out, I have decided on cellar wintering for central New York, except three or four colonies for experiment.

The loss of colonies in outdoor wintering, tho this may be of first importance, was not all that led me to decide on cellar wintering. The amount of stores necessarily consumed when wintering on the summer stands above that where the colonies are wintered in the cellar has quite a little to do with the profit or loss in beekeeping. By experiments made by myself and other close observers it has been proven that less than one-half the stores are needed for cellar wintering than will be consumed during the average winter when the bees are left out. This comes from the amount of food that is necessary to be used for fuel to keep up the same warmth in the cluster in a freezing or a tem-

perature 30 degrees below zero, which obtains in the northern part of the United States and Canada. By weighing a certain number of hives in the fall, each hive containing colonies of as near the same strength as to bees as possible, then setting half of that number in the cellar and leaving the other half out, the difference as to the amount of stores consumed can be ascertained approximately—near enough for all practical purposes.

I made an experiment with ten colonies one winter. November 20, at the time the most of the bees were placed in the cellar, I weighed ten colonies for the sake of making a comparison of the amount of stores consumed by bees wintered out of doors with that consumed by those in the cellar. The five outdoors weighed as follows:

| Wt. Nov. 20. | Wt. Apr. 19. | Loss in Wt. |
|--------------|--------------|-------------|
| 54           | 36           | 18          |
| 67           | 48¾          | 18¼         |
| 46           | 29¾          | 16¼         |
| 74           | 51¾          | 22¼         |
| 63           | 47¾          | 15¼         |

|                   |    |
|-------------------|----|
| Total consumption | 90 |
| Average           | 18 |

The colonies were weighed—hives, combs, frames, and all. It might have been a little more accurate if the stores could have been weighed separately; but for all practical purposes I think the experiment very fair.

Of the five put in the cellar, their weight and consumption of stores were as follows:

| Wt. Nov. 20. | Wt. Apr. 19. | Loss in Wt. |
|--------------|--------------|-------------|
| 55           | 47¾          | 7¾          |
| 58           | 48¾          | 9¾          |
| 62           | 54¾          | 7¾          |
| 49           | 42¾          | 6¾          |
| 63           | 55           | 8           |

|                   |       |
|-------------------|-------|
| Total consumption | 39    |
| Average           | 7 4-5 |

This shows a consumption of less than one-half by those wintered in the cellar as compared with those wintered outside. This, with the much greater security afforded, would seem a sufficiently strong incentive for the cellaring of bees during winter.

In former years I paid strict attention as to the temperature in the cellar, looking at the thermometer once or twice a day, but of late years the bees at the out-apiary are put in the cellar under the farmer's dwelling, and not once looked at or disturbed by myself during the whole winter. The cellar is used just as it always was. The entrances to the hives are turned toward the cellar wall next to the sides which have no windows and the windows are partially shaded. This plan might not work in all cellars, but has proven all right in this case for twenty-five years.

## NATIONAL PROBLEMS

### Article I.

BY PROFESSOR FRANCIS JAGER  
President National Beekeepers' Association

There was a time not very long ago when our great national industries—railroads, steel, sugar, lumber, etc., were in their infancy and were known only under the name of "our infant industries." They were struggling under foreign competition, domestic disorganization, lack of funds, low prices, and poor management. They were groping along a doubtful path toward success. At this critical time the government of the United States, ever alert for the ultimate success of home industries, reached forth its helping hand. By wise legislation and abundant appropriations and bonuses it raised these infants to sturdy youngsters who now are even veritable giants whom the government finds it difficult to manage. To encourage the railroad industry for instance, land grants were given to companies, amounting to a strip of land twenty miles wide along their whole right of way. Protective tariffs, easy credits, favorable banking laws, and our foreign consuls were engaged as nurses in behalf of these infant industries.

To extend to the struggling industries of the country all possible financial and moral help has become an established policy of our government.

As some industries get rich and self-supporting the paternal care of the government turns toward other infants—still young and struggling. Among these at present is our bee and honey industry.

It seems we have not yet realized how good a friend old Uncle Sam is to us. We have been straining our private energies and have been spending our limited funds to establish the honey industry on a solid footing. Spending time, energy, and money, talking, writing, organizing, attending conventions, etc., has achieved wonderful results. State organizations have been established, co-operative associations and marketing centers have sprung into existence, while methods of production of more and better honey have been devised.

But it has taken the beekeepers a long time to realize that there are limits to the enterprise of individuals. To place the honey industry, scattered throuth this immense continent, and consisting of number-

less small units, into a compact body endowed with life, power, and strength, we must have state and government aid. If we should feel inclined to boast of our organization and strength as developed at the present time we have only to contemplate the general advance of prices of all staple articles while honey has not advanced. On the contrary, the prices today, especially on extracted honey, are ridiculously low. This certainly should take away our self-conceit.

But ours is a contented profession. Just see. We say, "How much it costs to produce other foods, while honey costs practically nothing to produce! We can afford to sell it cheap," etc. Excuses to cover our own weakness and inactivity! If the steel and coal magnates would live up to this argument of "no first cost," the ore lands obtained for a song, the ore mined at a fraction of a dollar per ton, instead of complaining about our billion-dollar coal and steel trusts cutting juicy melons for their owners, we would be enjoying these gifts of nature at just as ridiculously low a price as honey is sold for today. But they are organized and that makes the difference.

In a few articles I wish to show what we need and how to get it.

The very first thing the beekeepers, both present and future, need is instructions. Beekeeping is a science, and a very deep and complicated science at that. Knowledge is power. It is also success and wealth. The ignorance of the average beekeeper is appalling, and the failure of the country to obtain better results is traceable directly to this ignorance. Yet the beekeepers are far from being unwilling to learn. The difficulty is that they have very small opportunities for learning. We have papers and periodicals and books—all good and thoro; but out of 800,000 beekeepers hardly 100,000 ever see any of them. Knowledge is such a wonderful treasure that everybody wants it, but nobody wants to fight for it. It must be brought to the beekeepers and presented to them with a how and free of charge. Only the State and the Government could do that. The beginning was made tentatively a few years

ago; and since the Department of Agriculture in Washington has established a bureau of bee culture, and a country-wide extension service, one state after another has added beekeeping to the curriculum of its university instruction and extension work. The undertaking has been a great success. Yes! the beekeepers are willing to learn if they are made to see the necessity. We only need to refer to the crowds which turn up at conventions the country over to hear lectures of the Government extension men and other prominent beekeepers, or to the demand made upon our universities to send out men to speak on beekeeping, or to the number of students taking the beekeeping courses; but for such work money is needed—State and Government money—money collected from taxes which we pay, and for which we have a right to ask these things in return, and which we shall obtain by showing them that our demands are reasonable.

A few years ago some beekeepers attending the National Beekeepers' Association of North America were gathered in a hotel in Minneapolis in the small hours of the morning, talking about bee problems as usual. One of them made a remark at that time, that our States and Government have plenty of money to spend on experiments with every imaginable bug and weed, and that we ought to go after them in the interests of the bee and honey industry. "Yes," said another one, "put the stress on 'go after them.'" This "go after them" stuck in the mind of some of our Minnesota beekeepers. They talked and planned how to "go after it," and this is the way they did it. At the next Minnesota Beekeepers' Association meeting a legislative committee was organized. One or more beekeepers in every county of the state were put on the trail of candidates for the legislature, and they talked to these candidates bees and honey, and the necessity of appropriations for bee inspection, bee instruction, and bee exhibits. When the legislature assembled the committee found the legislature not only well posted on bees, but found quite a number of warm friends and influential supporters in both houses. Why, our difficulties and obstacles that looked like mountains were really only mole-hills. We secured a bee-inspection law with \$2000 appropriation, a division of bee culture at the University of Minnesota with \$6500, and premiums for honey exhibits at our big State Fair building, amounting to nearly \$1600.

What did it? A strong state organiza-

tion with competent officers and committees. When you talk to legislators you must talk convincingly and with an organization to back you. Alone—as an individual—you have as much show to obtain results as a solitary queen in a hive would have to start a colony.

To give you another instance, at the last National convention in Chicago it became apparent that the demand for service made on the Bureau of Bee Culture at Washington was so great the continent over that Dr. Phillips and his small staff could not even begin to do justice to the demand made on them. The southern states especially clamored for instructors and organizers. The matter was brought before the National convention, and at its instance Mr. Root and Mr. Pellett went to Washington to put their request before the Senate Finance Committee. Representative beekeepers of many states sent in their letters of request at the same time to their representatives. In a few days letters from New York, Ohio, Michigan, Illinois, Indiana, Iowa, Wisconsin, Minnesota, Dakota, Colorado, Missouri, Idaho, Wyoming, Montana, California, practically the whole country, began to pour into the Department of Agriculture and the Senate Committee. I can well imagine senators and representatives from all parts of the States going in and coming out of the committee rooms like bees from the hive, all asking for an appropriation for Dr. Phillips in the name of their constituents, backing up the request made by our committee. But my imagination may be wrong. The fact, however, that the sum of \$5000 was allowed to put two more men in the field is not imagination.

This shows how easily great results may be obtained by organization in behalf of a worthy cause. Do not say, "I don't get any benefit from the dollar I pay for my annual dues in the State or National organization." Such a view is narrow and wrong. The train of beekeeping is moving ahead, and you are necessarily moving with it whether you act as engineer or are paying your fare as a passenger, or are just taking a ride on the trucks.

By the way, Dr. Eric Millen, East Lansing, Michigan, is the Secretary of the National Beekeepers' Association, and he is selling tickets at \$1.50 to those who wish to ride in a Pullman coach. He would like to see the train run in several sections with enough paying passengers to put a fund in the hands of the National Beekeepers' Association of at least \$25,000.

## A FEW FLORIDA HONEY-PLANTS ALONG THE ST. JOHN'S RIVER

BY C. H. CLUTE

Orange was a failure here last season.

The saw and cabbage palmetto were all right. The prairie yield starts before the cabbage-palmetto bloom is over. The prairie bloom lasts up to October or November. Last year it was a failure here on account of high water. If one had a launch a few miles would take the bees to bloom above the high water.

In December and January maple and willow yield pollen and honey. In February

and March, by moving, we have access on poor land to horse-wicker commonly called greasewood; also pennyroyal that gives a flow of 100 to 125 lbs. per colony if cold weather does not interfere.

Then by moving again we get orange, basswood, etc. In August the deertongue is in bloom. This yields well, giving a lot of nice honey; but it is found in only a few locations.

Sanford, Fla., July 22.

Looking down a "cutaway" road thru cabbage palmetto.

A beeyard in the distance under cabbage palmetto. The launch belongs to Mr. Olute, who at the time was just starting on a trip of 24 miles up to Lake Jessup, where the honey-flow is earlier.

## DO BEEKEEPERS WANT A DISTRIBUTING ASSOCIATION?

BY G. P. STARK

After having had various experiences in the honey business I have come to the conclusion that very few really want or need a distributing organization. On the other hand, on reading the bee-journals many correspondents seem much interested.

Early in 1915 several leading beemen who had no particular personal need of nor interest in such an association, having been in the business long enough to establish a market for their own and their neighbors' prod-

uct, saw visions of the need, and of the great good that could be accomplished by such an institution. These beemen started the ball rolling by incorporating the National Honey-producers' Association, to be capitalized by beemen only. When it came to the cash, however, the beekeepers in general preferred "watchful waiting," and the burden therefore fell on the few.

Not even a peanut-stand can run without capital. Sometimes I wish that J. P. Mor-

Smartweed, wild sunflower, and ironweed along the river. The cabbage palmetto in the background is a mile and a half distant.

gan controlled the business, for it takes a lot of cash to pay for carloads of honey and bee-supplies; and unless the manager of the institution has a bank his usefulness will be limited, and big dividends will not be likely to accumulate.

A MELON STORY.

A small boy who was given a dime to buy a melon met a farmer who had two large melons in his wagon. "Say, mister," the boy asked, "how much do you want for one of those melons?"

"Well, kid, I sold all the rest for 25 cts. each; but if you want one I will let you have it for 15 cts., or both for a quarter."

"Couldn't you let me have one for a

dime?" the youngster asked hopefully; but the farmer drove on.

Soon meeting a bunch of big boys the farmer sold the two melons for a quarter. The small boy, not belonging to the "gang," had to be contented watching the big boys fight for the core.

Usually, this is just the way the beekeepers will do—let the jobbers come in and get the core and then cuss the manager. A cooperative concern must be supported by its members. They must co-operate in every way. There is very little danger of the manager looting the treasury if no money goes in to run the business.

Kansas City, Mo.

BEE-HIVE RECORDS

BY C. E. FOWLER

Intending to write about hive-records I looked up the indexes of the last two years of GLEANINGS and found so many articles on the subject that I felt discouraged; but after reading them over my courage came back.

On page 224, March 15, 1915, Doolittle gives a whole page on the subject, and winds up by saying that he likes a board best, using "brief signs," but does not say what the brief signs are. Then there is Richardson's plan, page 510, June 15. He has a slip for every hive, and every visit. This seems too clumsy altogether. The McIntyre system, page 711, Sept. 15, 1914, gives too little room for remarks, allowing only one line per hive. Many make the records on the tops and sides of hives; others merely use pins, nails, bricks, clods of earth, and painted strips of tin, most of which give no record whatever, but merely an indication of the present condition of the hive.

My idea of a record is something that will give the past history of the hive, set down at the time of each visit, that can be saved for years. The illustration shows my year's record for hive 47. The first column gives the date of my visit; the second, the condition of the queen, and the number of pounds

of bees. The figure 14 at the top of the column means that the queen was a 1914 queen; the *m* indicates the name of the breeder.

The second illustration is merely a key to the signs used in the queen column. 0 means no queen; 1, eggs; 2, larvæ; 3, capped; 4, hatching; 5, egg in queen-cell; 6, grub in queen-cell; 7, queen-cell capped; 8, queen hatched (virgin); 9, laying queen;

| □ | Taken Out         |
| x | Excluder (4 Col.) |
| . | Shallow Super.    |

9 with a line thru it, drone-layer; W, laying workers; x, xx, xxx, quality of queen. A square means *put in*; therefore figure one inside a square means eggs given.

The third column of the record registers the frames of brood and honey (put in and out—remarks—where from).

The fourth column records the hives and

Exhibit of A. O. Raffington, of Hutchinson, at the Kansas State Fair. Mr. Raffington is a beginner in beekeeping, who has made good. The large bottles at the top contain honey vinegar.

supers. In this column x means excluder. The dot under it means shallow super, while a dash signifies a comb-honey super.

Reading the record, I find that the first visit was made April 1. There was then no queen nor brood; full-depth hive. Eggs were given from No. 40, and two frames of brood from No. 48 (to see if queenless).

The second visit was April 8. On this date there was a queen-cell with grub in it. A laying queen was given from No. 40:

two frames brood were found, and four more added from No. 48. There were three frames of honey (queen marked xx).

The next visit was April 15. I found larvæ and about 4 lbs. of bees, 8 frames of brood, 2 of honey. A full-depth hive was added on top, without any excluder.

On April 22 I found a grub in a queen-cell, 5 lbs. bees, 12 frames of brood, 4 of honey. The top hive and queen were put at the bottom; bottom hive and brood on top, with excluder between.

On April 29 four frames of brood were taken away, and an extracting-super added.

On May 6 a comb-honey super was added under an extracting-super.

On May 13 queen and brood shifted again. On the 15th the extracting-super was removed, comb-honey super added under No. 4 comb-honey super.

Hammonton, N. J.

[This record could not be read by one not fully understanding the system; but if it is legible to Mr. Fowler, that is sufficient. The point is that what might be called a shorthand system may be used, taking almost no time to make the record, and yet giving a full and complete account of what was done. Doubtless the system would have to be modified to fit the particular needs of each individual beekeeper.—Ed.]

## HONEY EXHIBITS AT THE KANSAS STATE FAIR

BY J. P. LUCAS

The Kansas State fair at Hutchinson, Sept. 16 to 23, 1916, was a grand success in every respect. The beekeepers made some exceptionally fine displays. Dr. G. Bohrer, of Chase, Kansas, says it was the

largest and best ever held in the United States.

The honey exhibits occupied 1845 square feet of space. There were displays from half a dozen Kansas counties—J. A. Nin-

ninger, of Nickerson; J. P. Lucas, of Topeka; The Cloverdale Apiary, of Mount Hope; F. E. Clark, of Nickerson; W. T. Measer, of Hutchinson; Dr. A. D. Roffington, of Hutchinson; Jas. Gilbert, of Harveyville; M. E. Andrews, of Larned, and Mrs. M. E. Andrews, of Larned. In all there were 3425 lbs. of extracted honey; 3375 of comb honey; 100 pounds of beeswax; 25 gallons of honey vinegar. There were also two displays of bee supplies, and 18 observation hives. A better showing could have been made if there had been more space. Next year we expect to have a new beehouse, the Horticultural Society being in the same building.

A meeting was called by the beekeepers, and "The Southwestern Beekeepers' Association" organized. This is the first organization of this kind in this part of the

state. Twelve men became charter members. It is their desire to boost the interest of the beekeepers, and they are putting up a hard fight for a new building. They have pointed out the fact that this display was far better than the Topeka beekeepers had, as Topeka prizes are so small they can not

Exhibit of C. E. Clark, of Nickerson, Kan. Mr. Clark is another beginner, and one who means business. He thinks a new building for honey will be necessary next year.

The banner display at the Kansas State Fair. This exhibit was put up by J. A. Ninninger, of Nickerson, Kan. Mr. Ninninger is not afraid to spend money and hard work on an exhibit. Note the pressed honey-plants, the honey, bees, etc. At the left of the exhibit (not shown in the picture) he had a log cabin made of honey.

afford to put up a show. If Topeka will pay better prizes they will have better shows. This organization is to work in harmony with the Kansas Beekeepers' Association. Dr. A. D. Roffington, of Hutchinson, was chosen president; J. A. Nenninger, of Nickerson, secretary, and J. L. Pelham, of Hutchinson, treasurer.

The *Hutchinson Daily Gazette* says:

Fruit canned with honey exhibited by J.

P. Lucas, of Topeka, is well worth the time of every housewife to visit. He has on exhibit a number of fruits canned with honey. He has kept some of these jars since 1910, and has shown them every year since. All are in good condition. Among the canned dainties are corn, peaches, pears, cherries, red raspberries, plums, plum butter, and strawberries. Mr. Lucas also has samples of honey made from 28 different flowers.

Topeka, Kas.

## IS THIS FAILURE?

BY CLOSSON SCOTT

For six or seven years I have been an enthusiastic beekeeper. I have bought most of the textbooks, read most of the journals, spent two years with a professional, and even traveled nearly a thousand miles looking for a new location. But lately I have had my doubts about continuing in the business. In this article I expect to give a little

for more bees, and then still more, and now am somewhat in doubt as to whether I have made enough of a failure to quit or not. The "some more" bees amount to only about sixty colonies; but as there has been no profit, and as I can't afford to keep bees for pleasure, they must be sold or given away or moved to a better location.

Exhibit of J. P. Lucas, of Topeka. Mr. Lucas was handicapped by reason of living so far away. As usual, his fruit canned with honey was a great surprise to the ladies. He had some put up six years ago. He also had 28 kinds of honey made from different honey-plants.

advice to beginners, and hope to get some more from the real experts.

I started beekeeping in the usual way. I hived a swarm, got curious about the myriads of little insects, bought a book, then another, subscribed for *GLEANINGS*, used patent hives and then scrapped them, worked

season was almost a complete failure, and I fed for winter with the thought that I would make it all back next year. But next year came; and when the winter stores were gone I had to get out the feeders and keep them going till fall. About that time our inspector came to look over the bees. They

The first two years I had from four to nine colonies. Then winter cut the number to one. I spent that season with a large producer, and learned much about wintering and other subjects of value to me. The next year I went back as one of the assistants, instead of being a mere student, at an increase in salary. The next year I thought I knew enough to start for myself, as I had helped handle 125,000 lbs. of honey besides seeing a few other beekeepers, and picking up quite a few ideas. Accordingly I purchased about thirty-five colonies and started on the home farm. We were living in town at the time; but I rode out on a bicycle to tend the bees. The

were free from disease, but I was discouraged any way, and told him so. "Stick to your bees," he said, and I thought it over and decided to stick. I even persuaded a friend to make plans to go in with me, and I started out to look for a new location. I found one too, a good one, and I came home bubbling over with enthusiasm. We were just going up there and clean up a fortune in about two years, and then we could spend the rest of our lives telling about it.

During part of the time I was buying my bees. As I said before we lived in town. But the renter didn't do very well, and so we moved back to the farm. My brother and I both had a little agricultural training, and so we took hold of things and began to work out some methods of our own. The farm hadn't been paying very well; but since we started "book-farming" things look much more promising. It now appears that if we stick together the old home farm will come back to what it used to be. But it is difficult to handle bees and a farm at the same time. Anyway, this is a poor location for bees, and I felt that it would be a waste of time to keep them here any longer. As it would be impossible to tend the bees if I should move them, and farm too, it became necessary to give up one or the other. At this time I got to figuring, and suddenly got cold feet when I saw what it would be necessary to make in order to come out even. I suppose cold feet is a "catching" malady; for in the next letter from my friend there were plain indications that he, too, was afflicted, and we agreed to quit before beginning.

Right here I will say that he has made more from his bees than I, and lost more, too. He lost about sixty colonies one winter—nearly all he had—and he was to ship the empty hives to me to be filled with bees. But he is under the necessity of making a living the same as I, and can't afford to leave a sure position for one as uncertain as beekeeping has proved to be with us. I know that, if some of our rich men had never taken a chance, they would still be poor; but if some of

our poor men hadn't taken a chance they would still be rich. As it is with us we are very doubtful about taking the chance.

I have learned a few things that will be valuable to me if I go on or quit, either one, so my time has not been entirely wasted. I have been interested in other lines of agriculture, and have noticed that there is nearly always some one yelling against education in certain lines for fear of overproduction. The fear of overproduction does not frighten me in the least. I have yet to see the time when I couldn't sell many times as much honey as I could produce, and at a good price too. I know there are hundreds of localities where honey is as scarce as it is here. When we get a greater production of honey, these places will be supplied with a good quality of honey, and the price will not drop because of overproduction.

There is one thing that I shall remember for a long time. That is this: No amount of good management will enable the bees to gather honey where there is none. In other words, if you would have success you must

Display by W. I. Measer. Mr. Measer is an old standby who always puts up a creditable exhibit. He is a live wire every time.

have a good location. I would rather face foul brood any time than try to keep bees in a poor location, and I know what foul brood is too. I don't think I made a worse mistake than starting in a poor location. However, one can't tell what the location will do without trying it.

Perhaps some one will ask if I would advise against beekeeping for a living. I

R. F. Holtermann and his helpers for 1916 standing in a field of alsike clover in full bloom.

can't say I would. I can't say I would advise any one to start in a small way rather than with a large number of colonies. A person truly interested will find out the proper manipulations and use them. I would advise a year with a large producer, if it is at all possible, and also work at a school of apiculture. I would advise standard-sized hives and simple fixtures, not that they are better, but because they are interchangeable with others you buy. Still, it is not for me to advise too much, as I ought first to make a success of bees. What

bothers me is not what is past but what I shall do in the future. Possibly this locality will yield better in the future. I may be too easily discouraged. Farming is sure to pay. Wouldn't it be better to take the sure thing?

I gave up some very desirable things to get money to buy bees. I have spent six years of the best part of my life preparing to care for them. I spent a little sum of money that looks large now it is gone. Shall I go on? Shall I take a chance? I think I'll take a chance.

Newton Falls, O.

## SUGGESTED WAYS TO DETERMINE HOW EUROPEAN FOUL BROOD SPREADS

BY R. F. HOLTERMANN

It seems strange that European foul brood, which has worked such terrible havoc, and with which beekeepers have come in contact so long, should be such a mystery. It is taken for granted that no one is going to be foolish enough to say that European foul brood is a boon to the country simply because it is likely to wipe out the smaller beekeepers. No objection can be found to an honest representation of the industry; but I have seen many statements in the press in our own country, giving the very large amount of honey secured from colonies. Those who were instrumental in cir-

culating these reports however were not very energetic in telling of failures of crops or of the many instances where men engaged in the business, owing to incompetence, inexperience, unfavorable environment, or adverse season, lost all they invested, nor even how many in 1914 not only did not make a dollar, but were obliged to spend a lot of money to put their bees in shape for the following winter.

Recently I have given some thought to the problem of finding out how European foul brood spreads. It appears to be a somewhat intricate question because of the

rapid spread of the disease and the wide range of territory over which it rams in a short time. To find out the way in which European foul brood spreads I would conduct some experiments under the following conditions, adding to them any suggestions of value that could be found, and eliminating, before undertaking the work, any which were deemed valueless.

1. Establish an apiary in an isolated section, letting the bees in each hive have a very large entrance. This entrance could be obtained by having a bottom-board with a deep space. The apiary should stand on a large sheltered pond of water. The object of the water under the hives would be to make it unlikely that the dead larvæ which the bees clean out could ever blow into the entrances of other hives.

2. Feed the bees extensively in the open. If necessary I would take them into a comparatively desert country where their only source of supply would be the feeders common to them all. If, under such conditions, the disease spread abnormally we would be justified in believing that the disease spreads thru the germs from bees of diseased colonies being left on the blossoms and after-

ward carried home by the bees out of healthy colonies visiting the blossoms.

3. Have enough colonies in a section where no natural stores could be gathered, thus eliminating the danger of common ground visited by the bees as in No. 2 and supply them with combs of honey and pollen, giving it to them in each hive. Or the bees could be fed thru individual feeders placed on each hive. The colonies should be set fairly close together, so if the disease is spread by the dead larvæ cleaned out by the bees there would be a good chance for it to get into hives in the vicinity.

4. Take queens from badly diseased colonies and introduce them with the least possible delay to healthy stocks, and take other queens; and, if possible (and I think it is), dip all but their heads in some disinfectant and note the result.

A careful work carried out along the above lines should give us some information of value. I am strongly of the opinion that worker bees, so far as it lies in our power, should not have the chance to clean diseased larvæ out of the cells. Such work *must* result in the spread of the disease.

Brantford, Canada.

## A YEAR WITH POUND PACKAGES OF BEES

BY KENNETH HAWKINS.

After treating all colonies in my home yard in the fall of 1914 for American foul brood, investigation in the spring of 1915 showed that I had seven breeding queens left, but that every colony that remained was again badly infested with American foul brood. Seven one-pound packages of bees were ordered from Texas to arrive here by May 1, and they were given the queens, being loosed on full sheets of foundation, with fruit bloom in full swing.

The bees had no more than arrived when the warm weather of April went somewhere, fruit-bloom froze altogether, days followed when it was impossible for the bees to get more than a few hours' flight, and there was nothing to feed on. They were fed daily a pint of warm sugar syrup, half and half, a super being put on, and a newspaper spread over the frames with a small hole cut directly over the cluster for the pepperbox feeder.

As soon as the bees had begun to build up a little, signs of American foul brood appeared again; and knowing that there must yet be a source of infection, the Illinois inspector, A. L. Kildow, was summoned. He found an apiary within a mile with every

colony but two dead with American foul brood, all the rest, about 18 colonies, being exposed for robbing. This was prevented only in a measure by the entrances being practically stopped up with dead bees and by the cold weather. These colonies were burned.

This infection necessitated treatment of the nuclei from the pound packages, such as shaking, giving full sheets again, and feeding. It was more than discouraging to see those bright new combs and sugar stores go into the fire. Lots of queen-breeders advertise queens proof against "foul brood," making no distinction in the advertising between American and European. Any queen-breeder who advertises in this way is a fake, as there never existed a queen the introduction of which brought about conditions proof against American foul brood. Any good Italian is some proof against European, and the purer the Italian the greater the insurance.

Now the weather turned so cold again that two of the packages, after treatment, failed to survive the weather, leaving five. Seven more were ordered, with queens, and the feeding of syrup continued as long as

the cold continued. Altho Dutch clover was abundant, it gave only a slow flow, no surplus, but just the thing for the 12 packages to build up on, which they proceeded to do with a vim.

About July 1, 14 more packages were received, to be used in forming nuclei, as this yard was intended for queen-rearing, containing as it did my best breeders selected from the best honey-gatherers for years. The packages were each immersed in a pail of water, to wet the bees and prevent their flying, then one screen was removed, and all dumped into a hive with a screen top. Virgin queens were given each nucleus, and the nucleus bees supplied from the packages. They were put on full sheets of foundation, four frames to the hive, each frame half Hoffman size. The bees were fed a candy such as is used in queen-cages the first day, but the honey-flow from sweet clover, just starting, made further feeding unnecessary. About 60 nuclei were started this way.

Brood and bees were constantly removed after July 15 from the colonies started early with packages, usually two frames per week. These were full Hoffman size, as more nuclei were constantly formed, and some bees and brood were needed to bolster up nuclei where the first queens given failed to return after the mating, on account of the continued rain. No further feeding was necessary for the colonies or nuclei, and the honey-flow continued slow but sure until frost.

From this yard several hundred queens were shipped last year, most of them as fine as I ever produced, being daughters of my breeders saved in the spring, and the drones from the remaining 11 breeder colonies.

One of these strongest packages was relieved of its queen about July 1, and was

White clematis that climbed from a trellis on to a tree and shot up to the unusual height of 40 feet. During the blossoming period in July and August the bees swarmed all over it.—From A. T. Cope-land, Olalla, Wash.

used continuously afterward for starting cells, a frame of young bees being shaken before the hive each week.

Plainfield, Ill.

## THE SAND VETCH AS A HONEY-PLANT

BY EDWIN TRINDER

The honey from the sand vetch is mild in flavor, but it has a dark-amber color. As the vetch blossoms at the same time as white clover and alsike, the bees mix the two kinds of honey together, thus, of course, spoiling the color of the white honey.

The vetch has been grown here on sandy soil for the past few years, but the bees have never worked on it until recently. During the last season especially, I think that there was so much rain and cold weather that they could not go very far away. The vetch was close to the apiary, and for that reason they could get to it. The white clover and alsike are further away. The honey, however, is

so mild that many of our customers think that it improves the clover flavor.

We are located three miles from Lake Erie, near Port Dover, the summer resort. The honey crops have been only fair since 1913. We run for extracted honey and depend on buckwheat and goldenrod for the main part of our surplus. We winter the bees altogether on buckwheat honey.

I shall soon be 77 years of age, but am in good health. I have been president of the Norfolk Beekeepers' Association for fourteen years. The Association has been steadily growing. Now we have over 50 members.

Simeo, Ont., Can.

## A BOY BEEKEEPER WHO HAS ALREADY MADE A SUCCESS

BY HUBER ROOT

It gives one a thrill to meet his namesake. I am not so sure that the great naturalist Francois Huber would have experienced any great thrill if he could have known of me; but I am speaking on general principles. Years ago it gave me a thrill to learn that a baby boy away off in Ontario had been named after me. It gave me another thrill when I learned not so very long ago that this boy had become a beekeeper. Now I am experiencing a third thrill, which I admit is mixed somewhat with envy, to know that this boy, now a man grown, has become a very successful beekeeper, and it has been a very great pleasure to meet him and to know him.

Five years ago Huber Burke began his beekeeping career with two colonies of bees. Without having bought any bees since that time he had sixty colonies this year, spring count, from which he secured an average of 230 pounds of extracted honey per colony, his best colony producing over 400 pounds; 10,500 pounds was fine white-clover honey, and the rest, 3300 pounds, was buckwheat. A year or so ago with twenty colonies, spring count, he increased to forty colonies and secured almost 100 pounds per colony.

I feel like congratulating this young man, not because he is named after me or after anybody else, but because he has made good in his chosen profession. Has any one in five years' time been able to make a better record?

Huber Burke, a successful and rising young beekeeper of Ontario.

## AN EXTENSIVE BEEKEEPER AND POULTRYMAN

BY R. A. MORRISON

The picture shows my poultry-plant. This pen was run as an experiment for close confinement, made up of 60 single-comb White Leghorn pullets hatched May 21, 1911. They were shut up in winter quarters on the following 15th of November in a room 14x14 feet square.

They were never let out of doors nor given any change from that time until they had to be removed in November, 1912, to make room for sixty 1912 pullets.

Their egg-laying record began Jan. 1, 1912. That day's record was 33 eggs. For the following ten months their record was:

January, 1093; February, 1123; March, 1302; April, 1346; May, 1307; June, 1141; July, 827; August, 956; September, 662; October, 116. For the ten months, 9873—an average per hen of 164½ eggs, or 822¾ dozen. The average price per dozen for the ten months was 30½ cents, a total of \$251.06. The cost of food per hen was \$1.48, or \$88.80 for the 60 hens, which left a net profit of \$162.20; for each hen, \$2.70½.

This photo was taken by flashlight on the evening of Aug. 31, after they had gone to roost. Notice that some of them are asleep,

White Leghorn pullets in confinement—an experimental pen belonging to the poultry ranch managed by R. A. Morrison, a 200-colony beekeeper.

others have waked up, and are intent on watching the photographers, while the most timid ones have left their roosts and hidden themselves away in the dark shadows under the roosts. Also note their worn tails and large combs; the worn and dilapidated tails come from two causes—wearing in the

nest-boxes, and moulting; the large combs, from careful breeding. In this condition they laid 30 eggs on this day, Aug. 31.

Cataraqui, Ont.

[Mr. Morrison is also an extensive beekeeper. A picture of his apiary appeared on our Sept. 15 cover.—Ed.]

## THE LAND FLOWING WITH MILK AND HONEY

BY PH. J. BALDENSPERGER

When the Hebrews, after more than forty years' suffering in the barren wilderness, approached the more fertile country of Canaan they very much resembled the modern Tayaba and Tarabeen—Bedouin tribes who delight themselves with the products of the land of promise. Sour milk and *dabash* are the two great staple articles of the nomad; and southern and eastern Palestine have changed but little in manners and customs, products and language, since the days of the Perizzites and the Amalekites. Since the Egyptian revolution of the 18th century, the passage of Bonaparte, and the last upheaval in

1883, firearms have been introduced into the peninsula of Sinai; yet a Bedouin or a "fella" "bows" his rifle instead of shooting it. The bow is an ancient weapon, while the rifle is comparatively new. When a weary Bedouin or a tired "fella" arrives at some settlement a wooden bowl of *labban*, or wholesome sour milk, is presented to him. This same *halb* was promised to the weary Hebrews in the desert. Fresh milk is never presented, and to some extent it is considered unwholesome. The *labban* is milk which has undergone a slight fermentation, and is to be found in every house or tent where sheep and goats are found.

Compared with the arid and sandy region of Sinai, Canaan was and is yet a very desirable country. Bread is to be found everywhere in Palestine. Labban is almost a necessity and a sweet dish—a kind of luxury. Hebron, in the south, is the great country of vineyards, and *dibs* is prepared from the juice of grapes. Joshua and Caleb cut off the luxuriant grapes from Eshcol; and if now the modern travelers inquire what is done with the grapes there, "dibs" will be the answer. Dibs is the name given to grape-treacle in all the south.

The Bible student reads the Bible as translated by Europeans in the 14th and 15th centuries, and by translators who knew Hebrew, Greek, and Latin, but who did not know Palestine nor the innumerable shades of meaning in their language. They could not distinguish between milk and sour milk nor between dibs and honey; and as they certainly knew nothing of sour milk and dibs they simply translated *eret zabath halab u'lebash* by "a land flowing with milk and honey," as in Exodus 3:8.

Very late in their national history the Hebrews began to make a distinction between grape honey and comb honey. Jonathan was probably the first Hebrew who tasted comb honey. In his memorable pursuit of the Philistines he saw the overturned booty, and with his staff picked up a piece of comb honey, *m'at dabash*, found in the spoil taken from the enemy—see I. Sam. 14:29. The text is very clear here. The Hebrew *dabash* and Arabic *dibs* are one and the same article. Dibs is made by crushing the grapes in rock-cut presses which are hewn out in the vineyards. Workers and vintners are allowed to suck the flowing juice as it runs down from the rock into the jar below. The Moslems, like the ancient Rechabites of Jeremiah 35, are not allowed to drink any strong drink. "Ye shall drink no wine, neither ye nor your sons for ever." The grapes in all Islam are transformed into *dibs* as it was with the Perizzites. The pressing in the rocks, the flowing into the jar, and the sucking of the *dabash* from the rocks are mentioned in Deuteronomy 32:13, in Job 20:17, and in Psalm 81:16; and the rocks alone prove the sweet to have been *dibs* and not *assal*, the Arabic name for honey taken from the bees. That bee honey was not meant by the writers of sacred history, every modern beekeeper will understand at once for several reasons: 1. Because honey remains in the comb if left alone, and will remain thus for years, even in the hottest part of Palestine, as the clefts of rocks are always cool—at least where bees have selected their dwelling.

2. Should the honey flow, bees would swarm around and become so aggressive that there would hardly be a beekeeper audacious enough to put his lips to the rocks and risk the furious stings of the robbers.

*Dibs* easily ferments when it is a few months old; and the prudent Arabs hurry the sale of the small jars, containing about 6 lbs. each, at the price of 40 cents—for so it was in the days of my youth, during the '80's.

By the end of January most *dibs* is sold in Hebron and its environs. Jerusalem and Bethlehem grocers may keep some in big jars and cool places till Easter. Later on, the *dibs* may ferment. This explains why the Hebrew legislator warns the people not to bring *dabash*. Offerings made by fire were to have a sweet savor. "No meal-offerings which ye shall offer unto the Lord shall be made with leaven, for ye shall burn no leaven, nor any *dabash* as an offering"—Leviticus 2:9-11.

In spring *dibs* begins to ferment, and is simply thrown away when the fermentation is irremediable. The Philistines, who originated in the islands, were more advanced in agricultural knowledge as well as in other industries. Then the Hebrew-Bedouin were obliged to have their weapons made by the Philistines; and beekeeping, no doubt, was not only known to the Philistines exclusively, but they kept their processes secret to some extent.

In this unchanging East, beekeeping still flourishes in the Philistine plains. It was introduced into the mountains of Judah very much later; at all events, the author of Proverbs knew honeycomb which he presented to his Edomite wife, altho he knew nothing about bees themselves. He had wisdom and understanding (Proverbs 1:2), and he speaks of "four things that be little upon earth, but they are exceeding wise. The ants are a people not strong, yet they provide their meat in the summer. The conies (hares) are but a feeble folk, yet make they their houses in the rocks. The locusts have no king, yet go they forth all of them by bands. The spider works with her hands, yet she lives in kings' palaces."—Proverbs 30:24-28. Very likely had Solomon seen bees he would have mentioned them in that place. The Arabs distinguish *dibs*, the grape-treacle, from *assal*, the honey of bees. The Hebrews of old had only one name for the sweet sticky matter, and they had only one name for hornets and bees—if they ever knew them. In later years honey was introduced from Syria or Assyria, and Egypt, and a name was given to distinguish it from grape-treacle—

*nafath dabash* or *nafath feem*—Proverbs 5:3, 16:24, 24:13, 27:7; Canticles 4:11.

The hornets, *dabareem*, only were known, and even in the case of Samson's riddle he evidently confounds hornets and bees, as the modern peasant in Europe will say bees or wasps without distinction. As the haunts of Samson were in the land of the Philistines he may have seen bees; but he could not distinguish them from hornets, and he calls them by the same name. We lived some twelve years about Timnath, Ekron, and the borders of the tribe of Dan, and could judge as beekeepers how erroneous the statement must have been. Jackals abounded by the hundreds; and when an animal dies it is laid beside the road and jackals feed on the carcass; yet for several weeks the skeleton is not clean enough to receive bees. Hornets, which are carnivorous, swarm about carcasses by the hundreds; and as the *dabareem* and bees had one name the confusion was easy, and he brought the riddle to the Timnathites.

The Arabs call the hornets *dabaheer*, or *dabur* in the singular. As the hornets are very voracious they build their nests under ground or under the cactus hedges about Ramleh and Jaffa, where they find plenty of food—carcasses by the wayside, and fruits, or bees when they can get at them. We lost dozens of colonies before we knew how to fight the hornets, and later found the only remedy possible was to remove the hives to desolate places where neither fruit nor carcasses abound.

The passages in the Old Testament, tho not absolutely against honey of bees, rather prove the minor article to have been meant. Among the articles brought to David in Mahanaim for his retreating army we find wheat, barley, beans, lentiles, butter, and dabash—II. Samuel 17:29. No doubt the same articles were used by the Turco-German army on their march toward Egypt in 1914 and 1915—at all events about Hebron. *Dibs* was put before the soldiers always, not honey, which, being rarer, was reserved for the staff and pashas.

Ezekiel mentions the articles exported to Tyre and Sidon from the land of Israel—wheat and balsam, *dabash* and oil—Ezekiel 27:17. The quantities exported indicate the abundant and inferior article to be meant. Vineyards were known all over the country, and the vine and the fig-tree are mentioned everywhere, while beehives were altogether unknown, and had no name in ancient Hebrew.

Bees are well known to the Arabs by the name of *nahel*, and swarms are called *tard*.

The beekeeper is a *nahal*, and a beekeep-

ing village is the beekeeper's *nahalin*. *Nahel* is also used in some places for a swarm, meaning a young bee. This shows the development of the word *nahel*, a bee, derived from *nah*, sighing, distinguishing it from *dabur*, one who flees, blows, etc.

After the Captivity, beekeeping was very possibly introduced by the returning Jews or Egyptian and Assyrian settlers. The prophet Isaiah, inspired by some who had seen bees in their native lands, says, "And it shall come to pass in that day that the Lord shall hiss for the fly (*v'zebub*) that is in the uttermost part of the rivers of Egypt, and for the bee (*v'la'deborah*) that is in the land of Assyria, and *they shall come* and shall rest all of them in the desolate valleys, and in the holes of the rocks, and upon all shrubs, and upon all bushes"—Isaiah 7:18, 19. Struck by the curious sight of swarms hanging on shrubs and bushes in Egypt and Assyria, or taking possession of clefts in the rocks, the returning captives foresaw the days when the same strange sight would be seen in Palestine, as many other foreign commodities had been introduced by them.

Modern Jews have lost contact with their original country, having been separated almost entirely from it for at least fifteen centuries, and it is rather with modern fellahin that the old manners and customs and even religious rites of the Hebrews are still found. Islam was founded partially on Judaism and partially on Christianity, and therefore they have preserved Moses and the Mosaic law, and all the prophets of the Old Testament as well as Jesus (Esa), the son of the virgin Mary, adapting them to Arabic ways.

Nice, France.

---

#### Probably the Odor of Newly Gathered Aster Honey.

While working about some hives here in Columbus, since the University opened this fall, I noticed on many occasions that the hives had a very sour smell. I could often smell this odor when standing from ten to fifteen feet away from the hives, and at other times it was not perceptible until I opened the hives. I noticed the same odor was present about some hives I voluntarily inspected in a small town south of Columbus last week. Can you explain what this odor indicates, or what circumstances or combination of conditions cause it?

Columbus, O., Oct. 17. John Eckert.

[We should judge from what you write that your bees have been working upon the asters. There is usually a peculiar odor when they are working on aster bloom. Some people call it sour, some call it a rather offensive odor.—Ed.]

# Heads of Grain from Different Fields

THE BACKLOT BUZZER.

BY J. H. DONAHEY

"What's that?" "Yes, this is Gleanings."  
 "What's the proper way to introduce a queen?"  
 "It all depends on whose queen it is. If it's your queen, you say, 'Permit me; etc., just like that; but if it is a bee you'd better write to Doolittle or Miller They don't do it that way."

## NOVEMBER THOUGHTS

BY GRACE ALLEN

Poor frosted blossoms, you must miss  
 The grace and beauty of those bowers  
 That spring laid here along the hills  
 And gladdened with her brimming showers!  
 Yet, no; you are not even ghosts  
 Of all the myriad April flowers—  
 They are gone—  
 Forever.

Dear morning-hours, how chill and slow  
 You creep from out the eastern sky!  
 More swift you came when from our hill  
 We saw June dawning—he and I!  
 Yet you are not the morning-hours  
 That found us there and passed us by—  
 They are gone—  
 Forever.

My bees, how quiet you are grown!  
 My heart recalls your springtime way—  
 How swift you flashed!—how gay and sweet  
 You made the blossomed plum one day!  
 Yet you, alas, are not the bees  
 That hummed so witchingly in May—  
 They are gone—  
 Forever.

## Where Else Could the Bees Have Got the Black Queen?

By chance I caught a swarm of black bees, and I put them in a box. I keep my bees in close rows with all queens clipped. This black colony was between two golden Italian colonies. In the spring the one yellow colony became queenless, and in due time I had a young queen in that hive, as black as a crow, which, later on, produced hybrid bees. If that was not a case of those queenless Italians stealing an egg from the black colony, I should like to hear from some one better versed.

Grand Valley, Pa. Geo. C. Morrison.

[A virgin from the black colony might by mistake have gone into a hive of the goldens. If so she might kill the old queen and take possession.—Ed.]

## How to Get Rid of the Cross Ones.

Apiarists are troubled sometimes by bees following them angrily while they are working and opening the hives. This is a very common occurrence; but no one tells how to be delivered of the annoyance.

My plan is this: Uncover the smoker; work the bellows until there is a good flame, and keep it blowing, keeping up a sort of circular motion. The movement and flying of the flames attracts the bees, which, by crossing against the flame, or jumping inside the smoker, disappear completely, and leave you free to do your work. I repeat the performance whenever two or three come to bother again.

I have used this plan for years with the greatest success. C. M. Carmona.

San Rafael, Trinidad, B. W. I.

## An Uncapping-can Made of a Barrel.

One day, while extracting, my uncapping-can filled up before I was thru. I had a 32-gallon barrel that I had formerly used for storing honey. I took out the head, cleaned it out thoroly, and nailed a block 5 inches high in the center of the bottom.

I then cut a piece of aluminum-coated wire cloth a little larger in diameter than the barrel and bent up the edge all around so as to form it in a shape similar to a pie-pan. This I tacked to the inside of the barrel, 5 inches from the bottom, putting a tack every 2 to 3 inches. The center of the wire cloth then rested on the block nailed to the bottom.

I bored a 1¼-inch hole just above the bottom of the barrel and made a spigot to fit it. A stick nailed across the top of the barrel, with a nail driven thru from below, completed the arrangement.

The whole thing did not take much longer to make than to tell about it, and it worked as well as any capping-can I ever used.

When I withdrew the plug the honey ran out so clear and free from wax particles that it was almost unnecessary to strain it.

Rhineland, Mo.

S. E. Miller.

Staple-supported frame as used by A. K. Clement, Brunswick, O. Instead of the spacing-pins in the rabbit Mr. Clement also uses spacing staples on the end-bars in the regular way.

[Almost exactly this kind of frame was devised years ago, with this difference, that it did not make use of metal pegs at intervals to regulate the spacing of the frames. The objection to a staple projection is the danger of splitting the end-bars and top-bars either while they are inserted or while in use.

The arrangement would not be very satisfactory where hives are moved about from yard to yard.—Ed.]

#### Should This Queen Lose Her Head?

On p. 701, Sept. 1, Dr. Miller says his best layer in No. 81 is marked for decapitation because her bees do not deliver the goods. Is it not a fact that the extra honey and pollen required to feed and rear these extra numbers of bees would make a fair surplus with a less prolific queen? Would it not be a fair test, doctor, to balance that hive at night with your best honey-gatherers; then decide if decapitation is in order? I have just such a queen, and I use her as a helper to my weaker colonies, and would not think of decapitation as long as she can lay eggs at the clip she is now going unless her bees were entirely worthless as honey-gatherers, which cannot be the case, and care for such fertility.

Indianapolis, Ind.

J. F. Kight.

#### Did the Galvanizing Make the Trouble?

The following experience may be worth something to many who are beginning in beekeeping. A citizen of this section failed to feed his bees as much last fall as he thought they might need; and when January came he became uneasy about them and went to a yard and stirred a lot of sugar into water, mixing it in a galvanized-iron wash-tub. The weather was so bad that he could not feed, and so he went away leaving the

sugar syrup in the tub. Now, this man was not a chemist, and failed to figure on any chemical action that might be taking place while he was away. About the first of March he went back to the yard and fed the syrup to twenty-six colonies, and, greatly to his surprise, he killed every one that he fed. He could not understand it; but he did notice that all the zinc on the tub was gone where the syrup touched it. Now, was not that a case of zinc poisoning, due to the fact that the syrup had enough acid of some kind in it to dissolve the zinc with which the tub was coated? He claims that he mixed 16 pounds of water to 25 pounds of sugar. The syrup was good and thick, and had not soured. Evidently the zinc did the work.

What about his combs? The combs have some honey or syrup in them; and to give these combs to other colonies would be a rather risky proposition.

Mt. Airy, N. C.

J. E. Johnson.

[We nearly always mix our syrup in an extractor-can, and very often store it for weeks at a time; but never have we had any trouble from poison. It would be our opinion that Mr. Johnson killed his bees by feeding too early. He should have given candy or frames of sealed stores. Mid-winter or early feeding overstimulates a colony, with the result that it starts breeding when the weather conditions are unfavorable. While we do not deny that poison may have had its effects, such early feeding is always attended with great risk.—Ed.]

#### Pays to have a Money Order.

In February, 1914, I sent an order of twenty-eight dollars to a party in California for bee supplies. In about a month's time I expected my freight at the station, also reply from the man, but in vain. I sent him a letter, but got no answer. I sent a letter to the postmaster to find out if the money reached them. In about three weeks came the answer from that postoffice that the party had received the money order, and would give it proper attention. I waited another month without getting more reply or goods than I had, and the letter from the postmaster. I went to our nearest town, about nine miles, horseback, to see an attorney, and explained to him the case. In two weeks I received my order with the money order, so you see he never cashed it. There was not a single line of excuse.

It is always safe in sending money by money order to save the slip, even if it is for only a small amount.

Weiser, Ida.

Mrs. Margarete Green.

#### How to Keep Bees away from Watering-troughs.

I tried the experiment of placing salt in the water where I wanted bees to drink, in order to entice them away from places where stock were watered. While I provided this salt in several different arrangements I could

not see that it was of any help whatever. However, I hit upon a scheme rather late in the season that seemed to work. The watering-place for my cow and horse, that the bees seemed to like so well, was an old cedar tub that had been part of a washing-machine. I found that, by sprinkling a little kerosene on the water and on the edges of the tub a day or two apart for two or three times, the bees deserted the tub entirely, and that it did not seem to bother the stock in the least.

N. Fred Gardiner.

Geary, Okla.

#### Starved-out Swarm.

I wish to relate an experience I had with a five-frame nucleus having an Italian queen. Altho I have kept bees for over thirty years, I never saw the same before.

The colony worked very well, and filled the frames with brood. In July I put on a super of 21 boxes; the bees partly filled these, and continued quite active. On September 15 I happened to look at the hive, and, to my surprise, it was silent. Two days before they were just as busy as they could be. I immediately examined it, and found it was deserted. The bees had left two days before. The frames were full of brood just hatching. I immediately transferred the brood to another hive, so that it could be cared for. There was no honey in the hive when I examined it. Can you explain this "desertion"?

Newton, Mass.

Frank Edwards.

[It is very apparent that the bees left because they were starved out. Had you fed them a little sugar syrup a day or two previous they would have remained. There are certain stages of the year when a colony that is increasing very rapidly needs to be watched very closely, or it will starve out or swarm out. It is, therefore, what we call a starved-out swarm.—Ed.]

#### Two Field Meetings in Pennsylvania

The Philadelphia Beekeepers' Association has recently held two very interesting field meetings. The first was at the apiary of Captain Weston, at Essington, Pa., when over 100 beekeepers were present. Some very interesting demonstrations with the bees were given, and considerable bee-talk indulged in. Not the least interesting part was the "cats," so kindly furnished by the A. I. Root Co., and in such profusion that we were asked to eat several fellows' share.

This meeting took place at about the opening of the "yellow" honey-flow peculiar to the section adjacent to the Delaware River meadows. The plant, yielding the nectar, has a profusion of names; but no one, not even our learned botanists at Washington, seem able to give it the proper one. Locally it is known as the yellow flower, coreopsis, marsh sunflower, etc. The fields and meadows were a mass of golden yellow, such as the traveler has never seen elsewhere. The plant seems to be a relative of the Spanish

needle, but, unlike it, the flower has golden-yellow petals, and the seed does not cling to the beekeeper's trousers "closer than a brother," as does the Spanish-needle seed (beggardweed as some call it).

About two weeks later another meeting was held at the residence of Dr. Weaver, 7103 Woodland Ave., Philadelphia. Over fifty members were present. In the early part of the meeting the genial doctor turned his apiary over to the crowd. "They're yours. Do what you wish with them," and they did.

During the inside meeting much that was good concerning the wintering of bees "in this locality" was brought out; but the consensus of opinion was that the prime requisites for successful wintering are plenty of young bees and a goodly supply of honey. The "cats" were not forgotten either.

At the Essington meeting those who waited were rewarded by the appearance of Editor Root at the 11th hour (due to train delays), and his talk on advertising honey.

Oct. 10 the writer visited the Taylor apiary at the Rifle Range at Essington, and assisted in taking off and extracting between 1200 and 1800 lbs. of the rich, heavy, golden honey of the much-named yellow flower. On account of the cool atmosphere, fast work in extracting was impossible; and as no nectar was coming in the bees rather resented an intrusion. These bees were brought from Malvern, about 25 miles distant, about Aug. 18, purposely for this fall flow; and, despite the fact that hundreds of combs had to be built from foundation, the surplus will probably be between 4000 and 5000 lbs. for the 100 colonies. Had it been possible to supply drawn combs, the crop would have been very much larger.

Chas. F. Hoser.

Norristown, Pa.

#### Nectar and Juice from the Cowitch Berry.

I am mailing you under separate cover two bunches of honey from the bloom in summer, but did not know we got two crops from it. A few days ago I was walking on the island near us, looking at the wild white asters just beginning to bloom, and found the bees on these berries very thick. You will see where they get the honey (?). I don't think they puncture the berry first. I think it is done by some other insect, and then the bees get the juice. I want you to taste the juice that is in one. From the taste it should be good honey. I want to know if they make honey every year from these berries. You can find four bees to each berry.

J. W. Potts.

Gunnison, Miss., Oct. 16.

[This was referred to our botanist, John H. Lovell, who replies:]

The letter and box of berries from J. W. Potts, Gunnison, Miss., was duly received. The species is *Cissus incisa* Desmoul., listed by Scholl in "Texas Honey-plants" under the name of "cowitch." It belongs to the vine family, or Vitaceae, and is found in all

the Gulf states from Florida to Texas. The blooming time is from April to August, and where the vines are abundant a surplus is obtained.

The black berries have a scanty pulp, and, when dried, are much wrinkled. The taste is sweet and pleasant, and the juice would undoubtedly be attractive to bees, not one but every season. Careful examination with a lens showed small holes or perforations in a number of the dried berries, thru which bees could easily insert their tongue. But in many of the berries I could find no punctures. Very likely Mr. Potts is right, and the holes are made by some other insects. If made by bees it would seem probable that all the berries would be punctured, since as many as four bees were observed on one berry. Before drawing any definite conclusion as to whether bees add largely to their stores from this source, further and more extended observation would seem desirable; and I would suggest you bring the matter to the attention of the readers of Gleanings.

#### Brood Being Carried Out.

The bees keep carrying out brood even after the young bees are nearly ready to leave the cell. They were carrying out seven-day-old larvæ, and I thought that it was lack of feed, so commenced feeding cane syrup, using the Boardman feeder. It did not seem to make any difference. The goldenrod flow is now on, and the bees are bringing in both honey and pollen, but as yet there is no change. I am just starting with bees in Florida. I never had this trouble in my apiary in Michigan. Ira J. Monroe.

New Augustine, Fla.

[It is a little difficult to decide what is your trouble without more detail. It is possible that the brood at some time was chilled or overheated. If the entrance of a hive be closed temporarily on a hot day, some of the brood may be injured, and the result will be that it will be carried out later. This will be shown by the young bees hatching out without wings. On the other hand, if the moth-worm is working among the combs it may destroy some brood, with the result that young bees will be carried out. If you were located in the northern states we should naturally conclude that the brood had been chilled by cool weather coming on. It is not an uncommon thing to see dead larvæ and some young bees out in front of the entrance of a hive as a result of the brood being chilled perhaps a week or two before. In your climate, however, there would be no such trouble. Possibly the bees have gathered something that has killed the brood. You would do well to look very carefully to see whether there are any moth-worms at work on the combs.—Ed.]

#### Losses in Parcel-Post Shipments.

I wonder if it will surprise Mr. Chadwick when I tell him that my wife and I have charge of the postoffice in this little town,

and that we know that certain packages must have been willfully broken or else handled in a very violent manner. I believe both are partly true. Mr. Chadwick weakens his own argument when he says, page 184, March 1, "These sacks are handled as carefully as is possible with the volume of other parcels that are daily going thru the mail." That is exactly the trouble—"as carefully as is possible." At the junction town just west of here I have seen fifty tons of mail transferred from the C. M. & St. P. to the C. N. W. in a very short time, and I know that more than one "fragile" tag was flattened out under a ton of other "fragile" stuff, as the clerks had neither time nor room to care for it properly.

I was writing about extracted honey, which was put into tin cans which had the covers soldered on and were packed in corrugated paper. Some of these arrived at their destination empty, but no complaint of mail-matter being injured with honey. I do not charge that the honey was stolen, but it beats any sleight-of-hand work I can do, and I am counted quite clever. When I went to insuring every package the trouble ceased.

Dr. A. F. Bonney.

Buck Grove, Ia.

#### Winter Protection for Southern States.

I live southeast of central Kansas. I should like to ask you if, for wintering in this locality, the regular eight-frame dove-tailed hive would be all right with felt roofing, 3 x 4-foot pieces, capping it down over the hive and folding the ends down well, and tying binder twine around the hive. Of course I would leave them on their summer stands on four bricks, the north wind fairly well broken off.

Very few people pay much attention to bees here. They put them in a box and don't pack at all in winter.

Geo. C. Ableson.

Fredonia, Kan., Oct. 16.

[Ordinarily the locality of southeast Kansas would not require any special winter case. That is to say, bees will winter in single-walled hives; but it would pay to wrap the bees as you describe; yes, to go even further, and put regular winter cases around them, supplying packing of two or three inches. The government experts who have been testing out this matter have come to the conclusion that winter packing in the southern states will save a good many bees and the loss of considerable brood. We believe that it would be advisable to err on the safe side by giving too much packing rather than not enough. Of course, wrapping the hives in paper as you describe is an old method that is used somewhat in the southern states, and it is a great deal better than no packing. Better go a little better, and place newspapers on top of the hive and around it, and then fold the other paper around in the manner that you propose.—Ed.]

### When Shaking to Cure Foul Brood, What About the Drones?

I bought the bees near me two and three years ago, and burned and burned and burned to free the country from disease. I also shook and shook and shook, and it took me three seasons to learn that bees with drones had better not be shaken. When shaken on to starters the old drones just starve out and go right into some other hive and take the disease on their feet or bodies right along all over the yard. What becomes of the drones when bees are shaken for American foul brood?

Where should a frame be placed after drone comb has been cut out to prevent the rebuilding of drone comb?

Bradshaw, Neb.

C. B. Palmer.

[When there are many drones in a hive it would be possible, after the shaking, for them to spread the disease right and left. During certain seasons of the year when the breeding season is on, drones will be accepted in almost any hive; and after a general shake-up the presumption is that many of them will go into other hives and be accepted, while the worker-bees themselves from the diseased hive would be barred entrance; but in modern apiculture an excess of drones is not very common. In any case, the hives adjacent to a colony after shaking should be examined carefully for two or three weeks afterward, to make sure stray drones or other bees have not carried the disease.—Ed.]

### Do Bees Shift Stores During Winter?

There is a statement in the A B C and X Y Z which I believe to be an error; and if not too late I hope to see it corrected in the new edition. 'On page 627, second column, near the bottom, is this statement: "The long-continued cold has given them no opportunity to warm up and shift the cluster over in contact with the sealed honey." I think the bees usually shift the honey over to the cluster—always do, in fact, if they have the least particle of brood. Possibly you did not intend the statement to be construed in that way; but I believe most beginners in beekeeping would so understand it, and feel as I did, when we had a mild day, say in February, that the cluster had moved over to the stores and was safe. Really their safety was in proportion to the amount of honey they had been able to uncap and carry over to the cluster. E. M. Cole.

Audubon, Iowa, Oct. 20.

This was forwarded to Dr. E. F. Phillips, of the Bureau of Entomology, who replies:

Mr. Cole is probably incorrect in believing that bees regularly shift honey during winter as they do in the fall, the fact doubtless being that the cluster is slowly moved toward the stores. The cluster is normally formed below the stores over empty cells

(usually to the front); and as the honey is consumed the cluster moves upward. If brood were present, as it should not be in mid-winter, they might move stores if the temperature within the hive were high enough. Under such conditions brood would probably not be present except in badly packed or unpacked hives, since brood-rearing often begins in response to cold within the hive and outside the cluster. We would expect, of course, that honey is moved from the edge to the inside of the cluster as needed.

There is much evidence that bees starve if they are not adjacent to honey, in case the temperature within the hive remains for some time too low to shift the cluster. This also would happen only in hives that were insufficiently packed and unprotected from wind.

Mr. Cole does not say what evidence he has of the moving of stores, as he seems to claim. If he has such evidence it would be well worth while for him to present it. The fact that the bees stay rather close to one place during winter is not proof of this, however, for in good wintering the amount of honey consumed is reduced.

The movement of the cluster is probably upward so long as there are stores above. When they reach the tops of the frames they go to the second story, if one is on, but in a one-story hive they move backward or forward more easily than to one side.

E. F. Phillips, Apiculturist.

### Foul-Brood Law in New South Wales.

The following is a copy of subsection, section 12, of the apiaries act, 1916.

"1. Every beekeeper shall each year, on or before a day in the month of September, to be fixed by the minister, apply to the Under Secretary and Director of Agriculture in the form prescribed, give in writing such particulars of and concerning his apiary as may be prescribed, including the number of colonies of bees in his apiary on the first day of the said month of September, and shall with such application forward a registration fee amounting to one penny for each colony of bees in his apiary on the said day. If any beekeeper fails to make such application, or fails to give such particulars as aforesaid, or gives any particulars which are to his knowledge untrue, he shall be liable to a penalty not exceeding twenty pounds."

We had a very poor honey harvest last year. We extracted 3720 lbs. from 74 colonies, three-fourths of which was gray-box honey (fall flow). Yellow box yielded little, and redgum turned out a failure. My bees have wintered well, coming out with no loss, in absolutely perfect condition. Bees are now (Sept. 25) just about to begin swarming.

I sold all my honey last season at 6 pence per lb.

A. P. Haberecht.

Henty, N. S. W., Sept. 25.

# GLEANINGS FROM QUESTIONINGS

B. F. S., Newburg, W. Va. Will bees start queen-cells when there is a caged queen on top of the frame?

A. No hard and fast rule can be laid down in answer to this question. Ordinarily the bees will, but sometimes they do not. If a queen-excluder confines the queen below in a double-story hive, and a comb of eggs and young unsealed brood is put in the upper story queen-cells are apt to be started on that comb.

F. A. C., Goleonda, Nev.—I have some weak colonies. How would it do to winter them over stronger colonies with an excluder between?

A. The plan of wintering two colonies with only an excluder between is not likely to be successful, for the bees are almost sure to desert one hive or the other, and all cluster together, leaving one of the queens to die because of being unable to get thru the excluder.

H. W. A., Watertown, Tenn. We still have a few drones. If a very late queen should mate now, how long would it be before she would begin to lay?

A. The queen may be mated this fall and not lay till next spring. In your locality she ought to lay soon after being mated.

C. R., Bedford, N. H. Do shallow extracting-frames have to be wired to prevent breakage in the extractor? I have 20 colonies. What size of extractor should I get?

A. Usually the shallow extracting-frames do not need to be wired. Some wire them, it is true, but only two strands of wire are necessary.

If you do not expect to enlarge your apiary a two-frame non-reversible extractor would probably be large enough.

S. S. B., Loveland, O. One of my colonies has just killed a queen which I introduced. What had I better do?

A. Rather than risk another queen as late as this we think it would be far better for you to unite the colony with some other colony weak in bees but having a good queen. While queens may be introduced as late as this it is a little risky, for the cold weather is likely to come on at any time to prevent any further examination.

A. G., Ben Avon, Pa. How can I get the honey out of some wired combs and still save the combs? I have no extractor.

A. It is very slow and tedious work attempting to get honey out of combs without a honey-extractor. If you do not wish to save the combs you could crush them up and strain the honey thru cheese-cloth by

means of pressure; but about the only way you can do and save the combs is to slice the cappings off, place the honey in a warm place, and let it drain out into a dish beneath large enough to catch it. This is very slow, however, for the honey evaporates and becomes quite thick so that you can not get it all out, but it is the only way that we know of.

L. S. B., Toronto, O. I have a colony with a young queen, and there are many small drones not much larger than workers. They were hatched in worker cells. What had I better do?

A. The chances are this young queen was reared late—too late to be mated—and has, therefore, become a drone-layer. Of course, there may be some other reason why she has become a drone-layer. At any rate, the colony will not be likely to winter. If there is a pretty good force of worker bees that are not old it might pay to unite the colony with some other colony having a queen; but if the bees are all quite old, and the colony not very strong anyway, we do not think it would pay you to try to save it as late as this.

O. B. C., Utah. Referring to your editorial on "Best Temperature to Heat Honey to Keep Liquid" you do not state the length of time that the temperature may be maintained at 160 F. We should also like to know if the can should be open while being heated, to give the best permanent results. Will a lower temperature maintained for several hours after honey is liquefied give the same results, say at 130 or 140, as higher temperature for shorter period of time?

A. When honey is heated to a temperature of 160 degrees Fahr., it should not be kept at that point much over an hour. The shorter the time the better. Honey that is heated to, say, 130 degrees and kept at that point for four or five hours, will keep liquid for a longer period under a variety of conditions than honey heated quickly to 160 and cooled quickly. But the trouble with the honey that is heated to 130 and kept there for four or five hours is that it turns darker than honey heated quickly to 160 and cooled quickly. Honey should never be heated except thru the medium of hot water or with steam. With the latter agent there is danger of getting the temperature too high. Hot water is better, provided the thermometer is used to test it. No honey should be heated without having a thermometer in it all the time the temperature is being raised. When the high point is reached, the heat should be shut off. The screw cap should be left off while the honey is heating if the can is full. If it is clear full some should be taken out or it will run over.

A. I. Root

## OUR HOMES

Editor

Blessed are the dead which die in the Lord from henceforth: Yea, saith the Spirit, that they may rest from their labors; and their works do follow them.—REV. 14:13.

SOME PERSONAL RECOLLECTIONS OF YEARS  
AGO, OF MY OLD FRIEND PROF. A. J. COOK.

I cannot recall at present just when or how my acquaintance commenced with Prof. A. J. Cook of Michigan Agricultural College. Soon after GLEANINGS was started he began answering questions sent us by our correspondents, both in regard to honey-plants and insects. I have always been more or less interested in maple-sugar making. In fact, it was one of the hobbies of my childhood; and when some one remarked that there ought to be a *book* on the subject of making maple sugar, as Prof. Cook had a maple-sugar bush of his own, I suggested that he write such a book; and while this matter was under way I made a trip to Agricultural College, Michigan, and Prof. Cook very kindly invited me to go with him to his home, and there I became acquainted with his estimable wife and two very bright children. I think, as far as I can recall, I made two and perhaps three visits to his home. During one of those visits I was greatly pleased with their form of family worship. Each one of the family read a verse. Then they all knelt down while the good father led in prayer. At one time the children were studying German with the view of having the whole family make a visit to Germany later on. They had a German Bible, and read the lesson first in German and then in English. I recall that on one of my visits I stayed over Sunday, and of course was present at the opening of the Sunday-school exercises. Prof. W. J. Beal led the Bible class; and I was impressed by his able way of talking to students about the Bible. I hardly need tell our readers that Prof. Beal, since that time, has occupied many high and important positions, besides his years of service at Cornell University. Of course I went along with friend Cook when he talked to his class of college boys. I remember that at dinnertime Mrs. Cook asked him what he had for the boys on that particular morning. His reply was simply "Night-dresses." At that time it was a novel idea to myself, and I presume it was so to the lot of young farmer-boy students, that men or boys should wear *night dresses* as well as the women-folks. I shall never forget that talk on night-dresses. In his peculiar and emphatic way he urged every boy present

to commence at once, if he had not already done so, to remove every bit of apparel worn during the day and replace it with a night-dress. I think he recommended a daily sponge bath; but he emphasized very strongly the importance of a good air bath any way, before putting on the night-dress. Altho I listened most attentively, and was sure he was right about it, I am ashamed to say it was toward twenty or thirty years after that before I adopted a daily bath and night-dresses.

Our good friend Cook was not afraid to carry his religion along with him in all the daily walks of life; and even when he was a boy, perhaps a bashful boy, he had the courage to stand up before the world for righteousness, purity, and temperance; and his good wife was right with him every time. I will tell you a little story of something that happened so long ago that perhaps I shall not get it all exactly as it occurred; but I can tell it so it will carry the moral.

Lansing is the capital of the state, and when the legislature assembles there are not only prominent politicians but prominent lawyers, doctors, and noted men in all the walks of life there. It happened one day that young Cook was obliged to ride in a stage coach with a lot of these "big men" who were on the way to the state-house. One of these commenced telling a low vulgar story. Prof. Cook, young as he was, protested. The great lawyer or politician with a contemptuous look at the boy said something like this:

"If a boy cannot stand men's talk, perhaps he had better get out and go afoot."

Our young friend was not at all vanquished. He replied something as follows:

"All right, I will get out and go afoot if this story is to be continued."

Then he called to the driver to stop, and stepped out. Just as the driver began clucking at the horses to go on, some one in the crowd spoke up:

"Hold on, driver! Come to think it over, I believe I too will get out and go on foot with the boy."

Then another one put in, "Well, if my wife were here I think she would admonish me to get out also."

My good friends, what do you suppose happened? Before the matter was settled every one of the crowd got out or started to get out, leaving the narrator of the obscene story to ride in the coach alone. I cannot recall how it was settled; but if

my memory serves me right it was something like this:

The man who started to tell the smutty story did the only *manly* thing he could do. He said something as follows:

"Gentlemen, get back in the coach and ride. I hereby apologize to the young man, and own up that he was right and that I was wrong."

I hope the state of Michigan has more young men of that kind. There you have, friends, a word picture of Prof. Cook when I first knew him.

The back numbers of GLEANINGS are full of his kind helps and suggestions. He was always present at the conventions of the Michigan beekeepers, and he was usually chosen to preside. He had a peculiarly happy way of making every one present say something. At one state convention at Lansing he commenced, as usual, calling on one after another. Well, there was a certain boy present at this meeting, and Prof. Cook kindly asked *him* about his beekeeping. He remarked that he was keeping bees "in company with his father."

"Well, now, that is a splendid idea," said Prof. Cook. "What better partner could a boy have than his father? and what better partner could a father have than his own son?"

That boy, by the way, is now Mr. A. L. Boyden, the husband of "Blue Eyes." I have mentioned their two boys, one of whom is taller than his father or mother. This *boy* of years ago has, perhaps, more to do now with our large honey business, buying and selling, than any other one of the firm.

In 1879 there were so many beekeepers who would persist in sending queens by mail in rickety home-made cages that the Postoffice Department issued orders, "No more queen-bees by mail." Now, even though the traffic was then comparatively small to what it is now, it was going to entail quite a hardship and a sudden check on this branch of rural industry. Somehow everybody seemed to agree that *Prof. Cook* was the man to go to Washington with proper queen-cages and present the matter to the Department in order that queen-bees might be once more permitted to go thru the mails. Now, as far back as 1880 Prof. Cook's well-earned reputation was such that President Hayes invited him to ride with him and Mrs. Hayes in the President's car. Mr. Hayes asked Prof. Cook many questions about the new industry of beekeeping, and promised to use his influence in permitting queens once more, if properly protected, to be sent by mail. It was a great disappointment to

me, and perhaps to a host of others, when we were told that friend Cook was to leave Michigan College and go to California. But what was our loss it seems was California's gain. Ernest gave you quite an extended sketch of Prof. Cook's work at Pomona, Cal., in GLEANINGS for March, 1912.

Prof. Cook was from boyhood a wonderful teacher. Teaching was his special forte. Some years ago it was my privilege to listen to Prof. Holden in one of his celebrated talks on Indian corn. He had various specimens of ears of corn, corn plants, corn silk, etc., that he held up before the audience, and his way of talking impressed me strangely. I kept saying to myself, "Why, who is it that Prof. Holden reminds me of?" I finally decided that he was wonderfully like Prof. Cook in his talks to his classes at Michigan College. After the lecture was over I said to Mr. Holden, "Are you acquainted with Prof. Cook? Have you ever met him?"

"Why, my good friend Root, he was my teacher away back years ago; and to him I owe more, perhaps, than to any one else, what I have been able to give the world in my corn talks."

There you see it, friends. In the language of our text, the lifework of any good man follows him ages after he is dead and gone, and so on thru all eternity. That little episode on the crowded stage coach started a wave of purity that may extend on thru the ages. Years afterward, when visiting Mammoth Cave, in Kentucky, on the way over to the cave in a crowded stage coach some one started an impure story. The memory of what Prof. Cook did prompted me to protest; and when the narrator snarlingly said, "Well, who are you, anyway?" I simply said that I was a professing Christian, and felt that such stories would do no good and might do much harm. He never finished the story.

---

#### "GOD'S KINGDOM COMING."

My frequent use of the above heading has already called forth considerable remark and comment. Just now a newspaper clipping has been sent me, but with no intimation as to its source. It is one of the utterances of that sainted woman, Frances E. Willard. As she died long before any intimation of the present war, her words come down to us as a precious prophecy or inspiration. As you read it will you not breathe a prayer that God may *hasten* the "Coming of his kingdom"?

We all believe that one of the choicest fruits of Christianity will be the growth of a bond of brother-

hood and sisterhood so close among all nations, races, and peoples, that we shall become truly kindred each to the other, and that great word "humanity," like a rolling wave of the ocean of God's love, shall wash out from the sands of time the words caste, creed, sex, and even that good word patriotism, because we shall feel that the whole world is our country and all

men are our kin. Every utterance of appreciation, affection, and friendship; every token of mutual co-operation; every stroke of honest hard work undertaken side by side; every sincere prayer, helps toward this beautiful day that we call "the coming of the kingdom of God."

## POULTRY DEPARTMENT

### WHOLE GRAIN INSTEAD OF GROUND GRAIN FOR POULTRY.

Some years ago, if I remember correctly, I saw a statement from some state or national authority to the effect that it does not pay to *cook* feed for chickens, swine, cows, or horses. I have been for many years under the impression that in a like manner it does not pay to grind grain for poultry—that is, the gizzard of the fowl will do the grinding in the natural way, and give as good results as if the corn, wheat, oats, etc., were ground for them. I do not recall just where I got the idea; but I have for several years supposed that if the chickens could help themselves to corn, wheat, and oats, and a plenty of green stuff, together with animal food of some sort, it was about all I could do for them. Of late years our experiment stations, I am well aware, have recommended different "mashes" kept in places where the fowls could help themselves. Down in my Florida poultry-ranch I have fed whole grain principally. At different times I have procured mashes particularly recommended; but whether the chickens were not used to mashes or for some other reason, they paid but little attention to them. I have always supplied them with ground raw bone, also with lettuce, cabbage, kale, etc., in abundance. Well, I have in my hand a statement from the University of Missouri from which I clip the following:

It should be remembered that one of the principles of poultry-feeding is that the hen cannot do well if fed on a whole-grain ration. Not only does a ration of grain fail to furnish the proper food nutrients, but such a ration is difficult for the bird to digest properly. The great fault with the farmer in his poultry-feeding is that he attempts to feed a whole-grain ration, and generally only one grain at that. Such a ration results in poor egg-production and also causes digestive disorders and liver and kidney troubles. Complaints of this kind frequently come to the department of poultry husbandry, and a suggested change in the ration has usually resulted in the elimination of the trouble. Efficient digestion demands a combination of whole and ground grains. A ration should consist of grains and ground feeds. Generally speaking, twice as much grain should be consumed as ground feed. This depends, of course, upon the nature of the foods fed.

After reading the above over for several times I decided to send it to the poultry

department of our Experiment Station at Wooster. Below is their reply:

*Mr. Root*.—It is a rather common practice among poultrymen who devote some special attention to poultry feeding to feed a dry mash made up of various ground feeds and milling by-products as a part of the ration. I do not know of any experiments along this particular line that have shown that such a course is justified by the results secured.

In an experiment which we began here last December, one lot receives a ration made up of 3 parts corn, shelled; 2 parts wheat, 1 part oats, with 10 per cent by weight of meat scrap fed in a trough each day at noon. On the basis of this one experiment, the use of a dry mash seems advisable, also we shall want to continue this work for a number of years before announcing definite results. You will note in our Bulletin 291 that a dry mash was used in all of the experiments. In the light of present knowledge it would seem advisable to allow about one-third of the ration to be a dry mash, composed of milling by-products and meat scrap, and probably ground corn.

W. J. BUSS,

Assistant, Poultry Husbandry.  
Wooster, O., Sept. 30.

Just now I am getting the best results in the way of eggs from a small number of pullets that I have ever had in my life so far as I can remember; and they have been having for a month past almost nothing but sweet corn in the way of grain.\* Most of the sweet corn is dry, hard, whole grain. They have a little sour milk and a few scraps from the table. I might say right here, however, that the way Mrs. Root manages our household there is but very little left for the chickens unless it is bones which we grind up. And this reminds me that, altho I have in years past tried about every bone-mill on the market, the one that pleases me most is the Wilson "Crown" mill. I think the list price is only \$9.00. It is made by Wilson Brothers, Easton, Pa. It is all easily "get-at-able," and very simple, with no loose parts to be dropping or

\* One reason for feeding the fowls almost entirely on sweet corn was to see if our good friend is right in what he says about sweet corn for chickens on page 689; and another thing, these pullets that I am writing about are the Eglantine strain that claims to be remarkable layers; and it may be the strain has more or less to do with the fact that these young pullets, after laying their first egg, the biggest part of them have given us an egg every day for a month or six weeks past. My experience has been heretofore that pullets seldom lay every day at the start, especially if they commence at the age of five or six months. There are seven pullets that for quite a spell past (it is now October 16) from which we have been getting five eggs one day and six the next.

tumbling down, necessitating soiling your fingers, etc. For a flock of a dozen fowls it is all right; but if you have a hundred or more you will probably need a rather larger-sized machine. This machine will grind "corn in the ear," so as to be available for chicks, at a very fair speed.

#### THE EGLANTINE CHICKENS UP TO DATE.

The article above, as will be seen, did not get in at the time I expected. On page 879, Sept. 1, I mentioned one of the Eglantine pullets that began to lay when four months and eight days old. She laid an egg every day, or almost every day, until she was about five months old, and then she wanted to sit. The novelty of seeing a pullet wanting to sit when only five months old, and a Leghorn pullet, too, wanting to sit, was such that I concluded to let her have her own way. I gave her 13 eggs, 2 of which were not fertile, and out of the 11 she hatched 8 chicks. The weather was so cold, however, and probably, also, on account of their being only pullet's eggs, she hatched out only 8, 6 of which are now following their mother all over the premises.

Some years ago the *Rural New-Yorker* gave a picture of a pullet that they called "The Youthful Mother." One of the friends who reads GLEANINGS sent a copy of the picture, and we had it for several years hanging up on the wall in our home. I think their pullet began laying at about 4½ months of age, so you see mine is a little ahead. She is a splendid mother except that when the weather is cold she does not brood her chickens quite as much as an old hen would. She just scratches and scratches out in the garden from daylight till dark; and she is about the busiest hen or pullet I ever had anything to do with. I said on p. 954, Oct. 1, that the Eglantines of which I gave you a picture on page 878 were still laying eggs. Well, I shall have to except one that was run over by an automobile. I have been in the habit of letting them out of the yard at four or five o'clock in the afternoon, and before I knew it they got up into the street. I suppose they were attracted by the droppings of horses passing along the road. I drove them back repeatedly, and now I am mourning the loss of one of my Eglantines.

\* Traveling over the country I frequently see dead chickens by the roadside—run over by automobile, doubtless. If this is true everywhere as it is around here, will it not pay farmers and others to have some sort of front fence to keep the chickens out of the main highway? Of course it is desirable to let them have the run of the farm in order that they may destroy insects, and thus save expensive feed, also. When one is in a hurry it often causes considerable delay to slack up to avoid running over any chicken that may take a sudden notion to cross the road in front of the machine.

I spoke about feeding sweet corn. Well, we grew enough sweet corn in our garden to supply the pullets until about the middle of October. Until the supply of sweet corn gave out I was getting five or six eggs a day; but just as soon as the corn was gone, and I gave them *field corn*, the laying dwindled until finally there were two days when I did not get an egg. I noticed that when I gave them field corn they looked at it rather suspiciously. They did not seem to feel sure that it was *good* to eat. It has now been a little over a week since I made the change, and now I am getting one or two eggs a day. Now, does the above indicate that sweet corn is a better feed for chickens, or was it simply a *change* of food? I think I have seen it stated that an abrupt change in rations will probably stop laying more or less; but I should hardly imagine that changing from one kind of corn to another kind would stop their laying entirely. We might think that the approach of cold weather (and we have had some very cold nights) just about the time they gradually stopped laying was the cause of it. The two older Leghorn hens I have mentioned are now moulting; but none of the pullets show any tendency to moult that were hatched in April in Florida.

#### THE "OUTDOOR SLEEPING-PORCH" FOR THE EGLANTINE CHICKENS.

On page 878, Sept. 15, I gave you a picture of said sleeping-porch. Well, when the weather came on cold, especially when we had cold rains, I was very curious to know whether the chickens had sense enough to go down inside of the coop and roost under shelter. I am glad to say they have gone down three times inside—twice when there was a big rain, and once when there was a very high wind. On one occasion there seemed to be a difference of opinion among them. The rooster and three hens went inside while the rest stuck to their outdoor roost. So far I regard the experiment as a success; and I do believe it would pay to make some arrangement to let poultry roost outdoors when the season or weather permits. I have now 15 chickens besides the 7 pullets and rooster which I expect to ship down to Florida by express the day before we start, Nov. 14.

#### A KIND WORD FROM THE HOME OF THE EGLANTINE CHICKENS.

*Mr. Root:*—I want to thank you for various mentions of Eglantine chickens in GLEANINGS, and I sincerely trust that your success with Eglantine stock continues. It will if you do not breed immatures or overdo inbreeding.

I enclose a clipping from yesterday's *North American* telling of the doings of some Eglantine birds. I

wish Queen Caroline would stop laying and go into moult, but she is slowing down gradually. She didn't stop with 510 eggs, but that was her accomplishment in two years.

We believe the generation of chickens now coming into laying will give some marvelous records, which doesn't mean that we hope to beat the individual record of Lady Eglantine.

If I knew chickens as you know bees I'd get along faster than I do. But we are putting deep study, hard work, and the utmost of conscientious care into the improvement of our strain.

October 30.

A. A. CHRISTIAN.

Together with the above came a clipping from the Philadelphia *North American* of Oct. 29. The clipping contained three pictures of the Eglantines. Below is what we find under the picture clipping.

#### TWO HENS LAY 1010 EGGS IN TWO YEARS.

These seventeen Eglantine hens in twenty-four consecutive months laid 7389 eggs—an average of 434½. In their pullet year they laid 3933—average 231 1-3, and in hen year, 3456—average 203¼. Queen Caroline, upper right circle, laid 510, and Queen Mary, upper left circle, 500. This picture, made Monday, found some of the birds in the roughness of moulting. Two more Eglantine hens are expected to complete 400-egg records—their period ending October 31. Eighty-seven Eglantine pullets this year qualified in the 200-egg class—the best record will considerably exceed 280. Eglantine Farms have entered two pens in the competition to open next Wednesday—one for scientific observation.

As some may be asking, we would state that the Eglantine Farms are located at Greensboro, Md. X

## HIGH-PRESSURE GARDENING

THE GARDENETTE; OR, CITY BACKYARD GARDENING BY THE SANDWICH SYSTEM.

Something over a year ago Robert Livingston, of the Livingston Seed Co., wrote me, saying that I must go and see Benjamin F. Albaugh at Covington, Ohio, who was making some wonderful improvements in the way of growing stuff on a small area of ground. Our friends will remember that our tomato book, part three, is devoted to "how to support a family on one-fourth of an acre." Well, I did not go to visit friend Albaugh; but I have just got hold of one of the books he has recently put out, and it has been a delight and a surprise to me to see how nearly he and I had been experimenting along the line of "high-pressure gardening" without either knowing about what the other was doing. This book has 138 pages, and it is not only full of beautiful and enticing pictures on the inside, but it is also covered with beautiful pictures of what he has done in his backyard garden on the outside.

The "Sandwich System" is much on the line of the hotbeds and cold-frames that I described on these pages twenty or thirty years ago. The reason why he calls it "sandwich" is, as I understand it, that he sandwiches rotting leaves, straw, coarse stable manure, etc., between layers of soil, river sand, etc. Let me make some extracts—first from page 24, where we read:

If only one square rod is available, it will pay to have a "gardenette."

Again, on page 7:

The author has repeatedly produced on a plot containing but four square rods about the following:

Then he makes an enumeration of about 40 different vegetables which he grew on the above four square rods, and adds:

At a low estimate these are worth \$40.00. Often they would cost much more to buy. But it is not only the market value of the vegetables, but freshness and fine quality that should be considered.

On page 10 we read the following:

Finest vegetables can be grown on hard, stony, or alkaline soils, where ordinary cultivation would be utterly fruitless. Even where "made" soils consist mainly of brickbats and old wall plaster, the sandwich beds flourish. A solid rock, a paved street, or the tops of flat-roofed buildings, could be made into a successful garden by this method.

Further on he describes what he calls his "plant-incubator." This consists of a bed for growing early plants for transplanting by the heat of a common coal-oil lamp. I think he uses sash with glass to some extent, but mostly frames of the size of ordinary sashes covered with cheap cotton sheeting; and in order to keep out frost the better, he stretches cloth on *both sides* of the frame so as to inclose a dead-air space. Let me digress a little right here:

During the past season here in Ohio we have had the finest tomatoes we ever grew, and we have also had more tomatoes to the plant than I ever saw before. When I got back from Florida, "Blue Eyes," who is now quite a gardener, gave me six tomato-plants. She said the seed came from one of the finest tomatoes that grew the year before; and the tomatoes from those six plants were large, smooth, and (if Mrs. Root had not forbidden it) I would say they were the most delicious tomatoes I ever tasted in *all my life*. Well, I thought I had made a big invention in the way of a tomato-trellis, and I was going to make a picture of it to put in GLEANINGS. It consisted of three straight stakes driven in triangular form, each one a foot or a little more from the tomato-plant; then for a support I got a

coil of pretty good-sized wire and stapled it spirally around the three stakes. The only mistake I made was that I did not have my stakes driven into the ground far enough, and my wire was not heavy enough. The consequence was, the great load of tomatoes bent the wire and pulled one stake out of the ground so that it could tip over. Well, now my good friend Albaugh has just "gone and done" the same thing, except that he uses *binder twine* instead of wire, which will be cheaper and easier to put on, and probably will last about as long. Well, you know that potatoes have been my hobby, not only up in Michigan and here in Ohio, but down in Florida. Page 43 of this book contains the following sentence:

Treated as above described, the author has grown, on a space 6x20 feet, seven measured pecks of choice potatoes.

You will see from the above he got over a peck of potatoes from a space of ground equal to a 3x6 frame. We do not understand that he used any cloth frame, but that the small amount of ground gave over a peck of potatoes. With potatoes \$2.00 a bushel, as they are now, just figure up how much could be done on a whole acre on the "sandwich plan."

I might go on and give accounts of what he has done with various garden stuff, but our space forbids. He has accomplished with flowers also the wonderful results mentioned in regard to vegetables, and the book is "chockful" of the finest pictures I ever saw in any book.

This book, in paper covers, when first put out, contained only 64 pages, and is offered at 60 cts. The large cloth-bound edition contains 138 pages, price \$1.25. We can furnish either one. Elsewhere will be found an offer of either book clubbed with GLEANINGS.

#### BEEKEEPING, DAIRYING, AND SOME OTHER FARM INDUSTRIES CONTRASTED.

We clip the following from the Iowa *Agricultural*:

The normal cost of beekeeping is exceedingly small in comparison with other farming pursuits. It costs cents for materials and appliances, where dollars are invested in expensive machinery for dairying, and the income from the first investment is the greater.

Not only is it the "materials and appliances," but for poultry, cows, etc., you have got to raise or buy feed. I often think of this down in Florida when purchasing grain at a big price for my chickens. A hive of bees, after it is once established, requires no expense for feed. They feed themselves as a rule, and the owner also. You may suggest that beekeepers sometimes

are obliged to buy sugar: to which I reply, very seldom unless you have taken away more of their honey than was wise or prudent.

#### GOATS, GOATS' MILK, AND GOAT PERIODICALS.

*Mr. Root*:—In your issue of Oct. 15, in regard to goats for milk, as we find it hard to buy milk of any kind here I shall be very much obliged for any word on the matter as to where one can buy a goat, and where the periodicals you speak of can be had. The name of such periodicals will be thankfully received.

CHAS. BLAKE.

Snow Road, Ont., Canada, Oct. 27.

We give the above because there have been a number of similar letters in regard to the goat industry. While down in Florida last winter we had several numbers of the periodical; but the only thing I can get track of just now is the *Angora Journal* (monthly, \$1.00), published in Portland, Oregon. I presume some of our readers can give the address of those having goats for sale; and I myself have been thinking of having a goat to milk on our three acres of wild land in Florida. Would the goat interfere with the chickens or the chickens with the goat? Who can tell?

#### "GOD'S KINGDOM COMING."

It is now too early, Nov. 9, to give a full report of what has been accomplished by the recent election: but we can well say, "May the Lord be praised" for what the following gives us, which we clip from the *Cleveland Plain Dealer* of Nov. 9:

#### 25 STATES NOW IN DRY'S COLUMN.

CHICAGO, Nov. 8.—More than half of the forty-eight states of the Union have been put into the dry column. Those which were added to the election Tuesday, making the total of dry states twenty-five, are Michigan, Nebraska, South Dakota, Montana, Utah, and Florida. The territory of Alaska has also been added to the dry possessions of the states.

The states which voted on the liquor question in which the dry forces seem to have been defeated, altho the returns are not all in, are California and Missouri.

F. Scott McBride, superintendent of the Illinois Anti-saloon League, thus stated the situation:

"A number of victories were gained for dry legislation in the defeat of propositions put forward by the wets intended to act as checks on the dry movement. In Colorado an attempt was made to secure an amendment favoring the use of beer under certain restrictions, and in South Dakota and Arkansas the wets championed local option as against statewide prohibition.

"In each instance the plans of the wets were defeated.

"The victory in Utah and in Florida was in electing a legislature favorable to dry legislation. The legislature is expected to pass promptly statutory prohibition.

"In the four other states which voted dry, the people voted directly on the dry issue.

"The statewide victories against the saloon were secured thru the Anti-saloon League in the various states, and give great encouragement to the aim of the league—a saloonless nation by 1920."

# "SCALECID"™

Fall Spraying Controls Leaf Curl. . . Does the Work; Cleans up the Trees.

Don't put off the dormant spray until the spring rush. The weather may be bad or the ground too soft. Spray this fall and make sure of controlling peach-leaf curl, San Jose scale, pear psylla, apple canker, collar rot, etc. You can save trees now that would die before spring. Use "Scalecide." Better and cheaper than lime sulphur—cuts

the labor cost. Never injures trees, hands, face or pump. Cost of spray materials will advance before spring. Order now and save money. Write today for free booklet, "The Whys and Wherefores of Fall Spraying." B. G. PRATT CO., Manufacturing Chemists, Department 6, 50 Church Street, New York City.

## Dangerous Indigestion

Indigestion, Constipation, and the more serious ills to which they lead are so common and cause so much needless pain and suffering that Dr. John Harvey Kellogg has written a book telling how to prevent and remedy such disorders. The greatest living authority on diet and digestion here gives you the results of his forty years' experience as Superintendent of the Battle Creek Sanitarium where he has studied and treated thousands of cases of indigestion and resulting ills. "Colon Hygiene" is a book of facts—not theories. Do you want to renew your energy and stamina, stop suffering from headaches and backaches, have clear eyes, a smooth, ruddy skin, feel the exhilaration of real good health tingling through your body? If so, send this coupon now for a free examination of this splendid book. Learn how easy it is to live life anew—to acquire the dominant personality that comes from good health—to become suffused with the joy of living. All this, and more, you may get from Dr. Kellogg's book of 400 pages, which the coupon will bring to you. This free examination offer is limited, so send the coupon NOW before it is withdrawn.

**Send No Money—Just the Coupon**

**GOOD HEALTH PUBLISHING CO.**  
1011 Main St., Battle Creek, Mich.  
Send me, all charges prepaid, "Colon Hygiene". After examination I will remit only \$2 or return the book within five days at your expense.

### HONEY AND WAX FOR SALE

All honey sold. C. R. ALLEN, Vicksburg, Miss.

A1 clover-amber-blend honey in new 60-lb. cans, at 8 cts. VAN WYNGARDEN BROS., Hebron, Ind.

FOR SALE.—White-clover comb honey; extracted in 60-lb. cans. HENRY HETTEL, Marine, Ill.

FOR SALE.—Clover honey of fine quality in new 60-lb. cans. THOS. PHILLIPS, Johnsonville, N. Y.

Light-amber honey, two 60-lb. tins to the case, at 7 cts. Sample, 10 cts. H. C. LEE, Brooksville, Ky.

Buckwheat honey, comb and extracted; also clover extracted, 60-lb. cans. E. L. LANE, Trumansburg, N. Y.

FOR SALE.—A1 sweet-clover honey in 60-lb. cans, two cans to a case, 7½ cts. per lb., f. o. b. cans. JOE C. WEAVER, Cochrane, Ala.

FOR SALE.—Clover, heartease, No. 1 white comb, \$3.00 per case; fancy, \$3.25; 24 Danz. sections to case; extracted, 120-lb. cases, 8 cts. per lb. W. A. LATSHAW Co., Carlisle, Ind.

FOR SALE.—A limited quantity of choice stock buckwheat and pure clover honey in 60-lb. cans and 5-lb. pails. C. J. BALDRIDGE, Homestead Farm, Kendaia, N. Y.

FOR SALE.—Fancy and No. 1 clover comb honey of finest quality, 4¼ x 1½, 9 cases to crate, at \$3.00 a case, f. o. b. Ruthven. MARTIN CARSMOE, Ruthven, Iowa.

No. 1 white comb, \$3.50 per case; No. 2, \$3.00; No. 1, fall comb, \$3.00; No. 2, \$2.50; 24 sections to case; extracted in 60-lb. cans; clover, 9 cts.; amber, 8 cts. Amber in pails, 6 ten-pound or 12 five-pound to case at \$6.00 per case. H. G. QUIRIN, Bellevue, O.

RASPBERRY HONEY.—Thick, rich, and delicious. Put up for sale in 60-lb. tin cans. Price \$6.00 a can. Sample by mail for 10 cts., which may be applied on any order sent for honey. Write for price on large lots. ELMER HUTCHINSON, Rt. 2, Lake City, Mich.

### HONEY AND WAX WANTED

WANTED.—Comb and extracted honey, in ear lots and less carlots. J. E. HARRIS, Morristown, Tenn.

WANTED.—Extracted honey in any lots. Send sample and prices. ED. SWENSON, Spring Valley, Minn.

Beeswax bought and sold. STROHMEYER & ARPE Co., 139 Franklin St., New York.

WANTED.—Comb honey, fancy and No. 1 white clover; also buckwheat comb; glassed sections preferred. HOFFMAN & HAUCK, Richmond Hill, N. Y.

BEEWAX WANTED.—For manufacture into Weed Process Foundation on shares. SUPERIOR HONEY Co., Ogden, Utah.

WANTED.—Comb and extracted honey at jobbing price. NATIONAL HONEY-PRODUCERS' ASSOCIATION, Kansas City, Mo.

WANTED.—1000 lbs. No. 1 white-clover honey in 60-lb. cans. Send sample and prices. S. S. LAWING, Ozark, Mo.

WANTED.—Several thousand pounds of clover honey, comb and extracted. Send price and sample. A. W. YATES, 3 Chapman St., Hartford, Conn.

### FOR SALE

Get our new Rubber Stamp and Label Catalog. ACME PRINTING Co., Medina, Ohio.

HONEY LABELS.—Most attractive designs. Catalog free. EASTERN LABEL Co., Clintonville, Ct.

SEND TODAY for sample of latest Honey Labels. LIBERTY PUB. Co., Sta. D, box 4-E, Cleveland, Ohio.

FOR SALE.—A full line of Root's goods at Root's prices. A. L. HEALY, Mayaguez, Porto Rico.

Pretty green mistletoe for holidays, 15 cts. per lb., f. o. b., Brady. M. C. STEARNS, Brady, Texas.

Beekeepers, let us send you our catalog of hives, smokers, foundation, veils, etc. They are nice and cheap. WHITE MFG. Co., Greenville, Tex.

FOR SALE.—Cedar or pine dovetailed hives, also full line of supplies, including Dadant's foundation. Write for catalog. A. E. BURDICK, Sunnyside, Wash.

Friction-top pails, 5-lb. size, \$4.75 per 100; 10-lb. size, \$6.50 per 100. Lower price on larger amounts. L. D. MARTINE, 206 E. Jefferson St., Louisville, Ky.

Good second-hand 60-lb. cans, 2 cans to the case, 30 cts. per case, in lots of 10 cases or less. In lots of 25 cases or more, 25 cts. per case. These prices are f. o. b. Cincinnati. C. H. W. WEBER & Co., Cincinnati, O.

FOR SALE.—22 new 8-frame comb-honey supers for sections 4¼ x ½ plain; 15 in flat just from Root factory; 7 nailed and painted, filled with sections and foundation; never been used; \$12 for the 22. CLARENCE G. LANGLEY, Rt. 2, Fennville, Mich.

THE ROOT CANADIAN HOUSE, 185 Wright Ave., Toronto, Ont., successors to the Chas. E. Hopper Co. Full line of Root's goods; also made-in-Canada goods. Extractors and engines; GLEANINGS and other bee-journals; Prairie State incubators. Get the best. Catalog and price list free.

### PATENTS

Protect your idea—don't give it away! Send data. Two wonderful Guide-books free. \$625,812.00 clients made. E. E. VROOMAN & Co., 834 F., Washington, D.C.

FOR SALE.—Apiary and 160 acres of land, cheap. Old age compels. JOHN G. SOLDAN, Oberlin, Mich.

In the Imperial Valley, 10-acre alfalfa ranch, good soil; large new house; place well improved; 230 stands of bees; 10-frame hives; good bee location, 4 miles from El Centro; 3 miles from Imperial on good roads. WM. BARTH, Rt. 1, El Centro, Cal.

A small farm in California will make you more money with less work. You will live longer and better. Delightful climate. Rich soil. Hospitable neighbors. Good roads, schools, and churches. Write for our San Joaquin Valley illustrated folders free.

C. L. SEAGRAVES, Industrial Commissioner A. T. & S. F. R'y, 1934 R'y Exchange, Chicago.

FOR SALE.—Eighty acres 1½ miles from the Columbia River; 20 clear good bottom land; 20 in growing timber; rest, pasture; 114 colonies of bees, leather-colored; supplies on hand for 300; large shop, modern house, and other outbuildings; trout creek runs here; the place is a splendid location for bees. Write for particulars.

Mrs. L. SCHMITT, Oak Point, Wash.

VIRGINIA AND NORTH CAROLINA FARMS, \$15 PER ACRE and up. Easy payments. Fruit, dairy, stock, climate, schools, churches, roads, markets, and neighbors of the best. Get our Farm Lists, Magazine, and other interesting literature, all free. Address F. H. LABAUME, Agr. Agt. N. & W. Ry., 246 N. & W. Bldg., Roanoke, Va.

THE SOUTH FOR FARM PROFITS.—Southern lands are low in price—give large yields of corn and other grains, grasses, and forage crops; all kinds truck; grow fine fruit. You can get good lands in healthful location, where climate is pleasant and works for you, where two and three crops grow annually, for \$15 to \$50 an acre, according to improvements. Great opportunity for general farmers, stock-raisers, dairymen, poultry-raisers, fruit and truck growers. Information on request. M. V. RICHARDS, Ind. and Agr. Commissioner, Room 27, Southern Railway, Washington, D. C.

## WANTS AND EXCHANGES

WANTED.—For spring delivery, 600 colonies of pure Italian bees. Write LEWIS H. FERGASON, Box 108, Windham, N. Y.

WANTED.—To rent bees in the Salt River Valley. Have had six years of experience in the Buckeye Valley. A. J. ROSS, 2209 N. Monroe St., Phoenix, Ariz.

WANTED.—To furnish every beekeeper within 500 miles of Boise, Idaho, with the best and cheapest bee supplies on the market, *quality considered*. Send me your order or a list of your requirements for 1916. Our catalog and price list will be mailed to you free. Order early and get the discounts.

C. E. SHRIVER, Boise, Idaho.

## BEEES AND QUEENS

Finest Italian queens. Send for booklet and price list. JAY SMITH, 1159 De Wolf St., Vincennes, Ind.

Well-bred bees and queens. Hives and supplies. J. H. M. COOK, 84 Cortlandt St., New York.

FOR SALE.—300 to 500 colonies in A No. 1 condition in famous Hagerman Valley, where failure is unknown. Address J. E. HANKS, Hagerman, Ida.

My choice northern-bred Italian queens are hardy, and will please you. Orders booked now for spring delivery. Free circular. F. L. BARBER, Lowville, N. Y.

FOR SALE.—Golden Italian queens that produce golden bees; for gentleness and honey-gathering they are equal to any. Every queen guaranteed. Price \$1; 6 for \$5. WM. S. BARNETT, Barnetts, Va.

FOR SALE.—Italian bees, 1 lb. with queen, \$2.25; one-frame with queen, \$2.00. Queen, .75 cts. each. Safe delivery guaranteed; 30-page catalog with beginner's outfit for stamp. THE DEROY TAYLOR CO., Newark, N. Y. (formerly Lyons).

My bright Italian queens will be ready to ship April 1, at 60 cts. each; virgin queens, 30 cts. Send for price list of queens, bees by the pound and nucleus. Safe arrival and satisfaction guaranteed. M. BATES, Rt. 4, Greenville, Ala.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, beautiful and gentle. Mated, \$1.00; 6, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SONS, Wilcox St., Binghamton, N. Y.

Golden Italian queens that produce golden bees; the highest kind, gentle, and as good honey-gatherers as can be found; each, \$1.00; 6, \$5.00; tested, \$2.00; breeders, \$5.00 to \$10.00.

J. B. BROCKWELL, Barnetts, Va.

Queens for requeening. Best on market. One untested, \$1.50; 12, \$12.00; one tested, \$2.00; 12, \$18.00; one select tested, \$3.00; 12, \$24.00. Special low price on 50 or more. Write. Safe delivery and satisfaction guaranteed. THE J. E. MARCHANT BEE & HONEY CO., Canton, Ohio.

QUEENS.—Improved three-banded Italians, bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.

H. C. CLEMONS, Rt. 3, Williamstown, Ky.

TENNESSEE-BRED QUEENS.—My three-band strain that has given such universal satisfaction for over 40 years. Orders filled promptly or money returned by first mail. 1000 nuclei in use. Tested, in June, \$1.75; untested, \$1.00; in July, \$1.50 and 75 cts. Postal brings circular.

JOHN M. DAVIS, Spring Hill, Tenn.

## HELP WANTED

WANTED.—Position in an apiary in the South, Southwest, or West. FRED E. OSBORNE, Ahearn, Florida.

WANTED.—Apiarist. State wages wanted, and give references, age, and experience. Permanent position and good home for right man. W. J. STAHMANN, Clint, El Paso Co., Texas.

WANTED.—Young man or lady to take charge of apiary, 146 colonies; steady employment at fair wages; board and washing. Must be of clean character; a lover of music and good books preferred; if preferred, wife could give piano lessons in part payment for service. No user of liquor or tobacco need apply. L. W. MAXWELL, Turkey River, Iowa.

## Convention Notices

The Indiana Beekeepers' Association will hold its annual meeting at the State House in Indianapolis, on Monday and Tuesday, November 27 and 28. We wish to arrange a good program for each day. Redkey, Ind., Nov. 1. GEO. W. WILLIAMS, Sec.

The Kansas State Beekeepers' Association will hold its annual meeting at Topeka, Nov. 20, 21. A good program is being prepared, and we hope all persons interested in bees will be present. There will be a honey banquet served at noon of the 21st. Topeka, Kan. O. A. KEENE, Sec.

The Wisconsin State Beekeepers' Association will meet in annual convention in the Assembly Room in the Capitol Building, Madison, Wis., December 7 and 8. An interesting program will be presented, and we are looking for the largest attendance at this time, altho we had an attendance of about 150 last year. We expect Dr. Phillips and other prominent beekeepers to be there. Headquarters will be at Simons Hotel.

Augusta, Wis.

GUS. DITTMER, Sec.

The Annual Stockholders' Meeting of the Idaho-Oregon Honey Producers' Association will be held in the City Hall assembly rooms, Ontario, Oregon, on Tuesday and Wednesday, December 5th and 6th. The first day's session will be given over to the election of directors for the coming year, while the second day's session will be more in the nature of a social one, discussions relative to honey production being in order.

All bee-keepers in this territory are cordially invited to attend. P. S. FARRELL, Sec'y.  
New Plymouth, Idaho, Oct. 27.

The fifth annual convention of the Iowa Beekeepers' Association will be held at Des Moines, December 5 and 6. Judging from the list of men high up in the bee-world who have written Sec. Miller their acceptance, this meeting will be the best ever held. The Secretary, H. B. Miller, is filled with energy and enthusiasm clear to the brim, and the arrangements he is now making will make it worth the while of every beekeeper who can possibly do so to attend. Those desiring information as to hotels, train services, etc., should write H. B. Miller, Marshalltown, Iowa, or F. C. Scranton, care of the A. I. Root Co., Des Moines.

Des Moines, Ia, Oct. 27.

F. C. SCRANTON.

The twentieth annual meeting of the Chicago Northwestern Beekeepers' Association will be held in the Great Northern Hotel, Room 138, on Monday and Tuesday, December 4 and 5, 1916. The program is not completed, but the following expect to be there and read a paper on the subject following their names: N. E. France, Platteville, Wis., "Marketing Honey;" Edward Hassinger, Jr., Greenville, Wis., "About Heating and Clarifying Honey;" Louis C. Dadant, Hamilton, Ill., subject not announced; Kenneth Hawkins, Plainfield, Ill., "Displaying Live Bees in Chicago Groceries;" Dr. E. F. Phillips, Washington, D. C., "Extension Work in Beekeeping;" Prof. Francis Jager, of Minneapolis, will be present and read a paper entitled "The National and its Problems." Dr. C. C. Miller writes that he hopes to be present. The question-box will be made a strong feature. Of course many others will have papers.

Valparaiso, Ind. JOHN C. BULL, Sec.-treas.

#### LAST CALL FOR MICHIGAN'S THANKSGIVING CONVENTION.

This is the last notice that will appear before Michigan is enjoying her fifty-first convention. Programs will be sent to all members of the association, and we shall be glad to mail programs to all interested beekeepers not members.

If you attended our last meeting at Grand Rapids you know what good times we had. This year we are looking for a larger attendance and a better time; so make your plans to attend. Your time and money can not be spent to better advantage.

The meetings will be held in the Capitol building, Lansing. Hotel accommodations can be had from 50 cents up, and cafes are reasonable in their charges. Headquarters will be the Wentworth Hotel, on Michigan Avenue East, and street-cars pass the door from all depots.

Come along, then, and eat your Thanksgiving dinner in Lansing. Following is the program:

THURSDAY—1:30 P. M.

President's Address, Mr. David Running.  
Prevention of Swarming, Mr. C. P. Dadant, Hamilton, Ill.

Establishing a Trade Name for Honey, Mr. E. R. Root, Medina, Ohio.

The Sale of Honey, Mr. E. D. Townsend, Northstar, Mich.

Extension Work in Beekeeping, Dr. E. F. Phillips, Washington, D. C.

Some Beekeepers I have Met (illustrated lecture), Frank C. Pellett, Atlantic, Iowa.

Possibilities of the Combless Bee Package, Mr. A. G. Woodman, Grand Rapids, Mich.

Choosing a Location for Beekeeping, Mr. Ira D. Bartlett, East Jordan, Mich.

Successful Winter Feeding of Bees in Cellar, Mr. Leonard Griggs, Flint, Mich.

Which Should Beekeepers Produce—Extracted or Comb Honey? Mr. Floyd Markham, Ypsilanti, Mich.

Efficient Beekeeping, Mr. E. S. Miller, Valparaiso, Indiana.

Some Reasons for Failures in Beekeeping, Mr. F. Eric Millen, East Lansing, Mich.

Banquet Supper, Gift of The A. I. Root Co., Medina, Ohio, and Messrs. M. H. Hunt & Son, Lansing.

This year the association is giving away four medals, to be won outright, for exhibits of about 150 pounds of comb and extracted honey. The comb-honey medals will bear the portrait of Dr. C. C. Miller, and the extracted-honey medals will bear the portrait of L. L. Langstroth. There will be a silver and bronze medal for each class.

For the small class exhibits there will be nicely gotten-up diplomas, and these will take the place of cash or bee supplies which have been given formerly. These diplomas should prove good advertisements to the winners in their home localities, and we feel sure that the winners will feel proud of them. Following is a list of exhibits:

A—150 sections comb honey; first premium, Miller silver medal; second, bronze medal; third, diploma.

B—150 pounds extracted honey; first, Langstroth silver medal; second, bronze medal; third, diploma.

C—12 sections clover comb honey; first, second, and third, diplomas.

D—12 sections raspberry or other light comb honey; first, second, and third, diplomas.

E—12 sections amber or dark comb honey; first, second, and third, diplomas.

F—12 pounds clover extracted honey; first, second, and third, diplomas.

G—12 pounds raspberry or other light extracted honey; first, second, and third, diplomas.

H—12 pounds amber or dark extracted honey; first, second, and third, diplomas.

I—12 pounds extracted candied honey, most saleable condition for market; first, second, and third, diplomas.

J—12 pounds beeswax; first, second, and third, diplomas.

K—one dozen honey cookies.

L—One dozen bran honey cookies.

M—Two pounds honey fruit cake.

N—Best apiarian appliance.

Diplomas will be given for Class J to N as in other classes. Exhibits must not bear the name or mark of exhibitor until after judged. All exhibits must be the product of the exhibitor or a member of his family.

Honey will be judged by the following scale of points:

Extracted—Style, 10; body, 20; color, 30; flavor, 40—total, 100.

Comb—Cappings, 30 (color, 15; finish, 10; no travel stain, 5). Honey, 50 (body, 10; color, 15; flavor, 25). Comb, 15 (well attached); section, 5 (clean).

Beeswax—Style, 10; color, 35; aroma, 25; cleanliness, 30.

Challenge medals will be competed for as follows: Classes C to I—Firsts, four points; seconds, two points; thirds, one point.

Classes J to N—Firsts, two points; second, one point; thirds, ½ point.

All exhibits must be in place on the evening of the 30th.

The silver medal is given by the Michigan jobbers in bee supplies, and is known as the Jobbers' medal.

The bronze medal is given by the Association, and is known as the Association medal.

The challenge medal must be won three times before becoming the property of the exhibitor. This is the second year for competition for these medals.

Programs will be sent to all members of the association, and can be secured by any other interested beekeeper.

F. ERIC MILLEN, Sec.  
East Lansing, Mich

# A Great Story Year

Everything from Every-  
where for Everyone  
in the Family

Just the best there  
is and the most of  
it for the money.

Think what a whole year of

## The Youth's Companion

52 Issues—All for \$2.00

will mean to your family—every one of them. It is a paper for every age—the favorite family weekly of America. It is both older and younger than its name. 1917 will be a great STORY YEAR in The Companion. 12 Great Serials or Groups and 250 Short Stories, a thousand Articles and Suggestions, a thousand Funnysims. Special Pages for the Family—Boys—Girls—Children. New Pictorial Sections—Sports, Games, Receipts, Doctor's Counsel, etc.—52 issues a year—loaded with the best. No other publication in the world like it.

The great "BEST TWO" Offer includes the famous Fashion Authority, McCall's Magazine—all for \$2.10.

### The BEST TWO Offer to *new* subscribers

Every NEW subscriber for The Youth's Companion who FD71 wishes to include McCall's Magazine by sending FD72 FD73 FD74 \$2.10 will receive all the following: FD75 FD76

1. THE YOUTH'S COMPANION—52 issues of 1917.
2. All the issues of the remaining weeks of 1916 FREE.
3. The Companion Home Calendar for 1917. FD40
4. McCALL'S MAGAZINE—12 Fashion Numbers 1917.
5. One 15-cent McCall Dress Pattern—your choice for 2c. stamp.

ALL THE ABOVE FOR

**\$2.10**

THE YOUTH'S  
COMPANION  
Boston, Mass.

# Bees, Poultry and Fruit

Most beekeepers everywhere realize the possibilities of profit in the combination of beekeeping with fruit-growing and poultry-raising. Both fruit and poultry may be economically cared for in connection with beekeeping: both are possible even on a small place; and both are becoming more and more profitable as city population increases everywhere. The beekeeper, too, has the best promoter of good fruit in his bees, and has time to care for poultry when his bees are not demanding his attention and when "hen fruit" is at the highest price. Bees, fruit, and poultry, properly cared for, make up a triple sure business.

## An Ideal Combination

Realizing that a large number of our readers would like practical information along these lines, we have arranged with the publishers of the leading fruit journals and poultry journals of the country to club their journals with Gleanings in Bee Culture, at a special low price.

### The American Poultry Advocate

published monthly at Syracuse, N. Y., is devoted to the interests of all practical poultrymen. It is helpful in all branches of poultry work to the beginner as well as the expert. Tells how to get eggs at the least cost, how to feed to get best results. No detail left out. It stands **SECOND TO NONE** in its value to poultry raisers. This paper will help you to success in the management of your poultry. Regular price 50 cents per year.

### Green's Fruit Grower

will be better than ever during the coming year. Whether your subscription is expiring right now or not, it will pay you to take advantage of this special club. All subscriptions will be extended 1 year from their present expiration dates.

No. 23

# A NEW MODEL TYPEWRITER!

The **No. 9**  
**OLIVER**  
The Standard Visible Writer

## BUY IT NOW

Yes, the crowning typewriter triumph IS HERE!

It is just out --- and comes years before typewriter experts expected it. For makers have striven a lifetime to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

### CAUTION!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models — famous in their day — never had the Optional Duplex Shift

It puts the whole control of 84 letters and characters in the little fingers of the right and left hands. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

### WARNING!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes — now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly — we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows you want the finest model.

**17 CENTS A DAY!** Remember this brand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the *Optional Duplex Shift, Selective Color Attachment* and all these other new-day features.

Yet we have decided to sell it to everyone everywhere on our famous plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous **PRINTYPE**, that writes like print, included **FREE** if desired.

**TODAY---Write for Full Details** and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

**THE OLIVER TYPEWRITER CO., 212 Eric Bdg., Cleveland, O.**

# SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

### Shipping-cases in Flat, without Glass.

|                     |                                                             |                          |

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT COMPANY, MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

**Extra Fancy.**—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

**Fancy.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

**No. 1.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

**No. 2.**—Combs not projecting beyond the box, attached to the side not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

## HONEY MARKETS

**CLEVELAND.**—The supply in market seems to be smaller than usual, but is equal to the demand, which is only fair. We quote fancy, per case, \$3.85 to \$4.00; No. 1, \$3.60 to \$3.75; No. 2, \$3.25 to \$3.40. Cleveland, O., Nov. 25. C. CHANDLER'S SONS.

**PITTSBURG.**—Receipts continue to be liberal, but no oversupply. Demand is good; extra-fancy honey, comb, is selling at \$3.75 to \$4.00; No. 1, \$3.50 to \$3.75; buckwheat, fancy, \$3.25 to \$3.50; No. 1, \$3.00. Pittsburg, Pa., Nov. 23. W. E. OSBORN CO.

**SYRACUSE.**—The demand at present is not over-brisk for either comb or extracted honey. The general supply seems to be fully adequate to the demand. We quote fancy, per case, \$3.60; No. 1, \$3.36; No. 2, \$3.00. White extracted honey brings 8 to 9 cts. in small quantities; light amber, in cans, 8. Syracuse, N. Y., Nov. 23. E. B. ROSS.

**BOSTON.**—There is a fair movement in both comb and extracted. We quote extra fancy comb honey per case, \$3.50 to \$3.75; fancy, \$3.25 to \$3.50; No. 1, \$3.00 to \$3.25; No. 2, \$2.00 to \$2.50. White extracted honey brings 9½ to 11½. Clean average yellow beeswax brings 28 to 30. Boston, Mass., Nov. 23. BLAKE-LEE CO.

**ALBANY.**—Receipts are free, and prices favor the buyer for comb honey. Of extracted honey there is an increased demand. We quote extra fancy comb honey, per case, 15; fancy, 14; No. 1, 13; No. 2, 12. White extracted honey brings 8 to 8½; amber, in cans, 7½. Clean average yellow beeswax brings 30 to 32. Albany, N. Y., Nov. 23. H. R. WRIGHT.

**PHILADELPHIA.**—We can report no appreciable change in market since last quotations. Comb is moving somewhat slowly; better inquiry for extracted honey; also buying pure clean country beeswax. We quote white extracted honey at 8 to 9; light amber, in cans, 7 to 7½; amber, in cans, 6 to 7. Clean average yellow beeswax brings 28 to 30. Philadelphia, Pa., Nov. 22. CHAS. MUNDER.

**INDIANAPOLIS.**—There is very little to report regarding the honey situation, except that inquiry and demand continue active, but the volume of business is, of necessity, limited, owing to inability to obtain the honey because the supply is so depleted. We quote No. 1 comb honey, \$3.75 to \$4.00; No. 2, \$3.50. White extracted honey brings 11. Clean average yellow beeswax brings 28 to 30. Indianapolis, Ind., Nov. 24. WALTER S. POWDER.

**NEW YORK.**—Fair demand exists for both comb and extracted, especially for fine white grades. We quote fancy, per case, 14 to 15; No. 1, 13 to 14; No. 2, 12 to 13. White extracted honey brings 7½ to 8½; light amber, in cans, 7 to 7½; amber, in cans, 6½ to 7; in barrels, 5½ to 6. Clean average yellow beeswax brings per lb. 31 to 32. New York, Nov. 24. HILDRETH & SEGELEN.

**PHOENIX.**—The last car of light-amber honey was shipped Nov. 11, and sold at \$7.20 per case, which was a slight advance over former shipments. Light wax is firm at 25; one cent better for choice lots. Light amber extracted, in cans, brings 6 cts. Clean average yellow beeswax brings 25 to 26. Phoenix, Ariz., Nov. 17. WM. LOSSING.

**KANSAS CITY.**—The demand for honey is a trifle better, but it takes cold weather to make the demand good. We quote fancy, per case, \$3.00; No. 1, per case, \$2.90; No. 2, \$2.65. White extracted brings 9½; light amber, in cans, 8; amber, in cans, 7 to 7½. Clean average yellow beeswax brings 25. Kansas City, Mo., Nov. 22. C. C. CLEMONS PRODUCE CO.

**PORTLAND.**—Nothing new since last report. Comb honey is moving a little freer. Extracted stocks are coming in slowly; in fact, many sections have had a poor crop. We quote extra fancy, per case, \$3.50; fancy, \$3.25; No. 1, \$3.00; No. 2, \$2.75. White extracted honey, per lb., 8½; light amber, in cans, 8; amber, in cans, 7½. Clean average yellow beeswax brings 25 to 26. Portland, Ore., Nov. 22. PACIFIC HONEY CO.

**LOS ANGELES.**—No supply of extracted here except for local use. We have surplus of comb, with little demand. Local prices are unchanged with little honey being used. We quote extra fancy, per case, \$4.25; fancy, \$3.85; No. 1, \$3.25; No. 2, \$2.50. White extracted honey brings 8½; light amber, in cans, 8; amber, in cans, 7. Clean average yellow beeswax brings 35. Los Angeles, Cal., Nov. 21. GEO. L. EMERSON.

**CHICAGO.**—The best grades of white comb are bringing 13 to 15; off grades from 1 to 3 cts. per lb. less. Extracted is selling well, and there is no excess of supplies. The best white grades are bringing 9 cts., and those off in color or flavor are bringing 8. The best grades of light amber bring 7½ to 8, with darker grades ranging from 6 to 7. Beeswax, if free from sediment, and good color, brings 32; dark grades, 28 to 30. Chicago, Ill., Nov. 17. R. A. BURNETT & CO.

**ST. LOUIS.**—The demand for comb honey, tho fair, has been very limited owing to mild weather; but extracted honey is in good demand, and the market not overstocked, especially with Southern amber. Extra fancy comb honey brings \$3.50; No. 1 comb honey, \$3.00 to \$3.25 (fancy white comb); amber comb honey, \$2.50 to \$2.75; white extracted honey, 9 to 10; light amber in cans 7½ to 8; amber in cans, 6½ to 7; amber in barrels, 5½ to 6. Beeswax is firm at 31 for average clean yellow wax. St. Louis, Mo., Nov. 23. R. HARTMAN PRODUCE CO.

**HAMILTON.**—Demand is only fair. Stock is good. We are not looking for large sales till January. We quote extra fancy comb honey, per case, \$2.50 per dozen; No. 1, \$2.25; No. 2, \$1.50 to \$1.60. White extracted brings 12 cts. in 60-lb. tins; light amber, in cans, 10. Hamilton, Ont., Nov. 21. F. W. FARMAN CO., LTD. MacNab Street Branch.

**TORONTO.**—Prices are unchanged since last issue. Comb honey which is now on the market sells as follows: No. 1, per case, \$2.40 per doz.; No. 2, \$2.25. Toronto, Ont., Nov. 20. EBY-BLAIN, LTD.

**CUBA.**—Light amber, in barrels, brings 47 cts. per gallon; amber, 47. Matanzas, Cuba, Nov. 20. A. MARZOL.

**LIVERPOOL.**—The honey market in England is inclined to be on the easy side, the supply being in advance of the demand at present prices. We quote Jamaica, pale, at \$10.56 per cwt.; Jamaica, amber, \$8.88; Jamaica, liquid, dark, \$8.40 to \$9.60; St. Lucia, liquid, dark, \$8.40; Haiti, pale, \$11.04 to \$11.52; Haiti, amber, \$8.88 to \$9.84; Cuban, pale, \$10.32 to \$11.04; Cuban, darkish, \$7.92 to \$8.64; Californian, \$11.52 to \$14.40; Chilian, pile X, \$10.56 to \$11.52; Chilian, pile 1, \$9.60 to \$10.08; Chilian, pile 2, \$8.88 to \$9.36; Chilian, pile 3, \$8.04 to \$8.16. Of Chilian, 1242 barrels have just arrived—sales 1055 barrels. Beeswax is scarce, and inquired for. Chilian brings \$35.22 to \$42.48 per cwt.; Jamaica, \$37.02 to \$40.08; West African, \$38.88; Abyssinian and East African, \$40.08. Liverpool, Eng., Nov. 13. TAYLOR & COMPANY.

**MEDINA.**—Offerings of comb honey have been larger the past fortnight than for any similar period this season, and prices are ruling low. We confidently expect an improvement after Jan. 1. Extracted of the better grades is in good demand, and offerings light. Medina, O., Nov. 27. THE A. I. ROOT CO.

# YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

- White Clover extracted and Amber extracted.
- A few cars of California Water White Sage.
- A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

**THE FRED. W. MUTH CO.**  
"THE BUSY BEE MEN"

204 Walnut Street.

CINCINNATI, O.

## HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual one. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

### Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. PREPARE! Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

#### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

G. B. Lewis Company, Watertown, Wisconsin, U. S. A.

Send for catalog giving name of distributor nearest you.

## DON'T FUSS

With your old combs and cappings, but send them to us. We will render them into beeswax for you on shares and pay you cash for your share, or we will make it into

### Dadant's Foundation

for you.

If you prefer, we will pay you our best trade price in exchange for BEE SUPPLIES.

Send for our terms. We feel sure that we can save you some money besides saving you a "mussy" job.

BEESWAX WANTED at all times.

**Dadant & Sons, Hamilton, Illinois**

## EDITORIAL

OUR California correspondent is developing into a racy paragrapher. See his department in this issue.

DON'T forget to take in Donahey's live-bee stunt in this issue, especially the expression on the face of the dog.

If any one has extracted honey for sale he should get bids from the different markets. Delay may be dangerous. The supply of comb honey everywhere is large, and prices easy.

THE very novel arch-way shown on our cover is in the apiary of R. A. Morrison, Catarqui, Ont., Can. The cover of the Dec. 15th number will show a beautiful winter scene in this same apiary.

THE secretary of the National Beekeepers' Association has announced that the next convention will be held at Madison, Wis., in February, exact date of meeting to be announced later. He says the officers have commenced on the program and will take up matters of great importance to beekeepers all over the country.

### The Effect of Sudden Cold Snaps During Early Winter

FROM Nov. 23 on to the 25th we had wind, rain, and snow, with a sudden drop in temperature on the 24th and 25th. Indeed, this cold spell caught many beekeepers who had not yet put their bees into the cellar. It caught us; and an uncomfortable feeling it was, as we knew they ought to be in the cellar. After a cold spell like this it is advisable to let the bees have another flight, providing there is prospect of a warm day in the near future. To put the bees into the cellar too early is almost as bad as putting them in too late. Everything depends on the season.

### Wintering at Medina

OUR Medina bees are put up for winter in four different ways. 1. In quadruple winter cases holding four hives; 2. Regular individual double-walled hives; 3. Single-walled hives packed in straw and cornstalks at one of the outyards recently acquired. 4. A few of the weaker colonies that have been used for window displays will be put into our big cellar.

We shall have an opportunity of comparing all methods of wintering; and, no matter what comes, our eggs are not all in one basket.

### The Distance Bees Fly

IN this issue, page 1114, Mr. Doolittle takes issue with Arthur C. Miller and the editor as to the distance bees fly. Evidently Mr. Doolittle has not read all that the editor has said on this subject. If he will refer to pages 965 Dec. 1, 1915, and of this year, pages 150, 256, 866, 964, and 966 he probably will not differ very widely from us. Then if he will turn to an article by Mr. Louis Macey on page 1127 of this issue he will see that Mr. Macey is apparently with the editor. Times, seasons, and locality, as well as conditions, are so different that it is impossible to lay down any hard-and-fast rules. Sometimes bees will go five miles and even more; and just as surely they will not go more than half a mile at other times and under other conditions. Why this is, we do not know.

### New Beekeepers' Paper in the Texas Field

MR. LOUIS H. SCHOLL, of New Braunfels, Tex., well known to GLEANINGS readers as the reporter of "Beekeeping in the Southwest," is to be the editor of a new beekeepers' journal, *The Beekeepers' Item*, soon to make its initial appearance. We understand that the new journal is to be published especially for the beekeepers of Texas and

adjoining states. Mr. Scholl says that the beekeepers of Texas feel that there ought to be some kind of medium thru which there may be an interchange of beekeepers' news matter and other information. Mr. Scholl further says that this need has become so vehement, and so urgent have been the persuasions on the part of many beekeepers, that he has finally decided to get out a beekeepers' "newspaper." It is Mr. Scholl's idea to emphasize the news feature of his journal, making it a "newspaper" in very fact. Along with the zealous reporting of beekeepers' "news" in his field, the editor will aim to make the educational influence of his journal as great as possible.

The new publication is to be a monthly, and we understand it will make its first appearance very shortly. Price, 50c a year.

Mr. Scholl will have the well-wishes of all forward-looking beekeepers in his efforts to advance the apicultural interests of Texas and the Southwest. GLEANINGS wishes him all the success possible in his new venture.

### The Starch-glucose Trust Ordered Dissolved

ACCORDING to the news dispatches of Nov. 13 the starch trust, with a capital of eighty million dollars, has been adjudged guilty of "unfair methods of competition" in violation of the Sherman anti-trust law. The defendants, including The Corn Products Refining Co., according to the decree, "shall be divided in such manner and into such parts of separate and distinct ownership as shall be necessary for that purpose." The dissolution of the "trust" is to be effected within 120 days, and failing so to do the court shall take steps by receivership or otherwise to dissolve the unlawful combination.

The Corn Products Co., it will be remembered, are the manufacturers of the glucose product called "karo." This does not mean that karo and the other products of the allied companies will be taken off the market, but that each of the concerns, according to the decree, shall be operated in harmony with the law. Doubtless the case will be carried to the Supreme Court of the United States.

Our readers will remember that karo was originally advertised as "better than honey and for less money." We have never regarded it as a competitor of honey, because it is in an inferior class by itself. Possibly there are some who would buy honey if they could not get karo. More probably those who buy karo cannot afford to buy honey or the more expensive

syrops. To that extent karo may be supplying a demand all its own, and perhaps enable some poor people to have a sweet that they could not otherwise procure, but a dark honey of a higher price would go further.

### Honey-market Conditions and Prices

While the extracted-honey market is becoming more and more firm, with prices above those of last year, the comb-honey market is going the other way, with quotations easier than those of last year. Possibly the firmness of the liquid-honey market will tend to stiffen the market on comb, but it is doubtful. Those who are holding extracted honey for better prices would do well to remember that the prices on comb honey and extracted ease up usually during and after the holiday period. See what Foster says in Rocky Mountain Department this issue, also Honey Column.

It is apparent that the heavy campaign of advertising honey by the publishers of this journal thru our popular magazines is creating an enormous demand for table extracted. It is impossible to advertise any one brand without advertising all brands of honey. We are reliably informed that the various bottlers, have sold in the aggregate over one hundred cars of honey in bottles and tumblers already this season. Such a call for liquid honey would have a tendency to stiffen the market. Before our campaign of advertising honey in the popular magazines such a demand would have been impossible. Honey in glass is cheaper than honey in comb; and if beekeepers had heeded our call last spring, see GLEANINGS May 1, and produced more extracted than comb, the market would now be good on both.

### The Hearing on Comb Honey Freight Rates

On page 647 of issue for August 1 we called attention to the proposed discrimination against shipment of comb honey in less than car-load lots applying to territory west of Chicago. At the time we urged producers to write at once, protesting to R. C. Fyfe, Chairman of the Western Classification Committee, Transportation Building, Chicago. Apparently beekeepers got busy, with the result that-comb honey in less than car lots may soon be sent at reasonable rates *provided it is sent* in carriers. Before this was allowed, a special committee of representative men appeared before the Committee on Railroads.

It will be remembered that the western classification effective Sept. 1 required the payment of two and a half times first-class rates on comb honey in cases not protected by carriers, and double first on comb honey packed in carriers.

On Oct. 26 there was held in Chicago before a sub-committee of the Western Classification Committee a hearing for a lower classification. Representing the beekeepers and others interested in the shipping of comb honey, there was Frank C. Pellett, of Iowa, assisted by Mr. Lewis, of the Iowa Commission; E. J. Baxter, of Illinois, president of the Illinois and Tri-state Beekeepers' Association and J. T. Calvert, of GLEANINGS IN BEE CULTURE. Mr. Francis Jager, President of the National Association, had spent several days in Chicago doing some good work but did not remain for the hearing.

It appeared from some remarks by Chairman Fyfe that the committee had been bombarded with letters as a result of notices appearing not only in GLEANINGS but in the *American Bee Journal* as well, and our case had been practically won before the hearing occurred. We were promised a concession in the first supplement to be issued soon, and to become effective January, 1917. The rates to be granted will probably be first class on honey in carriers, with no reduction on that shipped unprotected, if, indeed, such honey will be accepted at all in local lots.

It appeared in the evidence that the railroads had been called upon to pay damages in excessive amounts, not only on the honey broken in transit but often on other goods of greater value which were injured because of the leaking honey. Damage claims were more noticeable in the far West, where the use of carriers is not so common as thruout the East. The Southern Pacific Railroad alone had been called upon to pay over \$800 in claims.

There had also been numerous claims for losses in Texas and Oklahoma where friction-top cans and pails are largely used, showing that these containers are not entirely satisfactory for safe shipment.

The evidence presented at the hearing showed that where comb honey was put in carriers of not over 250 lbs. gross, having not less than four inches of cushion material in the bottom, and handles to move them with, it reached its destination without damage—especially if the honey was at all suitable for shipment. Out of nearly a million pounds of comb honey shipped in one year by The A. I. Root Co., there were less than five dollars in claims.

No one should offer for shipment, either

by freight or express, comb honey that is not well fastened to the wood section-box, top and bottom, or top and both sides. Honey not well fastened, if such is produced, should be disposed of locally.

It is unfair to the interests of careful beekeepers who use care, not only in the production but the packing for shipment of comb honey in safe carriers, to attempt to ship comb honey not well fastened, or to ship *any comb honey* in light cases without carriers.

The increased toll of many thousand dollars taken by the railroads in recent months is the direct result of excessive claims due to *careless, thoughtless, and slipshod shippers who have not been willing to take sufficient pains and expense in properly preparing their honey for safe carriage.*

While the lesson has been expensive we trust it has been well learned, and that shippers of comb honey will in future give the railroads a fair show by properly protecting comb honey for safe transport before offering it for shipment.

Beekeepers in western classification territory are to be congratulated that relief is in sight from the excessive rates now in effect.

There is need for a similar campaign in the territory covered by the southern classification where double first-class rates prevail on comb honey. We urge beekeepers and others affected to write to the Southern Classification Committee, W. R. Rowe, chairman, Atlanta, Ga., protesting against the present unreasonable rates.

We have already entered a petition to the committee for a reduction. If this is backed up by the right kind of appeals from those interested we may hope for action similar to that expected from the western committee.

This campaign should have been undertaken several months ago, but we overlooked calling attention to it then. Let a united effort be made now, and we may look for some relief.

## The 1917 Edition of the A B C and X Y Z of Bee Culture

THE new 900-page double-column volume is nearing completion. It has been a tremendous undertaking, because every subject has been either revised or entirely rewritten, the most important having been entirely rewritten or nearly so. The minor subjects, while they have received changes and corrections and additions, are much the same as before. A large number of new subjects that never appeared before are now incor-

porated. The new volume will not only be considerably larger, but will be clear up to date from start to finish. Each subject found in its convenient alphabetical order is a complete monograph in itself. While there are numerous cross-references, each chapter is handled in such a way that it is a complete text-book in itself, taking in all the latest developments.

Among some of the new subjects will be found the Foreword at the very beginning, setting forth the nature and scope of the industry. The A B C of Beekeeping is the initial chapter. This gives a general birdseye view of the whole subject treated in the volume so that the reader will have a fairly concrete idea of what bees and beekeeping are at the very beginning and before he takes up his other course of reading. It is, in fact, a little text-book for beginners.

Among other new subjects are Backlot Beekeeping, Breeding Stock, Brood and Brood-rearing, Buildings, Bumblebees, Combs, Drifting, Dzierzon, Dzierzon Theory, Frames, Honey, Analysis of; Inventions Relating to Bee Culture, Langstroth, Patents, Queens, Quinby, Races of Bees, Sense Organs of Bees, Shipping Bees, Solitary Bees.

The following subjects have been very largely if not entirely rewritten, and therefore are clear up to date:

Adulteration, Alfalfa, Apiary, Bottling Honey, Comb Foundation, Diseases of Bees, Foul Brood, Fruit Bloom, Honey as a Food, Invert Sugar, Laws Relating to Bees, Manipulation of Colonies, Moth-miller, Nectar, Swarming, Sweet Clover, Transferring, Water, Wax, Wintering, Xylocopa.

There have been such great changes in the subject of Diseases of Bees, Swarming, and Wintering that they have been handled in an entirely different manner.

A. Hugh Bryan, formerly of the Bureau of Chemistry, Washington, D. C., has rewritten everything in relation to honey, the adulteration of honey, glucose, invert sugar, and the like. He has also prepared a special chapter on the analysis of honey. While it is technical it will meet the needs of the chemists who have been following antiquated methods for analyzing honey. The introduction of artificial invert sugar has made it necessary for the chemist to use new tests.

Honey-plants have had a complete overhauling by J. H. Lovell. A large number of new engravings will serve to identify the various species. The subject of pollination has received exhaustive treatment by the same author under the head of Fruit-bloom and Pollination. Alfalfa and sweet

clover have both been enlarged and entirely rewritten.

The Laws Relating to Bees have been handled by a lawyer also an experienced beekeeper. The new chapter is handled in such a way that not only the laws but the procedure will be of immense service to an attorney handling a case for a beekeeper.

The subjects of Swarming, Comb Honey, and Wintering have been submitted to the best experts in the country for criticism; for around these center some of the latest developments.

Wax-rendering, under the head of Wax, is given an entirely new treatment in the light of some recent experiments conducted at Medina. The general subjects of Migratory Beekeeping and Shipping Bees have been entirely rewritten.

One can hardly conceive that such important changes have been made in the industry within the last four years; but some investigations on the part of the Bureau of Entomology by Dr. Phillips and his assistants have made it necessary to revise our former opinions on a number of subjects, and the new A B C has it all in.

One will naturally see that a vast amount of work has been undertaken, and it was carried thru when the editor, author, and reviser was in the pink of condition.

The new volume will be the largest work that was ever published on bees. It covers nearly every important method or process used by the best beekeepers of the world. Under Artificial Swarming and Swarming every scheme for the prevention or control of swarming has been discussed. In short, we have endeavored to make the A B C and X Y Z of Bee Culture just what its name signifies—a complete treatment of the subject of bee culture from beginning to end in the convenient form of an encyclopedia. It has cross-references from one subject to another, and a complete index at the close of the volume.

The author and editor does not claim that his volume is *better* than any other bee-book, but he does claim that it is *larger* and more comprehensive.

The large increase in the amount of matter, together with the increased cost of paper, will make it necessary to charge \$2.50. If we were to charge on the basis of the old volume the price would be \$3.00. As it is, we club it with GLEANINGS one year for \$3.00. While the work is complete so far as the work of revision is concerned, there are yet about 400 pages to be run thru the press. We hope to have the new volume ready for delivery by Feb. 1 at the latest.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

I'm eagerly waiting to see the first number of the new GLEANINGS, Jan. 1.

A. I. ROOT, in accordance with your wish, p. 1013, I'm doing my level best to live as long as you, and also to have the best kind of time, with no anxiety for the future, because I am trusting that future to One "who is mighty to save." Yes, indeed, I can sing "The Rock that is higher than I" just as well as when you heard it last.

A WAY given, p. 1088, to get honey out of combs without an extractor, is to crush them up and strain the honey thru cheese-cloth. An easier, tho not so good a way, is to melt them with gentle heat, allow the mass to cool, and then lift off the cake of wax.

SWEET CLOVER is getting bouquets from stock-raisers nowadays. In *Country Gentleman*, 1947, is given a report from Mitchell, S. Dak., where it is pastured on a large scale, and it was the belief "that three head of adult cattle to the acre was about the right quantity for a sweet-clover pasture. Needless to say, this is much more than ordinary native grasses or any other known pasture plant is capable of carrying."

J. E. CRANE, you ask, p. 968, "Are we to understand the moderate use of sugar will shorten a man's life, or that the use of honey will lengthen it?" I don't believe the moderate use of sugar will shorten a man's life; but more than 80 pounds, the annual average, is hardly moderate. I think that the substitution of honey for most of the sugar I would use will lengthen my life, or I'd eat less honey and more sugar. If I had used all honey from childhood, I suspect I would always prefer it as a matter of taste.

BEES stopped flying here not long after the first of November. The weather kept getting colder, and Nov. 14 it was 8 above zero. A perplexing question arose: "Shall I cellar the bees before their intestines become any more loaded, or shall I wait for another flight-day?" I decided to risk waiting; but it was not a pleasant frame of mind to be always thinking, "What if another flight-day never comes?" Finally my heart was rejoiced to see the bees in a glorious flight Nov. 19, with the thermometer at 52°." So in they go into the cellar the first day I can get Philo to take them in. [We had the same problem here. It turned steady cool or cold earlier than

usual. We are hoping for a warming-up spell, after which we will put the bees in the cellar. We are more likely to get it than you are.—Ed.]

"ORDINARILY it is not practicable for beginners to unite bees of the same yard... Wait till cold weather..." p. 940. You forgot the newspaper plan of uniting—didn't you? Any beginner can use it in the same yard, and without waiting for cold weather. Lay a sheet of newspaper on the top-bars of one hive, and set the other hive upon it. The bees will do the rest. [The newspaper scheme is all right and endorsed in our A B C and X Y Z of Bee Culture. During cool weather we have not found it necessary to use it. In hot weather, such as we sometimes have in October, the bees above may suffer some for the want of air.—Ed.]

SOME excellent talk about wintering, p. 1011. Along with it we can hardly emphasize too much the importance of pure air. That's where outdoor wintering has the cinch. You are right, Mr. Editor, in saying there is tendency toward outdoor wintering in very cold climates. But there is another tendency that must not be overlooked. That is the tendency toward having furnaces in cellars. In this region I think the number has quadrupled in the past ten years—perhaps in five. Wherever a furnace is put in a cellar the advisability of cellar wintering is greatly increased, simply because the higher temperature of the cellar allows the introduction of a larger supply of pure air without making it too cold for the bees. Another factor to be considered is the wind. You are dead right in saying, "If we had to choose between windbreaks and single-walled hives or double-walled hives out in the open, we would unhesitatingly choose the former." And before either of them you would probably choose a place so still that windbreaks would not be needed. The fact that a man in Canada finds outdoor wintering better for him does not convince me that it is better for me, altho 200 miles further south; for he may be where winds are neither severe nor long-continued, while my winds nearly blow me over, and make a business of blowing steadily day and night.

[Perhaps if you were where you could not inspect your cellar daily you would prefer the outdoor plan. Certain it is that a furnace with plenty of ventilation helps out a cellar for bees providing, of course, that the climate is cold enough. The new edition of the A B C and X Y Z makes quite a point of this.—Ed.]

Grace Allen

## THE DIXIE BEE

Nashville, Tenn.

Count us among those who, with the editors, are "looking forward to a bigger and better GLEANINGS with enthusiasm."

\* \* \*

All this part of Dixie has gone into winter quarters with the prettiest of prospects for clover in 1917.

\* \* \*

We have used carbolic acid to advantage around hives that are being robbed, but did not know it was of benefit applied to the *robbing* colony, as outlined on page 987. Sometimes more than one colony is in the mischief, and anyway it isn't always easy to identify the robbing colony, whereas the veriest novice knows who's getting robbed.

\* \* \*

Mr. Scholl, may I please take back my "Whew"? At any rate, I want to change the tone from one of amazement, tinged with protest, to one of downright respect. The explicit article on pages 1031, '32, Nov. 1, shows skill and efficiency developed to a high degree. If the quantity of smoke used doesn't hurt the honey a bit, and I assume it doesn't, or you wouldn't use it, you have a method of removing honey that is as excellent as it is rapid.

\* \* \*

The editor's warning, page 965, Oct. 15, against extracting unripened honey, is one that can well be repeated many times. We have run upon several customers who have complained about honey purchased other seasons from different producers, who, we know, mean to be careful, but whose honey soured, being extracted too green. One man complained, not about that particular honey, but about honey in general. "What I don't like about honey," he grumbled, "is that you gotta eat it up so quick or it goes sour on you."

\* \* \*

Today, Nov. 14, we of middle Tennessee are watching our thermometers in shivering amazement, for we have dropped to a freezing temperature and below. Last night Nashville fell to 28 degrees, which is very unusual for Nashville in November, with 15 to 20 promised for tonight. It is, of course, the same cold wave, somewhat penitent and reformed, that left Montana frozen stiff at 28 degrees *below* zero. Beekeepers naturally think temperature in terms of bees. I hope the blankets are tucked in tight around the Montana bees; and I half wish our own had an extra

quilt or two! I had planned to try out a few four-hive winter cases this fall, but somehow backed down when the time came, merely putting on a few shallow supers of leaves.

\* \* \*

Mr. Foster says, page 1014, Nov. 1, that when the producer retails his own honey he ought to hold the prices up. And so he should—decidedly. He also says that when he sells to retailers he should let them make a sufficient profit. And so he should. But when the producer sells for 7 cts. in 60-lb. cans, and the retailer sells for 16 cts. in 10-lb. cans, doesn't the retailer get the best of that bargain? He makes more for putting the honey in 10-lb. containers, and selling it, than the beekeeper gets for producing it, and then putting it in 60-lb. containers and selling it, for he gets 9 cts. profit, while the producer gets only 7 cts. gross. Of course, if there is a middleman it is a different story; then the 9 cts. must be divided.

## MOTHS IN EXTRACTING-COMBS.

We extracted in July, let the bees clean up the supers, then stacked up the extra ones in the supply room, treated them twice with carbon bisulphide, and thought no more about them. They were not touched again till October, when they were disarranged and rearranged, and yet not worried about, as it seemed too late in the season for moths, in spite of the warm weather. And then in the lean month of November we discovered them and their name was Legion. Sleek and prosperous-looking, the little white worms were scattered all thru our precious combs. But they had not done much damage yet, at that; and as we promptly dosed them again with the carbon bisulphide, we hope the trouble is over. It is true that the supers, piled one on the other, leave rather wide cracks, thru which I should think a moth might be able to enter, yet the combs must have been free from moths until rather late, probably when we disturbed them in October, or there would have been more galler-ies eaten thru the combs, and the larval development would have been greater. Mr. Sidney Olliff, in A B C and X Y Z, says the full-grown larva is about an inch long. I think none of these was more than a quarter of that length. The most interesting thing about it was that practically all the worms were in cells containing pollen. Where there was pollen, there was a worm, almost invariably. [Evidently the lesser wax-moth.—Ed.]

# NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Regarding the matter of packing for out-door colonies, page 1010, Nov. 1, is it practical or possible to give enough packing to keep the bees warm enough to permit them to throw out all dead bees during long spells of weather away below zero? The most of us up here in our "Lady of the Snows" will not debate that question very much, but will almost unanimously say that it is not necessary any way, when one considers that good wintering can be accomplished without going to so much trouble to make such large cases as that procedure would entail.

\* \* \*

GLEANINGS to be a monthly! It is up to the editor to change some subscribers' feelings on this question; for after speaking to a number of friends who take the paper they unanimously have said, "Sorry we shall get it only once a month from now on." But on reading the first editorial page, Nov. 1, it looks like a sure thing that all these subscribers will feel quite sure that the change has been made for the best. Quite a few thousand regular readers of GLEANINGS will await with no small amount of eagerness to see the initial number on Jan. 1. May their fondest desires as well as those of the publishers be realized.

\* \* \*

In the north location, which is mainly a hay-growing country, the alsike in the old meadows seems to be all right. Here at home, alsike is strictly a biennial; but at the north location all agree that the plant will live on for three years. In other words, plants that came up in 1915 blossomed in 1916, and are alive this fall with good prospects of wintering, and again blossoming next year. While I am not prepared to be positive as to the correctness of this claim, yet circumstances seem to prove that it is right. Will some seedman give us positive information on this point? Previous to the past three or four years I have always claimed that it is strictly a biennial. If I am wrong in changing that view I want to know it.

\* \* \*

## SOLID BROOD-COMBS OF HONEY.

Reading Allen Latham's article on page 973, Oct. 15, I am reminded of a practice followed by the late Mr. McEvoy in the spring of the year when he wished to give his colonies encouragement. He kept over

a number of full sealed combs of honey; and in the spring, after thoroly warming these combs he would place one flatwise right on top of the brood-combs of each colony, and then cover all up with packing again. Allen Latham recommends warming combs to give to the bees in the spring; and there is no doubt but that it would have a good effect. Whether enough help would be given to pay for all the work is another question. While temperature, as a matter of course, has much to do with regulating the amount of brood-rearing, yet there are cases that seem to disprove a few of the claims of friend Latham.

Referring to his flow from goldenrod, aster, etc., this fall, he says that the brood-nests are fast disappearing, and the brood-combs are becoming solid slabs of honey. This he ascribes altogether to temperature, the nights being cool, and also to the reduced number of bees in each colony at this season of the year. In the early fall of 1913 we had the only flow of aster honey that ever came our way—this was up north at the Lovering yard. Bees were abnormally strong for the time of the year, the whole fronts of the hives with supers on being covered each night. It is needless to say the weather was also abnormally hot for the time of the year as well. Comparatively little honey was stored in the supers, altho the supers were crowded all the time; but in the 13 days of the flow, about all brood was crowded out of the hives, and, as in friend Latham's case, the brood-combs became solid slabs of honey. We came to the conclusion that the time for the queens to lay was past for the season, for all queens, whether young or old, acted the same.

This year, as already stated, the clover flow was good, and lasted longer than usual. With hardly any swarming, colonies were very populous right thru the clover flow. But during the last ten days or so, practically all queens stopped laying, or at least allowed the bees to pack the brood-nests with honey, and this at a time when the thermometer was up around the 100 mark each day. This condition was relieved in many colonies later on in buckwheat flow, but the majority of colonies go into winter quarters with a lot of clover honey. In this case temperature had nothing to do with it, and I surmise that the queens were simply taking a rest after a long period of continuous brood-rearing.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Do you keep bees or do you make them keep you?

\* \* \*

The proper size for an entrance seems to be about as nearly settled as the mooted question of "how old was Ann?"

\* \* \*

There have been few seasons when my supply of bees has been greater at the beginning of the winter than at the present time.

\* \* \*

We are glad you have an auto, Brother Crane; but we don't like to hear so much about it until we can blossom out with one of our own.

\* \* \*

The average honey, even that weighing up to the standard, could be improved by a little more ripening. The riper the honey the less it will granulate.

\* \* \*

Bees are going into winter quarters in fine shape in this locality. There are plenty of bees, also plenty of stores, *where the beekeeper has been wise.*

\* \* \*

In response to the editorial headed "Are your bees packed for the winter?" I can say "yes," but they are not in chaff or leaves. I packed honey enough from the fat ones to supply the lean ones, and a little more for good measure.

\* \* \*

The state convention is to be held in Los Angeles some time in December. Well, I had already packed my grip to go up into the central part of the state, as that was my understanding at last convention time of the place for the next meeting.

\* \* \*

We vent our wrath on the wax-moth on several occasions, yet they are more of a benefactor in the long run than an enemy. Many are the old diseased trees and uncared-for hives where the bees have died out that they have cleaned up, thus preventing disease spreading.

\* \* \*

The man in California who fails to leave his bees not only sufficient stores for the winter but a surplus to fall back on in the face of a dry season as well, will, eventually, be found either in the sugar market or sustaining a heavy loss of bees. In my opinion a man can not afford to feed bees even

at a difference in price of five cents per pound in favor of sugar.

\* \* \*

So GLEANINGS is to have a new face and visit us only once a month. It will be a long time to wait to see who took the last dig at you. But then, if we get a larger and better magazine, one that will compare with the best, we will be up in the front row and thereby put the business of beekeeping on a higher plane. Good!

\* \* \*

The early October rains ceased as abruptly as they began. Much of the weather of late has been very dry and "electric," drying out the ground and leaving much of the surface vegetation in a dying condition. Rain is needed badly to keep vegetation coming on nicely. But, will we get it in time? That is the point.

\* \* \*

I have never seen the white sage stool out for blooming as extensively in this locality as it is this season. Each year when the plants are making their spring growth they also grow the base for the next year's bloom. This year the number of stalks on the stools for the next spring's bloom are very numerous; and should it be seasonable we may expect a wonderful bloom on this plant.

\* \* \*

Mr. Scholl, I accept your explanation of how you take off forty pounds of honey per minute. I did not wish to infer that it could not be done, but it brought to my mind a story of a bull that chased a man across a large pasture. Just as he reached the fence the bull struck him and sent him sprawling on the other side. He gathered himself up, feeling more secure than for some minutes; then turned, shook his fist at the bull, and said, "You can do that once in a while, but you can't make a practice of it."

\* \* \*

A very unnatural condition exists in a small area in the sage belt. Summer showers in September covered a small area just south of Redlands. This started the sage to take on its springtime hues. Then came the October rains which put an unseasonable growth on it in many places. In the canyons there are places where the growth has reached a length of from five to ten inches. The danger of freezing is great, for on the 14th of this month it got pretty cold, down to (there goes Chadwick knocking California again) so I'd better not tell.

# BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

## SWEET CLOVER.

The crop of sweet-clover seed will be very short here this year on account of the drouth in July. Some of the fields that were irrigated have a good stand, and will yield well; but the low price secured for seed last year will deter many from harvesting any. The demand for seed will apparently be pretty good this year.

\*\*\*

Dr. Phillips says, page 418, of the November issue of *The Beekeepers' Review*, that cautious spreading of brood will increase brood-rearing. Under what conditions may this be done? I have been taken to task for advocating spreading brood, and think that defense of the plan by Dr. Phillips might help me out of a hard position.

\*\*\*

Among the advances made in beedom during 1916 is the extension and establishing on a firm basis the shipping of bees in combless packages. The use of honey more generally has been helped by beekeepers thru circulars, demonstrations, advertising, etc. Consumption is very well apace with production. The advancing price of many things entering into beekeeping has seriously affected the profits of the business however. Financing the farmer has nationwide attention; financing the beekeeper is of as much importance to our business.

## THAT MATTER OF SUPERING.

On page 1013, Nov. 1, Dr. Miller says that my statement that we seldom have a honey-flow heavy enough to justify lifting supers and placing empty ones beneath is another one on "locality." Well, I don't know about that. I have an idea that I could handle one hundred colonies of bees in such a manner that in average seasons it would be possible to put supers above and below with success. Bee management is never as intensive with 650 colonies as with one hundred or less. My queens are not so carefully selected, nor are colonies so well cared for, as would be possible with a smaller number. I would not want to compare my colonies in strength with Dr. Miller's. But average yearly production of honey per *man* is more the aim in the commercial-honey sections of the West; and these successful ones are the fellows who best apply intensive methods in an extensive way. It is a credit to the old guard—Mr.

Doolittle, Dr. Miller, etc., that the thousand-colony beemen read their writings very carefully. Often I hear the expression, "Stick to Doolittle," or, "You will not be wrong to follow Dr. Miller." Our best teachers are those who have time to go to the bottom of things.

## THE HONEY MARKET.

Extracted honey is in good demand at a higher price by one cent a pound than last year. Comb honey is slow sale, and there is a tendency to shade prices to effect early sales. Beekeepers who have not sold their crop need money; and as interest rates are from 8 to 15 per cent it does not appeal to the beekeeper to borrow money on his honey to tide over until he can sell. The comb-honey producer is up against a hard proposition this year on account of the slow sale of honey and a much higher price for supplies. Help and all things entering into production are higher, while the comb-honey crop will net most producers less than the average of former years. Cars of comb honey are being offered at \$2.00 and \$2.25 in western Colorado, and at \$2.50 and \$2.75 in eastern Colorado. At these prices honey production is not profitable unless large crops are secured.

If some method could be worked out so that the comb honey could be shipped during warm weather, and then stored at destination, and money sufficient for the beekeepers' needs advanced upon it until sold it would help wonderfully. When beekeepers wait for buyers for a month or two they get desperate and have to sell for any thing they can get. This depresses the market so that those who have already bought at high prices lose money because they have to compete with the honey that has been unloaded on the market.

[Mr. Foster is quite right in many of his observations. The closing-out of the comb-honey crop late in the season at reduced prices to obscure channels of trade is very likely productive of great harm. Sales of an entire crop at a uniform price for the same quality will help the market in our opinion. For example, to sell one car at \$2.75, another at \$2.50, and the last at \$2.25, will net the producer no more than the sale of all three at \$2.50; but the market will be seriously affected by the reduction from \$2.75 at the opening of the season to \$2.25 at the close, leaving it in poor condition for the following season.—Ed.]

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

## THINGS MISLEADING.

"I have read what the two Millers have to say regarding the flight of bees—Arthur C. on page 866, Sept. 15, and Dr. C. C. on page 966, Oct. 15; also what the editor says on page 964. It seems to me that all but Dr. Miller put forth a misleading idea before the average reader. Editor Root says, 'That they will generally not go more than a mile in average localities and seasons we believe is not far from the truth.' This, I suppose, means a mile in a straight line in all directions from the apiary. Now, with 100 colonies could Editor Root, Dr. Miller, or Arthur C., in an average locality, secure the yields per colony reported, if the radius of flight were only a mile?"

In my memory of the days of the old muzzle-loading rifles I can see the champion shot of central New York putting the charge of powder in the barrel of his gun, then a cloth patch on the end of the barrel where the powder had gone in, and on this patch a ball of lead (100 of which it took to weigh one pound), molded in the bullet-mold, from a long-handled spoon of molten lead, heated on the coals in the open fireplace. Then with a wooden ramrod, made from a split hickory stick, this ball was pushed home, and a percussion cap put on the "tube." A chicken had been placed standing on a box 80 rods away (one-fourth mile), and whoever shot the chicken could have it. Many would shoot, but very few got a chicken. The old man would wait till all the amateurs had tried and failed, then he would raise the rifle to his shoulder, pull the trigger, and the chicken would drop. Now for Editor Root to tell us on page 964 that bees "very often do not go much over a quarter of a mile" for nectar does seem to me, as our questioner says, somewhat "misleading." And with 100 colonies set on the place where the old man fired from, I can hardly conceive of any beekeeper in this country securing an average of 85 lbs. of comb honey as I did for 15 years in succession.

Now for what I know to be positive facts, proven by actual observation when the first Italian bees were brought into this part of the country. The late Jerome Burtis, of Marietta, N. Y., a beekeeper of more than ordinary ability in the early seventies, procured the first Italian queen that came into central New York, receiving her in July. He raised some ten or twelve queens from

her the first season, so that he had nine colonies headed with Italian queens the next spring. As I had only blacks at that time I was very much interested in these Italians. When the apple-trees bloomed I watched the bees at work on the bloom, and, much to my surprise, saw several Italian bees at work with the blacks. A count was made, and the first gave three Italians out of a total twenty. Other counts gave from two to six Italians out of twenty, with apple-trees pink with bloom as far as the eye could see the orchards. Now, Marietta was  $2\frac{3}{4}$  miles distant, as the crow flies, and apple-trees were white with bloom all around the  $2\frac{3}{4}$ -mile radius from Marietta, yet Mr. Arthur C. Miller and Editor E. R. Root would have us believe that bees "will generally not go more than a mile in average localities and seasons."

That same year, with no Italian bees nearer, so far as I knew, I passed thru a field of red clover  $3\frac{1}{2}$  miles from Marietta, and, seeing bees at work on the clover, the first count gave three Italian bees out of ten. The fields were red with clover everywhere.

Editor Root speaks of moving "the Waterworks yard scarcely a mile in an air-line." This was done in the aster bloom, and "Not a one" came back. Now, asters bloom in September here in central New York, and bees are comparatively "sluggish" to what they are during May, June, July, and August; and with a whole apiary moved I should hardly expect many to come back, especially if everything about their former home was cleaned up so that the old site had no homelike look.

About 1880, I sold during the latter part of May a colony of Italian bees to a man living about  $1\frac{1}{2}$  miles away, and he carried them away after dark. The next morning at about eight o'clock I saw bees hovering about where the sold colony stood, and, being short of colonies, I put another hive on the stand having a frame of honey and one of brood in it. At night I had a good-sized nucleus in that hive, and built it up to a full colony which stored me several boxes of comb honey from the buckwheat bloom. A year or two later I sold a colony during the first days in June, having a \$10.00 golden Italian queen in it. This colony was taken two miles away, and enough bees returned the next day to make a small nucleus. (See Editorials.)

# GENERAL CORRESPONDENCE

## OUR GREATEST BEEKEEPING PROBLEM; HOW TO HELP SOLVE IT

BY GEORGE H. REA

Box-hive beekeeping as practiced by the average farmer is a serious menace to the whole industry, especially since foul brood has become so widely spread. The box hive will not admit of manipulation of any sort. The owner knows nothing of the inside conditions of his colonies, and in many cases cares less. When foul brood comes his way, his bees become polluted with it, and rapidly die out. The owner knows nothing of the real cause, but blames it on bad luck or "worms," or something else. This kind of beekeeping presents every inducement for the rapid spread of foul brood. Hives in which the bees have died are left standing for other bees to clean out and the combs later destroyed by moth. Our greatest present danger is the foul-brood phase of this question. In the fall many colonies are "taken up," or sulphured. The old hive daubed with honey, and the combs containing brood and a little honey, are scattered about for robbers to clean up. Often the ones killed are those that are too light to winter because diseased. Thus the disease may be scattered all over the surrounding country.

The box-hive beekeeper is constantly losing more than he makes out of his bees. No matter how willing he may be to make the most out of them, he is unable to produce results that will compare with the results obtained from good bees kept in good hives and operated by modern methods. From an economical standpoint alone, box-hive beekeeping is a losing game.

Ignorance regarding bees and beekeeping, and often regarding many other things, goes hand in hand with box-hive beekeeping. So far as the personal requirements of the box-hive beekeeper are concerned, real success consists in getting *swarms*. "That gum over there, he is a good one; he swarmed four times already, and I took ten pounds of honey from him," is a familiar expression. Some of the most ridiculous superstitious beliefs and practices are found among beekeepers of this class.

One lady, not far from Harrisburg, objected to having her bees inspected late in August because she said the honey would have to be disturbed, and to do so in the "eat days" would make it all sour, and she would lose her bees.

But that was mild in comparison to the

fellow who was afraid lest the inspector would charm his bees and they would all follow him home. He stated that the inspector could say a few words that would cause his neighbors' bees to leave their hives and go over into his hives—all excepting the queen. He was challenged to prove it, but he said he was afraid some one would find out his secret or make trouble for him.

One good old German lady solemnly told me that her bees had all died because no member of the family thought to rap on the hives when her husband died.

Not very long ago a man lay on his stomach before his hives for the greater part of three days, impaling certain large bees on a sharp stick which he wielded. A passing neighbor called to him asking what he was doing. "Killing these infernal robbers. I guess they come over here from Smith's." He was killing drones.

We are all familiar with the practice of "drumming" down swarms. I know one fellow who has a large circular saw suspended on wire, for this purpose alone. He uses a plowshare for a hammer; and when his bees swarm he makes a racket that may be heard a mile.

That is a harmless pastime, perhaps, and it serves to amuse and entertain the neighbors.

In the discussion of this subject I believe that we are safe in dividing box-hive beekeepers into four general classes:

1. Those who know something of the importance of better beekeeping, and who are ready and willing to transfer their bees and to co-operate in constructive work along this line. They are usually much interested in securing literature on the subject, and with a little encouragement become good beekeepers. I believe that fully 75 per cent of the farmers and backlotterers who now keep bees in the old-fashioned way belong to this class.

2. This class consists of the people who enthusiastically inform us that their bees are all in modern hives and all pure Italian. They get two swarms and ten pounds of honey from each hive, and expect to have one thousand colonies some day, etc. Do they read a bee journal? Oh, yes! they had GLEANINGS at one time. But all their ideas of beekeeping are so magnified that they scorn the bee journals, and then they

have no time to read anyway. We usually find the hives among weeds so tall that the poor bees have to crawl three feet to the top of them in order to see daylight. And such bees! They meet us on the far side of a ten-acre lot with a welcome that reminds us somewhat of the disposition of the booze gang the next morning after a dry election. Pure Italians—whew! The hives were made in a factory all right, but the combs are so crisscross that not a single one can be removed without cutting it or splitting open the hive with an ax. These conditions are far worse than in any plain box hive. Hives with immovable combs, whether factory-made or home-made, must necessarily put its owner in the box-hive class.

3. There is also a class of beekeepers who are discouraged because their bees are not doing well, and who do not care to do anything about it because the bees don't mean anything to them. Fortunately such people do not stay in the business long. If their bees do not soon die they are sold cheaply, or given to some one who does care.

4. Fortunately, also this class is small. I refer to the beekeeper who is a sort of combination of the three other classes with some things added. He knows that he is behind the times, and a menace to good beekeeping, and yet he takes a grim satisfaction in the knowledge. He knows that he is getting practically nothing out of his bees, but he wants no instructions as to how he may do better. He is suspicious if not openly defiant toward the inspector, and sullenly wants to be let alone. He wants no one, not even the state, to presume upon what he calls his rights, and yet he seems to have no realization of the menace that he may be to the general good of apiculture nor his obligation thereto.

Some prosperous, up-to-date, and wide-awake beekeepers advise us to steer clear of the box-hive man with his slipshod methods. They admit that the worst enemy to the honeybee and to good beekeeping is the box-hive beekeeper; but they say that foul brood is a blessing to the one who knows how to handle it, because it soon cleans out the other fellow, once it gets into a community. But is that strictly true? Do the facts bear that statement out? And even if it were so, is that the proper attitude for us to bear toward our fellows? As a matter of fact we usually find that a scourge of foul brood hits the specialist so hard that he might well afford to get out among his neighbors and do considerable educational work in order to save himself much loss and expense.

It has been said that if we encourage the

small beekeeper we shall soon overstock our territory as well as cause an overproduction of honey. Last summer one fellow threw up his hands in dismay and said to me, "What are we going to do with all the honey when you fellows get all these farmer beekeepers educated to modern methods?" Well, if it were possible to accomplish such glorious results it would take so long that we would be listening to Gabriel's trumpet, and the honey market would collapse with a crash anyway.

With probably not over one per cent of the people of this country eating honey, the idea that there is a possibility of producing too much honey has no good ground for fact. If all the honey now produced were properly distributed there would hardly be a taste for each one.

The man who can deliberately say, "Let my neighbors' bees die with foul brood and by adverse conditions, I shall be the gainer thereby," must be a selfish man indeed. Such selfishness, if put into action in beekeeping or any other phase of life, is sure to act as a deadly boomerang against the individual who is dominated by such motives. What if all the farmers, fruit-growers, dairymen, manufacturers—all the business men in all walks of life—manifested such a spirit. We may imagine the result, but we cannot take space to discuss it now. That is the spirit that destroys men as well as business.

Let us now look on the bright side of this problem. My neighbor—a farmer—keeps a few bees. I show him how to transfer them, how to fight foul brood, and get him interested in some good bee literature. I do not refuse, either, to answer his questions nor to give him help when he asks for it, even tho it may take my time and sometimes tax my patience. The next thing I know he is interested in planting honey-producing forage plants—a boomerang of the right kind this time. Perhaps that is selfishness too; but if it is, it works good to my neighbor as well as to myself, and it is worth more than gold to me to have my neighbor meet me with a smile. Men who used to be prejudiced against alsike clover because they said it did not produce enough hay to pay now sow lots of it because they get some help and encouragement with their bees. That makes those locations much better for beekeeping, and really in a most direct manner it has made those men better farmers than they were. I get more honey from my neighbors' alsike fields than they do, and a good many barrels of satisfaction and fun out of it besides.

Only a few days ago one of my adjoining

neighbors told me that he had purchased a few hives of bees and wanted to know about moving them. He had a very humble expression when he broached the subject. I suppose that he thought I would object to his moving them so close to me. He seemed somewhat surprised when I swept away his fears with a hearty "Glad to hear it, John, call upon me for any assistance that I can give you." He now has about eighty acres that I expect to see put in alsike if I help to make a success of his beekeeping.

There is a place for the expert specialist in beekeeping just as there is a place for him in the growing of fruit, potatoes, hogs, cattle, or poultry. However, we must remember that the smaller producers in all lines contribute as much as or even more to the prosperity of the commonwealth than do the specialists. My observation is that practically every county in my native state of Pennsylvania should have at least one specialist owning several hundred colonies and making good profits. Such specialist need not and should not interfere with the smaller beekeeper; but in order to be most successful he should co-operate with and help them. We need education, organization, and co-operation along with our legislation for the betterment of beekeeping.

As mentioned earlier in this article, the farmer who is really encouraged to become

interested in his bees, and who begins to see something of real value in them, may become a better farmer than he formerly was because of a new interest in the planting of the legumes, which are at once our best forage crops, soil-builders, and nectar-bearers. Along this line we must not overlook the importance of the bee as a fertilizing agent among fruit-bloom. Since fruit is grown on practically every farm we surely have no right to deny the farmer his right to keep a few bees for that purpose as well as for the many other profits of beekeeping.

Bees are of such importance that, beyond a doubt, the industry should be fostered among the farmers. Since this is true it is of the highest importance that the state and national governments provide the means necessary for the preservation of beekeeping as an industry and necessary equipment in our various schools for the proper study of the subject. Slowly we are coming to this. Let us do all that we can thus to bring about the elimination of the box hive and its attendant evils.

Reynoldsville, Pa.

[This article was written before Mr. Rea knew that he himself would be a government expert whose business it is to educate the farmer beekeepers. See the article by Mr. Webb, page 1120.—ED.]

## WAR ON HOME-MADE HIVES

BY LEWIS L. WINSHIP

E. E. Colien, p. 279, April 1, gave me and my article on home-made hives some hard knocks. As I said in my former article, this subject can be sifted and sifted, but will always be a live topic for a scrap.

Mr. Colien says I made some rather exaggerated statements, which in all probability is true; but if he were compelled to work with such make-shifts for hives as the one referred to in the photograph accompanying my article I think it quite probable that he would vent his wrath on would-be carpenters.

As Mr. Colien is over seventy he can be forgiven for making his own hives. A man of his age can spend his time doing so when he could not otherwise do heavy work. We are living in the twentieth century, a century of specialization. We do not, as formerly, raise our own sheep, shear them, card the wool, and spin it into yarn. We still raise sheep; but the wool is sold and bought back in the shape of yarn or in the finished garments. It is the same with

lumber for hives. Progressive beekeepers sell their lumber and buy it back in finished hives from some reliable manufacturer. By doing this they save themselves worry, annoyance, a lot of wasted lumber, time, and the necessity of buying expensive tools. The majority of large and successful beekeepers buy factory-made hives. If you still do not believe me, take a look around. I'll bet that you'll find the really successful beekeepers buy factory-made hives.

I know of only one man, an excellent carpenter, who makes his own hives, and he buys his frames. His hives are as well built and as perfect in shape as any factory-made hive. But he told me himself, and I quite agree with him, that he lost money on every hive he made if he counted his time worth anything. His lumber, the finest 7/8-inch white pine, cost him nothing, so really all he had to figure was his time. But if a man conscientiously goes at it to make a thoroughly good up-to-date hive he must focus all his attention on that one thing. This

man to whom I refer has nothing to do most of the time, and can profitably spend his leisure time making hives; but the average man who keeps a few bees, and whose business is not extensive enough to take all his time, and who is working by the day for a very meager wage, had better work for that wage rather than to knock off to make a few hives. He can buy what hives he wants cheaper than he can get ready to make them. And a beeyard of factory-made hives well-painted is an advertisement not to be slighted.

There are some beekeepers who could not make a success of their chosen vocation with all kinds of up-to-date equipment; but if I wanted to make a success, I would certainly start in by using factory-made hives. They are a pleasure to work with, as each part fits so perfectly; they are interchangeable (something few home-made hives can brag of) and they look much better than a grand *ensemble* of home-made freakish-looking, ill-fitting hives which are a drag on the beekeeping industry and invite foul brood.  
Springville, N. Y.

## THE VALUE OF EDUCATING THE CARELESS BEEKEEPER

BY ROSS SCOTT

There is nothing more exasperating to the progressive beekeeper than to have some box-hive apiarist as a close neighbor, especially when disease is known to exist in the vicinity. It is a peculiar fact that the majority of these farmer beekeepers think themselves well versed in bee culture, and know positively that there could be no disease among their bees, altho every colony may be in a box as impregnable as the rock of Gibraltar. Of course there are laws which permit the inspector to go thru an apiary whether or no; but as a rule the man with a few colonies resents inspection and regards the procedure as an intrusion on his rights. This causes more or less unpleasantness and hard feeling toward the person who called for the inspection; so, if possible, it is better to approach these stubborn beemen in some other manner.

An interesting case of this kind occurred with me last summer. Near by is a farmer who kept about twenty colonies in as many styles of hives. Disease was known to be present—in fact, the inspector found two or three cases of American foul brood in the summer of 1914; and, altho two colonies

were burned, the owner did nothing with the rest. So I decided this spring that, in self-defense, I would either buy the bees outright or get control of them somehow. To make the matter more difficult, the beekeeper in question had put together the two facts that his bees had been inspected, and that he secured no surplus in 1914, and therefore concluded that the inspector and myself had tampered with his bees to spoil his honey crop. However, after considerable bargaining it was agreed that I should trade some modern hives for a part of the bees, and shake all just at swarming time, thus controlling the swarms and treating the disease at one operation.

Well, the plan worked; and in addition to getting the bees all in modern hives and cleaning up the disease we each secured a fair surplus in spite of the poor season.

Now, instead of being suspicious of inspectors and modern methods, my neighbor is anxious for the time to come when he may have the inspector back to go thru his colonies, and also those of some other beekeepers who live within range of his yard. No more box hives for him.

La Grange, Ind.

## APIARY INSPECTION VS. EDUCATION

BY WESLEY FOSTER

The remarks of the editor, and the ideas of Mr. Ames, expressed on page 468, June 15, concerning "Education vs. Inspection," bring up some matters of vital interest to beekeeping. It appears to the writer that Mr. Ames enlarges upon the efficiency of education and minimizes the educational value of the inspection work.

The capable inspector in his work has the support and co-operation of the great

majority of the beekeepers in his district. Probably there is not over one beekeeper in ten but that considers the inspector a helper, friend, and adviser. In most counties in Colorado it is not necessary to show any authority whatever in the matter of cleaning up, but the power is there and is recognized.

It has been my experience, time and again, that the owners of diseased bees

express regret that their bees were a source of infection for their neighbors' apiaries, and they help the inspector to clean up the infection. In nine cases out of ten the cleaning up is done without any compulsion on the part of the inspector. After inspection has been in progress for several years the beekeepers learn the value of it and look for the coming of the inspector with pleasure, as he is usually better informed and can impart valuable beekeeping information. There is a small class in every community who object to what they consider interference with their private affairs, and this class *might* not be particular about spreading disease among their neighbors' bees. The fear of this is greater among some beekeepers than there is any foundation for. In a very few cases it doubtless has been done, but in no case should it deter the inspector in effecting a clean-up. If an inspector finds an apiary in a rotten condition at a time of year when robbing is being done, the procedure generally followed is to stay in the yard until no infection is left that the owner might use in spreading infection maliciously among his neighbors. The average man who neglects his apiary to such an extent does not value highly the diseased material that is destroyed. The aim of the inspectors is to help the owner rid his apiary of disease for his own protection as well as that of his neighbors.

Stock inspection, dairy inspection, and fruit inspection have been carried on so thoroly that the farmers are not opposed to inspection work. If they are persuaded that the inspector is competent and conscientious, the work is not difficult.

An inspector who succeeds is diplomatic and educational in his methods; but the beekeepers realize that he is backed up with sufficient authority if he needs it, and authority has to be shown in very few instances.

There is a certain amount of bluff in us all; and it is amusing to watch some people try to bluff the inspector, endeavoring to find out whether he means business. I have had farmers tell me that they would not do as directed unless they had to; and when told that is would be necessary for them to do the same as their neighbors were doing they agreed to it without any more objection. One man told me he wanted to know what authority I had, because he was not going to do any more than he had to; and when thru with my instructions he laughed and said he was just trying me out.

A few bonfires, where cleaning up is not promptly done, have a very beneficial effect, for the whole neighborhood soon hears of it.

In burning diseased material, we always endeavor to save anything of value that is possible. Thoro work, even tho it may seem rather destructive, gives the most lasting satisfaction, and these districts are the ones where the inspector is most appreciated in succeeding years.

The inspectors do in many counties examine nearly every apiary in the county, and the educational value of talking with and advising beekeepers is greater than can ever be reached by any other plan. But a small percentage can be reached thru institutes—we need both methods—but the personal contact of the inspector with the beekeeper is pretty much the same as that of the county agricultural agents advising with the farmers. More personal contact and less farmers' institute work will meet with better results than more extension work and less inspection work. We do need better-trained inspectors, and a combination of educational endeavor with the inspection work is advisable. The actual meeting with the beekeeper in his own apiary by the inspector is the great strength of the inspection work. The inspector should have time to demonstrate the best methods of disease treatment, and also some of the best beekeeping methods.

One of the most helpful ways is for one beekeeper to get several of his neighbors together and look over their bees together with the inspector, compare notes, and have a miniature field meeting right there.

There are several ideas expressed by Mr. Ames that should be answered. The careless beekeeper will never be eliminated. The stray swarms are caught about as fast as foul brood cleans them out. Thoro inspection is keeping disease under control where the majority of the beekeepers are of the careless variety. A few learn from the inspector, but the majority have too many other irons in the fire to pay much attention to bees.

Mr. Ames' idea seems to be that educational effort should supplant inspection laws and inspection work. If he really thinks this, as the editor's quotations lead one to believe, it cannot be too strongly condemned. We must improve the inspection methods, so they will be highly educational; but the individual responsibility of the beekeepers to the welfare of their neighbors yet needs enforcement. We could get nowhere if we tried to enforce our city health ordinances by educational methods only. There must be power behind any effective effort, whether it is bee-disease control or international treaties.

Boulder, Colo.

The first meeting of the beekeepers in Burke Co., N. C., at the apiary of L. E. Webb, Morganton, N. C. A splendid lecture and demonstration was given by G. H. Rea, just recently assigned to the state. Mr. Rea made such a hit that his spring trip will be anxiously awaited. The good results of his work are already being felt and a county association is under way.

## GOVERNMENT EXTENSION WORK IN NORTH CAROLINA

BY L. E. WEBB

While North Carolina ranks high in the number of colonies in the state it is far below in the production of honey, due to the fact that so many bees are neglected, being kept in box hives. Furthermore, a great deal of the stock is black, and weak at that.

Mr. Geo. H. Rea, the new government expert, is making a hurried trip over the state to get familiar with the different conditions in the mountains and lowlands. We did not have a chance to advertise his visit at Morganton the first week in October; but nevertheless we had a nice field-day meeting. Mr. Rea gave an excellent demonstration and lecture in my apiary. A county organ-

ization is to be formed. Mr. Rea made a hit with the beekeepers, and every one is much elated over the fact that the state is to have him permanently. His headquarters are at Raleigh.

Mr. Rea is enthusiastic over the prospects and possibilities in North Carolina. His first great task will be to bring about the use of modern methods and equipment. He has issued a warning that, owing to the extremely wet season, at least half of the bees in western North Carolina may die this winter unless they are fed to supply stores to carry them over.

Morganton, N. C.

## A GOOD SHOWING FOR COMBLESS BEES FROM THE SOUTH

BY S. H. BURTON

The past season has been one of the very best from the standpoint of honey production and increase. Bees are going into winter quarters in excellent condition with plenty of stores of clover, bluevine, golden-

rod, and some aster honey. The early frosts stopped work in the supers and sent the bees scurrying to the brood-chambers to hold the heat necessary to protect the brood. I have just finished taking off all

supers today, Nov. 8. The weather is mild, and the temperature is around 70° F. The bees are flying well, and are still working on a little aster that was protected in sheltered locations.

A sharp freeze or two does not seem to hurt the flow of aster. I found considerable nectar in the unfinished sections we removed today. As this aster honey granulates quickly it is a puzzle to know just what to do sometimes with these nice unfinished sections partly drawn out with some nectar in the combs. It is pure waste to try to carry this honey over in the uncapped sections, as it soon granulates; and if put back on the hives next spring the bees carry it out and dump it in front of the hive. If the foundation is pretty well drawn out and filled, but not capped, we cut it out immediately and sell it to the home trade to be used up as quickly as possible. If the foundation is only about one-third drawn, and contains some nectar, I figure that the comb in its present shape is worth more than the nectar contained therein, and we usually carry these over to be put back on the hives next spring as bait sections. Aster yielded very slowly this fall, and was extremely late in blooming.

Bluevine in the river-bottom cornfields made an excellent yield of pearl-colored honey, and our beekeepers here are looking more and more to this plant as a main crop yield. It stays in bloom fully as long as white clover, and I believe it is a better yielder, not being subject to the whims of the weather as much as white clover. There is no killing this plant out in our river-bottom cornfields, and it is held in check only by the cultivator. The minute the corn is laid by, which is usually about July 15, this plant commences to

climb the cornstalks; and by Aug. 1 it is winding around the young ears of corn, and reaching across the rows shaking hands with its neighbors. By Aug. 15 the plant is in full bloom, and continues to bloom till frost. It is very tender, and the first light frost puts it out of business for another year. I moved the greater part of my yards to the bottoms this summer in order to catch this yield. Thousands of acres of river-bottom cornfields give unlimited pasturage, and I consider this plant more valuable than sweet clover as a honey-plant.

This season I tried the experiment of sending south and buying one-pound packages of bees and queen; and I wish to say that I am well pleased with the results. Fifteen one-pound packages were purchased, and, barring an accident to one package, they all built up to good strong colonies and yielded considerable surplus. However, one swallow does not make a season, and I would not advise amateur beekeepers to go at this proposition too strong. Several factors must be considered in the results which I obtained. In the first place I believe I received an extraordinarily good lot of bees. They were very gentle and great hustlers, and they had vigorous young queens. They were put in hives containing drawn combs on which bees starved to death last year. Last, but not least, we had an extraordinarily good season. The bees arrived April 15, just as apple was blooming, and by July 1 these one-pound packages began to store white-clover honey in the supers. They were then moved to the river bottoms, where from one to three supers were secured from each colony. Next year this same stunt might prove an absolute failure, the biggest factors being the queen and the season.

Washington, Ind.

## KEEPING COMB HONEY IN FLORIDA

BY E. G. BALDWIN

To be sure! Everybody knows that there is not a whole lot of comb honey produced in Florida—that is to say, by large producers in any great numbers. While no exact figures are at hand, probably not one producer in ten is in the comb-honey business. With the exception of one or two extensive apiarists hardly any beeman attempts anything but extracted.

There are three very cogent reasons for the excess of the extracted-honey production over that of the comb honey. First, the long distance from large markets, or comb-

honey centers. Rates are high and weather often very warm, and distances great.

Secondly, the summers are long, warm, and damp. So, also, during much of the winter season the dampness is in excess, and the weather warm—warm and cool by changes. In such weather, as any beeman knows, combs, full capped, will tend to absorb moisture, and this excess of moisture will cause the honey to become thin, and to bulge the cappings; the result is leaking or “weeping,” as it is termed, or “sweating.”

Thirdly, the wax-moth makes holding-over of combs very hazardous. Not only is it exceedingly problematical to keep combs of honey over from the spring to the fall, but also it is only less so to keep them thru the winter. Our friends north of Mason and Dixon's line know relatively little about the ravages of this pest. In Pennsylvania we have left combs standing in hives, entrances wide open, for three weeks at a time, in midsummer, and have often under such conditions found not a single moth-web. We should like to see any one try that here (rather, we should *not* wish them to try it). Here, three days are enough to infest combs with tiny webs. In a week they will be alive with big fat larvæ—the dull gray larvæ of the wax-moth, with the voracious appetite. In two weeks a hive of empty combs left exposed will be hopelessly ruined, and in a few days additional nothing will be left but masses of webs in galleries and sheets.

The hive-bottom will be half an inch deep with debris, mostly dark-brown pellets, and the side walls of the hives, the rabbets, and the frames, will be built solid with cocoons, so dense and so closely joined that they can be pulled off in solid sheets. The soft pine or cypress wood of the average hive, after such an ordeal, is pitted, scarred, and worm-eaten, till it resembles a dead pine log eaten away by the sawyers or borers. Even the projecting ends of the tops of the frames will be eaten clear thru and break with the least touch.

One can easily see what a problem it is to attempt the keeping of comb honey in such a climate. Not long ago a letter came from an amateur apiarist in the central part of the state. We append a portion of this letter:

In looking over some sections in cartons which I have had in a dark room, and which I was saving for later use, I discovered that the honey was leaking. A careful examination showed signs of webs and worms in every section. I immediately placed the sections in supers, and put them back on

top of a strong colony, to be cleaned up. It is fine palmetto honey, and rather expensive for winter stores.

We wrote back at once about as follows:

I am afraid you have made a mistake in putting the honey on top of a strong hive of bees, if you expect to save any of it for market or table use. I am inclined to think the bees will open many cells, and perhaps "clean out" and remove all the honey, if, as you say, the combs are already leaking. In such circumstances the bees are likely to clean them up with a vengeance.

Then we told him of our experience, and our efforts to keep comb honey six or more months; and while the amount kept at any one time was not great, still the results are satisfactory. So we detail it here for what it may be worth.

We first put the combs into a tight cabinet or case, and kill all live insects or larvæ by a single treatment of bisulphide of carbon, by the usual methods. Then about ten days after the treatment (the combs remaining all that time in the tight box) each case of sections is wrapped in heavy wrapping paper, several thicknesses of it, and in strips large enough to wrap over and fold up all around, under corners, top, and bottom, thereby making a completely moth-proof package. The packages thus wrapped are then placed on a shelf in the kitchen, as near the ceiling as possible, and almost above the kitchen range, where the air is almost always warm and often very warm. We find that comb honey thus treated and preserved will keep intact all winter—no moth, no leaking, no candying. It seems that a specially warmed cabinet could be constructed along lines similar to the plan here suggested, provided the amount of honey were sufficient to warrant artificial heat. We feel confident the plan will work. We have tried it and are still doing it in a limited way.

To recapitulate in an alliterative way, the enemies of our comb-honey production in Florida are miles, moisture, and moths. Deland, Florida.

---

## NATIVE HONEY-PLANTS OF NEW ZEALAND

BY W. B. BRAY

It is a peculiar thing that, while there are no native honeybees in New Zealand, most of the native plants are honey-producing. Honeybees were introduced here by missionaries a hundred years ago, and they thrived exceedingly on the native flora. The following are some of the native flow-

ers of my district. They all help the bees to build up for the clover flow. The fuchsia and the kowhai are the most valuable flowers.

1. *Fuchsia excorticata*.—Maori or native name kotukutuku for tree, and konini for fruit. Shrub or tree 10 to 45 ft. in height.

*Fuchsia excorticata*

Leaves silvery beneath; lanceolate or ovate lanceolate; flowers drooping, one inch long; calyx dark purple, petals red purple; pollen blue; berry oblong; flowering period

*Parsonsia heterophylla*

August to December. This tree is most valuable for its honey and pollen which are a never failing standby in the spring months owing to its long period of bloom.

*Sophora tetraptera*

*Myoporum laetum*

One of my yards built up wonderfully and stored considerable surplus from this source before clover commenced to yield. It grows best in damp places along the bottoms of gullies and small creeks. I cannot say whether it would stand the severe winter of the middle states. It will stand a certain amount of frost, but I have seen the young leaves cut by a severe late frost. The flower is not as handsome as its South American cousin, but it is more valuable to the beekeeper as a spring stimulant.

2. *Sophora tetraptera*, yellow kowhai, a handsome tree attaining over 40 ft. in height; pinnate leaves; large gold-colored blossoms; trees often bare of leaves in spring; flowers produced in axils of leafless branches; calyx greenish. It blooms in September and October. The tree grows best on dry stony places. It is slow-growing, but produces a very hard and durable timber. The flow of honey and pollen from this source enables us to make an early start with queen-rearing operations. The photo shows year-old seed-pods, and the new pods just forming.

3. *Parsonsia heterophylla*. Native jessamine. This is a climbing plant which produces great clusters of pale-cream sweet-scented blossoms in October, and the bees work hard on it for honey while it lasts. The seed is produced in long pods. A seed with wings can be seen on one pod in the picture.

*Muhlenbeckia adpiessa*

it yields honey well. It grows readily from seed, and comes up thick after a forest fire. The timber is useless, and cattle often get poisoned by eating the leaves.

5. *Muhlenbeckia adpiessa*. A large rambling climber with very small green flowers which the bees work on in October.

*Leptospermum scoparium*

6. *Leptospermum scoparium*. — Native name manuka, altho it is called tea-tree by settlers. This is a sort of shrub which grows on poor soils. The blossoms vary in color from white to pink. There is a tree which has similar but smaller white blossoms. Both varieties bloom in December, and the bees work them both until the clover yields honey. It is not a desirable honey, being dark and strong-flavored, and too thick to extract. The honey in its purity has a strong resemblance to Scottish heather honey. The shrub has been called the New Zealand heather, and a whole hillside in bloom makes a very pretty sight. In some parts of New Zealand fair quantities of this honey are produced, mostly in sections.

Wainui, New Zealand.

4. *Myoporum laetum*. Native name *uiaio*. A large tree (30 to 40 ft.) which blooms in October and November. The flowers are inconspicuous. Some years

J. P. Blunk's Long Idea hives, the size of two eight-frame hives, side by side.

## MY EXPERIENCE WITH A SIXTEEN-FRAME HIVE

BY J. P. BLUNK

There has been some discussion regarding extra-large hives and double-story eight-frame hives. My latest plan is to use a sixteen-frame hive which is the full width of two bottom-boards or covers side by side. Notice in the photograph that one of the hives stands on two regular eight-frame bottom-boards, and that it is covered with two regular eight-frame covers. There is room for sixteen frames and a division-board.

These large hives about which I am speaking are fine for comb honey. The first year, however, colonies in these large hives do not make as much finished honey as they do in subsequent years. The large colonies build up faster and soon become the most powerful colonies in the yard. Such colonies store more, of course, than colonies in small eight-frame hives. I usually put on two supers at a time side by side, and I am not afraid later to put another super on top of each one as there are bees enough to fill four supers and then some.

If not looked after, the large colonies will swarm; but the treatment to prevent swarming is somewhat different from that applied to colonies in smaller hives. In a large hive there is always plenty of room. One can remove a comb of honey from the far end of the hive, and by so doing make

room for a comb of sealed brood, the space provided by the removal of this brood being filled with a frame of foundation. Room can be made at each end of the hive in this way; but when combs of brood are pushed to the outside it is important to see that they do not contain larvæ small enough for building queen-cells. Such combs are so far at one side that the bees sometimes take delight in building queen-cells on them about the time the white-clover season ends.

I have the entrance of each bottom-board open full width, thus providing an entrance the entire width of the double hive. These large colonies need a lot of ventilation, and no wonder, for there are so many bees. Some of these large colonies are ready to swarm as soon as those in small hives. I never saw big rousing colonies until I had these large hives.

When it is time to carry the hives into the cellar two boys can carry one of the big ones by means of the long handles extending out at each side, and do it easier than a man could carry a single eight-frame hive.

If a double-story eight-frame hive is used, and the bees are crowded down into a single story when supers are put on, then is when the trouble starts, as this procedure is so likely to cause swarming. By the plan I

have described, this danger does not exist; but I know one can secure more sections from such a hive than from a two-story

eight-frame hive. I find it necessary to requen these large colonies every year. Moorland, Iowa.

## COUNTING BEES AUTOMATICALLY

BY DOUGLAS D. BREARLEY

The engraving shows my "bee-meter" which I made out of an old watch. Before describing it I might as well say that it is not a complete success. As you will see, it works on the principle of a bee-escape; but instead of the bees passing between two side springs they pass under one spring which is suspended, near the inlet hole, and which terminates at the center of the neck in a narrow passage. Attached to the end of the spring is a rod which works the small lever of the watch, the wheel with the hairspring being, of course, removed. The bee, in passing under the spring, lifts the rod, which springs back into place immediately after the bee has passed. The lever has to be lifted 150 times to register one minute on the dial, and to arrive at the number of bees which have passed thru, it is only necessary to multiply the number of minutes registered by 150. Of course it is necessary to remember the former position of the hands.

A device for counting bees; 150 bees passing thru the escape cause the hand of the watch to register one minute.

This device works very well when the bees are not in a hurry to get out; but, as is always the case when the bees have been separated from their queen and brood, they are in a great hurry to get out, with the result that they are so close together the spring does not get a chance to come back into place every time. By

altering the shape of the spring that fault was done away with, but another equally bad was encountered. One bee would sometimes register twice, once for the thorax and once for the abdomen; and so it stands, a novelty, but of no practical use until, perhaps, some beekeeper with the skill of a watch-maker completes the job.

### A NEW MULTIPLE-EXIT BEE-ESCAPE.

My efforts have not been quite in vain, however, for my meter gave me an idea for a bee-escape which is a great success. The

details are plainly shown in the drawing. With this escape I have cleared a crowded super in two hours. There is not much chance that it can be blocked by dead bees.

Subiaco, W. Aust., Dec. 8.

[An escape having two exits is certainly very much safer than one having only one. It is a question, however, whether more than two exits are any material advantage. The Porters some years ago demonstrated that a multiple-exit escape is no faster than a single-exit escape. The danger of clogging by dead bees or because of propolis would certainly be reduced; but is there any appreciable danger of this in case of one having a double exit?

The device for counting bees would be interesting if it could be applied to the entrance of a hive in order to record the flight of the bees in and out. If it would work both ways the total result would have to be divided by two, assuming that each bee came back. The number of bees in the hive could not be ascertained in this way, of course, for the young bees would not be coming out; and, furthermore, the field bees would make several trips. But such a device would be valuable if it could be perfected, in order to record the frequency of the bees' flight.—ED.]

## THE DISTANCE BEES FLY

BY LOUIS MACEY

"The distance bees will fly for nectar" has been thrashed over a lot, but just lately I have been wondering if it may not be one of the most promising fields for investigation that we have. For years I have read in the books and journals such a jumble of views, assertions, proof, and "positive proof" that they would easily go 5, 6, and even more miles, do good work at 4 miles, also that they would starve with plenty of nectar-yielding bloom only 1½ miles away, do no good at over a mile, I have been interested and often amused.

But among those who differ so widely are quite a number whose names loom big in beedom, and not at all the kind with whom one might get fummy, so I just sighed and laid it up to that inscrutable enigma of "locality" and let it go at that. I also refrained from saying anything about my own experiences, for what's the use?

But now comes Mr. Chadwick, page 149, Feb. 15, 1916, with the firmly fixed idea that any perfectly healthy bee ought to go five miles and even ten; also "proof" that California bees at least will do splendid work at three, four, and five miles, with a strong presumption that the bulk of 60 lbs. per colony came from seven miles away.

Mr. Chadwick says, "If Mr. Baldwin's bees will not go one mile for nectar I am convinced there must be *something wrong with his strain of bees*" (italics mine).

Now that disturbs me; and if, perchance, we have been making a scapegoat of locality and saying "no use" when really the strain of bees has something to do with it—then we ought to know it; for California is not the only place where wide-ranging qualities are desirable. Indeed, I question if there is a single trait for which we have been aiming to breed that is more desirable than the ability or desire or will, or whatever it is, that will lead our bees to extend their flight even half a mile if necessary.

For some one to tell how long or how short a distance his bees will work under his conditions may be interesting to the rest of us, but not very profitable. If, however, some one has observed his bees working further afield than they used to, and if there is reason to believe that this has come about from a change of stock—different bees—rather than a change of pasture conditions, then we find something definite.

We have all noticed that some colonies work better when nectar is scarce than others. Is there a chance that this is be-

cause they range wider and have a monopoly of the bloom the other bees don't get to? My own experience has led me to believe that it is a matter of habit superinduced by locality. Ordinarily my bees do not need to range over a mile; but once or twice the grape bloomed on the Towhead Islands in the river when there was not much else doing. I myself from the river-bank could smell the delicious perfume of it, and I knew it was abundant. The low brushy islands were in plain view of my apiary with no "intervening timber, brush, or hills." but my bees never went after it, tho there was only a mile of land and less than half a mile of water between.

But the most striking instance occurred in 1914 when sweet clover was just at its best and the nectar just rolling in. A terrific hailstorm came down on us from the northwest, and in two hours' time or less there wasn't a blossom nor even a leaf left. Wooden hive-covers were split, and metal ones were all dented. Even the twigs of the trees were beaten off, and all that was left of the sweet clover was a pulp of stems and leaves among the hail, which was some four inches deep over the ground. The paths of such storms are generally comparatively narrow, and at a mile to the south and west there were a few straggling blooms; a mile and a quarter there were plenty, at a mile and a half the sweet clover was practically untouched, and white with bloom. But, tho it is a perfectly level bottom with not a stick or stone intervening, my bees never went to that bloom, and it just made me cross to see them loaf and fight and try to rob, with all that bloom so near.

It certainly seemed as if they lacked ginger; for with the compound eyes and all kinds of olfactories the books tell about they certainly ought to have seen or smelled those blooms; and even if they had gotten their daily grub out there and carried home only one little load a day, it would not have looked so shiftless.

What is the answer? If I could have gotten just then a colony of Mr. Chadwick's bees—used to ranging wide across canyons and barren land—they no doubt would have gone right after that nectar and made my bees ashamed of themselves. Had I gotten one of Mr. Chadwick's queens six months prior, would her bees have "got the habit" of short-range working the same as mine? or would the long-range

instinct have been inherited and persisted? and, if so, how long would it persist under my normal conditions?

If wide ranging is a trait of certain stock, and can be inherited, then I have

never yet gotten any of that kind of stock, tho I have bought queens from many different breeders. Some one else, however, may have had different experience.

North Platte, Neb.

## MY SUPERSTITIOUS NEIGHBOR

BY A. B. M'GUIRE

One swarming season my neighbor (whom I will call George) successfully hived a stray swarm of leather-colored Italian bees. I can still see him standing by the old box hive, with a cotton sheet over his head and body, pounding upon the hive and whistling like fury—just a continual whistle, when he would stop to get his breath. After the majority of the bees were inside the hive he got three small stones and placed them on top of the hive, and then went away and left them.

When George proceeded to take the bees home he asked me to help him. We cautiously approached the hive and plugged the entrance; then we gently lifted it and carried it across the fields to George's home.

"George, what did you put those three stones on top of that hive for?" I said.

"For good luck."

"But how can those three stones bring you good luck?"

"It is a great secret which you probably don't know; and if I tell you, no luck will follow, because a woman has to tell a man the secret if good luck is to follow."

"Well, George, I don't believe in anything like that."

"Well, I do, and my grandfather did, and he always had good luck with bees."

"If you have good luck with this colony of bees will you give me a swarm next year?"

"No, I won't give it to you; but I'll sell it to you for five cents. If I give it to you I shall give away my luck, and I won't do that."

I agreed to this and departed.

As the cold days of winter came, and brought with them great blizzards and zero weather, a death-like appearance seemed to settle over the old hive in George's back yard. There was no sign of life there; but as the dawn of another spring came and brought with it new life for every living thing, the bees awoke from their death-like slumber to take advantage of it.

Swarming season came again, and the bees swarmed. They were successfully hived, and I purchased my first colony of bees for five cents.

George had his lucky stones placed upon

the hive; but before he would let me take the bees he took the stones off and put them in his pocket, saying as he did so that he must not let them go with the bees or he would lose his good luck. Well, I got the bees home at last, and put them in the yard. They did well during the summer, making about fifty pounds of surplus honey; but during the next winter they died. George said something like this: "I thought you would have no luck with them. Now I tell you what I'll do. I will sell you another swarm for ten cents, and also make you lucky with bees."

I agreed to this; and when swarming season came, one forenoon about ten o'clock I happened over at George's place just in time to hear a wonderful racket, and a noise which seemed to come from the further side of the orchard. I hastened around the house and climbed over the fence; and as I looked down thru the orchard a great sight met my eyes, for there at the further side was George and his family pounding old tin pans and whistling as tho they were serenading some newly married couple. "Hello, George, for goodness' sake what is all this noise about?" I asked. "Are you having a serenade all by yourselves?"

"No, I am just trying to hold back these contrary bees. They took it into their heads to leave me this morning; but I guess I showed them a different stunt. This is the best thing that you can do to settle a swarm of bees. You just try it some time and see if it isn't." This was another new one for me; but I said nothing more, and George proceeded to hive the bees. I got them for ten cents—my second colony.

"Now," said George, "I am going to make you lucky with this colony of bees. Here are three stones which you place on top of the hive from west to east and you will have good luck."

The secret was then told to me, which is as follows:

Walk to the east three steps; turn to the south and walk three steps, and with each step to the south pick up a stone. Take the three stones and place them upon the hive from west to east, and good luck will follow.

## ECHOES OF THE ILLINOIS BEEKEEPERS' CONVENTION, NOV. 15, 16

BY E. R. ROOT

The Illinois State Beekeepers' Association is the only one in the United States, except one, that enjoys the distinction and the favor of having state aid. The only exception, so far as we know, is the New York State Beekeepers' Association. The Illinois organization first started out with a state appropriation of only \$500, but is now receiving \$1000. A part of the fund is used for state bee-inspection work under the direction of the inspector, Mr. A. L. Kildow, and the rest is used in getting out a stenographic report of the "Annual Proceedings" of the convention, bound in cloth. The organization is making plans to enlarge its scope of usefulness. It is stronger than the National Beekeepers' Association; but numerically it is not so strong, probably, as the Ontario Beekeepers' Association of Canada and the state organization of New York.

The president, Emil J. Baxter, of Nauvoo, Ill., and the secretary, J. A. Stone, of Springfield, were re-elected. The morning session of the first day was occupied by the usual routine, while the afternoon session consisted of reports of A. L. Kildow, state inspector, Putnam, Ill., and a talk by E. R. Root, on establishing a trade-name on honey.

Mr. Kildow, with his score of inspectors, is doing some excellent work, not only in the line of elimination of disease but in educating beekeepers on how to keep bees.

The question-box was a strong feature of the convention. Mr. J. E. Pyles, assistant state inspector, received all the questions, which were then answered by various ones of the convention.

## DADANT'S REMARKABLE SUCCESS IN SWARM CONTROL.

On the afternoon of the second day the editor of the *American Bee Journal*, Mr. C. P. Dadant, delivered an address on the subject of swarm control which attracted more than usual attention. The Dadants have for years operated their ten-frame Quinby hives; and while they produce large crops of honey, the amount of swarming they have is phenomenally low. See "Hives" in any edition of A B C and X Y Z of Bee Culture. During the past year, with 525 colonies in such hives, they produced 125,000 lbs. of extracted honey with only 25 natural swarms. The surprising thing is that this low percentage was due not to cutting out cells, but rather to the large hives, plenty of super room,

plenty of ventilation, shade, young queens, exclusion of drones, and spacing the combs  $1\frac{1}{2}$  inches from center to center. While Mr. Dadant admits that in the production of extracted honey the swarming problem is less complicated than with comb honey, yet when we consider their crop of honey, and the fact that they waste no time in cutting out cells, we must admit that they have gone away beyond the average beekeeper in swarm control.

A neighbor of his about two miles away operated the regular ten-frame Langstroth hives, and had thirteen swarms from eighteen colonies. While the difference in hives of course does not account for this difference, Mr. Dadant makes the point that a twenty-frame two-story Langstroth hive usually requires a queen-excluder to keep the queen out of the upper story. When the egg-laying powers of a queen are hampered, the colony is more inclined to swarm, he says. With their ten-frame Quinby hive they have little or no trouble from the queen going up into the extracting-supers, for the simple reason that the large capacity of the brood-nest with its large combs is able to take care of a good prolific queen. Such a queen will usually require more than a ten-frame Langstroth brood-nest, and, unless held down by the perforated zinc, she will go above. Mr. Dadant sets forth seven reasons for swarm control.

1. An ample brood-nest and super room.
2. Ventilation, by raising the hive up on four blocks.
3. Providing ample shade by means of shade-boards or roofs.
4. Plenty of empty combs.
5. Young queens.
6. Elimination of drones by cutting out all drone comb and by using only worker foundation.
7. Spacing the combs  $1\frac{1}{2}$  inches from center to center in the brood-nest rather than  $1\frac{3}{8}$ .

On this last point Mr. Dadant said they had been for years using  $1\frac{1}{2}$ -inch spacing, not supposing that it had any particular influence on swarm control; but when Mr. Allen Latham called his attention to that one point he began to think there might be something in it, because others using large hives with narrower spacing had a larger percentage of swarming.

President Baxter, who had been for years using the Dadant system, stated that he

secured last season 27 barrels of honey from 72 Quinby-Dadant hives, using the same principles. The number of swarms he had was no larger proportionately in spite of the fact that he did not cut out any cells. His main business is the production of fruit. This was an unusual season for both fruit and honey. Help was scarce, and it was impossible for him to give the bees much attention. All he did was to give more room and shade, and the bees did the rest. If he had been using small hives he could not have done this he argued.

We have always felt that the large hives used by the Dadants were ideal for the production of extracted honey; and we found years ago that by using two eight-frame hive-bodies, letting the *queens have access to both stories*, we practically eliminated all swarming in the production of extracted, and reduced swarming in the production of comb honey, by crowding the bees into one story just at the time of putting on sections. Dr. C. C. Miller follows the same plan.

#### CARBOLIC ACID FOR RIDDING SUPERS OF BEES.

The question-box called forth a lot of lively discussion, as it always does. Among other questions was the use of carbolic acid as suggested by J. A. Green in GLEANINGS on page 351 for May 1, this year. Some

had not succeeded in driving the bees out of the supers by the use of carbolic acid. Others had found it to be a great success. The fact that some good beekeepers had succeeded rather leads one to believe that there must be something in the method. Doubtless our readers can do well by following out exactly the plan outlined by Mr. Green.

#### BEES AND FRUIT.

President Baxter, in the course of the discussion, gave some invaluable testimony showing how indispensable bees are as pollinating agents. When the weather is bad, so the bees cannot get to the trees at the proper time, the quality and quantity of the fruit are considerably cut down and Mr. Baxter is mainly a fruit-grower.

One of the active men in the association is Dr. A. C. Baxter, a physician and surgeon, but in no way related to President E. J. Baxter. He is an enthusiastic backlot beekeeper. He gave us some valuable facts on the subject of honey as a food. Later on we hope to present what he had to say on the subject at the convention. Dr. Baxter is a man who knows how to go after legislatures and to get what he is after. The National could well afford to send him down to Washington to get an increased appropriation on the one now granted to the Bureau of Entomology for extension work.

---

## NO MORE SECTIONAL HIVES FOR HIM

BY ALFRED L. HARTL

Five years ago I was persuaded by different articles written on the subject of divisible brood-chamber hives that the hive had merits, so started to test them with a few new swarms hived in them. The results were very satisfactory, for that year was a year of plenty.

The next season, as I desired to increase my apiaries considerably, I formed 250 new colonies in the divisible hives. This has proven to be the greatest mistake I ever made. In a year when bees continue to work thru the summer the divisible or sectional hive does fairly well; but when a year comes with a long dry summer they are down and out. In such years the queens decline in egg-laying, and sometimes discontinue altogether during the dry summer, which consequently weakens the colonies; and when the fall honey-flow comes, which is usually fairly heavy in my locality, the bees will start to deposit the honey in the upper section and in a short time the queen is crowded out of this upper section altogether. As a result these colonies will only hold their own, and the following spring they are considerably weaker than those in the larger hives.

Some advocates of the sectional hives will advise inserting another section with empty combs. This I tried but without good results. Apparently the bees do not hesitate to store their honey above, but it is hard to force the queen to cross the top and bottom bars to deposit her eggs in the second story in the fall when the nights begin to get cool.

There are many other objections to the sectional hives, such as the greater difficulty of finding the queens and the nuisance of burr-combs. Normal colonies will not, as a rule, leave an empty space in the brood-nest; but with the sectional hive in the spring there is a bee-space in the middle of the brood-nest where I usually find a row of drone-cells with brood, which makes the handling of sections or frames anything but desirable. Especially do I find this trouble with the narrow top-bars.

I have tried the sectional hives alongside the regular dovetail hives in my different apiaries for a term of four years, and I have come to the conclusion that in my locality the sectional hive is anything but satisfactory.

Elmendorf, Tex., Oct. 2.

# Heads of Grain From Different Fields

THE BACKLOT BUZZER.

*Little Rosie, who lives next door, said her teacher promised to bring a tiny dead bee to school tomorrow and by the warmth of her hand bring it back to life again. Rosie says she can do it all right if she uses the same hand she warmed Tommy Smith with yesterday.*

## AMONG DECEMBER BEES.

BY GRACE ALLEN

These days of war and throneless kings,  
And carelessly dishonored things;  
These days of tragic lands and seas,  
There's comfort in the quiet bees.  
There's comfort just to lay aside  
This harrowing distress,  
And all the things the world has cried  
So long in anger or in pride,  
Or from its bitterness,  
And walk untroubled and at ease,  
Alone, among December bees.

The winter, like a frosty night,  
Creeps cold across their fields of light,  
And all the singing summer hours  
Are gone, and gone are all the flowers.  
Yet something, dauntless faith or will,  
Or hope's far-seeing eyes,  
Or instinct (scientific still!)  
Yet something, call it what you will,  
Has made them very wise.  
And I, a self-invited guest,  
Find peace and rest—find peace and rest.

And yet these winter ways they keep  
Are not indifference, nor sleep;  
Within each dusky-hearted hive  
Unconquered moods are still alive.  
Unceasingly the loyal wings,  
Aquiver to and fro,  
Keep warmth and life triumphant things,  
No matter what the winter brings  
Of weariness and woe.  
And so beneath the barren trees  
I find great comfort in the bees.

## The Leather-Colored Were More Resistant than the Golden.

As there is so much written about foul brood and Golden queens I will give my experience. Several years ago I went over into York state and bought 39 colonies of black bees in old box hives. I was told the bees had been examined by the inspector, and pronounced all right. I think they were as they were heavy with honey. I drove most of them into my hives in the cellar. When I set my bees out I put out several hundred pounds of that honey and let all my bees take it in.

About the middle of June I found my bees were not doing well, and there was a terrible stench in the yard. I never had seen any foul brood; but by looking at a little book that Inspector Wright from New York had given me, I saw very soon what the trouble was.

I had about 20 colonies of golden Italians, and about the same number of the leather-colored. The rest were black and mixed. I found almost every colony but the leather-colored had foul brood. I therefore ordered 100 leather-colored queens. Of these I lost but two and they were just what I ordered.

I did not get any honey from the bees, and had to feed a good many; but I have never seen any trace of foul brood since.

C. M. Lincoln.

West Rupert, Vt., May 15.

[Our correspondent does not say which type of foul brood he had; but we assume that it must have been the European variety, as the American would hardly have disappeared in this way.

Is it not probable that the Golden in question were not up to par?—Ed.]

## Starch Paste that is Paste.

Take a little lump starch (about a dessert-spoonful) and mix with as little cold water as is necessary to dissolve it. Now pour on boiling water, stirring briskly all the time until the mixture turns to a bluish color and has the consistency of a moderately dense honey. Now set aside; and when cool remove, skim off top, and if it has set like jelly (which it is sure to do if properly made) you will have the best label or photograph paste

it is possible to get. A little practice will show you when you have used too little or too much boiling water. Of course this paste will not keep more than a day or so in hot weather—a little longer in cold weather—so we find it best to make it only in small quantities and just as required. This paste will adhere to anything and is immune to insect attack. Phil Sommerlad.

Tenterfield, Spring Valley, N. S. W.

#### Forty Years of Beekeeping.

I commenced beekeeping in the spring of 1876. At that time I was using the American hive, made by King & Co., of New York city. I now have 120 colonies.

Apiary of J. T. Smith, Bellevue, Mich. Mr. Smith has been a beekeeper 40 years.

Log house erected in 1858, still standing and still serviceable.

The illustration shows the log house erected by my father, who moved his family into it in the fall of 1858. This house is still standing. J. T. Smith.

Bellevue, Mich., Sept. 24.

#### An Experience in Wintering United Colonies.

I have always wintered in the cellar; but last winter, having read so much about outside wintering I made two boxes of shiplap lumber, each to hold ten colonies, with an eight-inch entrance for each colony. I wanted to make sure that the bees would winter, so I did a good deal of uniting as follows:

I made one colony from two in October by putting one on top of the other; then packed them in leaves ten inches on the sides and top, and three inches in front.

I had eight nuclei that were strong in September, having 33 combs of brood. These I put into four thirteen-frame hives and wrapped them with fifteen layers of newspapers, finally covering with tar paper, and wintering with a full entrance.

I next took five full-sized colonies, wrapped them in double carpeting covered with tar paper, and gave a full entrance.

I put two swarms in thirteen-frame hives, placed one on top of the other, wrapped them in fifteen thicknesses of newspaper covered with tar paper, and gave a full entrance.

Two other swarms were in eight-frame hives. I placed one of these on top of the other, also wrapped them in fifteen layers of newspaper, covered with tar paper, and gave a full entrance.

My idea was that the colonies would be so strong in the spring that they would be in fine condition for clover. In May I reduced the colonies in thirteen-frame hives to one story, to divide them a little later. The other colonies were left in the two stories until May 23, then were divided, and were in good condition for clover.

Carl H. J. Baumbaeh.

Fall Creek, Wis.

#### Dead Air vs. Packing Material.

I should like to know the opinion of those who have used both the chaff-packed double-walled hives and the double-walled air-spaced hives as to their results in outdoor wintering and their qualities as a summer hive. Will the moisture gather any worse in the air-spaced than in the chaff-packed hive in winter with a packed super on each?

Freeport, Me.

Harold C. Dennison.

[The Bureau of Entomology, Washington, D. C., conducted some experiments to determine the relative insulating value of dead-air space and packing material. The proof was conclusive, showing that double-walled hives using packing were much warmer, much less subject to internal changes of temperature, than the same hives with no packing between the walls. The ordinary beekeeper, unless he has careful measuring apparatus, may not be able to determine the difference; but difference there is, there can be no question. The dead-air spaces are not dead air. When the temperature on the outside drops down the air between the walls begins to circulate. The air next to the outer wall will crowd against the inner wall. This will make the temperature of the wall next to the bees cooler. If, however, the space is packed with chaff, leaves, or planer material, there can be no circulation of air in large volumes, because the air is held in little pockets.

Packing material is so cheap that any beekeeper who would leave it out between the walls would be making a serious mistake.—Ed.]

**Stencil Dial for Nucleus Record.**

The illustration shows the system that I use for keeping track of twin mating nuclei. I use two on each twin hive—one for each nucleus. These give me the condition

Q, queenless; C, cell; C-V, caged virgin; V, virgin at liberty; S, saw; L, laying; T, tested; M, mismatch.

of the inside in case I place a cell or a caged virgin in before removing the laying queen. I have been trying several plans and I like this the best of any that I have tried. I place two metal hands upon each dial. They are bent so that one passes over the other without interfering. I have a metal stencil for painting the letters and figures on the lids of the hives.

Baldwin Park, Cal. H. M. Hess.

**The Honey Method of Introducing.**

Last summer I had several swarms cluster together, and so I had to find the different queens, as the amount of bees—four or five swarms—was too great for any common-sized hives. One queen that I found positively refused to stay in a hive. I then clipped her wings, put a little honey on her—enough to cover her about half—and put her on the alighting-board of a hive from which a swarm had absconded but still contained a few bees. I thought that, if she were accepted, I could then give more bees. On being placed in front of the hive, as she started for the entrance a bee attacked her from the side not daubed with honey. It was getting its abdomen in shape for a sting when about that time its “nose” came in contact with the honey. Of course it immediately forgot all about the queen and went after the honey (then I saw the point). When the queen disappeared in the entrance several bees were hanging on to her; but they were only after the honey. After a while, on going to the hive to see how things were going I found her sitting on the edge of the

alighting-board with several bees licking her off, after all efforts to induce her to remain inside failed.

Having a queenless nucleus I followed the method Mr. Clute gave F. M. Baldwin (Jan. 15, 1915, p. 66), immersing her completely in half a cup of honey and pouring her, honey and all, on top of frames of the nucleus. I watched her disappear between the combs, replaced the cover, and awaited results. The only strange thing about her was that it was at least a week or ten days before she began laying. Of course I do not think that the method of introduction had anything to do with this. I began to think that I had probably clipped an unmated virgin. However, there was soon enough proof that my fears in that respect were groundless. The short time it took for her to build up that small nucleus into a strong colony would seem to show that she was not hampered by the effect of any of her past experiences.

Berne, Ind. Moody Brenneman.

**Moving Bees on a Truck Without Screening.**

I have sold my home and bought another, and shall have to move my bees a distance of 21 miles by auto truck. I can make the trip in 2½ hours, barring accidents and bad luck. Will it be necessary to screen the bees at all, or can I fasten them up tight for that distance? I will move them about the middle of next month, and the weather more than likely will be cold.

M. A. Auliek. Bradford, Ky., Oct. 26.

[You can move your bees on the truck with or without entrance-screens. If the weather is a little cool, all that will be necessary will be to smoke the bees at the entrance to each hive, put them on the truck, and start on the journey. But before the load is started each entrance should be smoked a little, after which the trip can be made. You probably could nail wire screen over the entrances to prevent any bees from coming out, but if the weather should be a little warm and the colonies strong there would be danger that some of them would be smothered.—Ed.]

**Some Record.**

I had 10 colonies, spring count, increased to 12, which I have at present. I extracted and filled 50 dozen pints (Mason jars); sold 242 sections, also 80 lbs. chunk honey, and have all the honey we shall need until next season. The hives are very heavy. I should think there is not less than 30 lbs. in each hive for the bees to winter on.

I haven't lost a colony of bees for ten years—that is, in wintering, and I lay it to heavy stores. I give them from 30 to 40 lbs. I put a super cover over the brood-nest, then an empty section super, and fill an empty super with ground cork which I get from the stores when they sell grapes, paying 5 cts. for barrel and cork, and I have success.

Dover, Del., Oct. 26. Wm. Maag.

# GLEANINGS FROM QUESTIONINGS

T. C. J., Lake Cicott, Ind. I have some honey that has a queer smell, and it does not taste very good. Do you think it could be honey-dew?

A. Honey-dew honey is usually dark and cloudy—muddy-looking, in fact—and it has a mealy, bitter taste. There are certain kinds of fall honey that are very strong in flavor, but they are usually clear, even tho dark. Honey-dew nearly always looks dirty.

P. S., Epworth, Iowa. I am building a new honey-house with a bee-cellar under it. Will the odor of fresh cement injure the bees?

A. We do not believe the odor of the new cement would injure the bees in any way. The dampness would, provided the temperature remained very long around the freezing-point after the bees were in the cellar. Dampness combined with a low temperature always makes trouble. Probably it would be well to put a little lime about the cellar after you have it finished, to absorb the moisture.

A. G., Ben Avon, Pa. What is the proper weight of a hive—combs, bees, and all—at this time of the year?

A. It is difficult to give even an approximate answer to this question. Notice the different weights that Mr. Doolittle gives in his department in the last issue. You had better not rely upon weighing the hive, for this is too risky on account of the variations in the weight of the hive-body itself—bottom-board, cover, frames, etc. The only sure way is to wait until it is warm enough for the bees to fly, and then look over the combs rapidly. It would have been a good deal better, of course, to make sure about this before the middle of October.

T. C. J., Lake Cicott, Ind. When the white clover first started to bloom my bees went right to work in supers; but we had a spell of cold rainy weather, and they were not able to get out for four days, then as soon as nice weather came they started to swarm. All my queens are clipped, so I cut out all the queen-cells. The bees came out the next day again, so I took away all sealed brood—in fact, I took all combs except one and put in full sheets of foundation instead. That did not stop them from coming out. They came out and went back two or three times a day, and kept it up for four days. I left the supers on; but about all the bees do is to loaf and swarm.

A. (By Dr. C. C. Miller.) The fever for swarming seems to be a sort of cumulative affair. If you do something to thwart them, and it isn't quite enough to stop them, it seems to make bees all the more fierce for swarming afterward, and each move on your part seems only to make them more

determined. Some years ago one of my colonies swarmed, and I took away one or more of its frames of brood. It swarmed again, and again I took away brood; and as it continued swarming I left it each time with less brood, until I had taken away all its brood. Then it swarmed with nothing but foundation in the hive, and the only thing done with the foundation was the building of one queen-cell in which there was an egg! If, after it had swarmed the first time, I had left only one brood, I've no idea it would have had any further thought of swarming. If half its brood had been taken away two or three days before the actual swarming, it might have been sufficient; and if only one or two brood-had been taken away when queen-cells were first started, it might have prevented swarming, or at least postponed it.

Years ago it was the rule that a colony never swarmed until the first queen-cell was sealed. Nowadays it is nothing uncommon for a colony to swarm with not a queen-cell sealed, or even with only an egg in a queen-cell. I suspect that the bees follow the same rule as of old, except when the bee-keeper does something in the way of prevention—not enough to stop swarming entirely, but enough to make the bees more and more stubborn.

There seems, too, to be a difference in years. Some years a very little will prevent swarming, while in another year the bees seem to be swarm-crazy. You seem to have struck one of the worst of years in this respect, and may never see its like again.

Now as to what shall be done. First, a "don't" or two. Don't think of doing any good by cutting out queen-cells and leaving the old queen in the hive, after the bees have actually swarmed. Don't count on cutting out cells as a certain preventive in any case. If done before queen-cells are well advanced, in some cases it will delay and sometimes even prevent swarming. Generally it will fail to have the desired effect. Don't leave supers containing honey on the hive containing the swarm. I'm not sure but that was the mistake I made in the case where the bees swarmed leaving empty foundation.

From all this it may be easily understood that the thing to do is to take vigorous steps at the outset, taking away enough brood either before or after swarming so that the bees will feel too impoverished to think of swarming out. That will mean that not more than one brood will be left if it be just before or just after swarming. If no queen-cells are yet sealed, taking away half the brood may discourage the bees from swarming. If nothing beyond quite small larvae is found in queen-cells, it is possible that taking away two brood may answer.

A. I. Root

## OUR HOMES

Editor

Eye hath not seen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him.—I. COR. 2:9.

Ye shall teach these my words to your children, speaking of them when thou sittest in thine house, and when thou walkest by the way, when thou liest down, and when thou risest up: that your days may be multiplied, and the days of your children.—DEUT. 11:19, 21.

I have before mentioned that, about sixty years ago, when but a boy in my teens, I started out to "educate the people (?)" by going around to schoolhouses and giving entertainments with electricity and chemistry with a home-made apparatus. I have lately been reminded by an old friend of years ago that in one of those lectures I declared that if we had an electric wire clear around the globe electricity would make the circuit in about *eight seconds*. Well, just now our town of Medina is in a sort of jangle in regard to the best method of lighting the village by means of electricity; and there has been so much misunderstanding and unnecessary criticism that my son Huber wrote a lengthy article for the *Medina Gazette* in regard to electricity and the different methods and plans for lighting towns and cities, etc. Well, Huber's talk about "alternating currents," etc., went beyond my depth, and I interviewed him in regard to the matter. A little later a grandson, only sixteen years old, gave his old grandfather some *further* instructions in regard to electricity, especially alternating currents. When I was his age, sixty years ago, I built a little *motor* that would produce an alternating current, but I did not know it. At the time, I thought an alternating current would be no good, and so I spent considerable time and study in converting the alternating current into a direct current.

Well, both son and grandson took considerable pains to instruct me in regard to the advantages of the alternating current. For instance, with this sort of current the electric impulse goes to the end of the circuit and back ever so many times in a second. Wynne says, in fact, that an alternating current ("60 cycle") will go from New York to San Francisco and back again sixty times a second.

Now, that is about all I have to say in regard to electricity just now. I have mentioned it because it emphasizes the fact that particular traits are inherited. Both of my sons and all of my grandsons have inherited more or less my early craze for electricity, chemistry, etc. Last eve-

ning Wynne came over to borrow my little specimen of radium. By the way, I have forgotten to tell the readers of *GLEANINGS*, as I did about once a year for several years, that "radium *still radiates*." Well, Wynne tells me it has been lately discovered that radium does *not* keep on radiating for ever and ever. He says it has been demonstrated that radium will play out or burn out in about 2500 *years!* So radium is not perpetual motion, after all. Well, now for the moral to the above.

The good traits in the father, as well as the evil ones, go along down thru the generations. Lady Eglantine's disposition to lay eggs, as we might say, everlastingly, bids fair to be inherited not only by her progeny but by her sister's progeny. By the way, I am going to have a big story soon about the way those Eglantine pullets lay eggs. In view of what I have been saying, shall we not still more earnestly *consider* that the things we do while here on earth follow after us away down thru untold generations.

Well, friends, the above is only a preface to what I wish to say in this Home paper. In our issue of Nov. 1 I mentioned three remarkable answers to prayer, and what came of it as the years went by. I am going to tell you still another, which I think I have mentioned already in years past.

About forty years ago, after quite a trade had been built up in queens, tested and untested, and also in queens imported directly from Italy, we had continual trouble about finding somebody fully competent to take care of our queen business. It needed a man who would not only be careful about making mistakes, but one on whom we could depend on being *absolutely* truthful. If he killed a particular queen by carelessness it was of the utmost importance that he should report the full facts in regard to the matter, as letting another queen take her place in order to avoid exposure might do somebody a great wrong. I wanted above all a sincere and *earnest Christian* to carry out my ideas and plans for the queen-rearing apiary. After repeated disappointments, caused, perhaps, a good deal because I could not give the apiary the personal attention it needed, I said one night as we were ready to retire, "Sue, we shall have to ask God to send us, or point out the way for us to find, *somebody* who can take charge of this exceedingly important branch of our business." In fact, I do not know

but I said it was almost the cornerstone of the factory and of GLEANINGS itself. Then we knelt down and I prayed about it; and, if I remember, I prayed with so much faith that I was almost on the lookout the next day for some glimpse of an answer to that prayer. I cannot now remember whether it was the next day or a day or two later, that a letter came reading something like this:

"Mr. Root, I have a very good place to work. I like my work, and my pay is good—better, I often think, than I deserve. But my employers are both profane and ungodly men, and I feel as if I could not stay with them any longer. I am interested in the bee business, and have been reading your journal. If you have a place for me in the apiary I will go and work for you if you give me enough to pay for my board until you think I am worth more."

The letter came from away off in Canada. I showed it to Mrs. Root, and told her it was the answer to our prayer.

Right here I wish to give you something I found in the *Sunday School Times* in our morning lesson. It so completely takes in the idea of prayer that I give it here:

Learn to habituate yourself to taking the least detail of your life's work to the Lord. He loves to be trusted, and nothing is beneath his notice. Take your plans and program for to-day, and lay them in his presence, seeking guidance, wisdom, and grace to carry all out for his glory. This adds a wonderful luster to life.

Of course I told the young man to come on. When he arrived I told him that, instead of discussing the matter of board, we would start him at a dollar a day. But when Saturday night came I said I should be ashamed to make it less than \$1.25. That was a fair man's wages at that time. The next week I said the same thing and gave him \$1.50; and as he made himself increasingly efficient and useful, he kept being promoted, with better pay, right along. Right here I wish to digress a little:

I have not only thanked the Lord for our two sons, but I have thanked him also for our three sons-in-law, who are all good clean men, right up to date, and professing Christians. I could honestly say a good word or many good words for each and all of them; but for obvious reasons I am just now going to confine my remarks mostly to one of them. Before I go further let me mention just one incident in the boyhood of this young Canadian, or this young man of whom I have been talking.

It is not at all strange that, after a time, our oldest daughter, then about seventeen, became interested also in the young Canadian with whom I was so much pleased.

Well, John (for that was his name) used to come up to the house almost every morning before the whistle blew, to get instructions about the duties of the day. One particular morning he stood on the doorstep, and hesitated until I said:

"Well, John, what is it?"

"I think Mrs. Root came to the door just then, and then John commenced:

"Mr. and Mrs. Root, you have been very kind to me."

Then he hesitated until I said, "Well, John, we are very glad to hear it. But what brings the matter up just now?"

His bright ruddy face colored up for a little as he went on.

"Why, what I want to say is this: After all the kindness you and Mrs. Root have shown me since I have been with you, it would ill become me to go on with anything that might not meet your approval. Your daughter and I have of late been getting pretty well acquainted."

Then he stopped.

"Well, John, is not that all right?"

"Why, Mr. Root, it is all right if *you* say so. If not, do not hesitate about speaking right out."

I replied, "Well, John, if you and the young lady agree, that is all right; and I want to say furthermore that if I have ever in the past doubted your honesty and sincerity in whatever you do, this one incident dispels all such doubt."

As the years passed by, John, with Ernest, lifted the load from my shoulders, and permitted me to go to California, the Bermudas, Florida, and finally up into northern Michigan to raise potatoes. The business ever since John has been general manager has grown and paid a profit more or less. I have recently made notice of the marriage of Howard R. Calvert, their oldest child, and gave a picture of the baby, the first great-grandchild.

Just recently, on the 55th anniversary of our wedding, Miss Mildred Calvert was also married. Below is a sketch in regard to the wedding, written by our youngest daughter.

The wedding of Miss Mildred Calvert and Mr. Marshall Frye Bryant took place on Friday, September 29, at four o'clock, at the old Root home, now occupied by E. R. Root and family. Miss Eva McNaughton, of Oberlin, sang a selection from the Bridal Chorus from "Lohengrin," accompanied by Mr. Harold Smith, of the Oberlin Conservatory. Jean Boyden, Hall Kellogg, Helen Boyden, Alan Root, Marjorie Ainsworth, and Ralph Boyden held the white ribbons which formed the aisle thru which the bridal procession came. Little Elizabeth Boyden, as flower girl, led the way to the bank of green and white clematis at the east end of the living-room, followed by Katherine Root as ring-bearer. Mrs. Howard Calvert, in white net over pale-green taffeta, was

matron of honor, while Mr. James Hall, of Wooster University, was best man. The bride was beautiful in a white Georgette cr pe gown and a tulle veil fastened with lilies-of-the-valley, and carried a shower bouquet of white rosebuds. She was accompanied by her father, and was met by the groom at the bridal arch where Dr. Fritsch performed the ceremony, using the ring service. After congratulations, a quartette sang a song written by a friend of the family in honor of the wedding and of the fifty-fifth wedding anniversary of Mr. and Mrs. A. I. Root, grandparents of the bride. Then the guests adjourned to the Calvert home, where the wedding supper was served. Later the bride appeared in a going-away suit of navy-blue broadcloth, and the bride and groom said goodby to relatives and friends. Before leaving, Mr. Bryant, who is a musician of unusual ability, sang "The Serenade," by LaForge. The couple left quietly by auto for the Root cottage on Lake Erie; thence they motored to Toledo and other points in Ohio. Mrs. Bryant is a graduate of Medina High School and Oberlin College. Mr. Bryant is a graduate of Green Bay, Wis., High School, and was a student for three years at Oberlin College and Conservatory.

MRS. L. W. BOYDEN.

The following is furnished by our eldest, Mrs. J. T. Calvert:

Mr. and Mrs. A. I. Root were married fifty-five years Sept. 29. Mr. Root will be 77 next December, and Mrs. Root 75. They have five children, five children-in-law, ten grandchildren, two grand-children-in-law, and one great-grandchild. All are living, no deaths having occurred in the family in the 55 years of married life, and all are living near them.

The poem mentioned above was composed by Mrs. Borger, the wife of the boy Jacob whom I found almost forty years ago at a mission Sunday-school in Abbeyville, near here. Jacob is now foreman of the shipping department in our factory. Here is the poem.

Once, in the days to which your memories roam,  
When children's voices rang within this home,  
Out from its doors there rushed a happy throng;  
Out from each heart there gushed a joyous song;  
And thus the hours of every livelong day  
Filled were with care for you and us with play.

CHORUS.

Just a song of gratitude for two lives well spent,  
Filled with deeds of kindness, labor, and content.  
May we ever emulate all your virtues praised,  
And maintain the standard your noble lives ever raised.

Even to-day you're young in mind and heart;  
What though the milestones give you much the start?  
Life's heritage of faith and love and hope  
Be ever yours adown the sunset slope;  
And thus may we, when life's long shadows fall,  
This glorious sunset of your lives recall.

CHORUS.

Just a song of gratitude, etc.  
Sept. 20, 1916. NETTA FRASER BORGER.

I have given you the above story to illustrate two important morals. First, the wonderful outcome and far-reaching results as the years go by of one simple little prayer; and that clipping from the *Sunday School Times* hits the case exactly. Second, some trifling incidents in your life may, as the years go by, result in wonderful

transformations years hence. If you resist temptation, and choose the straight and narrow path, and take fast hold on God's precious promises scattered thru his sacred word, no man can imagine or contemplate (see text) what may be the result to *generations yet unborn*.

“WATER-WITCHING” AND THE “DIVINING-ROD.”

For forty years or more I have been protesting and fighting the foolish notion that certain people can find water by means of a peach-tree or witch-hazel cross-sticks; and I expect that just now, when some of our subscribers read the words I am dictating, they will bristle up, and, may be, send me statements of what they have seen “with their own eyes.” For some time back I have urged that our experiment stations, or, better still, the Department of Agriculture at Washington, should put out a bulletin giving statements from the best and wisest scientific men of the present day; and my wish has finally come to pass. In the *Cleveland Plain Dealer* for Oct. 10 I find an article of something like three columns on the subject. I will quote just the opening and closing paragraphs.

Arthur J. Ellis, a geologist of the survey, has now compiled a report giving the history of the divining-rod from the Middle Ages up to the present day, and exposing all the numerous absurdities in its record. This report is now in the pressroom of the government printing-office, and will soon be available for distribution. The divining-rod is likely to die hard; but the publication of the survey's report will undoubtedly mean the end of a good many professional water-witches in this country. According to the government scientists, nothing has ever been invented to detect the presence of water in the earth but common sense, the possession of which does not depend upon the divining-rod.

Let me repeat in closing what I have said before many times. Science is no respecter of persons. When X rays, radium, wireless telegraphy, etc., were discovered, they all worked with everybody, and especially with real scientific educated men and women. Now, please do not feel hurt, any of you, when I say that the peach-tree switch works with only a few individuals; and these individuals are not “college graduates” in *scientific matters*. In fact, an educated man acquainted with electricity, chemistry, geology, etc., would be ashamed to be seen carrying around a peach-tree sprout. One of the experts along this line when asked how he told the exact depth he would have to dig in order to find water said he did it by hanging a finger-ring on a horsehair loop; and by holding this in a tumbler of water the ring would begin to swing, and strike the sides of the tumbler just exactly the

number of feet he would have to dig, and then stop. I leave it to you, my readers, is there either sense or science in the above rigmorale? Well might the *Plain Dealer* say: "Nothing has ever been invented to detect the presence of water in the earth but common sense, the possession of which does not depend on the divining-rod."

---

GOATS AND GOATS' MILK—SEE P. 997, OCT. 15.

The following, from the editor of the *Angora Journal*, 306 Davis St., Portland, Ore., will answer a number of questions from many kind friends:

Replying to the latter portion your article in the October 15th issue on goats and their milk, the alkali in goats' milk does not form curds in the stomach as in the case of the acids in cows' milk, hence its superior digestibility. Prejudice against the odor said to be present in goat milk is imaginary; for if two glasses, one containing goats' milk, the other cows' milk, were tested by drinking from each, it would be impossible to tell the difference unless one could detect the richer, sweeter taste of the goat milk. There is no odor to the does, altho the bucks are objectionable in the breeding season. The Nubian breeders claim immunity from this drawback; but the does of all species are free, likewise their milk. Excellent cheese is made from goat milk, several goat dairymen in the West having marketed the product since the rise in price of European cheese. The familiar brands, such as Neufchatel and Roquefort, are made of goat milk. As to the uncouth appearance of which you speak, the pure-bred animals are deer-like in appearance, with alert intelligent expression, and, being harmless, make excellent pets for children. When thus petted they are improved in quality, and increased

flow of milk has been noted. The goat which you noted in Michigan, hitched to a cart, was probably a Mexican or native milk goat, of the straight-haired variety—a very sturdy and fecund animal, much used in crossing the strains of both milk goats and Angoras.  
A. C. GAGE, Editor.

#### STILL MORE ABOUT GOATS.

Tell A. I. Root that I should like to pat him on the back and whisper in his ear "good doggie" for that milk-goat write up, October 15. I take three goat papers—all that are published, but have no goats as yet. It is well to study the subject and avoid loss when one gets the goats; also to have a book on goats. A. I. Root should secure some Saanen goats and have better and safer, also cheaper milk. Goats' milk, if used by mothers, would blot out 90 per cent of infant mortality, I think. Raise the "kid" on goats' milk and honey, and have the undertaker's bill reduced 90 per cent. This would help some on the "high cost of living." Anything that spreads disease broadcast over the land is dangerous. That's what cows' milk does. I refer to the "great white plague." Goats are almost free from this disease. If I could get A. I. Root to "rise and shine" once he would soon have some milk goats.  
C. A. NEAL.

Jonesboro, Ind.

Many thanks, my good friend, for your kind words; but if you will give us the names and addresses of the three goat-milk publications a lot of our readers will be greatly obliged to you. Ever so many are wanting to know where they can get a periodical on goats and goats' milk.

I should be pleased to have A. I. R. dine with us and be served with a leg of nice fat goat. I think he would view the goat in a different light.

Harrisville, Mo.

D. H. PLANK.

## HIGH-PRESSURE GARDENING

TOMATO SEED FOR FLORIDA BY THE HUNDRED POUNDS.

The letter below properly belongs, perhaps, in the Kind Words department; but as it gives a glimpse of the tomato industry both in Ohio and Florida, I have thought best to put it here. In visiting the Florida tomato-fields and admiring the fruit I usually ask where they get their seed when so much depends on the variety in getting crops that go away into the thousands if not the millions. The reply is, almost every time, that they do not dare take a chance on any seed except that grown by the Livingstons. This illustrates the possibilities in any business that is handed down from father to sons, and possibly to the grandchildren. I might add that I anticipated what would happen with Irish potatoes in Florida when they are \$2.00 a bushel here in Ohio. Two different seedsmen who make a business of furnishing

potatoes to plant in the fall were sold out, but I finally secured a peck, and Wesley tells me that my Florida potatoes are up and growing "just fine." Right here my stenographer suggests that Florida is not the *only* place in the country where potatoes "are up."

Dear Mr. Root:—On opening your letter this morning, right glad was I to see the personal signature of A. I. attached to it. I presumed you were in Florida some time ago, and had your winter garden under way by this time.

In this connection why would it not be a good "stunt" to put in a crop of extra-early Irish potatoes as early Ohio or Irish Cobblers, and push them along as rapidly as possible for the northern market? But may be you cannot grow good potatoes in your section of Florida.

Intensive gardening is being adopted and looked into as never before, and this increases the demand for reading-matter on the subject.

I am sending you a packet of Honor Bright tomato, and want you to note the solidity of this variety in its mid-state. The color is a waxy yellow, and reminds me of honeycomb or beeswax. We had an exceedingly productive crop of it on our

muck farm this fall, and it certainly is an extra-long keeper. I had them two and three weeks after picking in the mid-state, and they would ripen up in fine color and quality; and, being so solid, I think they would easily go to Seattle and back to Columbus again by express. The plant has an unhealthy look; but that is natural to it. The quality is fine when well ripened.

Livingston's Globe is our great leader in Florida. We have been sending hundreds and hundreds of pounds to that state the past three or four months.

Our tomato crop was short again this season; but the past two weeks gave us several thousand bushels from late-set plants that we hardly expected anything from when those first frosts came along. I regret I did not send you word to come and see our muck-grown crops, especially tomatoes when they were at their best. This dry summer was just about right for our muck or peat soil farm. Last year was too wet. I think I told you this land was where the wild pigeons used to roost by the millions before the land was reclaimed. It was swamp, and had timber on it.

Next summer you must surely come down (not State Fair week, tho), as I want more of your undivided time. I often recall the time we were at the fair together, and how easy it was for the few folks who had not met you to scrape up an acquaintance. It reminded me of my own experience in meeting people for the first time. In most cases they say, "Oh, yes! I used to buy my seed of your father."

I am enclosing a packet of "Honeydew" muskmelon seed. Be sure to try it, both in Florida and at Medina. We like it very much, and we believe it will leap into general favor at once, as did Golden Bantam corn.

ROBT. LIVINGSTON.

Columbus, O., Oct. 27.

#### NEW IRISH POTATOES IN FLORIDA.

Just after dictating the above I find the following in the Jacksonville *Times-Union*:

The first new crop of Irish potatoes to be shipped from here this season was sent out last week by Oldham & Roberts, to a commission firm in Tampa. The potatoes were grown by John McCreddie on his farm tract in section 25, just north of town. The Tampa firm gave Oldham & Roberts an order for two hamperers at their own price, and the price named by the local firm was \$2 per hamper, or 5 cents per pound. Other shipments of Mr. McCreddie's potatoes at these fancy prices were made to a Tampa retail grocer, to a Plant City hotel, and to a Dade City firm.

In the Cleveland *Plain Dealer* for Nov. 11 I notice that Irish potatoes have advanced

from \$1.80 to \$1.85 wholesale. Now is the time for Florida to furnish the great hungry North with new potatoes before anybody else gets on to the racket.

#### THE DASHEEN UP TO DATE.

With Irish potatoes up to \$2.00 a bushel here in Ohio, it would not be strange if there should be a big rush to plant potatoes, say during the month of November, over a great part of Florida. And then there is another thing that would not be strange: With potatoes away up, and with the wonderful yield that may be secured from dasheen (a tuber that is preferred by a good many even to Irish potatoes), there is a big opening for the dasheen business. Let me repeat: I have grown a heaping half-bushel of dasheen tubers from one hill down in Florida. I think they were allowed to grow and spread a little more than a year; and I expect to find, when I get down in Florida, dasheens growing spontaneously almost all over my clear-off acre of ground. The matter has just come up by seeing quite a lengthy article in the Jacksonville *Times-Union* on the dasheen. I give you only the closing part of it.

As a vegetable for market and home use the dasheen apparently offers bright possibilities of profit for the Southern farmer; but if Southern enterprise will establish plants for the manufacture of this vegetable into flours and breakfast foods that can be sold all over the country, the value of the dasheen to Florida and the South might become, within a very short time, almost unbelievable.

Perhaps I should explain that I write this Nov. 11, just before starting for Florida.

#### THAT OKLAWAHA CORNFIELD DOWN IN FLORIDA.

We clip the following from the *Florida Grower*:

Eighty-five thousand bushels of corn, valued at \$80,750, were produced on one thousand acres of Oklawaha River muck land near Leesburg.

## POULTRY DEPARTMENT

#### BUTTERCUPS; HOGAN'S DISCOVERY.

Do you still think the Buttercup fowls the best breed? Can you give me any information on Hoganizing hens? I have had your literature more or less since 1877.

B. A. BEMIS.

Dinuba, Calif., Oct. 14.

I decided some time ago that Buttercups were no better layers than the Leghorns; and they certainly have never laid as well as the Lady Eglantine pullets I have been writing about in GLEANINGS of late.

In regard to Hoganizing, I believe our

different experiment stations have decided that, while it tells what hens are laying and what are not at the time the test is made, it does not by any means take the place of a trap-nest. Perhaps it may pay you to invest in their book; but the substance of the whole matter has been given thru our poultry journals again and again. I have had a copy of his discovery, that was sold for five or ten dollars some years ago, but I have never made any particular use

"THE YOUTHFUL MOTHER."

The above Eglantine pullet laid her first egg when she was four months and eight days old; and, surprising to relate, she continued laying an egg every day, or almost every day, until she had laid eighteen or twenty eggs, when she wanted to sit; and just for the novelty of the thing I gave her thirteen eggs and let her go ahead. Only nine eggs proved to be fertile; and from those she hatched seven chicks which you see above. The picture was taken when she was only a little over 5½ months old.

of it. When I wanted to sell off some of my old hens I could tell by the Hogan system which were laying at the time and which were not. It's simply measuring with your fingers the distance between the pelvic bones.

When a hen is laying right along regularly the points will be separated the width of two or three fingers. When she hasn't been laying for some time the points of the pelvic bones come almost up together.

## TEMPERANCE

### SALOONKEEPERS AND THE AUTOMOBILE INDUSTRY.

We clip the following from the *Plain Dealer*. It is dated Toledo, October 23.

Nine saloonkeepers who have enjoyed patronage from Overland Automobile Co. employes are under the ban of Ohio Anti-saloon League agents. A petition to oust the nine saloons from a district embracing the Overland factory was filed in common pleas court today. Overland officials are said to favor the ousting of the saloons.

I suppose every automobile factory, and I might almost say every other factory in the world, feels as the Overland people do about saloons; and yet, as I understand it, our United States of America legalizes or authorizes these fellows to go ahead and

say to the factory owners in substance, if not verbally, "Help yourself if you can."

### GETTING DOWN TO BUSINESS.

From the *Methodist Board of Temperance* we clip the following:

The Virginia prohibition law which goes into effect November 1 forbids liquor advertising in all periodicals published within the state.

### "GOD'S KINGDOM COMING."

*Mr. A. I. Root*:—I am very sure you will rejoice with me and many others because our state voted dry. Just think! a solid body of eight states all dry! Isn't it glorious? How little you and I thought when I began taking *GLEANINGS* many years ago that such a thing could come about in the lifetime of you and me! Our town voted dry two to one; the county gave a dry majority of 1700.

Falls City, Neb., Nov. 10.

# WHY NOT

## Order Your Supplies for Next Season Now?

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 2 per cent discount during December. Send in your order just as soon you find out what you require and we will take care of it promptly.

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

Discussions. Questions and papers not received in time, of which we are looking for several. Five-minute Talks and Discussions.—Conducted by A. C. Allen. Beekeepers are urged to bring anything new they have learned or have done during the year, of special interest to themselves, before the meeting for mutual information and discussion. Closing Business. Adjournment. The order of the program, and presenting of new topics, will be changed if necessary, at the discretion of the President, Mr. N. E. France.

## TRADE NOTES

### FURTHER ADVANCES IN PRICES.

The cost to us of some lines of metal and paper goods continues to advance, making it necessary to announce some further advances in price before the issue of our catalog for 1917 now in preparation.

Van Deusen hive-clamps are advanced to 40 cts. for 10 pairs with screws; 35 cts. without screws.

Tinned wire is marked up as follows:  $\frac{3}{4}$ -oz. spools, 5 cts. each;  $\frac{1}{4}$ -lb. spools, 15 cts. each;  $\frac{1}{2}$ -lb. spools, 20 cts. each; 1-lb. spools, 35 cts. each; 5-lb. coil, \$1.50 each.

A further advance of 50 cts. per 1000 is made on safety and folding cartons, plain and printed. Glass for shipping-cases as well as for hotbed sash is advanced to \$4.00 per box. Bee gloves are advanced to 60 cts. a pair. West cell-protectors, 5 cts. each; 45 cts. for 10; \$4.00 per 100; West spiral cages, 10 cts. each; 80 cts. for 10; \$7.00 per 100.

Several of the glass jars will be omitted from the new catalog, also scales which do not meet the requirements in some states.

We have advice from the publishers that Dadant's Revision of Langstroth on the Honeybee is advanced next year to \$1.50 each.

Owing to greatly increased cost of importing we are obliged to mark up the French edition of the A B C to \$2.50.

We have made no advance as yet on hives and other wood goods excepting a small advance on sections in quantities and on shipping-cases, because of the great advance in paper pads.

We find on getting new prices on the paper trimmings for cases that the \$1.00 per 100 added does not cover the increased cost. Lumber has already advanced over prices prevailing the past season; and if we did not already have a good supply in pile we should be compelled to advance prices on wood goods. If the present tendency continues, as seems most likely, higher prices on supplies are bound to come during the year ahead. The wise forehanded beekeeper will anticipate his requirements and order before these advances occur. He can also get these supplies nailed and ready for use before the season arrives when they will be needed.

### TIN CANS AND PAILS FOR HONEY.

We have been trying for weeks to get new prices on tin cans and pails for next year, but have been unable so far to get quotations good beyond Jan. 1, 1917. Every indication points to still higher prices beyond that date. Some are protected with contracts good till then. Quotations received good for immediate acceptance only are forty to sixty per cent higher than we paid a year ago; and new prices, still higher than those last quoted, will have to be made. Orders will be accepted only subject to stock on hand at present prices pending new prices to be announced as soon as we receive more definite information.

### SECOND-HAND 60-LB. CANS.

We are emptying honey-cans in our honey-packing departments at the rate of nearly a hundred cases a day. We have recently sold three cars of these cans to relieve the pressure on our storage facilities. With the much higher prices already in effect and soon to be still more noticeable it would seem to be economy on the part of producers to lay

in a stock of good second-hand cans, while available for next season's crop, even if not needed at present. While our stock at present is small we are accumulating more so rapidly that we can take care of ordinary requirements. For small lots we make no change in prices—namely, \$4.00 for 10 cases, \$8.50 for 25 cases, or \$30.00 per 100 cases of two 60-lb. cans in good condition to receive honey again. If any one would be interested in carload lots for later shipment we should be pleased to hear from him on such a proposition.

### ST. PAUL BRANCH IN NEW LOCATION.

Our St. Paul branch is moving to a new location in the down-town district at 290 East Sixth Street, where they will occupy three floors and basement in a brick block in the wholesale district. This location is only five minutes' walk from the Union Station or from Fifth and Robert Streets, the business center of the city. It is also located near most of the freight depots, and will permit of quick service. With increased storage room and more convenient quarters our manager expects to give better service than in the past.

### CHANGE AT SAN ANTONIO, TEXAS.

The Fraser & Harrison Co. is the new name of the company which succeeds the Toepferwain & Mayfield Co. at San Antonio, Texas. The new men took over the business last July, and have only recently changed the name. Mr. W. G. Fraser, the active manager of the new company, is the son of a retired banker, one of the early residents of San Antonio—a young man of pleasing address, who is making many friends in his new connection. We believe the company has greatly assisted beekeepers in disposing of their honey this season, and merits the support of the beekeepers of southwest Texas. They continue to operate the Weed foundation machinery.

### FLAT COVERS CLEATED.

Some time ago we had made up for us a quantity of the old-style flat-board hive-covers cleated on the end as shown above. These are made of Mexican white pine; and instead of being of one wide board they are made up of two or three boards, edge dove-tailed together in such a way that they cannot come apart, and are more inclined to lie flat than if made of one wide board. We still have in stock some two or three hundred each of 8 and 10 frame size which we offer, to close out, at \$3.00 for 10 8-frame; \$3.30 for 10 10-frame. For 100 or more the price will be 27 and 30 cts. respectively. They are offered subject to stock on hand at these prices, and should not last long.

### FIRE AT THE HOME OF THE HONEY-BEES.

A few minutes after 8 P. M., central time, Nov. 27, a fire of very evident incendiary origin was started in the central section of our lumber yard, and immediately gained such headway that it was with great difficulty confined to that section, which was entirely consumed. This section comprised a metal roof on poles 40 x 180 feet, with twenty-four piles of pine, basswood, and cypress lumber, and two cars on track alongside in process of being unloaded. There was a little more than half a million feet of lumber within the shelter structure, and two railroad cars entirely consumed. Approximate loss, \$20,000, fully insured. The fire ladders did valiant service in keeping the fire from spreading, assisted by a fifty-foot clear space at each end of the burning section.

### SUNDAY SCHOOL TIMES.

This is, without doubt, one of the most helpful and interesting family religious weekly papers published. It is particularly helpful in Sunday-school matters. No change in price is announced for the new year. The regular price is \$1.50 a year. In clubs of five

or more, \$1.00. We shall be sending in our Medina club this month; and if any of our readers not having the opportunity of joining a club in their own Sunday-school or town want to join our club they may do so on the following conditions: The subscription should be sent during the month of December—the earlier in the month the better. Send one dollar along with your renewal to GLEANINGS at one dollar, or two dollars for both. If you send after December, your subscription will be for only part of a year, ending with our club in December, or you will have to pay \$1.50, the regular price for a full year.

#### HOTBED SASH.

The season is here again when hotbed sash are needed for growing plants under glass during the cold winter months. We are offering our choice quality cypress sash shipped K. D. at the same price as formerly; but the price of glass is higher. The sash as regularly furnished are 3 ft. 4 in. wide, 6 ft. long, for four rows of 8-in. glass slid into grooves in the bars with ends butted together. We also furnish them with bars rabbeted, when so specified, at the same price:

One sash, K. D., \$1.00.  
Five sash, K. D., \$4.75.  
Ten sash, K. D., \$9.00.  
Glass 8 x 10 for same, \$4.00 per box of 90 lights; five boxes at \$3.80.

We are prepared to make special sash to order, including those with double tier of glass. Prices quoted on application, naming style and quantity required.

#### SECOND-HAND FOUNDATION-MILLS.

We have for sale the following list of second-hand foundation machines which will serve a good purpose for those who want to make up their own foundation. We can submit a sample from any mill in the list to anyone interested, on application.

No. 0153, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.  
No. 0156, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.  
No. 0165, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.  
No. 0183, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.  
No. 0230, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.  
No. 0234, 2½ x 6 extra thin-super mill in very good condition. Price \$12.00.  
No. 0237, 2½ x 6 thin-super mill in fair condition. Price \$10.00.  
No. 0238, 2½ x 6 thin-super mill in fair condition. Price \$10.00.  
No. 0239, 2½ x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.  
No. 0245, 2 x 10 hexagonal medium-brood mill in very good condition. Price \$18.00.  
No. 0247, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.

THE A. I. ROOT COMPANY, Medina, Ohio.

## Special Notices by A. I. Root

#### GOOD BOOKS AT A BARGAIN.

In our issue for June 15 we gave a list of good books that we offered at very low prices because they were, the most of them, old. The little book Poultry for Pleasure and Poultry for Profit that we offered there for 10 cts. you may have for 5. There are only six copies left.

The book Silk and the Silkworm that we offered there for 10 cts. you may also have, postpaid, for 5 cts.

Merrybanks and His Neighbor, which we offered for 10 cts., you may have for 5 cts. As the postage will be pretty near 5 cts. there will be no profit; but I think the book may do good. The same with the Story of Art Smith, the boy who made a flying-machine. We offered that also for 10 cts. You may now have it (a 25-cent book) for 5, postpaid.

Prof. Cook's book, Injurious Insects of Michigan, which we offered for only a nickel, postpaid, you can have for that now, but we cannot very well make any reduction.

We have four copies left of the book The New Agriculture; or, the Waters Led Captive. It is a \$2.00 book, but as the four copies were damaged by getting wet (but not so much but that it can be read easily), we offer them at 25 cts. each.

#### T. B. TERRY'S WRITINGS.

Since the death of Mr. Terry, as a matter of course his books (particularly his potato book) are being read with renewed interest. This book passed thru three editions of 10,000 each, and was revised and enlarged a few years ago. The price is 50 cts. in paper, and 75 in cloth—postage extra. We will for the present mail them at the above price, postpaid. See our Book Notices for June 1 for a description. The strawberry book, written not long after the potato book, has also had a great sale, and went thru two editions. We offer it now bound in cloth (former price 75 cts.) for 60 cts.; paper, 40 cts., postpaid.

Not long after the potato book appeared there was so much inquiry in regard to the best methods of growing clover to turn under for both potatoes and strawberries that Terry put out a little book entitled The Winter Care of Horses and Cattle. This has heretofore sold at 40 cts., postage extra; but we have so large a stock on hand that we offer it now for only 10 cts.

T. B. Terry's new book, "How to Keep Well and Live Long." Altho the above is a dollar book, by buying them by the hundred we are enabled to make the price 90 cents; and my opinion of it now is just about the same as it was when I wrote the following and placed it in our book list: "The above book by T. B. Terry is, in my opinion, destined to relieve more pain, sickness, and death than any other book in the whole world that has ever come to my knowledge. That is pretty strong language, I admit; but since Terry commenced, years ago, to urge the importance of pure air, pure water, and a simple diet of good simple food, in moderate quantities, the whole wide world, doctors included, seems to be gradually falling in with him. Of course other good and wise men commenced a similar crusade for better health long before Terry did; but he seems to have a happy faculty for getting hold of people and keeping their attention. After you once start in with the book you will be pretty sure to read it to the end, and you will ever after be a better and happier man or woman for having read it." We have a special low price for clubbing with GLEANINGS—that is, both for \$1.50. If you have already paid for GLEANINGS a year or more in advance you can have the book for 75 cents postpaid. Since it first came out, only a short time ago, we have sold nearly 1000 copies.

#### MISCELLANEOUS HANDBOOKS BY OTHER AUTHORS.

The A B C of Carp Culture. While not very much is now being said about carp culture, the directions in this book for making ponds and for other fish, or for other purposes, should be quite valuable. The book sold for 30 cts., postpaid; but as we have quite a stock on hand we now offer it for 15 cts. postpaid.

Asparagus Culture, heretofore 40 cts., we now offer for 25 cts. postpaid.

Alfalfa Culture, same price as above.

Barn Plans and Outbuildings, a very valuable book that sold for \$1.25 which we now offer for 75 cts.

Garden and Farm Topics, by Peter Henderson—a \$1.25 book which we now offer for 50 cts.

Gardening for Pleasure, by Peter Henderson—a \$1.25 book which we now offer for 75 cts.

Gardening for Profit, also by Henderson—a \$1.25 book which we now offer for 75 cts. until sold.

Gardening for Young and Old, by Joseph Harris—a \$1.25 book which we offer for 75 cts., postpaid.

Gregory on Squashes—a 25-cent book, now 15 cts.

Maple Sugar and the Sugar-bush, by Prof. A. J. Cook. The price of this was originally 30 cts., now 25 cts., postpaid.

Mauures and How to Make Use of Them—a 35-cent book, now 25 cts.

Nut Culture—a \$1.25 book, now offered for 75 cts.

Small-fruit Culture, by Andrew Fuller—a \$1.25 book which we now offer at 75 cts. postpaid.

Experiments in Farming, by Waldo F. Brown, including directions for making cement floors, etc.—a 10-cent book now offered for only 5 cts.

# A GREAT OFFER

Gleanings in Bee Culture . . . } All THREE  
Green's Fruit Grower . . . . . } \$1.00  
American Poultry Advocate } ONE YEAR

Just as the bee, fruit and poultry business hook up well together, so do these three journals—all leaders in their several fields. Realizing that a large number of our readers would like practical information along these lines, we have arranged with the publishers of a great leader among fruit journals and among poultry journals of the country to club with Gleanings in Bee Culture, at a special low price of \$1.00 for all three. (Canadian postage on the club, 75c extra.)

## Green's Fruit Grower

Rochester, New York

With Charles A. Green as Editor, is the oldest fruit journal in America, published at Rochester, the very birthplace of the fruit industry in the United States. It tells in season, all about spraying, how to beautify the home grounds, about ornamental shrubs, vines and trees, small fruits, home gardens, and successful orchards. In fact, it covers all phases of fruit growing, from planting the trees to marketing the fruit. It has a special department where subscribers' questions are answered, and a department devoted to the home and its interests.

## American Poultry Advocate

Syracuse, New York

This great poultry authority, established 1892, is devoted to interests of both fanciers and practical poultrymen. It is authoritative and helpful in all branches of poultry work, from hatching and rearing the chicks to maturing fowls for show room and market. Tells how to get eggs at the least cost, how to feed to get best results. No detail left out. It is the second oldest poultry publication in the United States and stands second to none in its value to poultry raisers. It is helpful to the beginner as well as the expert. The newest and best in poultry literature is found between its covers each month. This paper will help you to success in the management of your poultry, and by following the valuable information given you should be thrifty and prosperous.

### The Three for Only \$1.00

This combination can be secured only by writing direct to the publishers, and while the offer may be open to our readers for a year it may have to be withdrawn earlier on account of general increased cost of publication. Secure it now.

 BOSTON, MASS.

# Gleanings in Bee Culture

# WHY NOT

## Order Your Supplies for Next Season Now?

This last season was an unusual one and beekeepers felt the need of supplies during the honey season. It meant a loss to them if not on hand. Freight this year has been slow for some reason. Why not be forehanded and have the goods on hand when wanted? We try to get goods off promptly but the railroads were slow in making delivery---a month or more in some instances. Goods ordered now carry 2 per cent discount during December. Send in your order just as soon you find out what you require and we will take care of it promptly.

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

## Seasonable Goods . . . . .

- Tenement Winter Cases
- Buckeye Bee Hives
- Shipping Cases
- Five-gallon Cans
- Five and Ten Pound Pails

Two per cent Discount on Goods for Next Year's Use

M. H. Hunt & Son, 510 N. Cedar St., Lansing, Mich.

Established 1885

Send for our 64-page free catalog of Beekeepers' Supplies--full of information regarding bee fixtures, etc. Beeswax wanted for supplies or cash.

John Nebel & Son Supply Co., High Hill, Mo.  
Montgomery County

### When Ordering Supplies

remember we carry a full stock and sell at the lowest catalog price. Two lines of railroad—Maine Central and Grand Trunk. Prompt service and no trucking bills.

THE A. I. ROOT CO., Mechanic Falls, Maine.  
J. B. MASON, Manager

# SHIPPING-CASES FOR COMB HONEY

Don't make the mistake of putting a fine lot of section honey in poor shipping-cases. It will lower the price to you and damage your future sales. "Falcon" cases are A No. 1, and will be a credit to any crop of honey. Prices are as follows:

### Shipping-cases in Flat, without Glass.

|                     |                                                         |                          |

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT COMPANY, MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the side not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 1/2 s. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY, 6, 1915.

**COMB HONEY.**

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representative of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

**EXTRACTED HONEY**

This must be thoroly ripened, weighing not less than 12 pounds to the gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A," should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

**EXTRACTED HONEY**

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

## YOU DON'T WAIT FOR MONEY WHEN YOU SHIP MUTH YOUR HONEY

We Remit the Day Shipments Arrive.

We are in the market to buy **FANCY AND NUMBER ONE WHITE COMB HONEY**, in no-drip glass front cases. Tell us what you have to offer and name your price delivered here.

Will also buy—

White Clover extracted and Amber extracted.

A few cars of California Water White Sage.

A few cars of California Orange Blossom.

When offering extracted honey mail us a sample and give your lowest price delivered here, we buy every time you name a good price.

We do beeswax rendering; ship us your old combs and cappings. Write us for terms.

**THE FRED. W. MUTH CO.**

"THE BUSY BEE MEN"

204 Walnut Street.

CINCINNATI, O.

## HONEY MARKETS

**CHICAGO.**—Comb honey drags; otherwise there is not much change in values other than a stronger tone in extracted of all grades.

Chicago, Ill., Dec. 11. R. A. Burnett & Co.

**DETROIT.**—Extracted honey is scarce; selling from store, 9 to 10; comb has a good demand at 15 to 16; extra fancy 16 to 17.

Detroit, Mich., Dec. 7. F. P. Reynolds Co.

**CLEVELAND.**—Supply and demand are both moderate; very little call for any except fancy and No. 1 grades. We quote fancy, per case, \$3.75 to \$4.00; No. 1, \$3.50 to \$3.65; No. 2, \$3.25 to \$3.40.

Cleveland, O., Dec. 6. C. Chandler's Sons.

**PITTSBURG.**—No change in price or condition to report. We quote extra fancy comb, \$3.75 to \$4.00; No. 1, \$3.50 to \$3.75; fancy buckwheat, \$3.25 to \$3.50; No. 1, buckwheat, \$3.00. W. E. Osborn Co.

Pittsburg, Pa., Dec. 8.

**TORONTO.**—Prices are unchanged since last issue. Comb honey which is now on the market sells as follows: No. 1, per case, \$2.40 per doz.; No. 2, \$2.25.

Toronto, Ont., Dec. 6. Eby-Blain Limited.

**HAMILTON.**—Honey is going slowly this week. Only small lots are moving. We quote extra fancy, per case, \$2.50; No. 1, \$2.25; No. 2, \$1.60. White extracted honey, per lb., brings 12 in 60-lb. tins; light amber, in cans, 10. F. W. Fearman Co. Ltd.

Hamilton, Ont., Dec. 7. MacNab Street Branch.

**BUFFALO.**—Receipts of honey are more liberal with trade very quiet and stock accumulating in receiver's hands. We quote extra fancy, per case, 15 to 15½; fancy, 14½; No. 1, 14 to 14¼; No. 2, 11 to 13. White extracted honey brings 8 to 8½; light amber, in cans, 7½; amber, in cans, 6 to 7. Clean average yellow beeswax brings 32 to 33.

Buffalo, N. Y., Dec. 8. Gleason & Lansing.

**BOSTON.**—The sale of honey is somewhat neglected owing to Thanksgiving trade, holiday goods taking the lead. A healthy demand is present most of the time. We quote extra fancy comb honey, per case, \$3.50; fancy, \$3.25; No. 1, \$3.00; No. 2, \$2.50. White extracted honey brings 9½ to 12, according to quality and size of package.

Boston, Mass., Dec. 7. Blake Lee Co.

**ST. LOUIS.**—Southern extracted and strained—bright amber in barrels at 5½ and 6c per pound, in cans at 6 and 6½; dark ½ and 1c less. Comb, in cases—amber at 10 and 12c; dark and inferior at 9 and 11c per pound; broken and leaking at 7 and 8c; fancy clover at 14 and 17c. Comb, in cases (24 cartons)—fancy clover at \$2.75 and \$3.00, amber at \$2.50 and \$2.75, Southern at \$2; inferior less.—St. Louis Globe Democrat.

**KANSAS CITY.**—The demand for honey is very limited, and the high freight rates have curtailed the country consumption. Less honey is selling now than we ever knew at this time of the year. We quote fancy, per case, \$2.80 to \$2.90; No. 1, \$2.80 to \$2.90; No. 2, \$2.60 to \$2.65. Light amber extracted honey in cans brings 8; amber, 7½. Clean average yellow beeswax brings per lb. 25.

C. C. Clemons Produce Co.

Kansas City, Mo., Dec. 7.

**SAN FRANCISCO.**—Light demand on comb honey; trade generally well supplied; tendency is downward rather than firm market. Extracted of light grades in good request, and a free movement for all grades of extracted actually exists. White extracted is closely cleaned up, and wanted. Dealers find low grades in short supply. We quote extra fancy comb honey, per case, \$3.25 to \$3.50; fancy, \$3.00 to \$3.10; No. 1, \$2.40 to \$2.65; No. 2, \$1.50 to \$2.00. White extracted honey per lb. is nominal; extra light amber, in cans, 7½ to 8; light amber, in cans, 7 to 7½; amber, in cans, 5 to 6½. Clean average yellow beeswax brings 26 to 29.

Leutzinger & Lane.

San Francisco, Cal., Nov. 23.

**PHILADELPHIA.**—Comb honey is moving slowly. There is a fair inquiry for extracted honey, all grades. There is a somewhat better demand for country beeswax at prices quoted. Extra fancy comb, per case, 16; fancy, 15 to 16; No. 1, 13 to 14; No. 2, 11 to 12; white extracted honey brings 8 to 9; light amber, in cans, 7 to 7½; amber, in cans, 6 to 7. Clean average yellow beeswax brings 29 to 31.

Philadelphia, Pa., Dec. 7. Chas. Munder.

**ALBANY.**—Comb honey is moving slowly, but working off better than it would if weather were colder as usual this month. There is an increased demand for extracted, especially white clover or basswood. We quote fancy, per case, 15; No. 1, 14; No. 2, 11 to 13. White extracted honey brings 8 to 8½; light amber, in cans, 7½; amber buckwheat, in cans, 7. Clean average yellow beeswax, per lb. brings 30 to 32.

H. R. Wright.

Albany, N. Y., Dec. 8.

**LOS ANGELES.**—These prices are what the retailer pays our wholesale customers, not what we are buying at. We quote extra fancy comb honey, per case, \$4.25; fancy, \$3.85; No. 1, \$3.25; No. 2, \$2.50. White extracted honey brings 8½; light amber, in cans, 8; amber, 7; in barrels, not used. Clean average yellow beeswax brings 35.

Los Angeles, Cal., Dec. 6. Geo. L. Emerson.

**DENVER.**—We quote fancy white comb honey, per case of 24 sections, \$2.84; No. 1 white comb honey, per case, \$2.70; No. 2, per case, \$2.57; white extracted honey brings 8½ to 9; light-amber extracted, 8 to 8½. The above are our jobbing quotations. We are in the market for beeswax, and are paying 28 cts. in cash and 30 in trade for clean yellow stock delivered here.

The Colorado Honey-Producers' Ass'n.

Denver, Col., Dec. 1.

**ST. LOUIS.**—We have no great demand for comb honey, as weather so far is too mild. The supply here is fully ample for the demand. Extracted honey is moving much better, but prices remain about same as our last quotation. We quote extra fancy, per case, \$3.75; fancy, \$3.50; No. 1, \$3.00 to \$3.25; No. 2, \$2.50 to \$2.75. Light amber extracted honey in cans brings 9 to 10; amber, 60-lb. cans, 7½ to 8; in barrels, 7. Clean average yellow beeswax brings 31½.

R. Hartmann Produce Co.

St. Louis, Mo., Dec. 7.

**TEXAS.**—The honey is just about all in, also out. The last honey was disposed of as fast as could be gotten ready for the market by beekeepers of this section, also at one and two cents better than the prices for earlier honey, notwithstanding the earlier honey was of better grade. We quote No. 1 comb honey, per case, 10 to 11 cts. in two 60-pound cans; No. 2, amber bulk in two 60-lb. cans, 7 to 9. Light-amber extracted honey, in cans, 8 to 9; amber, in cans, 6 to 8. Clean average yellow beeswax brings 26 to 28.

J. A. Simmons.

Sabinal, Texas, Dec. 8.

**LIVERPOOL.**—Steady prices in good demand; 1800 packages sold as follows: Jamaica, palish, \$10.56 per cwt.; Jamaica, dark to amber, \$8.16 to \$9.84; St. Lucia, dark, \$8.16 to \$9.00; Haiti, dark, \$7.92 to \$9.72; Cuban, dark to pale, \$7.44 to \$12.60; San Domingo, dark to amber, \$8.52 to \$9.60; Honolulu, \$9.00 to \$9.84; Chilean, pile X, \$10.80 to \$11.52; Chilean, pile 1, \$9.84 to \$10.32; to \$8.52. Firm Jamaica beeswax, dark to good pale, brings \$37.02 to \$40.68 per cwt.; Chilean, \$38.88 to Chilean, pile 2, \$9.12 to \$9.60; Chilean, pile 3, \$8.16 \$39.48; West African, \$38.88; East African, \$39.48.

Liverpool, Eng., Nov. 24. Taylor & Company.

**MEDINA.**—The offerings of comb continue unexpectedly heavy, and western stocks are offered by distributors in the East in lots of ten cases or more at ridiculously low prices. Nothing could be more detrimental to the market than the present offerings. (See Wesley Foster's comments in GLEANINGS, Dec. 1). We hope, however, for an improvement after the holidays, as we do not believe the stocks are as excessive as offerings indicate. No new developments in the extracted market.

The A. I. Root Co.

**HONEY MARKETS**

*continued*

SYRACUSE.—There has seemed to be less honey retailed by grocers for the last week or two than for some time, which is affecting the jobbing trade to a degree. There also seems to be a goodly supply in the hands of the dealers at present. Extra fancy, per case, brings \$3.80; fancy, \$3.60; No. 1, \$3.36; No. 2, \$3.00. White extracted honey brings 8 to 9; light amber, in cans, 8; amber, in cans, 7 to 8. E. B. Ross.

Syracuse, N. Y., Dec. 9.

FLORIDA. — The demand just now is poor. Very little is on hand at present. Almost all on hand is of poor grade. Some little first-class stock is on hand. We quote white extracted honey, per lb., 8c; light-amber, in barrels, 5; amber, in barrels, 4. Clean average yellow beeswax brings 30 cts.. Wewahitchka, Fla., Dec. 7. S. S. Alderman.

CUBA.—Light-amber extracted honey, in barrels, brings 48 to 49 cts. per gallon; amber, in barrels, 48 to 49. Clean average yellow beeswax brings 31. Matanzas, Cuba, Dec. 8. A. Marzol.

**CANDY**

Bees sometimes starve with plenty of honey in the hive. Why not avoid this risk by placing a plate or two of candy on the frames when you pack for winter? It is a good life insurance. Send for circular also catalog of supplies.

# PROTECTION HIVES

Price: \$14.75 for five hives, delivered to any station in the U. S. east of the Mississippi and north of the Ohio River, or \$13.00 F. O. B. Grand Rapids, Mich. Prices will have to be advanced slightly January 1.

Air spaces or packing as you prefer. Seven-eighths material in the outer wall, which means that they will last a lifetime. Used and endorsed as the best hive on the market by many prominent beekeepers of this and other countries.

Norwichtown, Conn., May 24, 1915. (Extract from letter and order) Our State Agricultural College has just been voted a sum of money to be used in the construction of an apiarian building and outfit. They are negotiating with me for some colonies, and I will furnish them in your Protection Hives, for I believe them to be the best on the market. ALLEN LATHAM.

Send for catalog and special circulars. We are the bee-hive people. Send us a list of your requirements for 1917 and let us figure with you. We want both large and small orders. We have many pleased customers in all parts of the country.

A. G. Woodman Co., Grand Rapids, Mich.

## The Beekeepers' Review Announcement for 1917

Mr. Floyd Markham now holds the Gold Medal being offered by the Michigan State Beekeepers' Ass'n for the best honey produced in the State. This medal has now been won for the second time by Mr. Markham at our late convention. Mr. Markham also won all the first prizes on both comb and extracted honey at the Michigan State Fair at Detroit, this year. Mr. Markham is without a doubt the World's Champion Comb-honey Producer. How much would it be worth to you, Mr. Comb-honey Producer, to call at Ypsilanti and ask Mr. Markham all about how he proceeds to produce so much better comb honey than the average beekeeper? It would likely be worth a hundred dollars to you during a few years to come, what information you would get at such a visit. You can get it all for a dollar by subscribing for the Review for 1917, for Mr. Markham will write twelve articles for the twelve numbers of the Review during 1917, telling the entire procedure of securing the exhibition honey. None who aspire to greater things in beekeeping should fail to read how Mr. Markham accomplishes such results, which will appear in the Review during the entire year of 1917.

Mr. J. E. Crane is no stranger to the beekeeping fraternity. He has written much at different times relative to his method of beekeeping. We consider ourselves fortunate in securing Mr. Crane to write twelve articles for the Review for the year of 1917, covering the entire season with the bees. Mr. Crane's 40 years among the bees, as he will write it up for the Review, will be mighty interesting reading. In a book it would readily sell for a dollar. You will get this interesting series, including many other features, by subscribing for the Review for 1917.

E. D. Townsend, now owner of the Beekeepers' Review, used to produce comb honey on quite a

large scale. He originated the system now known as "Producing both comb and extracted honey in the same super." This system, if properly carried out, is one of the very best systems of comb-honey production that have been brought to light. The Editor of the Review has run large apiaries on this system of producing comb honey WITH ONLY 12% OF THE COLONIES IN THE ENTIRE APIARY SWARMING. An ideal system for out-yard work for comb honey. The Editor of the Review will write up this entire system of producing both comb and extracted honey in the same super for the pages of the Review for 1917. This series of articles alone ought to be worth many times the cost of the Review for a year.

Space forbids our mentioning more valuable contributions that will appear in the Review for 1917.

We will mention at this time that we are making arrangements with several of our very best honey-producers to furnish us material for the Review, written FROM ACTUAL EXPERIENCE of several years' standing. We will mention just one more of our 1917 correspondents who had 400 colonies of bees. He works the entire 400 colonies for extracted honey alone, in about 100 days, doing the work alone and securing very favorable crops. This party also sells his honey all in his home market at a price much above what is usually secured by producers. There will be many more valuable articles in the Review for 1917, including ALL the valuable papers read at the National Convention at Madison, Wis., next February. But we must stop, as space forbids us saying more about the valuable articles that will appear in the Review for 1917.

We hope there will be none of the readers of *Gleanings* so short-sighted as to miss sending in their dollars for the Review for 1917. Address

# HOW ABOUT NEXT YEAR?

The season of 1916, just closed, has been a most unusual one. Beekeepers who did not fortify themselves early in the season by securing their hives, sections, and other goods, and having their equipment ready for the bees, found when the honey season was upon them that they were up against the following conditions:

Everybody wanted bee goods, dealers had depleted stocks on account of the unusual demand, manufacturers were several weeks behind on orders, their factories were working overtime. Some beekeepers were delayed, some disappointed, some got their goods when it was too late.

## Now, Mr. Beekeeper, What are You Going to do about Next Season? ? ?

Prospects for a big Bee and Honey Season next year were never better than they are right now. PREPARE! Order your goods this fall. Write us or our dealer nearest you for a list of new prices owing to advances in raw material.

If you are not on our mailing list, write us at once and we will send you a catalog containing name of the distributor nearest you, and in this way you will also be sure to receive a copy of our new 1917 catalog when it is issued.

**Lewis** Hives and Sections and all other goods are made from the best material and are scientifically manufactured.

### OUR GUARANTEE.

We absolutely guarantee our goods to be perfectly manufactured of the best material for the purpose. On examination, if our goods are not as represented, we do not ask you to keep them. Return same at our expense, and we will refund your money, including any transportation charges you have paid. If you purchase our goods from one of our distributors, this same guarantee holds good, as we stand back of them.

G. B. Lewis Company, Watertown, Wisconsin, U. S. A.

Send for catalog giving name of distributor nearest you.

# DON'T FUSS

With your old combs and cappings, but send them to us. We will render them into beeswax for you on shares and pay you cash for your share, or we will make it into

## Dadant's Foundation

for you.

If you prefer, we will pay you our best trade price in exchange for BEE SUPPLIES.

Send for our terms. We feel sure that we can save you some money besides saving you a "mussy" job.

BEESWAX WANTED at all times.

## Entrances During Winter

It is important that winter entrances be small enough to exclude field mice. A couple of mice will ruin a colony in very short order; and they not only destroy the combs, but they keep the colony in a constant state of disturbance. It is an axiom now that a constant disturbance during winter is sure death to a colony. Many beginners, being anxious to see how their bees are coming on, make the mistake of opening the hives frequently. Fearing that the colonies will run short of stores they begin feeding; and feeding at such a time is likely to cause dysentery. On occasional very warm days when the bees are flying, a quick examination may be made if necessary; but it is far better to have the colonies so well cared for in the fall that no tampering will be needed until spring.

## Keeping Comb Honey Over Winter

It should be kept in a room where the temperature does not go below 70 nor above 100 degrees. If it could be kept at 80 degrees F., it would be better. Comb honey will granulate more quickly in the early fall if subjected to extremes of temperature. If it is kept in an atmosphere of about 80 degrees F., before it starts to granulate, from November on till Jan. 1, there is not much danger that it will granulate afterward; but we advise holding it at a temperature as near that of a living-room as possible.

The large demand now for extracted honey will possibly stimulate the demand for comb honey later on. If kept in a warm room it will bring a fair price by next March or April; and the price will continue good until the new crop comes on.

This year of all years, producers and dealers who have comb honey should carefully watch it, and see that it is not subjected to changes of temperature. The producer or dealer who is compelled to carry over his honey until next season will not lose by it, and he may sell at a good figure.

## The New Monthly Gleanings

AS announced in our issue of Nov. 1, GLEANINGS IN BEE CULTURE will become a monthly with its next issue, January 1, 1917. We have little to add to our original announcement of this important change in GLEANINGS' publication, except possibly to correct the wrong impression that the change from semi-monthly to monthly publication was to be made chiefly with a view of curtailing expense in these days of excessive cost for every kind of publishing. This was not at all the determining consideration in making the change. On the other hand, the fact is that our plans for publishing the new monthly GLEANINGS call for a larger financial outlay than that required for the semi-monthly. In size, in mechanical and artistic quality, in editorial amount and quality and in every other detail the new monthly will, we hope, surpass the former semi-monthly.

We wish to repeat with added emphasis what was said in our original announcement of the change, which was this: "The first and foremost purpose of the change from a semi-monthly to a monthly is to give the editors of GLEANINGS the needed time to make a better and handsomer journal." That expresses what was and is the one consideration in deciding upon the change from semi-monthly to monthly—to make a bigger and better and handsomer and more useful journal for our readers. As we further said in making our first announcement of the intended change: "There is no good reason for continuing a semi-monthly if it stands in the way of an improved monthly publication of a higher class."

We are glad to say that we have had some very satisfactory and explicit confirmation of this view from our readers. While some have written us expressing regret for the change from the semi-monthly to monthly, very many more of our readers have written us expressing approval of the change to the monthly, saying that a once-a-month publication for beekeepers

is sufficient, and that they would prefer to have GLEANINGS reach them in a single journal monthly than to receive it in separate journals twice a month. We believe that this judgment of a very great majority of our readers who have written us commenting on the intended change will be concurred in by most of GLEANINGS' followers.

We have intentionally and purposely refrained from drawing any highly colored picture of what the new monthly GLEANINGS is to be. We expect it to be a decided improvement on the old semi-monthly GLEANINGS. We are indeed enthusiastic about it, but we have repressed this enthusiasm so far as printing it, preferring to let fulfillment rather than promise furnish the basis on which our readers should judge us.

Accordingly, we shall submit the case of the new monthly GLEANINGS, without argument in advance, to the great jury of our readers, hoping for a unanimous verdict of approval when they have weighed the testimony that its first appearance will bring them.

### Moving Bees During Midwinter; Location of Yards

DURING mid-winter it is easier to move bees a short distance than during summer. If they are put into a cellar they can be placed the following spring anywhere, altho Mr. Dadant, of the *American Bee Journal*, feels that it is desirable to put them back on their old location. During mid-winter or after settled cold weather has set in we have moved yards short distances without any trouble.

If bees are to be moved during winter, the question of location should be carefully considered. There are three important requisites: First, accessibility to a common highway; second, windbreaks; third, shade. If a yard is located in the middle of a piece of woods or pasture two or three hundred yards from the general roadway, it means that an automobile truck or even a horse and wagon will have difficulty in reaching the yard in early spring when the frost is coming out of the ground. It is very expensive and wasteful of time for one man or two men to tote supplies crosslots over soft ground, across creeks and fences.

The second requirement, windbreaks, is very important, especially if the bees are wintered outdoors. Experience is proving that, while winter packing is essential, a screen of natural windbreaks is even more

so. An artificial windbreak, such as a high board fence, is better than nothing; but better still are hedge fences, trees, or anything that will break the force of the wind from those directions whence the prevailing winds come. Over and over again we have found that our colonies that are well packed out in the open will either die or be weak in the spring, while those well screened would be in the best condition.

Shade is not essential, but quite helpful during hot weather and during the swarming season. It may be secured artificially by means of shade-boards; but small deciduous trees that shade the hives only during certain hours of the day and certain parts of the season are more convenient, and more comfortable to the apiarist.

During these winter months plans should be made to find good locations if extra ones are needed. It is important to select such positions as furnish these three requirements, as they not only mean economy but more honey in warm weather.

### Drifting

THIS is a newly coined word that has been creeping into our nomenclature, and now for the first time finds a place in the A B C and X Y Z of Bee Culture. It means exactly what the word signifies—bees drifting from their homes by mistake into other hives. Young bees especially are inclined to drift at times. In their play-spells in spring and summer they will run out like a little swarm, and then gradually work back into the hive. One playspell begets another, and the result may be that there will be several colonies with a big demonstration in front. Young bees when out for the first time in the season after getting a considerable distance away from the parent hive will sometimes join the entrance where there is the largest number of bees flying, whether it is their own hive or not. The result is that one colony will be weakened and the other strengthened in numbers.

But the drifting that does real harm takes place when bees are set out of the cellar in early spring or when hives are placed too close together. Sometimes the drifting is aggravated when a high wind carries bees, young and old, clear across the yard, with the result that they will join almost any entrance, especially if they are a little confused as to where they belong. The effect of this is to weaken some and to give too many bees to the others. The former die of spring dwindling, and the latter from starvation.

Drifting is apt to occur where four hives are placed in a winter case because of the proximity of the two entrances on a side. When a nice warm day comes on during mid-winter, the inmates will come out in a general cleansing flight. The balmy air and sunshine keep them flying. Some entrances will be having more bees in front than others. As the day cools off, the bees are quite inclined to join the entrances of the strongest flyers, with the result that one colony becomes too weak and the other too strong. In the colder climates there is less trouble from drifting, especially if winter starts in snug and cold, and stays cold all winter till spring. Mr. Holtermann, for example, has no trouble from drifting, while we here in Ohio, using the same kind of winter cases, every now and then will find one colony weak and one strong, for no other reason than that the bees on a good fly day had drifted from their own to another hive.

Drifting when bees are put out of the cellar can be minimized by setting the bees out at night when there is a prospect of a nice day following. The barometer or the daily paper will usually tell what one may expect for the following 24 hours. If bees are put out the night before, with the prospect of a good day, they will get themselves settled down during the night, and the next morning gradually come out one by one, as the weather warms up. If the day is still, there will be very little drifting. If, on the other hand, the bees are set out on the first warm day, the general disturbance incident to moving will stir up every colony set out. The result will be that the air will be full of bees. Experience shows that the strongest colonies will draw from the weaker on occasions like this, as the bees are inclined to join the crowd where there is the most flying.

Sometimes the drifting nuisance can be controlled, and at others it cannot: but when it takes place the apiarist should equalize the colonies before some of them die of spring dwindling and others of starvation because there are too many bees for the stores.

### The Spacing of Brood-frames and its Relation to Wintering and Swarm Control

In our last issue, page 1129, reference is made to a statement put forth by Allen Latham, supported by C. P. Dadant, to the effect that 1½-inch spacing from center to

control tends to reduce swarming. While 1⅜-inch has been the standard in this country for 30 years, it has been generally believed that 1½ or 1¾ is better for wintering. Some beekeepers, therefore, while they use 1⅜ during the summer, space wider during the winter. But apparently no one has held that the 1½ distance tended to reduce swarming until Mr. Latham called Mr. Dadant's attention to the matter. Previous to that, the latter had never given the question any serious consideration; but in view of the fact that he had so low a swarming ratio—lower than that of any one else who used large hives when running for extracted honey—he began to think there might be something in it.

Practically all modern self-spacing brood-frames of various kinds are spaced 1⅜ inches from center to center. This is true of the Hoffman frame, the Hoffman metal-spaced frame, the Danzenbaker closed-end frame, and various other forms of frames using metal spacers, nails, tacks, or staples.

The question naturally arises, "How did the 1⅜-inch spacing come to be adopted thruout the United States after the 1½ seem to have the preference of some of the best beekeepers in the United States and Europe?"

In 1890 E. R. Root, on one of the first safety bicycles that was ever built, made a trip thru the state of New York, visiting some of the large honey-producers, among them particularly being Mr. P. H. Elwood and Mr. Julius Hoffman. The former was then, and is still so far as we know, using the 1½-inch spacing with his Quinby closed-end standing frames. Mr. Julius Hoffman, who adopted the frame now bearing his name, had settled on 1⅜-inch spacing.

So also had Mr. Langstroth. Mr. Root, after seeing some of the large producers in New York were making a success of self-spacing frames, concluded that the beekeepers of the West who were using unspaced Langstroth frames might perhaps adopt self-spacers to advantage.

The result of the trip thru New York led to a discussion of the merits and demerits of the self-spacing frames. In advocating self-spacers Mr. Root had the support of the Eastern producers and the opposition of the Western beekeepers. The matter was thrashed out pro and con for some years.

An examination of log gums and box hives was not altogether conclusive. The men who favored and advocated the narrower spacing seemed to find in box hives 1⅜ spacing as the average of brood combs.

The other fellow, who favored the  $1\frac{1}{2}$ -inch distance, would find that the wider spacing was the correct average. As a matter of fact, bees, when left to build their own combs, space them all the way from  $1\frac{1}{4}$  inches to  $1\frac{3}{8}$  from center to center. The distance is less in the center of the brood-nest and wider on the outside. When they build store combs they space them anywhere from  $1\frac{3}{4}$  to 2 inches from center to center.

Dzierzon gave  $1\frac{1}{2}$  inches as the right distance until Weyprecht, after a series of 49 measurements on natural-built brood-combs, found that the average distance was  $1\frac{3}{8}$ . These measurements were made on comb in straw skeps. Baron von Berlepsch, by 40 other measurements, verified this result.

In Great Britain, where self-spacing frames were in use to a considerable extent,  $1\frac{1}{4}$  to  $1\frac{3}{8}$  were the measurements adopted. Those who favored the  $1\frac{1}{4}$  measurement claimed that it practically excluded the rearing of drones, because it was practically impossible for full-sized drone brood to mature on this narrow spacing, for the simple reason that the bees would not have room to cap them over. It was learned, also, that quite a large number who used the  $1\frac{1}{2}$ -inch spacing had gone to  $1\frac{3}{8}$  at an enormous expense. The main reason for this was to discourage the rearing of drone brood and to prevent the storage of honey just over the brood in the brood-combs.

Worker-brood comb, on an average, is  $\frac{7}{8}$ -inch thick, and capped brood one inch thick. On  $1\frac{3}{8}$ -inch spacing this allows  $\frac{1}{2}$  inch between the uncapped comb, and  $\frac{3}{8}$  inch between capped worker brood. When drone brood is capped, there is scarcely room on  $1\frac{3}{8}$  spacing for the bees to work properly, much less to hover over and keep the brood warm. This matter was discussed back and forth for several years, with the result that the great majority favored  $1\frac{3}{8}$ -inch spacing as against  $1\frac{1}{2}$ .

All Hoffman and other modern self-spacing frames are spaced  $1\frac{3}{8}$  from center to center. If it should finally develop that the  $1\frac{1}{2}$ -inch spacing in connection with other factors for control exerts an influence on swarming in spite of the rearing of drones, it would entail an enormous expense, not only on the part of supply-dealers but beekeepers as well to change from  $1\frac{3}{8}$  to  $1\frac{1}{2}$ . Suppose that it should be definitely decided that  $1\frac{1}{2}$  is better, and that the supply-manufacturers should modify their machinery so as to make the self-spacing frames  $1\frac{1}{2}$  inches from center to center. The  $1\frac{3}{8}$ -inch frames and  $1\frac{1}{2}$ -inch would become interminably mixed, and the beekeeper would be compelled to discard his

old frames. This he would hardly be willing to do, even tho the wider spacing were a proven factor in discouraging swarming.

There is one more reason in favor of  $1\frac{3}{8}$  for Hoffman frames. The propolis accumulation will in time increase the width of the end-bars until they approach  $1\frac{1}{2}$  inches in width.

In favor of the  $1\frac{1}{2}$ -inch spacing as against the  $1\frac{3}{8}$ , there is the testimony of the Dadants. Mr. Allen Latham has built a let-alone hive that works for nothing and boards itself, allowing its owner to take off the surplus at intervals.

It will be remembered that Mr. L. A. Aspinwall, of Jackson, Mich., invented what is known as the Aspinwall non-swarming hive. The basic feature of this was the separation of the brood-combs so that the actual spacing between the worker brood, instead of being  $\frac{3}{8}$  inch would be one inch. Mr. Aspinwall proved that when the combs are spaced wider apart, allowing more clustering room in the brood-nest, the bees did not swarm. To prevent the bees from filling these wide spaces between the combs with extra comb, he put in what he called slatted dividers, which were really dummies made up of a series of vertical slats spaced  $\frac{3}{8}$  inch apart, and  $\frac{3}{8}$  inch thick. It was found that the bees would occupy the spaces between the slats, and instead of clustering out in front of the hives they would be in the hives. Apparently, then, the ordinary spacing between the brood at a certain season of the year is too close to allow a proper ventilation and to keep down the temperature of the brood. Accordingly the bees when the hive is overcrowded are forced out in front of the entrance and finally swarm.

While the  $1\frac{1}{2}$ -inch spacing is relatively only  $\frac{1}{8}$  inch wider than  $1\frac{3}{8}$ , yet it is apparently approaching the Aspinwall idea.

Having said this much in favor of the wider spacing it remains to be proven whether there is an actual reduction in swarming when  $1\frac{1}{2}$ -inch spacing is used instead of  $1\frac{3}{8}$ . If the reduction were proportioned to the reduction in actual measurements, the difference would be negligible, and would hardly compensate for the enormous expense of any changing over.

We have gone into the history of the various spacing distances for the purpose of drawing out discussion. Those who have adopted in their apiaries  $1\frac{3}{8}$  will try to prove that that is the right distance. Those like the Dadants who have always had  $1\frac{1}{2}$  spacing will feel happy and commiserate the other fellow who has  $1\frac{3}{8}$  and can't change.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

"JONATHAN was probably the first Hebrew who tasted comb honey," p. 1081. I wonder, now, I wonder.

HOFFMAN frames are spaced  $1\frac{3}{8}$  inches—when they're new. The bees, wise little creatures that they are, think that is too close spacing, and so they plug in bee-glue, seeming to aim to get in  $\frac{1}{8}$  inch of it, so as to make the spacing  $1\frac{1}{2}$  inches.

J. F. KIGHT, p. 1084, you think a very prolific queen doesn't deliver the goods because it takes so much to feed the brood, and that it would be a paying thing to use her as a helper to weaker colonies. If that were the case, an equally paying thing, and easier, would be to cage the queen part of the time. I don't believe either pays. I don't think the workers of an extra prolific queen are necessarily poor storers; but in any case I think it's a safe thing to rate a queen, not by the number of eggs she lays, but by the number of pounds her bees store.

You say, Mr. Editor, p. 966, that you find out whether another super is needed in three ways: "Watching the flights of the bees going into the entrances; tilting up the supers at the back and looking under; and by hefting or lifting the back end of the whole hive." But you don't say how. I should especially like to know *how* you tell about the need of a super by watching the flights of the bees. [We can't tell without the help of the two other means. Turn to last edition of A B C and X Y Z, under "Frames, to Manipulate," p. 286, and you will see *how*.—ED.]

THE DEMAREE plan for preventing swarming is thus modified by W. J. Shepard, *British Bee Journal*, 319:

The queen is found and transferred with one frame of brood to the lower body, which is then filled up with empty combs, and a queen-excluder placed above. Next will come a second body, containing empty combs, to receive the incoming honey, shallow frames being preferable. Above the latter second story either wire cloth or a second queen-excluder is placed, and the remainder of the brood is then put in a third story. Between the second and third stories, that is, above the wire cloth or second queen-excluder, a small entrance is provided, thru which the old bees will return to the main entrance below and the drones can escape. All queen-cells are destroyed. Should there be none at the time, the bees will immediately build them in the third story, where they must be

searched for and cut out up to about the tenth day, when the brood will be too old for any more to be built. The wire cloth, or second queen-excluder, can then be removed, leaving the upper entrance intact until the end of the season, if preferred.

"WIND, just wind," is the answer from somewhere near Providence. This "re" apiary locations, pp. 866 and 966. Some time before you and I were boys the glaciers traveled down across here from north-east to southwest, cutting the surface into grooves and ridges. Our prevailing winds are southwest—good nice strong zephyrs. As bees "follow their nose" it just naturally happened that those on the crest and west of the ridges referred to worked on one set of pastures while those on the eastern slopes worked another set, and there was virtually no trespassing on each other's territory. Surely bees go many miles from home. D. A. Jones, when he had his Cyprians on an island in the Georgian Bay, found them working on the mainland seven miles away. Thus writes Arthur C. Miller, and no doubt he's right. The bees' noses are to be reckoned with; and so it may happen that they go seven miles if the wind from that direction entices them, while they may fail to find pasture half a mile away if there is no wind from there.

FIFTY years ago 45 degrees for a beecellar was the orthodox thing. I don't know why, but Dr. Phillips suggests because that was about what could be easily attained. Somewhat strangely, within the past few years 40 degrees has been advocated. Now the tendency is upward, probably due largely to the investigations of Dr. Phillips. About 45 or 50 is mentioned approvingly, p. 1011. I think that can be safely shoved up still more, partly because of my own experience and partly because of what Dr. Phillips says. In his "Beekeeping," page 347, he gives between 57 and 69 as the best temperature for the cluster; and as to the air in the cellar, he says, "The majority of beekeepers consider 40 to 50 as the best cellar temperature, but it is clear that the temperature can usually be raised to at least 50 F. with beneficial results." That "at least" makes 50 the minimum, and it is not unlikely that we may some day settle down upon 50 to 55 as the best cellar temperature. [The cellar temperatures are going up. The new A B C and X Y Z favors 50 to 55.—ED.]

J. E. Crane

## SIFTINGS

Middlebury, Vt.

It is good news to know that asters yield better after a frost—page 1009, Nov. 1.

\* \* \*

The editor discusses the importance of windbreaks on page 1011, Nov. 1. I for one am glad more and more emphasis is being placed on this point in outdoor wintering of bees.

\* \* \*

Page 923, Oct. 1, Mrs. W. T. Lively gives some theories on the color variation in honey. While in Florida a few years ago I was told that the sugar-cane syrup grown on high, dry, sandy soil was of much lighter color than that grown on the rich hammock lands.

\* \* \*

Except the law had said, "Thou shalt not covet," I feel sure I should covet Mrs. Allen's many acres of crimson clover, page 906, Oct. 1. It must be a comfort to have the gap between fruit-bloom and white clover filled in. The past season we had nearly four weeks after fruit-bloom when bees could gather little.

\* \* \*

That announcement in Nov. 1st GLEANINGS that GLEANINGS is to become a monthly after this year has caused a feeling of pain to many who have been for so many years cheered by its bi-monthly visits. We expect, somehow, we don't now know just how, to be "disappointed," and to enjoy the new way as well as the old.

\* \* \*

That "sousing method," as Mr. C. D. Cheney calls it, page 986, Oct. 15, of introducing queens with dilute honey certainly seems an improvement over the use of thick honey. The danger, by use of thick honey, of injuring the queen seems to me very great in our cool climate. I am glad, too, to know of his success by this method.

\* \* \*

George Shiber, page 853, Sept. 15, estimates there is a saving of one-third of the stores by wintering in the cellar. I have found, by actually weighing, it is even more than a third. About 7 lbs. more is required out of doors than in a cellar, but these figures might vary with the amount of protection given out of doors, the severity of the winter, or the excellence of the cellar.

\* \* \*

One of the interesting things about GLEANINGS is that we get interesting pic-

tures of different parts of the beekeeping world. That on the cover, Nov. 1, is especially interesting. The editor tells us that already they have 4,000,000 acres under cultivation in Imperial Valley and very soon will have 2,000,000 more—almost as much as the whole state of Vermont, and vastly more productive.

\* \* \*

I have just returned from the New England fruit show at Montpelier, Vt. The magnificent display of fruit, especially apples, will go with me as long as I live. Apples, apples, apples! of every kind, color, and flavor. Surely no other fruit can compare with it. It is the king of fruits. If bees had no other claim to our attention than the part they play in the production of this magnificent fruit they would still be worthy of our thought and care.

\* \* \*

The editor puts up a good argument, page 776, Sept. 1, in favor of the use of comb foundation in sections, and I believe he is right. Still, I cannot help feeling that, while a comb built on light foundation may have less wax than one built without foundation, especially if it is drone, as it is apt to be, there is a tenderness or flakiness about the average comb without foundation that the other lacks. But for all that I shall continue to fill my sections with foundation, as the advantages overbalance the objections.

\* \* \*

Reference on page 840, Sept. 15, to sweetened spraying solution for destroying insects is of interest to beekeepers. I doubt very much if the formula as given, two gallons of molasses to 50 gallons of water, would attract bees when honey is coming in at all, but it might do so. Would it not be better to substitute glucose or corn syrup, as it is called now, for the molasses? My apples have been seriously injured for a number of years by the apple-maggot or railroad worm, as it is often called. The eggs are laid by a fly that appears usually early in July in this section. Like other flies they are fond of sweets, and a little spraying on one side of the tree seems to answer the purpose. Last July I sprayed with a solution of arsenate of lead and corn syrup, with the result that this fall my fruit is the finest I have had for many years, showing that the corn syrup answers every purpose, and with no danger to the bees.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Loquots and bluegum (eucalyptus) are blooming (November 27.)

\*\*\*

No rain since the middle of October. The unusually heavy growth of filaree is fast becoming a thing of the past, as there is no surface moisture to keep it alive.

\*\*\*

Did you see those pictures of the Kansas exhibits in the November 15th issue? They make me feel proud of my home state in which I learned the most valuable lessons of my life in beekeeping.

\*\*\*

I have been watching my bees work on the stem scars of the umbrella-trees, where the leaves have dropped off. A secretion forms where the leaves are broken away, and the bees are taking it up. Not all of the trees seem to have this secretion; but wherever it is, the bees are there.

\*\*\*

I have just killed a queen that has completely puzzled me. I cannot see why she should not have mated, with plenty of drones in the air at the proper time—perfect wings, ideal weather, etc. I supplied her with brood for two months as an experiment, but to no avail. She laid nothing but drone eggs.

\*\*\*

Mr. Editor, I stand corrected on that diagnosing matter, page 1052, Nov. 15. But still it seems to me like recommending some new way of curing disease that would be safe for the experienced but not for the amateur. It would be better not to advocate it so strongly as a protection to amateurs, even tho they are warned.

\*\*\*

During the past month I have been fortunate in meeting J. E. Wing, the well-known queen-breeder of San Jose. Mr. Wing is touring the southern part of the state with his wife and child, visiting beekeepers in various sections of the South, and getting acquainted. He has a good reputation as a queen-breeder. Last year he put out over four thousand queens besides many pound packages of bees.

\*\*\*

There is a motive for every action of the bee. To be able to solve the meaning of their actions is to be able to add a contribution to science. If queen-cells are torn

down, virgins killed, or if introduction fails, there is a strong chance that one is trying to force nature in an unnatural channel. When bees are busy they will accept more help than when they have plenty of time to look after details. Then, too, the old bees are largely engaged in the field when there is a honey-flow; but when it stops, look out for trouble, for it is impossible to "pull anything over them" as easily as over the younger generation.

\*\*\*

A number of my hives are three supers high. Last September I placed a full super of honey on quite a number that were empty, or comparatively so, in the middle super. I recently made a visit to my apiary on a cold day, having the task of giving honey to some colonies that were short. I was greatly surprised to find that the bees were clustered in two divisions in nearly all of these hives. In the brood-chamber there was a good supply. The next super where the combs were empty there were no bees. In the upper super, where the honey was, there were many bees, doubtless their mission being to protect the honey above. Where there were no excluders on, all three sections were occupied, the main portion being in the upper or middle sections.

\*\*\*

Dr. Bonney asks, page 1086, Nov. 1: "I wonder if it will surprise Mr. Chadwick when I tell him that my wife and I have charge of the postoffice in this little town, and that we know certain packages must have been willfully broken or else handled in a very violent manner." That packages containing liquid are often broken in the mails and arrive at their destination empty is no sign that they have been tampered with. When such a package is broken the muss must be cleaned up and the rest of the mail protected, and it would not be the policy of wisdom to put a broken package back in the mails with enough left in the container to destroy other mail matter still further. I cannot agree with you, doctor, that mail matter is willfully destroyed or appropriated, as you suggest, by postal employees. I have helped to clean up some of these "musses" and know what it means. If you have reason to believe that the mails were being tampered with, it was your plain duty to report the matter thru the proper channel. I consider your criticism on the postal employees as being based on insufficient knowledge.

# BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

Even Uncle Sam has learned the value of honey as a food, and now furnishes it to his soldier boys as a part of their "rations." At Camp Wilson alone, located near Fort Sam Houston, San Antonio, Texas, tons of extracted honey have been used up by the guardsmen encamped there. Ten cents a pound was paid for it in 60-pound cans, which is indeed a good price if we but consider that the finest grades of extracted honey sold at 5 and 6 cents a pound earlier in the year.

\*\*\*

Dr. Miller, p. 1061, Nov. 15, proclaims surprise at the "physical possibility" of bees building drone-cells on one side of a comb and worker on the other. I proclaim surprise at the possibility of such a thing never having occurred during Dr. Miller's long years of beekeeping experience and close observation as intimated by him in answer to Allen Latham. "Locality" again must have something to do even with this matter. In my locality I have frequently seen such stunts in naturally built combs, in combs built on foundation, and in cases where the worker-cells of part of one side of a drawn-out comb were torn down and replaced by drone-cells.

\*\*\*

GLEANINGS to be a monthly magazine hereafter! Good! I have called GLEANINGS a magazine for several years, because it has been more like one than like a journal; yet it was not quite complete nor large enough to belong in the class of other magazines of the country. I feel, too, that the monthly issue will be welcomed. Two weeks fly by very rapidly with the average busy beekeeper, and it gives him hardly time to read and properly digest the contents of one issue before another appears. Even if the larger monthly contains more reading-matter it can be more easily "handled" because it is all bound in one volume, and that with comparatively less advertising matter to "wade thru" than in the case of the semi-monthly.

\*\*\*

## HOW BRENNER GETS CELLS.

In relating some of Mr. Hy Brenner's remarkable success in queen-mating, in the last issue of GLEANINGS, I promised to de-

scribe the method employed by him for getting queen-cells.

After providing a cell-building colony, strong and queenless, in the usual manner, he inserts a comparatively new, empty, and perfectly clean worker comb in the center of the brood-nest of his breeding colony for the breeding queen to fill with eggs.

Next he provides an empty super with cleats just below the super rabbets, so that these will support a frame laid flat on them. The open spaces on either side of the frame and super sides are filled up with two pieces of board laid on the same cleats that hold the frame in place. This super is then placed on top of the strong cell-building colony. Mr. Brenner now takes the comb with eggs from his breeding colony and prepares it for the cell-builders. With a sharp implement he destroys the entire length of the first row of worker-cells in the comb of eggs. Then he skips one row and destroys the next, and so on until each alternate row of cells has been demolished. Reversing the comb from side to end, he proceeds in the same manner across the comb. When complete, there will be a checker-board of single worker-cells, each containing a worker egg.

This comb is now laid carefully in place on the cleats of the prepared super on the cell-building colony. Altho several inches away from the top-bars of the brood-frames, it is directly over the broodless brood-nest proper, and the nurse bees soon take possession of the prepared comb.

According to Mr. Brenner's statement, as many as 95 cells have been built on a single one of these combs. Nothing is done on the opposite side of the prepared comb, and, when placed in position, the whole top of the super is covered up warm with old sacking or the like. The bees do not have access to the upper surface of the comb, therefore, and the eggs in these cells simply dry up.

The progress of cell-building can be easily watched by carefully lifting the comb and holding it perfectly level, being careful not to jolt the inmates of the queen-cells, thus crippling them. When these cells are fully "ripe," almost ready to hatch, they are cut out of the comb by cutting right thru it. Mr. Brenner gives them to the newly formed nuclei with cell-protectors. If the cells are to be given to stronger colonies he prefers to place them in Rauchfuss cell-protectors.

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

## PIONEER PATENTS.

A friend and neighbor beeman of mine, at Glenwood, Fla., has shown me an ancient certificate that will elicit a smile from the modern apiarist. It reads as follows:

"To all whom it may concern: This certificate entitles R. B. Sproul, of Lee Co., Illinois, to make and use W. A. Flanders' semi-circle and Book Bee-hives, patented July 14, 1863, and April 5, 1865, upon one farm only. Elijah Benner & Co."

Can you beat it? How many of the fraternity know anything of W. A. Flanders? Hands up—but remember you will be giving your age away.

\* \* \*

## THE HONEY METHOD AGAIN.

Many times the omission of some apparently simple factor of a manipulation will spell failure. Practically all reports from beemen who have tried the honey method of introducing queens have been favorable. But one report from Arkansas is so distinctly dismal that we cannot refrain from quoting it in full here, as a warning to others "how *not* to do!" It is as follows:

Mr. E. G. Baldwin:—I have tried your method of introducing queens as stated in Gleanings, July 1, page 525, to my sorrow. It did not work for me. I ordered a queen by mail, and thought I would introduce by the honey method (as I had lost the last queen I tried to introduce by the cage method). It seemed easy. I therefore removed the old queen and took about half a cup of honey and soured the new queen in it, and poured it into the hive. It wasn't fifteen minutes before the bees began to get in an uproar. Whether the queen left and came back I don't know; but anyway this morning the bees were all excited. After awhile I noticed them dragging her out dead.

Wm. R. Lindsey.

Buckner, Ark., Aug. 30.

In the first report we gave in these columns (June 1, p. 525) we omitted to emphasize the fact that the entrance should be contracted during the operation, and remain so for a day after it. But in the recapitulation, p. 845, we did emphasize this essential feature as follows: "Then close the hive-top, and see that the entrance is narrowed to a point where robbers can be kept out according to the strength of the colony."

Without doubt our correspondent from Arkansas had a full-sized case of robbing on hand in about ten minutes after the op-

eration. Of course the queen was killed. Odd if even the colony escaped. We are sorry we omitted the entrance-contraction clause in the former article. It is an essential to success with the method. An experienced beeman might have thought of it anyhow, but not so an amateur. We sincerely hope that our correspondent will give the method another thoro trial, and report. We feel sure the method will work all right if performed all right.

\* \* \*

## ANOTHER HONEY-PLANT REPORTED.

Recently a specimen plant was mailed as from southwest Florida to which the local name "minkweed" had been given. We have never before heard that particular local name. The sender declared it is a splendid nectar-yielder, and that there were hundreds of acres of it near him. He added that he had been told it was the boneset of the North (*Eupatorium perfoliatum*). The plant is not the boneset at all. It is the vanilla plant, or deertongue (*Trilisa odoratissima*), one of the numerous and widely differing members of the great thistle family. The stem is smooth, the lower leaves are spatulate, the upper are oval or oblong, and smaller. The heads have about 7 or 8 flowers that form a convex cluster, each flower on its own stalk, and rising from its own stem. The blossoms are purplish, verging on white. It grows in the flatwoods pretty generally over the state. The thistle family is pretty widely represented in eastern-central Florida, there being no fewer than 147 genera and species in Volusia Co. alone. Of these the following are among the honey-bearing plants: Thistle, three species: ironweed, *Liatris* (or blazing-star); *Chrysopsis* (golden aster). We have six species of the golden aster. Of goldenrod we have 7 species in the county. Of asters proper we have 7 species; sunflower, five species; and cosmos, cultivated. Just now the bees are working vigorously on the asters, the wild-sunflowers, and the Spanish vines (*Antigonon*.) Oddly enough the bees never seem to work on the goldenrod hereabout, tho we have made special examination many times. Goldenrod seems to vary thus in different parts of the country. Dr. Phillips, we recall, told us a year ago that the bees never touch the goldenrod in the region of his home near Washington, D. C. We wish other beemen all over Florida would report whether the bees in their localities work on this plant.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

## BEEHIVES

THE accumulation of the past three years has made me willing to write upon the well-worn topic of the beehive, because there is, perhaps, no point relating to bee-keeping about which I am asked so many questions as this. Allow me to say at the start that it is well to understand that the bees themselves are not much concerned about the shape or dimensions of their home. They will store as much honey, other things being equal, in a shoe-box or part of a barrel as in a hive patented by some elated novice. Hence the form of the hive is only a question of convenience to the apiarist. The beekeeper may make its shape to secure the object he has in view. But from the stack of letters I have on this subject it would seem that beekeepers have many objects, as hives are wanted for producing comb honey; for extracted honey; for wintering bees; for preventing swarming; for producing bees; for rearing queens, etc. Fortunately a different kind of hive is not required for each.

The hive best adapted to the production of honey is that which the majority are seeking after; and if a hive is to be selected for this one object an eye may be had also to other objects that are subsidiary. To illustrate: While queen-rearing is a legitimate department of bee-keeping, yet the characteristics of the hive best adapted to that branch are of special interest to only a few, and thus the hive in use for the production of honey, both comb and extracted, will generally be found sufficiently serviceable for this branch of our pursuit. The successful production of honey is the one overshadowing object of apiculture; and therefore, in my view, there are some positive qualities to be sought for in any hive at all well calculated for an apiary to be conducted for the highest net profit.

Where an apiarist has a love for exploring the inside of the brood-chamber during the honey season, the contraction of the brood-chamber at the height of the flow will bring almost astounding results in white honey, which, as a rule, brings almost double price over that from buckwheat or fall flowers; yet, considering that the rank and file are more prone to leave the bees alone, only as manipulation tends toward better success, I consider the ten-frame Langstroth hive, when used in connection with the Italian race of bees, to be the better

for the average beekeeper. This hive gives sufficient room for the production of brood so that the maximum as to the number of bees can be accomplished in good time for the harvest from clover and basswood, while it allows of sufficient stores to be carried past the winter consumption, so the bees feel no need of retrenching by way of scrimping the brood during the latter part of April or in May. Plenty of stores in sight at all times is with the bees like a good account in the bank with the average thrifty family who have something to invest where a profit can be made as well as the wherewith to tide over a period of scarcity. And a colony of good Italian bees seem to know just when and where a good investment of stores looking toward a return in numbers of bees at just the right time in the season can be made, and so we find them using on their stores quite lavishly the last half of May and the first two-thirds of June. They will retrench in brood as the flow of nectar becomes more bountiful after June 20 till the close of the basswood bloom in July. Thus with the Italian bees the ten-frame hive will accomplish all that could be accomplished with the small hive and contraction advocated so vigorously during the latter part of the nineteenth century by the beekeepers living north of latitude 40, and without all of the manipulation and feeding which this contraction or small hives required.

The ten-frame hive need not be very expensive. Thirty to forty cents should purchase lumber enough of sufficiently good quality for body, cover, and bottom. Lumber with sound knots will answer very well. The apiarist should not be led by one or two good crops into failure in point of economy. Then this ten-frame hive is not cumbersome. Its bulk and weight will allow of its being handled easily by one man when it contains a colony of bees with stores enough for winter, as a rule. If the hives are to be seldom moved, then a large double-walled or chaff-packed hive may prove an exception.

In the production of extracted honey I consider this ten-frame hive as good as any, as story after story can be placed or tiered to the utmost requirements of either the bees, queen, or apiarist. If it is undesirable that the queen have access to all of the hives, a queen-excluder may be placed between any two stories, and thus the extracting-frames kept free of brood.

# IMPORTANT CHANGES

## To All Readers of Gleanings in Bee Culture:

We shall make some important changes in the business conduct of GLEANINGS on and after Jan. 1 next as follows:

### TO BECOME A MONTHLY.

As announced in the editorial columns of Nov. 1, GLEANINGS will become a monthly instead of a semi-monthly on Jan. 1. We hope to make our journal the handsomest and best bee publication of the world—and better than anything hitherto known in the apicultural publication field.

### ALL SUBSCRIPTIONS TO STOP ON EXPIRATION.

On and after March 1, 1917, all subscriptions will be promptly stopped on expiration and all subscriptions in arrears, after due notice, will then be discontinued. Altho many of our subscribers have preferred to have GLEANINGS "continue right along" (and have so expressed themselves), a growing number of our readers today express a preference for the better business method of stopping subscriptions on expiration, and this is right. There is no more reason or justification for a publisher's sending another order (or year) of his journal, without the express order or cash payment of the subscriber, than there is for the grocer to send without an order a second delivery of coffee because his customer has given one or several previous orders for coffee. Accordingly, beginning March 1, we shall adopt the better plan and run no one into debt for a subscription to GLEANINGS. The rule will be: Stop on expiration.

ONE EXCEPTION to the above rule will be willingly made by GLEANINGS, namely; when a subscriber writes us and expressly states that he wants GLEANINGS continued beyond his subscription date and that he will pay for it at some designated time, we shall be glad to continue such subscription.

### PREVIOUS SUBSCRIPTION OFFERS.

On and after Jan. 1, GLEANINGS is forced to withdraw all subscription offers of other years, except such as may be contained in the subscription catalog of 1917 or in the bee-supply catalog of The A. I. Root Co. for 1917. Many of the combination subscription offers of other years cannot be made good for the reason that books and articles then offered are no longer obtainable. Unparalleled advances in prices have made others of these offers impossible. These old subscription offers have also made endless trouble and delay in our Subscription Department and to our subscribers. GLEANINGS is not advancing its subscription rates, as very many magazines are doing, altho the cost of publishing the new monthly GLEANINGS will exceed the cost of publishing the semi-monthly of the past. But we must limit our clubs and premiums to PRESENT liberal offers. You will receive the current subscription catalog when notice of the approaching expiration of your subscription is sent you—a matter we shall always carefully attend to in advance so that you may not lose a single number of GLEANINGS if you renew promptly.

### PREMIUM OFFERS FOR SECURING NEW SUBSCRIBERS.

Instead of the former merchandise premiums and subscription extensions offered for new subscriptions, we shall offer agents cash subscription terms or an equivalent in extension of their own subscription. Such terms may be had on application.

A new monthly, a rule of never running our subscribers into debt, and a restriction of combinations and premiums to present offers, are changes that we trust to make welcome to our every reader.

Grateful for your past favors, we hope for your continued favor.

Very truly,

## GLEANINGS IN BEE CULTURE

The A. I. Root Co., Publishers.

# GENERAL CORRESPONDENCE

ONE OF THE SKILLED CANADIAN BEEKEEPERS. E. T. BAINARD, OF LAMBETH, ONTARIO

BY R. F. HOLTERMANN

Traveling thru the county of Middlesex, one of the best agricultural counties in Ontario, I reached the city of London. From there, going by the electric line, I reached the home of Mr. and Mrs. E. T. Bainard. This was not my first trip to the Bainards; but since my last visit quite a number of changes have taken place.

Mr. Bainard has been keeping bees for twenty-five years. When a boy on the farm he became interested in bees thru reading articles in the *Farmers' Advocate*. That he had a natural inclination in that direction was pretty well shown in the way in which he studied the bumblebee in its habits, keeping their nests under his observation. At first, beekeeping was combined with farming; but as success warranted, and circumstances permitted, the farming part was laid aside, and for the last seven or eight years beekeeping has been his sole occupation. He is now running three apiaries, each containing in the neighborhood of one hundred colonies. He confines himself exclusively to the Heddon hive. Two apiaries contain eight-frame hives, and the last ten frames, which is equal to a 13-frame Langstroth hive. Mr. Bainard produces extracted honey only. From a few words dropped, I believe that there is a little controversy on this question between Mr. and Mrs. Bainard, the latter wanting to devote one colony to the production of comb honey for occasional family use, and, as I put it, to amaze her friends with the beautiful comb honey her husband can produce.

The source of honey is almost exclusively clover; but under favorable conditions a little basswood is obtained. This shows that the honey-flow is not prolonged.

Four colonies in a case is the method of wintering. The outside entrance thru the case to the hive is about 2 inches high by  $\frac{3}{8}$  wide; and by means of a movable piece

which swings on a screw the entrance can be enlarged to 2x10 inches. The hive entrance is  $\frac{3}{8}$  in. deep by the width of the hive.

That Mr. Bainard has learned the value of a sheltered place I can best explain by quoting him. He said, "At one time I tried to get a cover to a hive that would not blow off; but now I seek to have the apiary where the wind will not blow the covers off the hives." He aims to have the outer cases 8 or 10 in. from the ground, considering that they are dryer in the spring of the year, and there is less danger from the ice on the ground chilling the flying bees.

The first visit to the bees—to satisfy curiosity—takes place in early March; but on this trip, if any attention is needed it is

Bainard's winter case with the upper pieces partly removed. These are separate from the lower main part.

given. Rarely an outer case may need to have the snow removed. If there are dead colonies the entrances to such hives are closed. Whenever weak colonies are found the entrance is contracted with paper. This the bees can remove as fast as they require the entrance room.

The next visit is made in fruit-bloom when more room is given by adding another section of the Heddon hive to the two sections upon which the bees are almost invariably wintered. The need of the bees is judged from outside conditions. In 1913 one colony had a super on before fruit-bloom; but this is rarely the case. The bees are unpacked some time during fruit-bloom; but if the bees do not do much during that

period they are left until later; but they are always unpacked before the clover flow.

The work of packing and unpacking is lightened very much by having the permanent nailed sides of the packing-case no wider than the depth of the hive. After the hive is set in the case, a board the depth of the packing is set on top of each side, kept in position by three "stakes" which extend down just inside of the case wall. The joint between the two parts is beveled to shed water. There is five inches of packing at the sides and ends of the hives, and about 8 inches on top. The extension-boards are not nailed to the case; and during the summer they can be laid inside of the case to which they belong. I must confess that I consider this plan decidedly superior to the full-depth case that I use.

Both summer and winter Mr. Bainard uses a honey-board  $\frac{3}{8}$  inch thick. In the preparation for winter he breaks the propolis joint after the bees are packed. The only cover he has in summer over the honey-board is an inverted "pan" made of galvanized iron for shedding water. This pan is put over the hive in the case, with about 4 inches of packing below and 4 above. A gap of several inches is left at the backs of the hives. Mr. Bainard claims without any hesitation that in this way no moisture collects under the metal covers.

#### WEIGHING AND FEEDING.

The hives are weighed as they are packed; and when necessary the bees are fed after weighing, the time for this being as near Oct. 1 as convenient.

In melting sugar Mr. Bainard heats the syrup, puts in the sugar, and uses a stick with a suction contrivance at the end which moves the sugar on the bottom of the tank and soon dissolves it. This stick is what is called in Canada a "Manitoba washer." In my estimation the plan of feeding the bees after packing is correct.

#### LEVER FOR LOOSENING SUPERS.

Mr. Bainard has shown considerable mechanical ingenuity in designing a clamp or lever for catching one side of the hive or super below and the other side of the super above. When the lever is moved, the super above and the hive or super below are wrenched in opposite directions and loosened. He uses this device when examining the colony or when putting on escape-boards.

#### HIVE-LIFTER.

If I am not mistaken I am the father of a hive-lifter myself—one of the first published; but—well, it took too long to use it, even if it lightened the work. I could ad-

just myself as a lifter to the hive more rapidly than I could locate the contrivance; and physical energy in a rush did not count for much. But Mr. Bainard has not only designed a lifter but he has used it. It is simple, saves a lot of heavy lifting, and perhaps he is not in quite as big a hurry as I am. It is made as light as efficiency will allow, weighing only 23 lbs., and it will support 200 lbs. The supers can be raised high

Bainard's hive-lifter in use raising supers.

enough to permit an examination of the brood-chamber underneath. The lifting-device has four legs, and has in connection therewith and at the top a part like an old windlass on a well. The shaft is made of five-inch gas-pipe. The super is clamped or clasped at the ends, and works best if there is a cleat; but it can be made to fit into the hand-holds generally found.

#### IMBEDDING-WIRES.

The wires are imbedded in the foundation by means of electricity.

#### POINTS IN MANAGEMENT.

Mr. Bainard has found that a small entrance to a hive, giving insufficient ventilation to the colony, irritates the bees. This first came prominently to his attention in an outyard when for experiment the  $\frac{3}{8}$  x 3-inch bridges, in front of the winter-packed hives, were not removed when unpacking. The object in leaving so small an entrance was to see if the bees would go more readily into the supers. The weather turned very hot about that time, and the bees became cross, and remained so for quite a time afterward. After-experience confirmed this. This quite agrees with my own experience when moving bees during hot weather.

## EXTRACTING CONVENIENCES.

A tank some 6 feet deep and 3 wide is used as a storage-tank. Two inches below the top there is an overflow pipe which returns the honey to the extractor when the tank is full. The tank holds about 3000 lbs.

The honey which drains from the cap-pings is carried by gravity into the extractor, entering the can just below the level of the baskets to prevent a back flow of honey from the extractor. The uncapper stands close to the extractor. A central extracting station is used, to which all the honey is hauled and extracted.

To be able to strain honey rapidly, a very unique plan has been adopted; and that is to run a quarter-inch steam pipe in the center of the eight-foot pipe thru which the honey is pumped from the extractor to the tank. Mr. Bainard said that this pipe should not be too hot, and that the flow of steam, therefore, must be regulated. The upright pipe should really contain only condensed steam. He thinks that a better way would be to have the heat outside of the honey-pipe.

## A HONEY-STRAINER.

Another beekeeper, John W. Campbell, who lives next door to Mr. Bainard, but who has his bees nine miles from there, gave me some interesting information. Mr. Campbell uses a new strainer material which Mr. Bainard has also adopted, as it is far superior to cotton cheese-cloth. Linen cheese-cloth is used. It is stronger than cotton, and the threads are less fuzzy, so that the material acts more like fine wire cloth. This strainer is laid on a 5/16-in.-mesh wire cloth which is fastened to a hoop that catches on the top of the storage-can. The cloth is removed frequently—at noon and before starting extracting in the morning—and put into a pail of cold water. After the honey dissolves it is rinsed and shaken out. Perhaps some of the readers of GLEANINGS do not realize why a honey-strainer should be washed in cold water. It is to prevent the

wax from melting and sticking to the threads.

## A LEVER FOR PUTTING ON COVERS.

Mr. Campbell told me of a way to put friction-top ("slip top" or "penny lever") covers on honey-tins, which is away ahead of my own way, and I have put on many thousands during the last ten years. He simply hinges a lever to something solid with a round piece of wood on the under side of the lever that will fit inside of the cover to be put on. He regulates the height for each tin by using varying thicknesses of blocks under the tin. The covers are pressed into place by pressure of the lever. Very rapid work can be done in this way.

Mr. Bainard told me that the late Wm. Elliott, of Adelaide village, near Lambeth, had a device used in connection with putting wet combs back on the hives after extracting. It consisted of a solid bee-escape board with an additional opening covered by a slide, thus controlling the communication between the brood-chamber and the supers containing the wet combs above. The slide could be manipulated from outside of the hive. The bee-escape in the board also had a shield above it to prevent dead bees and wax from falling into the bee-escape, and perhaps clogging it. It seems that Mr. Elliott used these boards on top of all hives upon which wet combs were to be placed, and left the means of communication closed until night or until after all the supers had been located. This prevented the very undesirable excitement and tendency to rob which is well known to be the result of the bees having access to the wet combs.

For the edification of the inexperienced I wish to say that it is a comparatively easy matter to remove combs of honey from the hive by means of bee-escapes, and to extract the honey in a bee-tight house; but the excitement is sure to begin as soon as the wet combs are put back upon the hives. The bees appear to sound an alarm which sets every field bee on the hunt.

Brantford, Ont., Canada.

## OPENING UP THE FRONT OF THE HIVE DURING HOT WEATHER

BY WALTER J. BAILEY

---

Every experienced beekeeper who keeps bees for profit and not pleasure is aware that, in order to secure the largest amount of honey, he must cut swarming short if he possibly can. When operating for extracted honey we can control the swarming much better than when running for section honey.

When I first became a beekeeper I had trouble with the swarming problem. My bees would get a nice start in the supers, and, about the time the supers were two-thirds full, the bees would swarm, and there I was with a partly filled super. Of course I gave such supers to other colonies to com-

plete; but if the bees can be kept at home, and swarming prevented, we can secure a greater amount of surplus honey.

I have a plan that I have followed for the last ten years that has proven very successful. I had only four swarms this season out of forty colonies. Some colonies will swarm, regardless of what is done to prevent it. I can prevent swarming by cutting the queen-cells; but every beekeeper knows that this is a very troublesome job.

I control swarming by giving plenty of ventilation to the bees. It is useless to give plenty of supers unless there is also plenty of air. I use the eight-frame dovetailed hive; and before I nail the hive-body together I rip a piece 5 inches wide off the

lower side of one of the end pieces, this end that has been ripped is to be the front of the hive. I then put the hive-body together, leaving the five-inch piece out. I saw the dovetails off the five-inch strip, and fasten

it back in place with two small hinges. This makes a five-inch door the width of the hive, for an entrance door. In hot weather, when my bees begin to get strong in the spring, or at the beginning of the honey-flow, I open this door and turn it back up against the hive. This gives the bees plenty of air. If there is also plenty of super room there will not be one swarm in ten colonies. With this large entrance it is no trouble for the bees to force plenty of air up into the supers where it is needed in hot weather. I have two small buttons on each side of the door to hold it in place when closed for winter.

At the close of the honey-flow in order to prevent robbing I close the door to all hives that are weak and not able to guard so large an entrance; but the doors to all strong colonies are left open until winter. These large entrances keep the bees cool and comfortable during hot weather when no honey is coming in, and when the bees are idle.

I have an Aspinwall hive that has made over 200 lbs. of honey this season. I have had this hive for five years, and the bees have never swarmed; but it is much trouble to take out the dummy frames in the fall and put them back before the honey-flow. During the honey-flow the bees build the comb in the brood-frames clear out even with the edge of the frame; and in the fall, when one takes the dummies out, there is no bee-space left between the frames when crowded up for winter.

The plan I have given, if properly carried out, will nearly do away with swarming. It is the best thing I have found.

Owingsville, Ky., Aug. 18.

## THE BEE-SUPPLIES USED IN HOLLAND

BY J. H. J. HAMELBERG

Considering the population of this country, we are well provided with opportunities for buying our bee-supplies; but the supply stores furnish only the hives and fixtures used by the majority of the Holland beekeepers. Those using American hives, as I do, have either to make their own fixtures or order them from the United States, which is rather expensive.

With the exception of hives and their fixtures, honey-jars, and comb foundation, most of the articles sold by our dealers in bee-supplies are of German make, and in general they answer all purposes. I do not consider our hives and fixtures the equal to the American product, for as a rule they

are much frailer and not so well finished. This can be accounted for by the limited trade, which does not permit the use of such expensive machinery as American manufacturers use.

I can not understand why our comb foundation is so inferior, for American machines or the equivalent of American machines are used in its manufacture. The brood foundation here is so thick that only thirteen Danzenbaker frames can be filled from a kilogram (2.2 pounds), and extra-thin foundation suitable for sections is not manufactured in this country at all. Dealers claim that the bees will draw out the wax in this heavy foundation so that they

are saved the necessity of producing so much at a time. In this I do not agree; besides it is a question whether it would not be more profitable to let the bees gather honey and make their own wax for cell-building than to make them spend their time in reducing the sides of the cells of thick foundation. Furthermore, the thick midrib may not be objectionable for brood-comb, but is very bad when used in sections, or even in shallow frames when the honey is to be sold as bulk comb honey. Samples of comb foundation I have had from Germany and Austria are little better than our own product, but still they remain far behind that made in America, and the reason for this I do not understand.

I wish to give some particulars about my own appliances and methods, so far as they differ from those usually described or illustrated in GLEANINGS.

#### BOTTOM-BOARD.

The end-piece of my bottom-board is not nailed fast but is fastened to the sides with a brass hinge at one end and a hive-clamp at the other. I consider the movable end very convenient because I use shallow tin trays for stimulative feeding; and by throwing open this end-piece the trays may be pushed in from the back and filled readily without disturbing the bees. The robbers are also less of a nuisance than when they can smell the diluted honey at the entrance.

The greatest advantage, however, of the loose end is that it enables me to clean the floor-board in winter without disturbing the bees above. The sides of my bottom-board are about an inch high, and the distance between the floor and the bottom-bars of the brood-frame is  $2\frac{1}{2}$  inches, permitting a large scraper to pass freely under them. This scraper is made of a common flat file forged to the dimensions  $\frac{1}{8} \times \frac{1}{2} \times 8$  inches, and fitted with a long handle made of stout wire fastened to it in the middle with a screw thread and nut. I push the handle thru the entrance and haul the scraper thru the hive from the back so that all the dirt and dead

bees will be drawn out in two or three strokes.

By examining the refuse that I pull out I am enabled to know the condition of the colony. If I find it damp, more ventilation is needed at the entrance. A large number of honey crystals or wax grains in the sweepings show that the bees need water. Larvæ of wax-moths indicate the bees have been cleaning out the cells for brood-rearing. Dead bees with extended tongues indicate starvation, while the finding of a dead queen shows me that I have to overhaul the colony as soon as the weather will permit. To make this kind of examination it is necessary, of course, that the floor board be scrupulously clean when preparing the bees for winter in the fall.

I make the end-piece higher than the sides of the bottom-board so that it extends up on the back of the hive.

#### ENTRANCE-BLOCK.

I make my entrance cleats  $1\frac{1}{2}$  inches wide, and take care that they do not fit too tight, else when swollen by the rains I would have too much difficulty in removing them. If necessary I fasten them to one of the sides with a small wedge. These wedges often are handy, as, for instance, in giving a

Hamelberg's hive-bottom. A, entrance cleat for winter. B, entrance cleat for summer. C, galvanized iron piece to close either entrance of B. D, back cleat opened.

little super ventilation or in fastening Alley traps to the entrance.

I have a vertical saw-kerf in the block on either side in which I can slip a strip of galvanized iron. When not in use this strip is simply turned up in a vertical position against the hive so that it will not get lost.

For winter I use special entrance-blocks the same dimensions as the other, but with

an opening of only  $\frac{1}{4} \times 2\frac{1}{2}$  inches at one end, so that the entrance will be at the right side of the hive.

#### HIVE-STANDS.

My hive-stands are like those commonly used in the United States, consisting of four pieces of inch material nailed squarely together. I strengthen these frames, however, by nailing triangular blocks in the corners. I have these stands supported on legs about eight inches long so that I can put my feet underneath. This is very convenient when lifting heavy supers.

Before nailing the hive-stands together I soak all the lumber for twenty-four hours in carbolineum so that the stand will last for years before showing any signs of decay. I can not recommend this disinfectant too highly for all wooden structures that come in direct contact with the soil.

#### SUPER-COVERS.

My super-covers have a hole in the center to fit the mouth of a common fruit-jar. Besides feeding syrup I also feed rock candy, and the holes in the boards answer very well

for this also. In mild winters, when the bees consume a great deal of stores, I sometimes fear that they have too little to last until spring, then I feed candy cakes made after the recipe in the A B C and X Y Z of Bee Culture.

In January we often have one or two fine days when the thermometer rises above 50 degrees, when the bees have a chance for a cleansing flight. On such occasions I scrape the peat dust (the packing material in the super) to one side, thus uncovering the thin board that rests over the hole in the super-cover above mentioned. Then I can replace the thin board by a cake of candy (about 6 pounds) which I cover with a piece of burlap and scrape the peat dust back over it. This takes less time than to tell about it, and the bees are very little disturbed.

A further advantage of the holes in the boards is that they enable me to take a hasty glance at the interior of the hive at times when it is too cold to overhaul the brood-nest.

Soest, Holland.

## SANITARY CONDITIONS IN THE BEEYARD

BY J. E. JORDAN

\* Much of the bee disease of today is spread by the unsanitary conditions tolerated by beekeepers. Many give the matter no thought whatever; some know just enough about bees to take the honey from them, and do not think that there is any more to learn. Sanitary conditions are just as important in beekeeping as elsewhere. I think the greatest thing that could happen would be to devote a certain day or week of each year to *cleaning up*, all the beekeepers to get busy on that day.

In getting things sanitary, first look into the location of the apiary. Are the grounds clean? Cleanliness is next to godliness. I have found it best to place the hives so that the sun will shine on them during the whole day. The rays of the sun are known to kill many germs. I do not advocate shade here, as some bees are inclined to be cross in a cool shady place and will not work as early and late as those in the sun. Of course if in a hot climate a little shade during part of the day is desirable.

See that the hives are well up off the ground, so that plenty of air may circulate under them. Never let grass grow so tall in front of the hives that the bees can hardly get in and out. Keep the grass clipped short; and if you haven't time to mow it

yourself, put a few sheep in the apiary and they will keep it short for you.

When examining a colony, and the frames have burr-combs on them filled with honey, do not allow this honey to drip to the ground to attract other bees. Hold the dripping frame over the hive so that the bees of that hive will take care of it. If you wish to scrape or cut off the burr-combs do not throw them out in the yard. Put them in a lard-can fitted with a tight cover. Do not give other bees a chance to get at these wet burr combs, as it will be more than likely to start robbing.

Never leave combs, fixtures, or tools on the floors where people have to walk; for if you have visitors, and they happen to be beekeepers who are careless, germs from diseased honey or combs may be on the soles of their shoes. Shallow steel pans are fine for holding supers or combs; but old newspapers are cheaper and better than the pans, as they can be burned when soiled.

If an inspector comes to your place to examine your bees, have him wash and disinfect his hands and tools before beginning his work. Have this done in your presence—do not take his word for it. A good many inspectors obtain their positions thru

political pull, and know very little about bees. These are more likely to scatter the disease than to clean it up. There are many fine inspectors who are doing a world of good, and who are experts in their line; but for fear that one of the careless kind may happen along I have given this word of caution. We want good inspectors; so when you find one who is not doing the work properly, report the matter at once.

Shippers of extracted honey in barrels should see that these barrels are perfectly tight and that no honey adheres to the outside. Leaky barrels are very dangerous, as the car in which they are being

shipped may be put on a siding and remain for days, allowing bees in the vicinity to rob the honey. This also happens on the platforms of stations and in the wagons which carry the honey from the station. I believe that if a national law could be passed to prohibit the use of barrels in shipping extracted honey we should be able to keep our bees in a better condition. Nothing but *tight tin cans* should be used. It would be a good plan to have extra outer cases for section honey. to catch the drip should a section get smashed.

Morgan, Ky.

## COUNTING THE COST OF SUGAR

BY JOSEPH GRAY

We never feed in this locality. The discussion regarding the feeding of sugar is of vast importance. Let me take J. L. Byer's statement, page 1016, Nov. 1, "with a good flow from buckwheat, say 40 to 60 lbs., even the Jumbo hives will need feeding after supers are off." Buckwheat honey is a poorer grade than clover. Figure the cost of taking off that honey and marketing it. Again, figure the price of sugar, and freight on the same—labor of making into syrup, and time occupied in feeding.

We leave sufficient honey to carry the apiary thru. When we get to our last extracting we estimate by previous experience how much will be needed. If we decide it is necessary to leave four full combs in the super, four are left; or if it is a question of apiaries, possibly four out of ten apiaries are not extracted the last time.

We motor to a yard; and with a long box holding 40 combs we pick up full combs and

replace with empties. We next go to a yard needing feed. The hives are hefted, and those needing stores are fed by exchanging full combs for empties. If necessary to go below we do so, and a bucket of mud is used to close the joint between the brood-nest and super and *destroy the scent*. A sharp eye is kept for robbers, and every caution taken to insure against them. On some days we can work right along; on another day it will not be two hours before it is necessary to stop. Sometimes we can work well part of the day, and during the rest of the day be unable to touch a hive. Much depends on the bees. With an auto, if we can work only half an hour at one apiary we close up and motor to the next.

I think if some of the beekeepers will stop to figure out the cost between a low-grade honey and a feed-bill they will be likely to cut out the latter.

Heber, Cal.

## LAWS TOO DRASTIC COULD NOT BE ENFORCED

BY HARRY LATHROP

In the June first issue, page 425, appears an editorial, "Legislation too Drastic." I wish heartily to second this. Relative to laws regarding the sale of honey from apiaries in which American foul brood exists, I once asked in our Wisconsin convention what a beekeeper would do with a crop of forty thousand pounds of nice extracted honey if the discovery should be made before marketing that foul brood actually existed in the yard. The only answer to such a question is, "Sell it." There is no other common-sense answer. Much of the

extracted honey placed on the market in certain parts of the West and of the East during the past ten years has been produced in yards where foul brood existed. Foul brood in the brood-chambers does not affect the purity, for food purposes, of honey produced over queen-excluders, and no chemist on earth could tell which is so produced and which is not.

I have had opportunity to observe American foul brood closely for a number of years, altho I think my apiary is now free from it. The disease is not very contagious

unless the hives are so neglected that bees from healthy colonies are allowed to rob weak or dead foul-broody colonies. Honey from the extracting-supers will seldom propagate the trouble. Extracting combs cleaned up by the bees and placed away dry will not cause foul brood thereafter. Hive-bodies that are perfectly dry and clean will not spread the disease if used for clean stock. Frames from which the comb has been boiled in a melting-vat are safe to use again, and need not be destroyed.

American foul brood need not discourage any one who attends properly to the bees. It will ruin a neglected apiary if time enough is allowed.

The wintering problem is the question of greatest importance with us. Dysentery will destroy more bees than foul brood on the average. It reduced an apiary of 140 colonies to one of 30 for me in one winter. Foul brood never was that bad in my experience. So far as legislation is concerned, it would be an easy matter for an official to forbid a beekeeper to sell a nice crop of honey that had been produced in an infected apiary; but if the official should happen to discover it in his own yard the case would look different. Laws not founded on common sense will not be enforced in this country.

Bridgeport, Wis.

## THE REASON FOR THE DRONE-LAYING QUEENS

BY A. C. AMES

On my inspection trips among beekeepers over the state I find some complaint in regard to queens purchased from queen-breeders, turning out to be drone-layers. The complaints have been directed against men whom I am personally acquainted with, and whom I know to be among our very best queen-breeders. It is possible for a well-meaning queen-breeder to send out unintentionally a drone-laying queen as an untested queen.

To illustrate: I wish to describe a case that occurred in my home yard this season.

I had produced a batch of fine cells and used one to requeen a colony that had a failing queen. In due time the cell hatched, and on one of my visits home some three weeks later I found the queen to be laying; and as she was a very fine-appearing queen I took it for granted that *that* colony was in good condition or soon would be. On account of being away from home almost continuously I am sometimes unable to give my bees the attention they should have.

On my last visit home (Sept. 22) I

Home of O. B. Griffin, Caribou, Me.

noticed from an entrance examination that that colony did not appear very strong, and that the bees flying were all old ones. I examined the colony and found the greatest amount of drone brood I ever saw in one colony, without a cell of worker brood. I am certain that that queen never mated, and, as a result, never produced a worker bee. Judging from appearance alone one would consider that queen very good. She must have been confined to the hive by bad weather. I examined her for a defective wing, but the wings seemed normal.

The past summer has been for the most part rainy and cold, and there is probably more of this kind of trouble than usual.

Peninsula, Ohio.

## BEES IN A SOLID MASS SIX FEET HIGH

BY O. B. GRIFFIN

The picture shows the largest swarm of bees I ever took down. This swarm was hived in July, 1915, and consisted of six or more swarms all in one cluster. From the ground to the highest point it was 6 feet 4 inches in length. The extreme width was 4 feet 2 inches. Where the cluster was solid it measured three feet thru, altho the smallest diameter was only  $4\frac{1}{2}$  inches at the ground. It was certainly a magnificent sight to one who loves bees. I divided the swarm and hived the divisions, but they

A mammoth cluster of bees, six feet high, made up of six swarms that settled together.

made quite a bit of trouble before they were settled to stay.

Caribou, Me.

## IS IT BEST TO HAVE ONE DOMINANT RACE OF BEES ONLY?

BY T. T. TAYLOR

There have been frequent discussions regarding black bees versus Italians. In the March 1st issue for last year the editor says that the blacks seem to be the dominant or persistent variety. This suggests to me that a wider and more important question can be raised here than that of whether the black or the Italian bee is the better. This question is: Is it desirable to have a number of varieties and hybrids, as at present, in any country, or only one dominant variety? This is not a question for beekeepers of the United States only; it is a question which, I think, should be considered by beekeepers of all countries where there is more than one variety. In fact, I think this question pertains more to other countries than to the United States, where the Italian bee is so popular, tho apparently not the dominant one. I will put my

arguments in favor of this question in a few numbered paragraphs which, I think, involve more or less the conclusion which I draw from them—namely, that it is best to have only one dominant variety in certain countries if not in all.

1. The aim of beekeeping is predominantly an economic one. It is the gathering of honey, a food which is otherwise going to waste, in the largest quantity and with the least effort. In other words, the predominant aim is monetary profit. Personal pleasure, hobby, or the color of the bee, are but secondary considerations.

2. If all the varieties of bees in a country were left to interbreed and compete, a single variety would in most cases, if not in all, be produced which we should call a dominant variety because of its being a resultant survival of all the others. Only

one variety, the best, all things considered, is required. Such a dominant variety would tend to become fixed in its characteristics; but it would always be capable of very considerable gradual and permanent improvement by elimination and selection.

3. Tho there is much difference between the different varieties in honey-gathering, swarming, disposition, etc., there is not so much difference between the economic results of that which we may call the dominant variety of certain countries, and the best imported variety or improved strain. We are, perhaps, as likely or more likely to obtain a better bee by consistently improving the dominant variety than by improving any other variety or by producing hybrids.

4. Bees differ from other domestic live stock, such as cattle, in that we cannot control their mating and breeding to the extent that would enable us to maintain a non-dominant variety as our sole variety. That is, so long as we continue to breed non-dominant varieties we must always expect to have along with them numerous mongrels of undesirable quality; whereas if we breed only one dominant variety we should be practically free from such mongrels. The maintenance of the queens of an apiary will, on the present system of cross-breeding, always be a more or less troublesome and costly item; and it is desirable that this cost and effort should be reduced, as it could be if we had only one variety.

5. There may be said to be three methods of improving the bee as of improving plant and animal life generally; namely, by elimination, selection, and hybridization. The hybridization method breaks up the hereditary constitution of the organism so much that we lose one good point while breeding for another. Thus improvements made by the hybridization method are not easily fixed but are easily lost. The hybridization method is unnatural and undesirable except as a means of inducing slight variations to work upon when the stock is too fixed. The eliminative method is slow but sure; the selective method is quicker but less sure. The eliminative method is a safe one because it is comparatively easy to judge what a defect is, and the rest is left to nature. The selective method is not so safe, because, while one may judge a good quality, such as honey-gathering, there are other qualities which may go along with it, such as a tendency to disease, that are not so easily judged. Thus in breeding from one parent on the strength of one or more selected good qualities, we may carry

forward, quite as extensively, a bad quality that is either unrecognizable or ignored. In the method of elimination we rear our future stock from a large quantity of individuals having very numerous points which are intermixed by cross-fertilization; whereas in the method of selection we rear our future stock from comparatively few individuals which may not contain all those points which it is desirable to carry forward. Suppose, for sake of argument, 100 queens of one variety, but each having slight differences of quality. If we eliminate 10 defectives we rear from and carry forward the points of all or some of the remaining 90. If, on the other hand, we rear from two individuals selected for desired points, we leave behind the various points of the remaining 98, and at the same time lose, to a great extent, the assumed advantages of varied cross-fertilization in maintaining vigor. The method of elimination can be and should be carried out by every beekeeper; but the method of selection may be of doubtful future benefit, even when carried out by an expert. In the elimination method we co-operate with nature; but in the selection method we may be fighting against nature. Therefore elimination, the primary method of nature, is still the primary method by which man can adapt domestic organic life to his requirements; and selection, tho more rapid, should be used only in moderation, and subordinated to elimination, for fear of specializing in defects, and inbreeding; while hybridization should be regarded as a dangerous method to be used only occasionally, and in such a way as not to break up the hereditary constitution of the organism.

I do not expect that all the arguments in the foregoing five paragraphs will be accepted. I do not say that I accept them all myself without qualification or further consideration. But considering the argument generally—namely, that the aim of beekeeping is mainly economic; that nature has a tendency to produce one variety in a country; that one variety is sufficient; that there is little difference in the economic results of any of the varieties; that the breeding of bees cannot be completely and continuously controlled by man, and that some of the present methods of breeding are unnatural, and unlikely to result in permanent improvement without accompanying weaknesses, I am inclined to draw the conclusion from them that it would be much better for the present and future of beekeeping, in some countries at least, if beekeepers were to co-operate in improving

that variety of bee which is found to be the dominant one of their respective countries. I think that, in the case of some countries, if only a fraction of the effort that has been expended on importing, producing, and maintaining non-dominant varieties had been applied to the gradual improvement of the dominant variety, greater progress would have been made than has been made in those countries up to the present time.

But this question is not only one of improving the bee, and, thereby, beekeeping; it is one, perhaps, of saving beekeeping from partial disaster. Many plants and animals are now more subject to disease than their less cultivated progenitors were. Why is this? It is not a condition that we should regard as unavoidable in the culture of plants and animals. I think it is due to carelessness in not letting nature have more of her own way. That is, it is due to an insufficient application of the slow and natural method of elimination, to too much selective propagation and in-breeding, and to a mistaken degree of hy-

bridization, thereby breaking up the hereditary constitution of the organism. So it may be in regard to bees. Many beekeepers in the British Isles would give up all thought of improved strains if only they could get a bee that would live at all. It is probable that the reason why Isle of Wight disease is so bad here is that the dominant race has been thus broken up by intercrossing with foreign varieties, thus producing hybrids and mongrels of weak constitution which cannot resist what is, perhaps, only an old-standing bee-disease.

If this policy, which we may call the dominant bee policy, is correct, how can it be carried out? It can be only partly done by legislation prohibiting the importation of bees; for no doubt selected non-dominant strains could be maintained in some countries indefinitely, tho the number of such strains would certainly be reduced. In addition to legislation it would be necessary for beekeepers to co-operate thru their associations in cultivating and improving the dominant variety only.

Acacia House, Beverley, England.

## MICHIGAN STATE BEEKEEPERS' CONVENTION

BY E. R. ROOT

It is impossible to give a detailed report of this convention, on account of the limit of our space; and we can do little more, therefore, than give some of the important points brought out in the discussions.

Mr. David Running, one of the best beekeepers in the state and in the United States, made a most excellent presiding officer. He not only understood the fine points of discussion but took particular pains to draw them out. In some cases he kept the speaker upon the platform, after delivering his address, so that those who desired to do so could ask him questions. This feature, apparently original with Mr. Running, added no little to the value of the address, and at the same time drew out points overlooked or not thoroly understood. The general character of the papers was of the very best, and credit is due to Sec. F. Eric Millen for the excellent program which he prepared.

### HOW MUCH MORE COMB THAN OF EXTRACTED CAN BE PRODUCED?

Some of the beekeepers held that they could produce a half more of extracted—some nearly twice as much. The question received more than ordinary attention for the reason that extracted honey appears to be going up while comb honey is going

down. Whether one could afford to produce comb honey in view of the rising prices of extracted was a fair question to ask. The general feeling seemed to be that both comb and extracted should be produced, but more of the latter, as it is not wise to put all our eggs in one basket. Moreover, there are some colonies that do better for extracted, and others better for comb.

### STRONG OR MEDIUM COLONIES FOR THE PRODUCTION OF COMB HONEY.

Practically all of those present taking part in the discussion agreed that the strongest colonies in the spring are not necessarily the best for the production of comb honey, for the reason that they are inclined to swarm before the actual honey-producing season comes on. On the other hand, medium-strength colonies are at about the right strength by the time the honey-flow opens up, and are, therefore, less inclined to swarm.

### COMB HONEY WITHOUT SWARMING.

Mrs. Wilber Frye, of Sand Lake, Michigan, was pronounced by Pres. Running one of the most successful comb-honey producers in the state. She was called to the platform and asked to give her method of producing honey. It will not be possible

or necessary to give here the full details, because we have asked her to prepare an article for GLEANINGS, telling just how she proceeds. But for the present, at least, we may say that she produces comb honey by dequeening her colonies, then cutting out cells nine days afterward. In answer to repeated questions she said that she could not discover that the queenless colonies were much inferior to those operated by other methods and with queens. She has worked out a system of dequeening colonies for the production of comb honey that seems to give remarkable results in her locality and with her management. She and another woman do all the work, running a series of outyards, producing very fine comb honey, and that, too, without any swarming.

#### DIFFERENCE IN COLONIES IN THE PRODUCTION OF COMB HONEY.

It was clearly shown thruout the discussion that there is quite a difference between different colonies in the production of comb honey. Some that are well adapted for extracted are not fitted at all for comb. Colonies that produce dark-colored cappings, or are inclined to swarm, should be run for extracted. Those that show the best results in previous years in the production of comb should be selected for comb honey.

In this connection the color of the cappings received considerable consideration. Some argued that the dark cappings are caused by too little ventilation. Others held that the strain of bees and the season have something to do with it. It was stated that a slow flow causes darker-looking comb honey than where the nectar comes in rapidly.

#### EFFICIENT BEEKEEPING.

This question was handled in a masterly manner by Mr. E. S. Miller, of Valparaiso, Indiana. Mr. Miller called attention to the wasteful methods employed by many beekeepers, and he explained how, by the use of proper tools and equipment, with the right kind of planning one may very greatly increase the crops with the same labor. He mentioned a case particularly of one beekeeper who was kept busy thruout the season taking care of 60 colonies, while another, his successor, took care of 400 colonies in the same locality, with an expenditure of time equivalent to only two days in the week, the rest of the time being devoted to another business. This called forth a lively challenge from several, and then it developed that Mr. Miller was the man who was able to accomplish the feat. Mr. Miller is manager of a local telephone

company, and is not only a trained business man but a good beekeeper. Just how he is able to accomplish so much work with so little labor he will explain later on in GLEANINGS. When the question was raised whether it was possible for him in so small an allotment of time to do good work among so many colonies, a neighbor of his, Mr. Bull, said he actually knew that he did do it.

#### CHOOSING A LOCATION.

This was admirably handled by Ira D. Bartlett, of East Jordan, Mich. In the order of their importance he puts the man first, location second, equipment third. The locality and the man must work together. The flora is of paramount importance. It is desirable to have a succession of honey-producing plants to build up the bees in the spring, to provide good forage in the height of the season when the main crop is secured, and a fall flow if possible to put the bees in proper condition for winter. A protected spot in the locality is essential. He would have woods or shrubbery around the apiary, not only to protect the bees but to give them an opportunity to get out in early spring to get pollen. Proximity to water is important, but he avoids putting the yards in a low damp place. If possible the locality should be where there are good roads, churches, and schools. He does not place the bees too near a lake or stream. Many bees are lost by dropping on the surface of the water.

A southeast or southern slope is best. The apiary should be placed on the upper part and the honey-house and buildings on the lower. Mr. Bartlett places the hives in long rows for convenience in shoving a wheelbarrow from one hive to another when loading on supers. When asked whether bees placed in long rows do not drift more or less he admitted that this might be true, but his hives are far enough apart (ten feet) so that it does not cause any trouble.

#### A SCHEME FOR EQUALIZING COLONIES.

Mr. Bartlett then went on to tell how he had equalized his colonies one season by putting a weak one in place of the strong, causing the flying bees of the strong to join the weak. He admitted that this required a great deal of care to prevent some brood from being neglected in the stronger colony; but he never made it a practice to equalize them except in warm or hot weather.

This brought out considerable discussion, but thru it all Mr. Bartlett held his point well. We have asked him to describe

his methods more in detail. He is a busy man; but if we can get him to write we know our readers will be pleased with what he has to say.

#### THE SALE OF HONEY.

This question was handled by Mr. E. D. Townsend. While he admitted that honey could be sold by the producer to the jobber, yet the objection to this method is that it has to go thru two or three hands before it reaches the consumer. He rather favored selling to the consumer direct. He puts up his honey in friction-top pails, five and ten pound sizes, the former selling for 85 cts. and the latter for \$1.60. If one sells the honey at wholesale he should sell to the one who sells to the consumer.

Mr. Townsend was asked whether he was a friend of the grocer when he sold his honey in pails from house to house. He replied by saying that the grocer does not object if producers do not undersell him. Then the question was asked whether, at the present price of extracted honey at wholesale or jobbing, a retail price of \$1.60 for a ten-pound pail, pail thrown in, is not too low. At this point Mr. R. F. Holtermann, of Brantford, Ontario, made the statement that many beekeepers are not business men; that too many of them retail and wholesale honey at a time when the difference between wholesale and retail is often very small—so little, indeed, that the wholesaler has no encouragement in buying honey to sell again. He believes that one should sell to the jobber at jobbing prices, to the wholesaler at wholesale prices, and to the retailer at retail. When asked how much honey he produced, Mr. Holtermann stated that his crop last year was five ear-loads, and that he sold thirteen more. He sells only to the jobbers—not to the retail trade.

After Mr. Holtermann had closed there were two or three who took exceptions to his statement that the average beekeeper is not a business man. But Mr. Holtermann hung to his ground. He considers the middleman a blessing in disguise, not "a necessary evil."

Mr. J. F. Moore, a large honey-producer in Ohio, felt that there should be no clash between the two systems of selling. At this point, Mrs. Wilber Frye, of Sand Lake, Michigan, stated that, while she formerly sold her comb honey at 12 cts., she now sells to the jobber at 13½, the jobber taking the entire crop off her hands and paying cash.

Every now and then a joke was fired at Mr. Holtermann for saying that the average beeman is not a business man,

#### SUCCESSFUL FEEDING IN A CELLAR.

While it is usually regarded as bad practice to feed in a cellar, yet Mr. Leonard Griggs, of Flint, Michigan, successfully fed 58 colonies three days after he put them in the cellar, and they all came out in fine condition in the spring. The cellar is first warmed up with an oil-stove, so it is about the temperature of a living-room. He takes ordinary ten-pound pails, punches small holes in the top, fills them with a thick syrup, and gives the syrup (hot) to the bees on top of the brood-nest. The syrup is all taken down in two or three days, and then the feeders are taken off.

#### THE POSSIBILITIES OF THE COMBLESS PACKAGE.

This was discussed by A. G. Woodman, of Grand Rapids. He has had very satisfactory results getting bees from the South early in the spring, and has almost come to believe that a beekeeper could afford to let his bees die after securing the main crop, sell the honey, and then buy bees in combless packages early in the spring to fill up his hives. Three pounds of bees in a hive by the first of May give a nice start; and the rapidity with which the queen lays in these combs soon builds up a good colony. In a good season a pound of bees pays for itself well. The feasibility of the pound-package business depends somewhat upon the price at which the bees can be delivered in the northern states. Mr. Woodman thinks that \$3.00 for three pounds of bees and a queen is a fair price; and if they can be secured at these figures one ought to make a fairly good return on the investment.

While in Canada a few days ago we ran across a beekeeper who from eighteen 1-lb. packages of bees and a queen secured 1800 pounds of honey, and 18 colonies fit for wintering packed outdoors. While this was quite a remarkable record we heard of a number of instances at the Michigan convention where others had done quite as well.

#### PROTECTING COMBS FROM THE MOTH-MILLER.

One of the questions from the question-box was what to do with wet extracting-combs just from the extractor. President Running made the suggestion that they be placed in a cool cellar. The temperature of the cellar he said is too cold for the eggs of the moth-miller to develop: that as soon as cold weather comes on, if the combs are taken out a freezing kills the eggs. This is quite a valuable point that many beekeepers would do well to consider.

On the evening of the second day a

banquet was served by The A. I. Root Company, of Medina, Ohio, and M. H. Hunt & Son, of Lansing, Michigan. This was served at the Baptist church. About 150 were present. Among those who responded to toasts were President Francis Jager, Chief of the Division of Bee Cul-

ture, Department of Agriculture, University of Minnesota, St. Paul; Mr. F. Eric Millen, formerly foul-brood inspector for Michigan; Mr. B. F. Kindig, and Mr. Morris.

Numerous prizes were offered for best displays of honey. At this writing we have not received a list of the winners.

## LETTING THE BEES FASTEN THE FOUNDATION

BY M. JOHNSTONE

Enclosed find an illustration of a method of fastening full sheets of foundation without using the groove or wedge. The method permits the use of a shallow top-bar. This is experiment number twelve, issued by the Apicultural Department of the Ontario Agricultural College, and originates with Professor Pettit.

As seen in the illustration the wiring differs from the ordinary in that the top wire is comparatively close to the top-bar (one-half inch), and is fastened in the center of the top-bar by a small staple. The wire otherwise is used as in the ordinary method with the precaution that it must be drawn tight.

The foundation is placed in position on a board the size of the inside dimension of the frame used. The wired frame is then laid on top, the sheet of foundation being pressed firmly against the top-bar; and while in this position it is imbedded firmly.

For some time I have felt the inconvenience of the wedge-and-groove system for extracted honey. The wedges are difficult to drive in firmly, and the sheet of foundation is likely to buckle in putting in the

groove, especially when one is hurried so that it is a relief to turn to this method and fasten so firmly and neatly. Of course the bees do the fastening, perfect combs being obtained in the brood-chamber as well as in the supers. These were obtained the last season in a good flow, which likely would be one requirement.

The method has an added advantage in that broken combs may be replaced without the necessity of digging out the grooves or removing the wedge. The shallow frame also gives the use of two more rows of cells ordinarily occupied by the deeper bar.

Cayuga, Ont.

## STATISTICS FOR ONTARIO

BY J. L. BYER

In an article in a recent issue of the *American Bee Journal* Mr. Geo. Kingsmill, of Guelph, gives some startling figures as to the honey production of Ontario this past season. He states it is estimated that there are 10,000 beekeepers in Ontario keeping an average of 30 colonies each—a grand total of 300,000 colonies. With this year's estimated average of 89.6 pounds per colony, that would mean 25,880,000 pounds of honey — I figure it out at 26,880,000 pounds; but a million is not much one way or the other in dealing with figures of this magnitude. He goes on to say that it would take between eight and nine trains

of 50 or 60 cars each to carry the crop if all were marketed. Here I again figure that, counting cars of 25,000 pounds each, it would take 1075 cars to hold the honey, and that would take about 20 trains, each of 50 cars, to handle the product.

But my purpose in making these comments on friend Kingsmill's article was not primarily to try to "figure" differently, but to confess honestly that I was amazed at the magnitude of honey production in Ontario, assuming that the figures are anywhere near correct. Personally I think the estimate too high; for among thousands and thousands of colonies not reported, but

"estimated," I have an idea that the average would be away below the 89.6 pounds mentioned. I base these opinions from conditions locally; for while the crop was extra good here this year in our county, yet I know of many neglected lots of bees that produced practically nothing in the way of surplus. But making allowance for a great falling-off in the estimate, the fact is apparent that there was "some honey" produced in Ontario this year—no mistake about that. Bear in mind that the figures are for Ontario alone. The maritime provinces produce quite a lot of honey, and Quebec still more if I am correct. The western provinces also produce quite a quantity—this year the crop was good in parts of British Columbia and other western provinces as well. A lot of honey is imported from the British West Indies each year—largely by the baking establish-

ments. Summing all together, an enormous amount of honey will be used in Canada this year, as practically none is exported. Considering the population of Canada, I wonder if we are not entitled to be classed as being among the greatest honey-eating nations of the earth. Many beekeepers, and the writer is among them, feel that but for abnormal conditions this year caused by the war, poor fruit crops, etc., the market would have tumbled—in other words, the supply would have more than equaled the demand. As it is, honey is practically the same price as before the war, while many—in fact most—other foodstuffs have advanced from 20 to 100 per cent or more. Under present conditions this year, honey is being used extensively in hundreds of homes that previously hardly knew the taste of it, so the advertising we are obtaining should be worth something.

---

## WHEN JOHNNIE COMES CALLING

BY FLORENCE B. RICHARDSON

"Johnnie" is an ex-circus clown who came to this "neck of the woods" a few years ago with the avowed intention of "showin' these fellers how to keep bees!" He came well prepared with his beautifully made and ornamented *box* hives, painted a lovely shade of some bright color. Green is his favorite at present—a real green, too.

The first real shock to his enterprise came when the county bee inspector warned him to put his little pets into movable-frame hives and gave him ten days in which to do so. Mad? Why, he is said to have buzzed about like a hornet whose nest has been destroyed; but he obeyed orders, much to his chagrin, altho he had to hire the inspector to do the transferring for him, as he had no idea of the method of procedure.

Johnnie came to call on me, not knowing that I knew anything about bees, and in his inimitable way proceeded to introduce me to the first principles of beekeeping, when he caught sight in the back yard of a box hive I had just bought and hadn't had time to transfer.

He began by saying, "Great country fer bees;" and when I agreed with him he continued, "Know much about 'em?"

I admitted not knowing it all, and then Johnnie launched out on his hobby. He looks funny while talking earnestly, and any one would know by just a glance at his queer little face that his idea is to help and not alone to appease his vanity.

"Tell ye one thing;" and the stubby first finger of his right hand beat time to each word in the palm of his left; "ye'll haf to move them bees onto them boxes, and do it *pronto* or thet bee feller will make ye do it!"

With this information he looked up at me very knowingly, and slowly winked one eye.

"Yes, Johnnie," I told him, "I'm going to do that very thing just as soon as I can get over to town to get a smoker."

"No need to go to town a-tall," he answered; "got a puffektly good smoker down to my place, and yer jest as welcome as ye can be."

"Well," I said, "I've also got to get some frames wired," and—I got no further, for Johnnie broke in with a snort:

"Now, ma'am, don't ye go gittin' foolish like thet! Why, them wires is the worst things ye can put inter hive. They jest plays all kinds of tricks, and they'll make ye all kinds of trouble."

"But why?" I asked. "Every one who keeps lots of bees in the East wires the frames and there is no trouble."

"Well, now ye've *hit* it. East is East, and California is California. Now," with a knowing twinkle, "I tried thet wirin' business once, and I *know* what I'm a-sayin'. Why, I had the combs melt right down jest 'cause them tormented wires got so hot!"

"But, Johnnie," I protested, "how do

Fifty-first convention of the Michigan Beekeepers' Association, held at Grand Rapids Nov. 29 and Dec. 1. See report pages 1173-1176.

you know it was the wires that melted your combs?"

"How did I know? Well, what else could hev done it? Never had no others melt, and you know 'swell' as I do that them wires attracts heat!" This was said with a finality that brooked no dispute.

"But how can honey be extracted from frames that are not wired?" I asked, wondering what possible reason he could offer; and it was a typically Johnnie remark, given with a grin which showed the absence of a couple of front teeth.

"Well, ma'am, I'll tell ye. I ain't never done no extractin'; comb honey's good 'nuff fer me!"

I must have looked either convinced or beaten, to judge by the smirk of self-satisfaction he gave me.

This was my first lesson from Johnnie, but not the last. His smoker talk was to me a keen bit of enjoyment, altho to this day he doesn't know it, and I hope he'll never find out!

"Now, ma'am," Johnnie's usual approach, "never try to light that smoker frum th' top, fer she jest won't ketch, and

ye'll fiddle away a hull forenoon, may be, 'fore she gits agoin'."

"No, Johnnie," I said, "I always——" I had forgotten for the moment that I knew nothing. "I'll try it from the bottom;" and to hear out my statement I tried to insert a match in the air-hole at the base.

"Here! here!" he cried in alarm; "ye'll spoil that whole contraption if ye do that. Them smokers is funny things—jess like my ole mule, contrary as n'thing. Now this thing here," taking hold of the bellows, "fills up with air;" and when I looked innocently up and inquired, "Hot air, Johnnie?" he answered:

"Oh! no, ma'am, any kind of air," altho he is not usually slow at a joke. When he is giving instructions, however, he is too much in earnest to pay any attention to such feeble attempts as this.

He continued, "Well, ye pull them sides together this way, and it blows air inter the can part; and ye see if ye light her from the top all yer fire goes out the smoot 'stead of lightin' the rest of it. Now I takes a chunk of gunny sack"—who in California would be guilty of saying burlap?—"and I lights

the fringie place on the edge, then drops her in quick and pumps like all Sam Hill on them bellers, and fore ye know it ye've got some smoke."

This whole performance had been acted out for my benefit; and if Johnnie ever made the *hit* as a clown that he made with me I can't understand his escape from the circus manager.

"What's this little jigger on the side of the bellows?" I asked him.

"Oh! that—well, I'll tell ye. I ain't never been able to find no real use fer that. It's always in the way, and I've threatened to take it off, but knew it must've been put on there fer sompn'."

"Wouldn't it be to hang it up by? Looks to me as tho it might just bang beautifully on the side of a hive."

"By jings! I bet ye've struck it, and here I've ben a bustin' my back reachin' fer the thing when it orter ben right there all the time."

On raising queens and controlling swarming Johnnie has his own ideas—or, rather, he believes in letting "nater" do it for him.

"But, Johnnie," I protested, "you must

lose lots of swarms. You're not always here to see to things, are you?"

"Well, now, I'll tell ye. Sometimes I *do* lose a swarm; but, Lor' bless ye, what's losin' a swarm to disturbin' the poor critters every few days? and I'll tell ye I don't hev much faith in this business of keepin' bees from swarmin'. 'Cordin' to my notion the more ye fuss with 'em the more they swarm! An' look at that feller over here, fiddlin' away raisin' queens' (contemptuously): "why, they ain't no good after he's raised 'em, fer it's good deal better to let nater raise yer queens 'stead of puttin' in a stranger that may be will be crosser than m——m!"

Johnnie takes off no honey until fall, and then has nothing but section honey, which is so cheap here that it seems a crime to waste the bees' time making it; for wax is as high as it is anywhere, and he could increase his hec income four fold by extracting. Years when other people get a big crop of extracted, Johnnie complains of a poor yield, and shakes his head unbelievably when he hears of some other fellow's big crop.

Hughson, Cal.

# Heads of Grain from Different Fields

THE BACKLOT BUZZER

BY J. H. DONAHEY

*Jerry Aster thought he was all thru with his extracting for the season till his new truck he had loaded with comb honey got a skiddin' on the asphalt pavement. Jerry says it went around so fast that he not only lost all his cargo but a set of upper teeth besides.*

## SONNET ON THE PASSING OF A YEAR.

BY GRACE ALLEN

And must we bid you too farewell, dear year,  
 And see you pass with drooping aged head,  
 Tho with unhesitating stately tread,  
 Down long dim paths the timid-hearted fear?  
 Aye, go you must, you too, however dear,  
 And pitch your tent among the quiet dead  
 Of numberless forgotten years that fled  
 Long since across our world of Now and Here.

Yet not uncomforted we see you pass.  
 Our hearts have let us know this thing is true;  
 Tho Time may trail his garments o'er our grass,  
 The things he claims shall God Himself renew.  
 And nobler than the old the new shall be,  
 New years, new faith, new life, eternally.

## Western New York Meeting.

The Western New York Honey-producers' Association held its annual meeting at the American Hotel, Akron, Tuesday, Nov. 14. The attendance was large, and the meeting proved the most interesting and profitable in the history of the association. Nov. 14 was known as "Honey day" in Western New York for 1916.

Many new members were enrolled at the meeting, and the association is in a very flourishing condition. According to all reports the honey produced by its members was sold at a good price. There seems to be an increased demand for honey produced in western New York.

Bees are in fair condition for winter, and clover conditions are about 75 per cent.

The morning session, Nov. 14, opened at 10:30. The secretary and treasurer made their reports, and the assemblage then discussed how, when, and where to buy supplies.

At 1:30 the afternoon session was called to order. Discussions of the regulation of field meetings came next, and we voted to make the field meeting a general basket picnic, each member inviting his customers to attend and enjoy a good time. Delegates to the state meeting were then elected.

"Do we co-operate as we should for our mutual benefit?" was the title of an interesting talk by Charles Stewart, of Johnstown, N. Y. Discussions and questions followed.

"Why I Produce Extracted Honey Only" was the title of a subject by J. Roy Lincoln, of Niagara Falls. Jas. Srout, of Gasport, spoke on outdoor wintering, and discussions followed. "Acting as Our Own Commission Man" was the title of a subject by Mr. Meyers, of Ransomville. Mr. J. N. DeMuth, of Pembroke, spoke on queen-rearing nuclei, and also exhibited an outfit. Mr. G. C. Greiner, of La Salle, N. Y., spoke on necessary and unnecessary appliances around the apiary. Mr. Greiner handled this subject in a very satisfactory manner, for he is a man of many years' experience with bees.

The present officers were re-elected for the ensuing year, as follows: President, John N. DeMuth, Pembroke; Vice-president, J. Roy Lincoln, Niagara Falls; Wm. F. Vollmer, Akron, Secretary-Treasurer.

The next field meeting and basket picnic is to be held at the apiary of Vice-president Lincoln, at Niagara Falls. The date will be announced later. John N. DeMuth.

## Then the Moths Can't Get Them.

Mr. Byer's difficulty, p. 1016, Nov. 1, as to saving combs from the moths and still getting the brood-nest in shape for winter without much feeding (some years none) may be met by placing the brood-chamber on top of the super after the main flow is

over. This will give the bees room, preserve the combs from moths, and send the fall honey (if it comes) into the brood-nest. If more is gathered than is needed it will be stored in the super below, to be carried up into the brood-nest later on. This is the way I managed 20 years ago. It is some work; but the knowledge that the honey is stored where it is needed, and that your combs are safe, pays for the trouble.

On page 906, Oct. 1, Mrs. Allen speaks of a swarm deserting a shallow hive because the hive was not shaded. Possibly the hive was too small in the judgment of the bees. I wish Mrs. Allen would try putting an empty super under the hive for 24 to 48 hours till the swarm has cooled off, and is down to business.

Toronto, Can., Nov. 10. F. P. Clare.

### How I Tighten the Wires.

I read Mr. Niver's description of his plan of wiring frames, page 323, April 15; also a number of similar plans that provide for pushing in the end-bars while wiring to insure tight wires. After trying that plan I found it quite hard to bend the end-bars without injuring the frame.

I use a wide board like a hive cover, and drive two nails to hold the top bar, and then another to spring the bottom-bar down, which causes the wires to be tightened when released.

W. C. Campbell.

Grant City, Mo., April 26.

### An Insoluble Whitewash.

Unless it is something old, which I have not chanced to see, the readers of Gleanings may be interested in the following clipping from the Pacific Homestead. It may be similar to the "powdr paint" which has been mentioned recently.

"In one of the foreign countries a whitewash is used which will not rub off, it being prepared as follows:

"Dissolve two pounds of ordinary glue in seven pints of water; and when all is dissolved add six ounces of bichromate of potassium dissolved in a pint of hot water. Stir the mixture up well, and then add sufficient whiting to make it up to the usual consistency, and apply with a brush in the ordinary manner as quickly as possible. This dries in a very short time, and, by the action of light, becomes converted into a perfectly

insoluble waterproof substance which does not wash off, even with hot water, and at the same time does not give rise to mold growth, as whitewash made up with size often does. It may be colored to any desired shade by the use of a trace of aniline dye or powder coloring, while by the addition of a small amount of calcic sulphite it: antiseptic power is much increased."

L. L. Sechrist.  
Fair Oaks, Cal.

### Winter Cases for Seventeen Colonies.

When putting my bees in winter quarters I first filled three long winter cases which hold 17 hives. These have dry, tight,  $\frac{3}{4}$ -inch floors, eight inches from the ground. The hives are arranged carefully on these floors, then the entrance "tunnels" are put in place. The sides and ends are set up, hooked securely, and straw and clean chaff closely packed around and above the hives. Lastly the roof is put on and nailed securely. The roof is made of  $\frac{3}{4}$ -inch tongued-and-grooved siding or flooring, which is covered with three-ply asbestos roofing nailed on with tin caps and short, heavy nails. These houses are cheap, dry, wind and chill proof, and save wonderfully in stores and winter loss.

The remainder of the colonies are wintered where standing, by first jacketing with heavy, double manilla paper, and lastly with a double roof made of a large piece of asbestos roofing laid loose on top of the hive, and held in place with brick or heavy stones. With plenty of stores in the brood-chamber, and a burlap bag filled with clean chaff in an empty super, the bees winter all right.

Covington, Ohio.

### A Drone-Laying Queen Becomes Fertilized.

Some time in June I had occasion to shake a swarm from a single-story hive; and the combs having a surplus of honey I placed over a weaker colony with an excluder between, intending to use them as an extracting-super. Not giving the colony any attention until the season for extracting arrived I was much surprised to find the queen in the brood-chamber had been superseded, and the only laying queen in the colony had been bred in the super; and having no exit to allow of a mating-flight she was laying eggs producing only drones.

The queen was from my best stock, and I caged her a few days to figure out an opportunity for testing whether a practical plan of having her mated were possible. About the third day after caging I found a nucleus that was suited to make the trial, it having had neither queen, brood, nor eggs, for a week or ten days.

The queen began laying the day after introducing, and her eggs hatched worker brood or bees. None of the brood had emerged from the combs where she had previously laid, so her activity as a layer had not been long continued.

Howardsville, Va.

B. F. Averill.

# GLEANINGS FROM QUESTIONINGS

L. P., Ryors, Mo.—When is the best time to sow buckwheat for the bees, and what variety is best?

A. The first week in July is considered the best time to sow buckwheat. The Japanese buckwheat has been preferred for a good many years, altho of late the silverhull has given the best results in honey.

W. J. N., Cleveland, O.—What are the names and addresses of good French, German, and English bee magazines?

A. Schweizerische Bienenzeitung, Editor, Hans Moos, Sonneggstrasse 61, Zurich, Switzerland. German.

Deutsche Imker aus Bohmen, Prague, Bohemia, Austria. German.

British Bee Journal, 23 Bedford St., Strand, London, England.

L'Apiculteur, 28 Rue Serpente, Paris, France.

L. P., Ryors, Mo.—Which is the best method of keeping bees in the summer—under a good shade or in a regular bee-shed?

A. Partial shade is better than either plan. Small grapevines at the south of each hive to afford partial shade during the heat of the day are preferable to anything else, altho the majority who find some shade necessary use shade-boards to prevent the hives from becoming too hot.

W. F. B., Akron, N. Y.—Do black, hybrid, or Italian colonies affected with European foul brood ever rear queens naturally and have the queens mature? If artificial methods of queen-rearing are used, the larvae in the queen-cells usually develop the disease, even if pure Italian stock is used. Is this a rule or an exception?

A. Our Mr. Pritchard says that when he was in Virginia he grafted cells in a colony that was quite badly affected with European foul brood, and he succeeded in raising a part of them. As a matter of fact, it is probable that a larva in a queen-cell has an equal chance with any other larva in the hive. There are always some healthy larvae, even in the last stages of the disease.

A. B. C., Illinois. What are the duties of a bee inspector?

A. A bee inspector should look over every square inch of comb in a hive during the breeding season. There is no use looking at the outside of the hive or smelling at the entrance, because bee disease of no kind can be detected except by opening up the hive and examining every piece of comb therein.

There is not much use in going thru a hive after the breeding season or before it, altho one can detect the scales in combs where American foul brood has been present the previous season.

An ordinary bee inspector will not be able

to cover all the territory. He will not pay so much attention to the hives belonging to the best beekeepers and people who are neat and clean, and who, he has every reason to believe, are watching their own colonies very carefully. It is the small beekeepers, those who do not know bee disease when they see it, those who have had very little experience in the keeping of bees, that are more to be feared than these large producers who would for their own sake keep bee disease well within bounds.

Wherever queens are reared, every inch of combs should be examined at least once in a season, and it is better twice a season. Whether the queen-breeder is a good one or not, it is very important that he should have nothing but clean healthy stock.

C. A. S., Ohio. I am puzzled whether to use double or single walled hives. I propose using single-walled hives, and in the fall contracting down to about six or seven frames and placing these frames in a large colony hive which is on the plan of a double-walled hive, but long enough to hold 40 or 50 frames—seven or eight colonies. Do you think this plan will work if I place light division-boards between them, and have a small bee-entrance for each colony so that on nice days they can fly out?

Is it possible to place a queen on each side of a hive separated by a division-board which allows the workers to go back and forth but not the queen? Is one inch of packing enough for this climate, where the temperature ranges from 60 to 10 below?

A. (By Dr. C. C. Miller.) Others have thought of conserving mutual heat by having a hive wide enough to hold seven or eight colonies for winter, but if any one has made a permanent practice of it I have never heard of it. A serious difficulty in carrying out the plan is that, when the change is made in the fall, many of the bees upon their first flight would not return to their new locations, and there would be the same trouble upon making the change in spring.

It is possible to have a hive with two queens in it, one on each side of a middle partition with excluder zinc in it allowing workers to pass back and forth freely, yet keeping the queens separate. Years ago a good deal was said about a hive of that kind in use in England, but I think nothing is said about it nowadays. There seemed to be a good deal of trouble with one side or another going queenless, and no great advantage over a strong colony with a single queen.

In your climate, with thermometer ranging from 60 above to 10 below, an inch of packing may do for outdoor wintering, but more is likely to be better.

A. I. Root

## OUR HOMES

Editor

O foolish people, and without understanding; which have eyes, and see not; which have ears, and hear not.—JEREMIAH 5:21.

And this is the condemnation, that light is come into the world, and men loved darkness rather than light, because their deeds were evil.—JOHN 3:19.

## A BEEKEEPER WHO IS A DEAF MUTE.

A few weeks ago I was called for, and found a beekeeper who by his motions signified that he was a deaf mute. He did not seem to be sad nor downhearted, however; and even if he could not hear and talk he was one of the brightest and happiest men (apparently) I ever came across. With a tablet of paper in one hand and a pencil in the other he would write not only so plainly that anybody could read it at a glance, but his hands and face added emphasis to the comical way which he had of expressing himself. He called to invite me to take a trip in his Ford automobile down to the Ohio Experiment Station. I shall have to explain right here that he is the entomologist having care of the shade-trees of the city of Cleveland. He was on his way down to confer with Professor Hauser, Entomologist of the station. Perhaps I had better state right here that his name is Charles R. Neillie. Well, with him in his automobile were his two sons—the oldest one, I think, 17, and the younger one perhaps 5 or 6; and it was really a wonder to see that little chap talk to his father by the use of the deaf-and-dumb alphabet. In riding along he would give his father a punch, and then, pointing to some object, make a lot of signs with his little hands; and several times I was tempted to think that the relations between this father and child were happier and purer than, may be, nine out of ten who have the full use of hearing and speech. The older son acted a good deal as an interpreter along with his father. He has been for some years a newsboy in Cleveland, and has saved up money enough so he will be prepared very soon to take a college course.\* They seemed to be well acquainted with the heads of the station, and it was a pleasure to me to see the kind and genial reception the different professors gave him at every turn.

\* Once on our trip I noticed the father turned around and made a quick sign with his hand to the older boy, who quickly replied. I was curious enough to know what it was the father signaled. The son replied, "He asked me to listen carefully to see if I could hear any unusual rattle with the automobile." You see if the father himself could not hear, as he was making a pretty good speed, he wanted the benefit of his son's hearing to know if everything about the automobile was all tight and secure.

Well, I have something to tell you still more wonderful—yes, several things. First of all, the good mother is *also* a deaf mute, and they have brought up a family of four children; and every one, from the bright little girl only three or four years old, is clear up to date in every line of juvenile progress going on in the world just now.\*

My good friend Neillie told me confidentially, but I think he will not object if I tell it here, that his grandfather was an temperate man and the father followed the grandfather, or was, perhaps, even worse. For this reason friend Neillie is out-and-out *dry*, from the top of his head to the sole of his feet. His three boys, one of them near maturity, have never tasted any liquor nor tobacco in any form or shape.

By the way, it is a wonderful thing to see a man entirely deaf run an automobile; and you might think it unsafe; but after riding with him over fifty miles I could not feel safer, even at a good high speed, with the majority of chauffeurs who can both hear and talk. At a later date it was my great pleasure to visit the humble home of friend Neillie, at 4317 East 116th St., Cleveland; and their beautiful little garden (containing hives of bees) was one of the finest illustrations of supporting a family on a small area of ground that I have ever met. It was *high-pressure* gardening "with a vengeance." Almost every sort of fruit-tree was found on less than one-fourth of an acre, and the limbs were just bending with beautiful fruit of every description.

As friend Neillie is an entomologist, and has (not at his *tongue's* end but at his fingers' ends) the whole matter of spraying the shade-trees of the city, he certainly ought to know how to spray his garden stuff. Huber and I made our trip to Cleveland in a new sedan Ford. Now, friend Neillie had invited us to look over the children's garden in the city of Cleveland; and he suggested that *he* could run our Ford where he wanted to go easier than he could

\* Just think of it, friends. How can a father and mother teach a baby to talk when neither can say a word nor hear one? After the first baby has grown so it can talk, I suppose he might teach the other one. While Mrs. Neillie was showing me thru their little home I looked inquiringly at a sheet of paper fastened to the wall, containing the deaf-and-dumb alphabet. She explained that she kept it there so as to teach the children. Now, try as you may, you cannot in imagination comprehend or realize the tremendous task these two parents have gone thru in building up a home and bringing up four children "in the straight and narrow path" in which they should walk.

direct Huber. Now, please consider. He had never seen an automobile before like this in his life; and altho he is a deaf mute he ran that machine all over the city, dodged vehicles, gave a wave of his hand to policemen everywhere, and did not get into a bit of trouble.

There is a beautiful little periodical published by the Ohio State School for the Deaf, entitled *The Ohio Chronicle*. It is in its 44th year. Well, now, in this periodical I find an article written by Mrs. Neillie, that I am going to copy. It ought to prove not only a rebuke, but an inspiration to millions of people who can hear and talk. May God bless the message that it is my pleasure to give from my good friend Mrs. Neillie.

#### HOW WE GOT OUR HOME

MRS. NEILLIE'S INTERESTING STORY SHOWS HOW ANY ONE WHO WILLS TO OWN A HOME CAN DO SO—THE EFFORTS GIVE A GREAT DEAL OF PLEASURE AND FINAL HAPPINESS—ONLY ABOUT THIRTEEN YEARS WERE REQUIRED TO ACQUIRE A COZY MODERN HOME, ALL PAID FOR.

We were married two years when we decided to buy a home. We had only a very small account in the bank when we started the venture. After looking it up we decided to buy a lot 40 x 200 feet, paying \$25 down and \$5 per month with 6 per cent interest; and we heard of a house for sale, so we decided to take it and move it on our lot, two miles distant. It was a three-room house, and, small as it was, it would be a home for us. "Be it ever so humble, there's no place like home."

We moved into it as soon as it was on the lot, mounted on stilts. The day being Thanksgiving Day, we gave thanks. At the time, my husband was earning only \$1.75 a day, and there were three of us. The factory shut down shortly after we bought the home, and, after a few weeks without work, my husband got work in a tin-mill at \$1.37½ a day. An awful comedown it was to us, so we had to be very frugal.

We decided to get something from the garden. We planted fruit-trees the first year, and had a good garden that helped us out a lot.

We had been in our home just a year, and again it was on Thanksgiving Day that we were discussing how to better ourselves. I had learned the dress-making trade before I was married, and suggested that I put up a sign "Dressmaking." No, Mr. Neillie would not. Just at that minute in stalked Prof. I. F. Patterson, a brother of Miss Nora Patterson, of Columbus, asking Mr. Neillie how he would like to work in the city parks. Of course we were delighted, and gave thanks. It was \$1.50 per day, eight hours work, so it looked good to us.

We were able to keep up the payments on the lot all the time. We borrowed some to pay on the house and for the moving. Then by and by better times came to us; an advance in wages, and we continued to make progress. At times things did not look very encouraging, but a little reflection always showed me that it would be worse paying the same amount for rent, perhaps more. Most of the needed repairs we did ourselves, as we felt we could not afford to hire the work done.

Our trees grew well. We planted grapevines of three different kinds, also berry-bushes, currants, etc., and managed to make use of every foot of land. We kept chickens and bees, and they have always brought us a neat sum.

By and by we got the place paid for, only to venture into another debt to enlarge the home. My

family had increased in size, hence the necessity. We borrowed money from bank at 6 per cent interest, and we were informed we could have the loan for 99 years, and we had to pay interest twice a year.

Would we have the loan for 99 years? Nix! We saw the amount we borrowed would double up in a few years, so we began paying on the loan as soon as we got straightened. There was not quite enough money to get everything done as we wanted, so we let some things go and did all of the interior painting and varnishing ourselves and all small repairs we could, so I got to be a master of saw, hammer, and brush. We built a new coop and out-building—what it is called I don't know, for my husband calls it shop, my boys call it barn, tho we have no horse. To me it should be a storage barn, which, I am proud to say, I helped to build. People gasped seeing me on the roof, putting shingles on, and on ladder painting, and some came to advise that I'd be in the hospital if I worked at that rate. Thank goodness, I have never been there.

Where there is a will there is a way. Any one can own his own home if he has the will, and it helps to teach one to save and make money go the furthest.

Last January we got all clear, and since then we have put in a furnace, cupboard in the pantry, and paid for forty feet of sidewalk that was laid last summer by the city. Furnace and cupboard have been paid for too.

Last summer we had a fine crop from our fruit-trees—four bushels of pears from one young tree, three bushels of plums; there was none to buy for our canning, and we gave quite a lot away. Our grape crop was a sight to behold, so thick with clusters, so any one can imagine how we are enjoying the fruit of our labor, and we are carrying the air of "I am monarch of all I survey" if I do not look beyond the line of the fence-posts.

There are six of us in the family now, the oldest being fourteen years old and youngest three next July. All but one of our children were born in our own home, and all have grown up outside in the yard with the chickens, bees, weeds, and flowers, and they do grow like weeds under these conditions, being outdoors all day except on very bad days, when I have to drag them in. There has been nearly no sickness to speak of, owing to their manner of living outdoors. So just think how nice it is to have a home all paid for while children are small.

My oldest boy goes to high school next fall, and the older the children grow the more they cost; so there is a consolation in the thought we can do well by our children since we already have a home of our own.

All these years I had to be as saving as I could be, and I do all my work and sewing, so my hands are full; but there is a pleasure in that, and it is our aim to keep going up the ladder.

I just wrote this thinking it would help some of the readers wanting to own a home but who are not sure they can do it. May be some will profit by my experience.

MRS. NEILLIE.

After the above was in type I submitted a copy to our friend Neillie, and he gives us some additional facts as follows:

Mrs. Neillie deserves all you said about her and more. She has done all the managing, as I turn over to her my pay envelope, unopened, which has grown from \$1.50 a day to a yearly salary of \$1400. Perhaps I should tell you I have been working for the Forestry Department and Parks 17 years—3 years as gardener and 14 as a tree-warden, and as the city entomologist.

There are 5 children in the family—four boys and a girl. The oldest boy is 18. You never saw him, tho I stopped at your home September 16, when I

was taking him to the Ohio State University in Columbus—Mrs. Neillie and the little girl accompanying us in our machine. Mrs. Root saw him, and said you were away in Springfield. Mrs. N. and I wish to be remembered to Mrs. R. The boy has to earn half his expenses at the University. He is taking the general course at the College of Agriculture.

The big boy who sat with you in the machine on the trip to Wooster is Edison, named after Tom Edison. He will be 15 on the 19th of November, and is heavier than I am. Last night he was making a new wireless instrument-board to replace an old one he made last year. If he has any real aptitude for the study of electricity I think I will notify Mr. Edison that I named a baby after him nearly 15 years ago, and ask that he be taken into his laboratory; otherwise he goes to the Ohio State University. He is now in high school.

There were two other sons in the machine with you—Elmer, 9 years old, who can tell his older brother more about a Ford than they know, and Franklin, 7 years old.

Please tell Huber that we made Columbus in seven hours from Cleveland (actual running time), and that I think I can do it in 6 if not 5½ hours if I have no precious load like wife and children in the car.

The article Mrs. Neillie wrote was written four or five years ago. We swam out of that sea of debt some seven years ago, into it, buying the corner lot next to us.

You seem to think it a bit strange a deaf man can drive a car. There are several of us in this state who do, and one is reported to own and drive a *taxicab* in Toledo. Deaf people have a sort of "sensimeter" which is more developed than with hearing people, and which is *still* more perfectly developed with the blind. We notice any unusual jarring or loose vibration that ordinary people don't notice. The antenna of my "sensimeter" is always "on the job" on my car. I look after my car, keep my sight straight ahead, sparing five per cent of it for rear-sight mirror, and *do not take any chances*, and am all the more careful *because* I am deaf. However, I have "the other fellow" to reckon with. The same as Huber or any one else, and I may get hurt yet. I have driven motorcycles between 25,000 and 30,000 miles, and autos over 40,000, and no accidents at all yet.

Oh, yes! we are all happy here. We have books, the yard, the children, the car gives us all the country we can want, and I have a host of intelligent friends all over the city (including the police, to whom I "wave my hands") whom I acquired in the capacity of consulting tree "physician and surgeon," whom the Park Department sends out to advise people who ask for some one to look at their trees and plants. It is generally the cultured people who take enough interest in their plants to send for some one.

My friends number from the secretary of war down to the wives of the Great Lakes sailors.

Mrs. Neillie says I am a garrulous old man, and that I *must stop*; but I hope this letter will prove a little of a diversion for you.

Most fervently imploring God's blessing on you and Mrs. R., and praying that he will spare you to us for a long time yet, I am your friend,

Cleveland, O., Oct. 24.

CHAS. R. NEILLIE.

sider I have ever come across. In fact, some of us veteran beekeepers never knew or thought of some of the things mentioned, especially in the matter of "housekeeping" in the hive, and that the honeybee is a model housekeeper. Just one suggestion: If I am correct, bees do instinctively object to a dirty man; and if I am right about it a man with the fumes of whisky or beer on his breath would be *more* likely to be stung "at sight" than the one who has just come from the stable without being washed up.

D'YOU LIKE HONEY? BY EDNA K. WOOLEY.

The Honey Man sat down beside my desk and smiled at me.

Now, please don't draw any hasty conclusion. I'm calling him the Honey Man simply because he knows all about honey and its makers, the bees.

"Do you know," he began, "that there are never any multi-millionaires among the bees?"

"Indeed?" I politely responded.

"The fact is," he continued, "that the honeybee never reaps the reward of its labors. It's the saddest thing in a bee's life. A bee's life is short at best. It works so hard that its wings soon become frayed and inadequate for long flights. However, the bee works up to the last minute, and is never able to carry its last load of honey home.

"I wish you could see the inside of a beehive and understand it as I do. It's a regular city, with its officials, its sanitary squads, its police—everything about as we have it, only everything is so much better done than we do it. A beehive is the most sanitary spot on earth. Bees can't and won't stand dirt. Put a dirty honeycomb into a hive and in a couple of hours the bees will have that comb clean and actually glistening.

"Every bee has to go thru a course of thoro home and civic training before it is allowed to leave the hive to do outside work. For the first sixteen days of its life the bee does housework, you might say, and tends the babies. At the age of sixteen days it is considered mature and educated, and may go out into the world to live the fuller life."

"Bees are wonderful," I admitted. "I'm happy to say that I'm one of the few people that they don't sting."

The Honey Man laughed gently.

"Now, that is, an old idea that ought to be exploded—that bees will sting some folks and not others," he remarked. "The fact is, you can handle bees at certain times and they'll be so busy thinking of something else that they won't sting. For instance, when they swarm they seldom sting.

"Bees distinguish everything according to odor. Possibly one person's odor may be so agreeable to the bees that they let him alone. The bee's sense of smell is so acute that it will scent what is imperceptible to human nostrils. Bees are known to each other by their odor. Every bee has its own colony odor, and no bee will be admitted into a hive unless it has the colony odor of that hive.

"A bee will sting where it is offended by an odor. A man who has been in the stable, we will say, may go direct to the apiary and be stung by the mildest bees there, while the same man, fresh from a bath and wearing clean clothes, could go about unharmed among the most vicious bees in the apiary."

"Tell me something," I asked. "Do the bees really make all the honeycomb, and why is extracted honey cheaper than comb honey?"

"Bees make all the honeycomb," he answered. "A satisfactory substitute has never been found.

#### MILK AND HONEY FOR THE GREAT WIDE WORLD.

The following, clipped from the *Cleveland News* of Nov. 7, is about the best write-up for bees and honey from an out-

You may be sure that you are getting absolutely pure honey when you buy it in the comb.

"In extracted honey there is, of course, a chance for adulteration, and while it may be as pure as comb honey it lacks just a little of the exquisite flower flavor of comb honey.

"Comb honey is more expensive because it takes the bees a long time to make the comb. It is a very expensive product of the bees. They don't like to fill the small frames which we give them, but we have a process by which they are compelled to do so before they pass on to the large permanent combs which they not only fill with honey but in which they raise their families. These large permanent combs are used again and again. When one is filled, a knife made for the purpose slices off the thin sealing of the cells, the comb is put into a machine which whirls it rapidly, and every bit of juice is extracted. Then this comb is returned to the hive.

"People seem to think all honey is a luxury," he went on. "Bulk for bulk, it may be more of a luxury than sugar; but considering how much richer, sweeter, and more digestible it is than sugar or any of the cane syrups, I should say that it would not be found more expensive. It should be used more in cooking. Remember, it's the purest and finest of direct nature products. I should say that of all other natural products it is equaled only in its many virtues by milk.

"Honey is one of the few sweets that is digested the moment it is taken into the stomach. It never sours on the stomach, never causes indigestion. You might say it is really a predigested food. It contains far more energy than sugar. It is an ideal food for old people and children. Our own children have never been given any sweets except honey. They have had free access to it always. The result is that our children have no bad stomachs, no unpleasant breath, and no decayed teeth as the result of eating too much of indigestible sweets.

"Did you ever try honey and milk on your cereal for breakfast?" he asked. "Now, sugar and cream combined may make an acid in the stomach. Honey and cream never do that. Take just about half as much honey as you would take sugar, on your morning cereal; pour over as much milk as you wish, and it's the surest cure I know for that morning grouch!

"Use honey in place of sugar on all fruits served with cream and sugar, and you'll think life is one long poem."

"Could a woman keep bees in a city back yard?" I asked. "I could establish an apiary on the top of the *Leader-News* building and the bees would travel two and three miles to find the honey to bring home," he answered. "It might be rather dark-looking honey, because of all the smoke in Cleveland air, but it would be honey!"

## HIGH-PRESSURE GARDENING

GRAND RAPIDS LETTUCE GROWN UNDER GLASS,  
AND WHAT HAS COME OF IT.

During the years since GLEANINGS was started I have exploited so many different things in the line of gardening, etc., that didn't "pan out" I have sometimes wondered why my good friends did not throw it up to me that my hobbies as a rule were, too many of them, "air castles"—German carp, the Gault raspberry, then some great black-berry of which I cannot remember the name, etc. Well, it often transpires that, while these things are a success in some particular locality, they do not succeed everywhere. I can thank the Lord, however, that many of the things I started have resulted in great and important industries. I want to tell you about one of them:

Almost thirty years ago I got a glimpse of the Grand Rapids lettuce grown in Grand Rapids, Mich. It was not called "Grand Rapids" lettuce then, for the world knew nothing about it. Some of our older readers will remember that, after I got just one glimpse of the *Eugene Davis* lettuce-greenhouse, I began bartering for half a pound of the seed which he said he had. First I offered him ten dollars. He shook his head. Then I went on to twenty, thirty, forty, and finally fifty dollars. You see I made up my mind that I was going to have that half-pound of seed, even if it cost a *hundred dollars*. He finally said that, if I was deter-

mined to have it, he hadn't the heart to charge more than at the rate of a hundred dollars a pound. Do some of you remember what I did with it? I gave each subscriber of GLEANINGS a little pinch, and went to growing it in my own greenhouse and writing it up with my characteristic enthusiasm. Grand Rapids lettuce is now cataloged by almost every seedsman in the world.

Several times recently I have had intimations from different sources to the effect that there was one particular locality in Ohio where Grand Rapids lettuce-greenhouses covered literally *acres* of land; and on the 13th of November it was my pleasure to get a glimpse of something like *fifty or sixty* acres, covered with glass, expressly for growing Grand Rapids lettuce. One man had about seventeen acres mostly devoted to this industry; but he begged me not to use his name nor locality more than to say Ohio. It would take a book, almost, to tell you what I saw and learned on that visit of two or three hours.

When I first got a glimpse by lantern-light of Eugene Davis' greenhouse filled with luxuriant lettuce I thought it was one of the brightest and most thrilling sights I ever beheld; and what I saw on this day brought back the old fever and enthusiasm. Oh how I did wish I could get down on my knees and help the boys *transplant lettuce!* I suppose, however, my enthusiasm would

not have lasted very long, for my old knees and back would demand straightening up every little while.

Well, a couple of these boys, perhaps twelve or fifteen years old, would plant seedlings so fast that one could hardly see them do it. There was just a quick dab of the finger, and a little morsel of dirt thrown over the roots, and it was done. They did not take any pains to stand the plants straight up. The plant itself lay flat on the ground; but in just a few hours, with the proper heat and moisture, and especially with a little sunlight, they straightened up of themselves. I was told that one of those boys had on a special occasion transplanted 22,000 *plants* in ten hours. The seedlings are raised in very rich black soil—I should say a mixture of about half muck and half of stable manure.

The sides of the bed were a wooden plank; and on the upper edge of this plank is a long strip of angle iron; and this strip of angle iron forms a track for neat little cars that carry stuff back and forth. In fact, the cars run so easily that one could give them a push and they would go away off in the distance to the end of the greenhouse. Stable manure is used everywhere, almost without stint. It comes by the carload from the large cities; and talking about carloads, our good friend said he handled the lettuce *only* by the carload. My first question was, "Where do the people live who want lettuce all winter long, by the carload after carload?" I suppose it goes mostly to the great cities. You know it has been pretty well demonstrated that *chickens* do not thrive unless they have green food as well as grain. And, by the way, your chickens will soon show you, if they have a chance, that *lettuce* suits them better than any other green food in the world. Well, it seems that people as well as chickens have begun to learn the value of lettuce as a form of green food; and I suppose our doctors will tell you that lettuce is one of the most *wholesome* products of the soil. It is *uncooked food*; and you know a great deal has been said about the importance of having at least a part of every meal uncooked—food straight from the hands of the great Father, without any artificial tinkering.

Overhead heating is used, particularly for growing lettuce; and the most desirable temperature seems to be about 45 at night and 55 in the daytime. The green fly is kept down by means of hydro-cyanic acid; and this reminds me of something. These lettuce-growers, many of them, grow *cucumbers* also. Of course the cucumbers require

a very much higher temperature; and we saw some beautiful cucumbers trained on a wire trellis, in full bloom. For the cucumber-house they have one or two colonies of bees, the number depending on the size of the house; and it was to investigate this part of their business that our party went out on this expedition. Of course there is no need of any *bees* in *lettuce-greenhouses*; but when they fumigate the cucumber-house the bees have to be removed and set out, until every trace of the terribly poisonous gas is gone. The same greenhouses also grow tomatoes largely; and right in the middle of November they are gathering tomatoes grown under glass, and shipping them by the carload. The tomato-houses need no bees. Let us now go back to where I started. When I was scattering Grand Rapids lettuce seed, not only all over our nation but away across the water, little did I know the outcome.

One of the greenhouses we visited, that went away up in the center toward fifty feet in height, and covered an acre of ground, cost something like \$50,000. I do not remember now how much money there is in a carload of lettuce; but it is probably away up. Large numbers of men and boys are employed in this industry, and very likely women and girls also; and they have a comfortable and pleasant place to work all winter long when there are storms and blizzards outside. One reason why I recommended greenhouse work thirty and forty years ago is that it affords such a nice pleasant place for work during stormy weather.

On page 1183 I have told you the story of the outcome of one single individual who caught the fever by reading *GLEANINGS* about gardening under glass—or, if you choose, "support a family on a quarter of an acre of ground," as we have it in our tomato-book. By the way, in closing let me tell you that before I dictated this article I hunted up the description and directions for cultivating lettuce as given in our book "What to Do, and How to be Happy While Doing it." In that book our friend Eugene Davis, who first sold me that half-pound of lettuce seed, answers questions and tells us all he can about how to grow Grand Rapids lettuce. To Eugene Davis is due the credit of first starting this great industry, while I only gave it its name, Grand Rapids, and scattered it by pinches far and wide to the good people who read *GLEANINGS*. I think that this one article in the book mentioned is abundantly worth the price of it to anybody who is in any way interested in growing lettuce.

## OUR FLORIDA GARDEN.

When I first took a look at it, Nov. 17, I felt a good deal discouraged, for my beautiful beds of corn and velvet beans that I left the last of April were a wilderness of great tall weeds, sand-burrs, dried-up cornstalks, and velvet beans. I had been *told* the latter would crowd out everything else, even weeds; but I never before realized what a "pusher" the velvet bean is. Our experiment station advised me to plant corn with beans every third row; but they didn't all come up, altho what did come evidently recognized the opportunity. They don't seem to relish bearing *beans* unless they can climb up on something, so they first mounted the tall corn and then proceeded to load down stalks with great clusters of pods until the corn fell flat on the ground, then they went for the poultry-netting fences, festooned *them* with bunches of pods, but, apparently still unsatisfied, grasped the pine-trees on the other side of the fence, and went up 20 and *even* 30 feet.

I said to Wesley, "Why, Wesley, that vine cannot be velvet beans away up there?"

"Yes, it is, Mr. Root; don't you see the great bunches of green pods stringing along clear away up?"

And I had to admit it. You see the ground was pretty well fertilized for the potatoes, and I also invested in the "nitro culture" when I planted them; and, altho the plants looked sickly and discouraged when I left in April, they must have got "down to business" later.

As we had moved the chickens all away, I told Wesley to plant corn and velvet beans all thru the chicken-yards; and the result was, when I arrived not a gate could be opened, and even the houses were covered. Bunches of beans were hanging from the eaves and everywhere else. You may recall that I put netting overhead in one yard, to keep out hawks. Well, this yard just took their fancy. They roofed it over and dropped bunches of pods down thru the netting. In places in the garden the vines are knee-deep, and the ground under them is so mellow with the decaying black mold it looks as if it must grow potatoes or anything else. How about the corn? Well, Wesley had gathered a heaping barrel; but it was so much trouble to find it when the vines had broken the corn down that I gathered a big armful of beautiful ears after I got here. The summer has been so dry the corn was in perfect condition except that rats or some other animal had shelled part or all of some of the finest ears. In

consequence of the almost unprecedented drouth many of my choice plants and trees have died; but the dry hot weather seems just to suit the velvet bean. Like all legumes, the vines and beans also are fine for feeding stock, and I believe they are used to some extent for human food. We have tried them a little, but do not fancy them much so far.

Another plant that seems to rejoice in dry hot weather is the roselle I have repeatedly spoken of. Our plants were, once more, "great trees," and we are supplying fruit to neighbors far and near. Stewed and sweetened with honey from *our own* hive, I verily believe I enjoy them as much as I did peaches and cream a short time ago in Ohio. If well started in a greenhouse I feel sure they could be made to fruit in the North. We are busy planting potatoes; but there seems to be trouble about getting seed that will sprout promptly. Red Triumph, planted two weeks ago, is not showing yet. Seventy-five cents a peck is the price, and many think they will soon be a *dollar a peck*.

With the large amount of rotting bean-vines, cornstalks, and big weeds Wesley is spading under, there seems a good prospect for potatoes if we have rain enough. We have some very fine sweet potatoes, but *they* bring only a dollar a *bushel*.

As usual, while eggs are 50 cts. a dozen our 40 full-grown hens are laying very little; but we are trying everything for feed in order to get them started.

Peas, beans, Bantam corn, radishes, and lettuce are up and growing finely that were planted about two weeks ago. Spineless cactus has made a fair growth during the summer in spite of weeds.

## FIRST NEW POTATOES FROM FLORIDA.

The Jacksonville *Times-Union* says:

"What is believed will be the first full carload of new fall-crop potatoes to leave Florida this season was shipped from the celery-farm siding north of Crystal Springs, Wednesday," says the *Manatee Record*. "Almost all of the potatoes will grade as number one, fancy, and they are bringing a fancy price. The price paid was \$2.71 per hamper at the car." The *Record* says that these potatoes were planted in September, and will pay the growers handsomely. The wonder is that more potatoes are not planted for the fall crop, as the demand is now greater than even in the early spring. From the planting to digging, the time was seventy days. Great is Florida, and her wonderful climate and soil!

## SWEET CLOVER; DOES IT EVER BLOSSOM THE FIRST YEAR?

In my experiments with white sweet clover (*Melilotus alba*) during the years past, I think I have several times seen an

occasional stalk that would blossom the first year. The matter was called to mind by the following:

A field of *Melilotus alba* sown here last spring bloomed profusely when about four feet high. I enclose a sample, and ask the cause if you know of any parallel case. I have never known it to bloom the first year.

Earle, Ark., Sept. 26.

C. W. RIGGS.

To the above, Mr. Calvert replies as follows:

Mr. C. W. Riggs:—I have yours of the 26th, with sample of what you say is *Melilotus alba*. Where seed is sown as early as July or August, it usually makes sufficient growth that year to produce bloom the year following. I do not recall a case where it would bloom the same year if sown in the spring, altho *Melilotus indica*, the annual yellow, does bloom the year sown.

Medina, O., Sept. 29.

J. T. CALVERT.

Later on came the following:

The seed of the plant I sent you, supposed to be *Melilotus alba*, was sown some time last April, so the party who sowed it told me. I was particular to ask if he sowed it the fall before or the spring before last. Both he and his women folks declared that it was sown last spring, grew to about four feet in height, when it bloomed profusely, the field being covered with a nice white bloom. I thought it might be a yellow annual, so I went to see and found the white bloom in various places. The party had cut it several times and pastured it most of the summer—had hogs on it, pastured heavy. You, of course, have seen the plant in its second year, when it has been pastured heavily, struggling to perpetuate itself. This is the condition in which I saw it. The party was not satisfied with it, and said he was going to plow it up and put in alfalfa. I begged him not to do so until I had communicated with you. I never saw or heard of anything like it in my experience with white sweet clover.

Greenland, Ark., Oct. 4.

C. W. RIGGS.

Neither of the letters tells us definitely the date at which the bloom appeared. The first letter is dated, you will notice, Sept. 26. Perhaps the locality, Arkansas, has something to do with it; but if the seed was sown only the last of April, the last of September would give just five months for the plant to grow 4 ft. high and bloom profusely as he states. The question arises right here, is this a special strain of sweet clover because it blossoms so early, or is it because the climate and environment down in Washington Co., Ark., are so particularly favorable? Will the friends who are growing sweet clover, especially those in the South, tell us if they have had any like experience? If they have not, some measures should be taken to secure seed from this particular field, as it would seem to be quite desirable to get a strain of sweet clover that will give a yield of honey the first season.

THE PRICKLY PEAR OF AUSTRALIA — IS IT SUCH A TERRIBLE PEST, AFTER ALL?

When I published the article referred to below, I felt sure it was an extreme state-

ment in regard to the prickly pear, and I rather expected we should get something on the other side. Well, below is a letter from one of our friends in the same locality:

Mr. Root:—I see by the June 15th issue, p. 506, that our friend W. Mertons is troubled about the prickly pear. He says he has 130 acres of land, and it took five years to clear 30 acres. I know plenty of men to clear nearly that much in one year.

If you want to keep the land clear you must plow it and put in a crop. Corn is a good crop, as prickly pear is a plant that requires sun and air; and as for seeds, it would take at least two years before they would be large enough to be noticeable. So you could soon settle them with a good scarifier. He says the land costs from 10 to 50 dollars. It is a long way from that, as you can have the prickly-pear farms by applying for them. The only condition is that you have to clear them; then you get your title rights, and labor is not so high as he says, as there are plenty willing to work for \$5.00 a week and board, and a place to sleep.

I know several farmers saved the lives of their cattle thru the drouth by boiling the pear and mixing it with chaff; and there are hundreds of pigs fattened with boiled prickly pear and corn. A friend of mine took up one of these prickly-pear farms. He took out a lot of pigs and 20 hives of bees. As soon as he cleared a patch he put in a patch of corn, and fattened the pigs with boiled pears and corn also; and he got a large crop of extracted honey from his bees. The honey is so transparent you can see thru the sides of the bottle as easily with the honey in it as you could if it were empty; and it is a good thick liquid. The pears have a large cream-colored flower, and the fruit is bright-red and pear-shaped. It makes a very good jelly, and it is nice to eat like fruit, as it is sweet, and comes in very handy when there is no other about. In fact, there are many children that get hardly any other fruit, as it is too dear to buy. Peaches, early sorts, bring 5 cts. each, and apples 4 cts.; apricots, 2 cts., and plums 2 cts.

As for the pear spreading at the rate of one million acres, it is what we call "putting it on thick," and trying to deter people from coming out here. At the rate the pear is destroyed, fed to stock, and used in various ways, there will not be much left. It is boiled, and the liquid is mixed with lime or whiting, and it makes a good whitewash. You cannot rub it off when dry, and I hear they are making petrol oil out of it.

A pear is full of very fine thorns on the young leaves; but when boiled they collapse and are harmless. The old stems have large thorns; but when they use them they make a fire on them with grass or small brush, and that is the end of the thorns. The leaves are about 3 by 4 inches on the young plants, and the older about 6 by 8 inches.

On the whole, the prickly pear is a blessing in disguise.

WALTER LINCOLN.

Toowoomba, Queensland, Aus., Aug. 20.

From the above we learn that even the Australian prickly pear has its uses. I am glad to know that it yields honey, and honey almost if not quite water-white and of excellent quality. If I understand it, it is desirable to put in some cultivated crop like corn or potatoes after the prickly pear is turned under. I know by experience that it takes quite a long time for the seeds to germinate, and I can hardly think it is a worse pest than some weeds we have to contend with here in the United States.

# HEALTH NOTES

## DEAF PEOPLE—WHAT HAS SCIENCE DONE FOR THEM?

Can any one estimate what spectacles have done for the sight? Why, it seems to me I could hardly live without the help of my eye-glasses; and yet I suppose people got along after a fashion before lenses were invented. Well, for years past I have been wondering why something could not be done for the ears (or to a certain extent at least) what science has done for the eyes. Various contrivances claim to do this very thing. On page 868, Dec. 1, 1913, I gave a lengthy account of my experiments with the acousticon, ear-phone, ear-trumpet, artificial ear-drums, etc.; and I concluded by saying that I received more benefit with my bare hand placed back of the ear than with any contrivance I could find advertised or get hold of. Another thing in favor of this method is that you always find your hand "on hand"—always with you; whereas your ear-trumpet or ear-drum might be somewhere else when you want it most. Well, during the three years that are past I have still been answering advertisements and testing all the advertised appliances. A year ago I got some little ear-drums from a company in Detroit. For a time I thought I could hear a little better with the ear-drums; but after careful and repeated experiments I decided they were of no benefit to *me* whatever. I emphasize the word *me* because I have had satisfactory evidence showing that they are a benefit to *some* people. Perhaps I should add, however, that this evidence has always been in print. I have never met and *talked with* any deaf person who felt, after a lengthy trial, that he had received any benefit from artificial drums. Perhaps you may not be aware that the vendors of helps for hearing have a list of the names of deaf people. I do not know how they get them; but I am getting circulars continually. Even when in my Florida home as well as here in Medina I get circulars from the Wilson Ear-drum Co., of Louisville, Ky. The price of their ear-drums is \$5.00. I told them I was willing to test their device, but added that, so far as I could learn, if no benefit was received the whole \$5.00 was wasted. They made no reply except to send a lot of testimonials; and a short time ago they sent me quite a little book of testimonials praising in extravagant terms their ear-drums; and they said these testimonials were all of recent date, and that I might write to any one of them, tho they were scattered

all over the United States. Finally I wrote as follows:

*Wilson Ear Drum Company:*—In reply to yours of a recent date, I enclose \$5.00. That so many people have been benefited is a big showing, of course; but I can find no word anywhere in regard to the number that are not benefited at all. I presume there must be some, and may be a great number of them. Wouldn't it be honest to say, "Quite a few receive no benefit whatever"? It would hurt your trade somewhat, no doubt; but isn't the honest truth worth more than dollars?

I am nearly 77 years old. I have used some ear-drums made in Detroit. I thought at one time they were of a little benefit, but later I could see no difference. If I receive any benefit whatever I will gladly publish it in our journal. If I do not, I will also publish it, because I think it's due the great public to know that *not* everybody is helped. If you don't object, I wish you would tell me about what per cent of your customers fail to receive any benefit whatever. A. I. ROOT.

The drums came promptly, and with them the following letter:

*Mr. A. I. Root:*—Your letter with check for \$5.00 has just been received, and in compliance with your request we are sending under separate cover by mail today a complete set of our ear-drums with the hope that you will be greatly benefited by their use. Full instructions for using the drums will be found in the little box; and after reading the same carefully you should have no difficulty in inserting and removing them at will.

Should it be necessary to exchange you will have the privilege of doing so free of charge at any time.

We wish to state that it would be impossible for us to know how many people we have benefited and how many we have not benefited; but we take it for granted people are benefited when they write and order new sets, and some write and state that their only regret is that they did not get the drums many years sooner. We wish to assure you that we will do everything in our power to assist you in getting the best results by making any change necessary. WILSON EAR DRUM CO.

Louisville, Ky., Sept. 14.

These little rubber drums are certainly in some respects an improvement over the ones I received from Detroit, and I followed directions most carefully with much faith and enthusiasm; but when tested by the ticking of the clock I could perceive no benefit. If anything I could hear a little better *without* the drum.

Let me mention another thing in closing. The directions for using the ear-drums include washing out the wax and accumulations most thoroly with castile soap and water, even using antiseptic cotton to remove all accumulations. If the ear-wax has become so hard that even the soap and water do not get it away, the directions are to apply sweet oil until the hard cakes are softened up, and the ear can be thoroly cleansed. Now, this treatment alone will improve the hearing with most people. A

doctor of my acquaintance has given great relief, especially in one case, by a thoro cleansing of the ear. I do think the ear-drum people should give at least a few testimonials from those who, like myself, have received no benefit from the drums. Perhaps that would not be "business;" may be it would not be the common kind of business. Years ago they used to call me a sort of fanatic who had a habit of mixing religion with business; and I think the ear-drum people and every other business man, for that matter, would be benefited in the

end by being honest enough to say there were also quite a number of people who received *no* benefit. It might, however, occur to some stupid people like myself that in that case they ought to give back the five dollars, or at least a part of it.

Oh, yes! there is one thing more. These little ear-drums that cost \$5.00 it does not seem to me ought to cost over five cents—at least where made in quantities. If weighed on the scales they probably would weigh about as much as a bumble-bee's wing.

## TEMPERANCE

### "GOD'S KINGDOM COMING" TO OHIO.

The temperance forces are much gratified in winning four states for constitutional prohibition: Michigan, Montana, Nebraska, and South Dakota; two states for statutory prohibition: Utah and Florida; the winning of the territory of Alaska, every municipality in it going dry; the overwhelming defeat of wet proposals submitted in the five dry states of Oregon, Washington, Colorado, Arkansas, and Arizona. In view of the foregoing splendid victories it behooves the temperance people of Ohio to begin at once to plan the battle in our own state

#### OHIO ANTI-SALOON LEAGUE

Columbus, O., Nov. 14.

### ANOTHER BIG DAILY GONE DRY.

We clip the following from the *New Republic*:

The Washington *Evening Star*, one of the leading newspapers of that city, and recognized as one of the great dailies of the country, has put a ban on liquor advertisements. No longer will this great medium carry any sort of advertising which boosts alcoholic beverages.

Announcement to this effect is carried on the first page of the *Star*. It says:

"In deference to the wishes of its readers, the *Star* will not print advertisements of intoxicating liquors hereafter."

### ONE HUNDRED MILLION DOLLARS LESS FOR DRINK IN 12 MONTHS.

We clip the following from the *Farm and Fireside*. Read it over carefully and consider; then read it over again.

#### BOOZE BILL DWINDLING.

Cold figures from an unprejudiced source are what really furnish an authentic verdict as to whether increase of dry territory decreases the consumption of alcoholic drinks. The last government fiscal report, including the first half of 1916, shows that there were 2.7 gallons less of intoxicants per capita consumed than in the preceding year. One hundred million dollars less was paid out for drink in twelve months by the American people than during the previous year.

In the consumption of beer there was a decrease of ten gallons for each family. Even with this reduction, Uncle Sam's records show there was a total expenditure for intoxicants in twelve months of

over a billion and a half dollars—seventy-five dollars for each family.

A comparison of the money going into the building of churches and liquor-making plants is an interesting side light on the question. In 1905, for every dollar expended for new church buildings there were \$2.80 put into new breweries and distilleries. In 1915, for every dollar put into new liquor-making plants there were \$38.20 put into building new churches in this country. There were \$14,000,000 less invested in the construction of breweries and distilleries in the past ten years than in the decade preceding 1905.

It is now evident that John Barleycorn is mortally hit; but he is working his pulchricity harder than ever before, to show he is still in the game and that when a state goes dry it becomes wetter!

### BELGIAN CHILDREN STARVING, AND 12,000 TONS OF BARLEY FURNISHED THE BELGIAN BREWERS.

We clip the following from the *Christian Herald*:

Alcohol well nigh wrecked Germany's forty years of preparedness. In spite of the cry of starving Belgian babes and little children hungry for bread, the Belgian government demands monthly imports of twelve thousand tons of barley for the Belgian Brewers' Federation.

Is it possible that there is no power on earth or up in heaven to give the barley to the starving babies and children instead of using it to manufacture beer?

### DOES PROHIBITION PROHIBIT?

The following clipping comes from the *Vorfolk Ledger-Dispatch* and reads as follows:

Norfolk is unmistakably dry. King Alcohol and his court which for 306 years have held sway in this city have been completely ousted. The great wave of prohibition which has swept thru the Old Dominion (and, indeed, the entire South) is now in force in this city. For the first time in the history of the oldest member of the police department and of the oldest court attaché the docket in the mill of justice was this morning free from any charge of drunk. When the clock struck the midnight hour that ushered in the fatal day that banished liquor the ax fell with great force, and since that time there

has been no liquor sold. Yesterday the few dealers who had stock still on hand shipped it out of the state. The amount shipped was small.

For several weeks (in fact months) past, the police-court docket has been crowded with a long list of drunks who were holding what they termed their final celebration. This morning Clerk Billy Stevens in the Mill of Justice called charge after charge in practically all classes of law violation but drunk. The court which is usually held up by innumerable drunks was free from the pests this morning; and, while the docket was large, the session was snappy and short.

"Guess we are about thru with the drunks," said Justice Arnold at the close of the session. "I never saw so many on the dockets as we have had in the past few weeks."

#### ONE DRUNK IN RICHMOND.

RICHMOND, Va., Nov. 2.—Business for the police department suffered a tremendous slump yesterday, the records for the day having shown that the number of arrests had fallen off to a mere shadow of former days, and that the effects of prohibition were early discernible in the absence of the usual long list of "drunks" on the police blotter. Up to 1 o'clock this morning only one member of the body politic of Richmond slumbered behind the bars dreaming of his trial this morning before Justice Crutchfield.

#### "NO MONEY TO RUN THE CITIES."

On page 992, Oct. 15, I gave a list of the cities that were having financial trouble, and also a list of cities that voted dry, not any of them crying "bankruptcy." But it seems the wets are making so much ado about the terrible state of the finances in Denver that the *Kansas City Star* sent a reporter to find out exactly the condition, and below is a brief clipping from his report:

Even the old cry of no money to run the city is given a hard wallop. Auditor Markley reported today that 94 per cent of all 1916 tax moneys are in the treasury, and many delinquent taxes are being paid. September was \$40,000 better than September, 1915, in collections. The city redeemed \$636,500 in improvement bonds and has issued only \$94,800 this year.

#### POLICE FORCE IS 100 LESS, BUT STILL ABLE TO WORK EFFICIENTLY.

A good friend sends us a copy of the *Toronto Globe* for Oct. 27. He says:

Dear Mr. Root:—The enclosed clipping is self-explanatory. Coming from such an unbiased authority you can have your own ideas as to how prohibition is working in the largest city in the world under such an ordinance. The clipping is from the *Toronto Globe*, the most influential paper published in Canada.

J. L. BYER.

Markham, Ont., Oct. 27.

We have not room for the whole of a marked article in it, but below is the heading:

Prohibition is Doing Big Work.

Chief of Police Grasset Sees Vast Change.

Men Take Money Home.

Police is 100 Less, and Able to Do Work Efficiently—Storekeepers Getting the Money Saved—Decrease in Arrests.

The paper goes on to tell of drunken sots who are now at work and taking their money home to their families instead of spending their time lounging around saloons. Husbands go to market with their wives, and carry home the purchases, etc. I wonder if our large cities here in the United States would not do well to "sit up and take notice." In Cleveland there is a continual plea for more policemen; and the workhouses and city prisons are so overcrowded that they are talking about larger buildings. But not a word is said in any of our dailies in regard to *closing the saloons* instead of building bigger jails and workhouses. When I can find a Cleveland daily that has the courage to reject liquor advertisements, and suggest closing the saloons as a means of getting a revenue, I am going to swing my hat and thank God.

#### THE WHITE SHOES, WHITE DRESS, AND BLUE SASH.

I went to hear Wm. Sunday yesterday in his talk to the Ypsilanti students, more than a thousand of them, at the Normal, and then we went on to Ann Arbor by motor car. The Coliseum, which is said to seat 13,000, was packed, and we heard as best we could. I had an opportunity to distribute all of the leaflets that I had with me. Henry Ford sent to me a large package. He is giving his life and what he has accumulated to worldwide peace.

I was delighted with your temperance talk in the last issue of GLEANINGS; and I wish to say right here that I have the leaflet "White Shoes, White Dresses, and a Blue Sash" in the original. I have seen the woman and heard her talk. She took an active part in the first convention called by the Crusade women of Ohio in Cincinnati. I do not see why her name was not mentioned in the leaflet. It was Mrs. Abbie Leavitt. Her husband, Rev. S. K. Leavitt, was a Baptist minister in Cincinnati. It really was a true story, and she was gone from her home but about two hours. Truly the Spirit of the Lord was with us in those days; and when his name and power are acknowledged sufficiently we shall see victory over evil. We must depend on him and give him the honor and praise, to whom it is due, before success can crown our efforts.

I do wish many more could have heard Mrs. Leavitt tell of their work in Cincinnati, when 43 of the best women in the city were arrested for blockading the sidewalk, when they knelt in prayer on the pavement in front of a saloon. In reporting it she said something like this:

"You have heard of the man who drew an elephant in a lottery, and did not know what to do with it. The mayor of Cincinnati looked just like that man. The pavement was 18 feet wide, and we occupied about 30 inches. I was leader that day, and gave out the hymn 'Rock of Ages,' when a policeman laid his hand on my shoulder and said, 'Mrs. Leavitt, you are under arrest.' 'All right,' said I, 'Let me hide myself in thee.' Then we prayed for that policeman and for the others, and for the crowd. We tried the patience of that policeman a little, for our service lasted 60 minutes. Some shouted, some cried, but all were happy; and then we arose and walked in an orderly manner, two by two, about two miles to the station house."

RHODA C. W. DERBYSHIRE.

Ypsilanti, Mich., Oct. 24.

# Index to Gleanings in Bee Culture

## Volume XLIV

In using this index the reader should not fail to note that it is divided into five departments, namely, General, Editorial, A. I. Root's writings, Contributors, and Illustrations. The index of General includes everything except Editorials, Illustrations, and A. I. Root's writings.

### GENERAL

## Bugs or Birds—Which?

Bugs could damage this country more in 10 days than a foreign war could in 10 years! What prevents them? The birds.

Birds are your friends, your crop protectors. Let's all be good to them. No other institution has done as much as The Farm Journal to instill love and guardianship into the hearts of America's boys and girls. Today the Liberty Bell Bird Club—organized and promoted by The Farm Journal—has eight hundred thousand loyal members. But The Farm Journal is *always* doing things for the farmers and their families. Always trying to make life brighter, happier. It goes into nearly one million homes every month. Why not into yours? \$1 for 5 years. Money back any time. Ask for Free sample and Free copy of the 1917 Poor Richard Almanac.

Mention "Gleanings"

### As Nearly Perfect As You Can Procure

Clover, Alfalfa, Sweet Clover, Timothy and all kinds of grasses (and seed grain of highest quality. Samples and special price list free)

PROTECT YOUR FIELDS **Iowa Seed Co., Des Moines, Iowa**

# Auto-Intoxication

Dangers and Relief

Sent for your FREE examination

A hazy feeling—dullness—hazy headaches—inability to think—these come from stupefaction, or partial paralysis, of your brain by poisons generated by food waste, fermenting in your colon—the lower part of your digestive tract. This is called "auto-intoxication"—that is, intoxication from poisons generated inside the body. Indigestion and constipation are its symptoms. It may lead to nervous exhaustion, high blood pressure, liver and kidney disorders, and sometimes malignant growths. A clean colon, doing its work thoroughly and well, is easy to have, however. Dr. Kellogg tells you about this in his new book—"Colon Hygiene." It teaches natural methods only—diet, exercise, rest, sleep, and regulation of working hours. No drugs. Following its teaching will give you permanent relief from indigestion, constipation, and their attendant ills. Thus you may regain bodily comfort and have a keen mind, renewed energy, a clear eye, and abiding health. Send the coupon for a FREE examination of this book. Over 400 pages—many illustrations—substantially bound—only \$2. Get this book and rid yourself for all time of the dangers of indigestion, constipation, and auto-intoxication. Examine it FREE first.

Send Only the Coupon—No Money

GOOD HEALTH PUBLISHING COMPANY  
1012 Main St., Battle Creek, Mich.

Send me "Colon Hygiene" all charges free. I will return the book to you in \$2 within five days. (Write your name, address, and business or occupation in the margin.)

## Classified Advertisements

Notices will be inserted in these classified columns for 25 cts. per line. Advertisements intended for the department cannot be less than two lines, and should not exceed five lines; and you must say you want your advertisement in the classified columns or we will not be responsible for errors.

## HELP WANTED

WANTED.—Experienced beeman familiar with Rocky Mountain conditions to handle bees on shares. Can offer good proposition. Write with details of experience, etc. A. H. Dunn, Fort Collins, Colo.

## Special Notices by A. I. Root

### GOOD BOOKS AT A BARGAIN

Talks on Manures, by Joseph Harris—a \$1.50 book now offered at 75 cts.

The Dollar Hen—a \$1.00 book that had a large sale, which we now offer at 75 cts.

The New Rhubarb Culture—a 50-cent book which we now offer at 35 cts.

Title Drainage, by W. I. Chamberlain; recently revised and brought up to date; a 50-cent book which we now offer for 40 cts., postpaid.

Practical Cement Work. An elementary treatise on cement construction. The way cement is rapidly taking the place of stone, brick, and lumber, and the way almost everybody is getting to handle it more or less, makes it exceedingly important to have a reliable handbook for the people at large. This book has 110 pages, and the regular price is 50 cts. Instead of 50 cts. you may have it for just 15 cts. as long as the 11 copies last which we still have on hand.

"Letters from an Old Farmer to his Son." This book was put out in 1914, and was advertised to be clubbed with GLEANINGS about a year ago. The book (by W. R. Lighton, author of "Happy Hollow Farm") contains many valuable and praiseworthy suggestions. It is a dollar book; but as we have only eight copies left you may have them for 50 cts. each postpaid.

Tomato Culture—a 40-cent book. This book has also gone thru several editions. The last part of it is by A. I. Root, and is devoted chiefly to the matter of supporting a family on one-fourth of an acre of ground. It is also devoted largely to gardening under glass. The price of the book is 40 cts.; but as we have quite a stock on hand we offer it for 25 cts. postpaid.

Last, but not least, the book "What to Do and How to be Happy While Doing It." See notices of this book under Special Notices in our issue for May 15 last. The book has been sold for years at 65 cts., bound in cloth; paper, 40 cts. We have reduced the price to 25 cts. for the cloth-bound copy and 15 cts. for the paper. For extended notices of the above books, see Special Notices in our issues for May 15, June 1, and June 15, 1916.

## TRADE NOTES

In GLEANINGS for Nov. 15 we announced a clubbing arrangement of the book "Gardenette" with GLEANINGS. In that announcement we said that we could offer the paper edition together with GLEANINGS for one year for \$1.40, and that the paper edition alone sold for 60c. We have since received notice from the publishers of the book that the paper edition is out of print and can no longer be supplied. Therefore, it is only the larger and later edition that we can offer clubbed with GLEANINGS. The price is \$1.75 for both.

### HIGHER PRICES ON TIN CANS AND PAILS.

The market price of tinplate today is double what it was a year ago, and the prices quoted us where we have been able to get quotations at all on tin cans and pails are almost double what we were asked a year ago. In this situation we must advance still further the price on tin cans and pails. Till further notice we quote as follows:

Box of 1 5-gallon can, 68c; 10 boxes, \$6.50.  
 Box of 2 5-gallon cans, \$1.15; 10 boxes, \$11.00.  
 Box of 10 1-gallon cans, \$2.00; 10 boxes, \$19.00.  
 Box of 12 1/2-gallon cans, \$2.00; 10 boxes, \$19.00.  
 Box of 24 1/4-gallon cans, \$3.00; 10 boxes, \$29.00.  
 Crate of 100 one-gallon cans, \$16.00.  
 Crate of 100 1/2-gallon cans, \$13.00.  
 Crate of 100 3/4-gallon cans, \$10.00.  
 2-lb. friction-top can, crate of 500, \$18.00; case of 24, \$1.15.  
 2 1/2-lb. friction-top can, crate of 462, \$18.00; case of 24, \$1.20.  
 3-lb. friction-top can, crate of 420, \$18.50; case of 24, \$1.30.  
 5-lb. friction-top pail, crate of 200, \$15.00; 50, \$4.00; 12, \$1.10.  
 10-lb. friction-top pail, crate of 100, \$11.00; 50, \$5.75; 6, 85c.

We will accept a limited amount of orders for shipment from Medina before Jan. 1 for 60-lb. cans, 2 in a case, at 95 cts.; 10 cases, \$9.00.

Manufacturers of tinware are dependent on tinplate makers for their raw material, and predict still higher prices next year.

### CATALOG FOR 1917.

The forms for printing our catalog for 1917 are complete, and we expect to have catalogs ready for mailing early in January. The catalogs in use the past year are about all used up, and many of the prices in them are no longer good because of the numerous changes which we have been obliged to make during the year. If you cannot wait till you receive our new catalog, send us a list of the supplies you want prices on and we will quote you.

From general market conditions now prevailing we anticipate that the prices in the catalog we are now putting out will have to be advanced before many months more radically than the advances which have taken place the past year. Lumber on new contracts is costing ten to fifteen per cent more than former prices, and metal prices are still going up. While we have tried to cover our requirements for the season ahead we have already booked large advance orders; and when we have to begin using higher-priced material we shall be compelled to increase our selling prices to make up for the increased cost. The prudent beekeeper who knows pretty well what he is going to need the coming season will be acting wisely in our judgment by placing his order early while the goods are available, and before further advances occur. In some lines of material it is not so much a question of price as it is being able to get the stuff at all when needed at any price you may be willing to pay. It is very largely the greatly increased demand with a somewhat restricted supply which is keeping prices on the up grade.

### LOWER RATES ON COMB HONEY.

We have received a supplement to the Western Classification, effective Jan. 25, 1917, in which we find an item changing the rates on comb honey. In cases without carriers the rate will be double first class. In cases with or without glass fronts pack-

ed two or more cases in boxes or crates, with not less than four inches of cushioning material underneath, and marked on top "Fragile, this side up," the rate will be first class. This is the result of concerted effort on the part of beekeepers and others interested with the Western Classification Committee. Now for the benefit of southern beekeepers as well as the trade we ask for a similar campaign with the Southern Classification Committee, which holds a meeting in Baltimore in February. Write to the Chairman, W. R. Rowe, 816 Grant Building, Atlanta, Ga., presenting your arguments for more equitable classification of comb honey, asking especially for a lower class on comb honey packed in carriers, as provided for in both the official and Western classification. In our experience in shipping millions of pounds there is practically no loss when protected by carriers properly made and packed.

### HOTBED SASH.

The season is here again when hotbed sash are needed for growing plants under glass during the cold winter months. We are offering our choice quality cypress sash shipped K. D. at the same price as formerly; but the price of glass is higher. The sash as regularly furnished are 3 ft. 4 in. wide, 6 ft. long, for four rows of 8-in. glass slid into grooves in the bars with ends butted together. We also furnish them with bars rabbeted, when so specified, at the same price:

One sash, K. D., \$1.00.  
 Five sash, K. D., \$4.75.  
 Ten sash, K. D., \$9.00.  
 Glass 8 x 10 for same, \$4.00 per box of 90 lights; five boxes at \$3.80.

We are prepared to make special sash to order, including those with double tier of glass. Prices quoted on application, naming style and quantity required.

### SECOND-HAND FOUNDATION-MILLS.

We have for sale the following list of second-hand foundation machines which will serve a good purpose for those who want to make up their own foundation. We can submit a sample from any mill in the list to any one interested, on application.

No. 0153, 2 1/2 x 6 hexagonal thin-super mill in very good condition. Price \$14.00.  
 No. 0156, 2 1/2 x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.  
 No. 0165 2 1/2 x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.  
 No. 0183, 2 1/2 x 6 hexagonal thin-super mill in very good condition. Price \$14.00.  
 No. 0230, 2 1/2 x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.  
 No. 0234, 2 1/2 x 6 extra thin-super mill in very good condition. Price \$12.00.  
 No. 0237, 2 1/2 x 6 thin-super mill in fair condition. Price \$10.00.  
 No. 0238, 2 1/2 x 6 thin-super mill in fair condition. Price \$10.00.  
 No. 0239, 2 1/2 x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.  
 No. 0245, 2 x 10 hexagonal medium-brood mill in very good condition. Price \$18.00.  
 No. 0247, 2 1/2 x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.

### SUNDAY SCHOOL TIMES.

This is, without doubt, one of the most helpful and interesting family religious weekly papers published. No change in price is announced for the new year. It is particularly helpful in Sunday-school matters. The regular price is \$1.50 a year. In clubs of five or more, \$1.00. We shall be sending in our Medina club this month; and if any of our readers not having the opportunity of joining a club in their own Sunday-school or town want to join our club they may do so on the following conditions: The subscription should be sent during the month of December—the earlier in the month the better. Send one dollar along with your renewal to GLEANINGS at one dollar, or two dollars for both. If you send after December, your subscription will be for only part of a year, ending with our club in December, or you will have to pay \$1.50, the regular price for a full year.

A B C AND X Y Z OF BEE CULTURE.

Work on the new edition of this book has been interrupted by one thing and another to such an extent that we see little hope of completing first copies till some time in February. In the meantime the old edition is entirely exhausted. We have secured and made available on orders every copy of the old edition on hand here and at our branches and agencies, so far as we have been able to locate them. If any of our readers have or know of any new or uninjured books available we should be glad to hear from them, stating the number of copies, the date of the edition, and the price at which they will be furnished.

THE A. I. ROOT COMPANY, MEDINA, OHIO.

# To Sell Your Honey

you must create and sustain a demand. . . Nothing better for this purpose than our stickers.

The A. I. Root Co., Medina, O.

# Bees, Fruit, and Poultry

An ideal combination for the small-place owner. Gleanings in Bee Culture, Green's Fruit Grower, and American Poultry Advocate are the highest authority on these three subjects. Then why not take advantage of our low-price clubbing offer of all three journals for one year for only \$1.00? . . . Write today.

## Gleanings in Bee Culture Medina, Ohio

### HOW TO KEEP TRACK OF YOUR SUBSCRIPTION.

The date on the address label shows the time to which your subscription is paid; Jan. 17 means that your subscription is paid to January, 1917. Renew within the month before the expiration of your subscription to avoid missing any copies. It takes a month to change date on label, or to put a new name on our mailing list after we receive the subscription.

"The world hated them because they are not of the world, even as I am not of the world."

I have been experimenting with a few bees here the past summer, making four good colonies out of one. I am taking GLEANINGS, and like it very much; but, most of all, I enjoy "Our Homes." I am glad you are situated to do so much toward bringing in the kingdom. There is a crying need for men of your type just now, or, I should say, Christians of your type—the "not afraid of public opinion" sort. What we need at present is not more battleships and soldiers, but more saints. The average Christian today is too much hand in hand with the world. We need to get back to the place where every Christian, as such, was at war with the world. May you be given strength and wisdom from the never failing source to carry on the work.  
Pittsburg, Sept. 29. ANNA H. DAWSON.

# Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER. By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE. By "The Spectator," of the Outlook. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES. Our new complete catalog, mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER. Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES. The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING. Just the thing for the up-to-date housewife. Price 10 cents.
- BEES AND POULTRY, how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES. A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE. A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES. A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.
- THE BUCKEYE HIVE, or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET CLOVER, the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE. A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth, \$1.00 postpaid.

**3 Garden Tools in 1**  
The **BARKER** Weeder, Mulcher and  
Cultivator

The only garden tool that successfully, in one operation, kills weeds, and forms a complete soil mulch to hold moisture. "Best Weed Killer Ever Used." A boy with a Barker beats ten men with hoes. Has shovels for deeper cultivation. Self adjusting. Costs little. Write for illustrated folder and special Factory-to-User offer.

# ONLY 75 LEFT

We have before said that when our present supply of Prof. Cyril G. Hopkins'

## "The Story of the Soil"

is exhausted we shall be unable to furnish more in this low-price edition. We bought the last paper-bound volume of this wonderful book that the publishers had, and now we have only 75 left. If you want one of them you must act quickly. The price with "Gleanings" one year remains \$1.15. You can purchase single copies of us (while they last) at 30 cts., postpaid. Send today. Don't delay.

"OUGHT TO BE IN THE HANDS OF EVERY FARMER  
IN THE WORLD."—Farmer and Breeder.

We want you to own this book. Don't fail.

Gleanings in Bee Culture, Medina, Ohio

# Bees

# Poultry

# Fruit

They go well together---  
So do---

|                                |                                    |
|--------------------------------|------------------------------------|
| Gleanings in Bee Culture . . . | } ALL THREE<br>\$ 1.00<br>ONE YEAR |
| Green's Fruit Grower . . . . . |                                    |
| American Poultry Advocate      |                                    |

**GLEANINGS IN BEE CULTURE** will be bigger, better, handsomer, more useful in 1917, than ever before. That is the Editor's promise to its readers—and it will be kept.

**THE AMERICAN POULTRY ADVOCATE**, published at Syracuse, N. Y., has the newest and best in poultry literature each month. It is helpful to the beginner as well as the expert. No detail of successful poultry-raising or egg production left out.

**GREEN'S FRUIT GROWER**, Rochester, N. Y., is the oldest fruit journal in America. It tells in season all about spraying, how to beautify the home grounds, about ornamental shrubs, vines and trees, small fruits, home gardens, and successful orchards. In fact, it covers all phases of fruit-growing, from planting the trees to marketing the fruit.
