THE IDEAL BEE-VEIL

Oftentimes when out in the yard working with the bees one stoops over to pick out a frame, and, as usual, bees keep buzzing around his head, watching for a chance to sting. The cloth veil which is often used sticks to the face when one bends over, and gives the bees an opportunity to sting. The IDEAL BEE-VEIL is constructed of cloth of wire, there being a cord at the top of the veil used to pull the cloth around the crown of the hat. The lower part also has a cord which fastens around the waist. The wire on the IDEAL veil does not strike the face, and prevents the bees from stinging. It can be readily seen that a veil of this kind has the cloth veil far outdistanced for comfort and utility. Sparks from the smoker do not burn holes in the IDEALS as in the netting veil.

The veil is manufactured by us, and is recognized by the best and largest beekeepers as the most practical veil on the market.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and capping white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

- Honey packed in second-hand cases.
- Honey in badly stained or mildewed sections.
- Honey showing signs of granulation.
- Leaking, injured, or patched-up sections.
- Sections containing honey-dew.
- Sections with more than 50 uncapped cells, or a less number of empty cells.
- Sections weighing less than the minimum weight.
- All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color, and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH

1. *Extra Fancy*.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2*.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

CHICAGO.—The market is simply stagnant on all kinds of honey. Prices are without material change. Beeswax is selling at 28 to 30 cts. per lb.

Chicago, Jan. 4.

R. A. BURNETT & Co.

ST. LOUIS.—Our honey market lately has been very dull and slow, but stocks quite ample for small demand. We are now quoting white comb honey in 24 sections at \$3.25 to \$3.50; amber from \$2.50 to \$3.00; dark and inferior, less; extracted honey in 60-lb. cans, from 5 to 8½; in barrels, from 5 to 6, according to quality. Beeswax, 28 for pure; impure and inferior, less.

St. Louis, Jan 6. R. HARTMANN PRODUCE CO.

ZANESVILLE.—The demand for honey is about normal for the season. Prices remain as per previous quotations. Choice to fancy grades sell in single-case lots at \$4.00 to \$4.25; lighter weight and inferior grades correspondingly lower, with usual discount to the jobbing trade. Best grades of extracted are selling at 9 to 11, according to quantity. Twenty-eight cents cash, thirty in trade are ruling prices for wax as received first-hand from producers.

Zanesville, Jan. 6.

E. W. PEIRCE.

INDIANAPOLIS.—The demand for honey, both comb and extracted, has not been very brisk since our last report, but this we believe is due mostly to the holiday season. We are being offered honey by many producers, and they seem very anxious to sell. No. 1 choice comb is selling at \$4.00 per case; No. 2 at \$3.50 per case. Extracted of fine quality is bringing 9 to 11. We are paying 28 cts. cash or 30 in trade for good average wax delivered here.

Indianapolis, Jan. 5.

WALTER S. POWDER.

KANSAS CITY.—The supply of both comb and extracted honey is good, but the demand is only fair. We think the mild weather has something to do with the light demand. We quote No. 1 white comb honey, 24-section cases, \$3.15 to \$3.25 per case; No. 2 ditto, \$2.75 to \$3.00; No. 1 amber ditto, \$3.00 to \$3.10; No. 2 ditto, \$2.50 to \$3.00; white extracted, per pound, 7½ to 8; amber ditto, 5½ to 7; No. 1 beeswax, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.

Kansas City, Jan. 5.

We are in the Market to buy both comb and extracted honey. Write us what you have to offer, naming your best prices delivered. Every time an interesting price is named us, we buy, and remit the day shipment arrives.

Ship Us Your Old Comb We render it into wax, and pay market price.

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring besides saving 3 per cent

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the bee-keeper requires for the proper conduct of an apiary.

C. H. W. Weber & Company, Cincinnati, O.
2146 Central Avenue

The Prospect for 1916 is Very Good

It would be wise to be one of the beekeepers who are now ordering supplies for another season; besides, there is a discount for January of 3 per cent and February of 2 per cent. Send us a list of goods required and we shall be glad to quote you prices if you have no catalog. Catalog will be sent only on request. Our stock for season of 1916 is now here, and we can fill orders pretty promptly. We carry a full line here at Syracuse; and by ordering from here you will save time and freight. Goods will arrive in better condition on short hauls. Better make out a list before you forget it.

QUEENS OF QUALITY

The editor of *The Beekeepers' Review* and his sons have 1100 colonies of bees worked for extracted honey. With all those bees working with equal advantage, all having the same care and attention, they have an opportunity unexcelled to ascertain without a reasonable doubt colonies desirable as breeders from a honey-producer's standpoint. Likely, never in the history of beekeeping was there a better opportunity to test out the honey-getting strain of bees than this. Think of it, 1100 colonies with equal show, and a dozen of those colonies storing 250 to 275 pounds of surplus honey this last poor season (with us), while the average of the entire 1100 being not more than 40 pounds per colony. We have sent two of our best breeding queens (their colonies producing 275 pounds surplus each, during the season of 1915) to John M. Davis, and two to Ben C. Davis, both of Spring Hill, Tenn., and they will breed queens for the *Review* during the season of 1916 from those four superior honey-gathering breeding queens. Those young queens will be mated with their thoroughbred drones. Our stock is of the three-landed strain of Italians; also that of John M. Davis; while Ben C. Davis breeds that disease-resisting strain of goldens that is becoming so popular.

By this time you are likely thinking that your strain of bees may be improved some by the addition of this superior strain of *Review* queens, and how you can secure one or more of those superior honey-gathering queens as a breeder. We will tell you. They will be sold to none except *Review* subscribers. If you are a paid-in-advance subscriber to the *Review* for 1916, we will mail you one of the daughters of those famous queens in June for a dollar. If not a subscriber to the *Review* for 1916, send \$1.75 for a year's subscription to the *Review*, and one of those famous queens. These queens are well worth two dollars each compared to the price usually charged for ordinary queens, but we are not trying to make money out of this proposition, only we are anxious to have every subscriber of *GLEANINGS* a subscriber to the *Review*, and we are taking this way to accomplish the object. A few of the very first orders for queens that we receive can be mailed in May, but the majority will not be mailed until June. Orders filled in rotation. Have your order booked early and avoid disappointment. Address with remittance

THE BEEKEEPERS' REVIEW, Northstar, Michigan.

Constipation--Causes and Relief

Constipation causes much unnecessary discomfort—discomfort easy to relieve by slight changes in daily habits. This Dr. J. H. Kellogg proves in his latest book—"Colon Hygiene"—in which he tells you of the common causes of constipation and how they may be removed by a little careful attention to daily habits in your home and wholly without drugs. Dr. Kellogg speaks with authority because, for nearly forty years, he has been Superintendent of the Battle Creek Sanitarium—an institution which, through its remarkable achievements in relief of human suffering, has earned a reputation as one of the greatest scientific medical institutions in the world. Here Dr. Kellogg has had opportunity to observe, treat, and prescribe for thousands of cases of indigestion, constipation, and the more serious disorders to which they often lead. Thus, Dr. Kellogg writes from the standpoint of extensive experience—he deals with facts, not theory. What Dr. Kellogg recommends you can depend upon. His book contains nearly 400 pages, with many illustrations, diet tables, and full instructions for exercise, rest, and sleep. Price of the book only \$2 postpaid in the U. S. Order today. You take no risk. If you are not entirely satisfied, return book at once for prompt refund. Send order to

GOOD HEALTH PUBLISHING CO., 100 W. Main St., Battle Creek, Mich.
On Sale at Leading Book Stores
Always mention *GLEANINGS IN BEE CULTURE* in writing to advertisers.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Candy for WINTER STORES

Why not be sure your bees have enough for winter by giving each colony one or two plates of candy? We have it in large paper plates weighing about two pounds, enough to last a colony three or four weeks. Can be sent by post. Write for prices, also catalog of supplies.

H. H. Jepson, 182 Friend St., Boston, Mass.

BEE SUPPLIES Send your name for new 1916 catalog out in January.
Dept. T, CLEMONS BEE SUPPLY CO.,
128 Grand Ave., Kansas City, Mo.

Equipment purchased during the quiet winter months may be made ready for busy spring and summer months. The early-order discount pays you interest on your money.

“Root Quality” equipment means BEST QUALITY equipment. The Root bee supplies are up to the minute. The most complete line of bee supplies made.

We sell Root's Goods in Michigan. Order from Root catalog, or we will quote on request. January cash discount, 3 per cent; February, 2 per cent. Beeswax wanted.

M. H. Hunt & Son, 510 N. Cedar St., Lansing, Mich.

When You Think of Bee Supplies, Think of Indianapolis

We Sell Root's Bee Supplies
 ---the Goods that Satisfies....

Indications just now are very favorable for a good season next year. A good season means an excessive demand for Root's goods at Root's prices. By ordering now you will receive your goods promptly, also save the cash discount for early orders, which is three per cent in January, and you can put them together in your spare time.

If you are interested, and it is your intention to order your supplies before goods are really needed, just try placing a trial order here. We are quite sure you will continue with us year after year. Some, of course, never buy supplies till after they are needed. But the men who are most successful are preparing *right now* for next season.

We allow you 30 cents a pound in trade for good average beeswax delivered here.

Finest extracted honey in five-gallon cans ready for immediate shipment. Write for quotations.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

The Dollar Hen

My opinion is that "The Dollar Hen" is not only one of the best books on poultry that we have at the present time, but it is worth nearly as much as a dozen other books. Perhaps this is extreme, but we have very few books that are strictly up to date, and still fewer that pitch right into the superstitions and humbugs scattered thru all our poultry books and journals.—A. I. Root.

This book will be clubbed with GLEANINGS for one year at \$1.35; or, if you have already subscribed a year or more in advance you can have the book for 60 cents.

GLEANINGS
IN
BEE
CULTURE,
Medina,

"Next Door to Everything"

reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business, distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

January cash orders are subject to a special discount of 3 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to prepare carefully the bees for winter, and anticipate all possible requirements.

TERRY IS DEAD

BUT the great work he wrought in pointing out Nature's way to health will go on. So broken in health at 40 years of age that the doctors gave him up to die, he began all over again with fine courage to build himself up on a plain common-sense basis.

He tells about it in his book, "How to Keep Well and Live Long." He did not live to be 100—but he did create a wonderful book. It is clear, simple, and straightforward. Thousands of copies have been sold. They are making people healthier and happier who sensibly follow his teachings. Mr. A. I. Root heartily endorses Mr. Terry's writings on health subjects.

"How to Keep Well and Live Long" is a substantial book, illustrated, 6 x 9 inches, 222 pages, and bound in cloth.

Price: \$1.00, postpaid; or clubbed with Gleanings in Bee Culture for one year at \$1.50.

Canadian postage on Gleanings, 30 cts., foreign 60 cts. extra

Gleanings in Bee Culture
Medina, Ohio

Many have stated that the 1915 Lewis Catalog was by far the best bee supply catalog ever issued.

The New Lewis 1916 Catalog is still better than the 1915 edition particularly in the illustrations, most of which will be found to be entirely new and of the finest work the engraver is able to produce in this line. As in previous editions, all descriptions and lists of prices are comprehensive and very plain.

This new Lewis 1916 Catalog is now out. If you have not been receiving the Lewis Catalog annually send in your name at once and we will see that you get your copy promptly.

VOL. XLIV.

JANUARY 1, 1916

NO. 1

EDITORIAL

OUR apologies are due to our readers for allowing the Dec. 15th issue to be a little late. The only explanation we have to offer is the extra number of pages and the very complete index, comprising 3737 references. This issue is likewise delayed for the same reason. If our readers will use this index as they should we feel sure they will pardon the delay.

In the Shade of the Spanish Moss

OUR cover picture in this issue shows a part of the apiary of Harry Hewitt, Apopka, Florida. The bees in Lakeside apiary enjoyed a good flow from orange blossom, but since that time the proprietor has had to feed forty pounds per colony to keep the colonies alive. He hoped to get enough from partridge pea to carry them through the winter.

Forest fires in April took all the palmetto, gallberry, and red-bay pasture.

Prominent Wisconsin Beekeeper Dies

IN recording the deaths of prominent beekeepers we have seldom found it necessary to make mention of a death so sudden as in this present instance. On Thursday, Nov. 25, Mr. H. C. Ahlers, who had just returned from a hunting-trip in the northern part of the state, had a severe hemorrhage, from which he did not rally, his death taking place at his home in West Bend the following day.

Mr. Ahlers was an extensive beekeeper, having four or five out-apiaries, and he made a specialty of selling honey direct to the consumer. He also sold bees and queens from his best honey-producing strains. It was only in November that he advertised for a helper in his beeyards for the coming year.

GLEANINGS extends sympathy to the bereaved wife and daughter.

Honey Post Cards.

AT the New York State meeting a year ago a publicity committee was appointed to consider the ways and means for improving the honey market, which committee was held over this year. Some time ago the State Association got up a writing-tablet with illustrations, information, etc., regarding the honeybee. This publicity committee is now contemplating putting out post cards with snappy designs and pictures, tending to call attention to honey and educate the public concerning it.

In order to secure designs, prizes are being offered for sketches—\$15.00 for the first prize, \$10.00 for the second, and several more prizes of \$5.00 each. Correspondence is invited. Address F. Greiner, Naples, N. Y.

The Quebec Beekeepers' Association

WE have just received a full manuscript copy of the secretary's report of the latest meeting of this society, held in Montreal Nov. 10 and 11. This report is all in the French language, as were also the discussions themselves. Lack of space alone prevents a full translation and presentation of the report, altho much of it relates to the mere routine work of the society. As a whole, however, it shows great activity on the part of our beekeeping friends in that far-north country. There were present a great many officials connected with the provincial government, and, in fact, from most of the higher educational walks in life, which is certainly an encouraging feature.

We note that Dr. Pilon gave an interesting talk on the advantage of bees to agriculturists in general, saying he was convinced of the necessity of bees for pollination of fruit.

As a copy of this report can be had, probably, for a nominal sum, we would advise all our readers who understand

French to send to the secretary, Oscar Comire, Abenakis Springs, Quebec, and get a copy.

That Record-breaking Car of Honey

On page 832 of our issue for Oct. 15 we mentioned the fact that Mr. William Lossing, of Phoenix, Arizona, was loading the biggest car of honey that was ever recorded. He crowded into that car 646 cases, or a total of 87,589 lbs. As the average car does not go much above 40,000 lbs., we raised the question whether our correspondent was not overdoing it by piling the cases, as we supposed, clear up to the ceiling and thus putting an enormous pressure on the cases below. He comes back at us as follows:

Mr. Editor:—Some time ago I wrote you about a large car of honey I was loading—so big a car that you thought I was overdoing it. Well, that part is quite natural for easterners who are not accustomed to western ways, especially in Salt River Valley, where milk and honey flow in large quantities.

As per your request I wish to make another report on the big car which you imagined was filled to the top. Why, it was only three tiers deep the full length of car, and four tiers at either end. Each single tier was ten cases wide. When this car arrived at its destination it was reported that they never heard of such a big car, and that it got thru all right. Well, the next four cars were loaded as follows: 644 cases, 633 cases, 444 cases, and 457 cases. I will load two cars this week with over 500 cases in each. While I would not advise loading to the roof of a car as you feared, I deem it perfectly safe to load at least four tiers high if so desired, as, when cases are properly loaded six or seven tiers high, they cannot break down.

Our usual way of loading is lengthwise, cases packed close both ends and sidewise. I have my first loss yet to come when loaded as above, and I have been shipping for some nine years. So far this year I have produced 4100 cases, which is not over half of what is produced in Maricopa County, as we have between 22,000 and 23,000 colonies in this county, and no foul brood.

Phoenix, Ariz., Nov. 22.

WM. LOSSING.

We take it all back, friend Lossing. You Westerners often do things on a big scale. The fact that the cars were large in proportion to the load they were carrying shows that you were not taking the risk we had supposed.

The Amount of Stores Necessary for Good Wintering Outdoors

ELSEWHERE in this issue, page 9, Mr. J. L. Byer, commenting on our statement that less stores are needed in the North than in the South, says:

"As we are further north than Ohio, on the same basis of reckoning we should require even less honey than they do in Ohio. But I wonder where the producer here in Ontario lives who would trust his colonies

outdoors to go into winter quarters with stores aggregating but 20 pounds, combs included."

It would hardly seem to us that bees in Ontario would require less stores where they have a longer period of confinement than in Ohio. Indeed, the very reverse would be true. In our locality (and that represents most northern localities south of the Great Lakes) 20 lbs. of good sealed stores is enough to carry the bees thru from November till the middle of April, or even to the beginning of May. Our bees fly as late as December 1, and as early as the first of March. By April 1 or 15 they gather some natural pollen and nectar from the soft maple. From April 15 to May 10 they gather considerable honey from dandelion and fruit-bloom. Mr. Byer says that in his north yard he has heavy snowfalls as a rule, and this yard is never visited by him from late fall till early spring. Reports from other Ontario beekeepers show that bees may be confined five months without a flight. Such continuous cold and severely cold weather would cause a larger consumption of stores than a milder cold. When it is so cold, indeed, that bees have to go into a state of activity, as Dr. Phillips has described in Bulletin 695, they begin exercising, and activity means consumption of stores. We proved that, in our observation hive, the colder the weather, the more the bees consumed.

But there is another very important point overlooked by our correspondent. Bees in the South consume more stores because they will rear brood more or less *all winter*, while those in the North will do so under normal conditions only toward spring. On this point there would not be much difference between Ohio and Ontario.

Taking it all in all, the inference of Mr. Byer, that bees in Ontario would consume less stores than here in Ohio, is hardly warranted. The facts are, and Dr. Phillips' bulletin, from a theoretical point of view, proves it, that, in a mild cold, bees will consume less stores than where it is colder or warmer. When the temperature outside of the cluster is 57 F., the bees actually consume less than when it is higher or lower. See Farmers' Bulletin 695 reviewed on page 876, Nov. 1st issue. Bees in Ohio consume less stores because the winter temperature is more favorable, and the winter is shorter, so that they can gather nectar and pollen a month or six weeks earlier than Mr. Byer's bees. Thus we have a distinct advantage in smaller consumption.

Mr. Byer says he himself would require from 40 to 50 lbs. of stores, and Mr. Sib-

bald uses 70 lbs. The former, at least, says he prefers honey to syrup. Good extracted honey in Ontario sells at about 10 cts., and according to that it costs between four and seven dollars for stores to carry Ontario colonies thru winter. This does not include the cost of the investment, winter cases, and putting bees into winter quarters and the labor of unpacking. Does not Mr. Byer make some mistake? The cost of between five and eight dollars for winter stores would seem to be an excessive burden on the business. No wonder some of the beekeepers of Ontario are thinking that it would be cheaper to brimstone in the fall, and buy bees in pound packages from the southern states. It certainly would, at this rate.

Mr. Byer by inference made a statement (see p. 905, Nov. 1) that too much packing during winter was too much of a good thing. Is it not true that he and some of his fellow beekeepers would save stores by using more packing instead of less?

Do Bees Perish During Winter when their Hives are Completely Covered with Snow for Long Periods of Time?

IN the same department Mr. Byer takes issue with our statement made to a correspondent, "When hives are completely covered with snow for several months it is enough to kill any bees." He said he used to think that way; but he has changed his mind. Some of his bees at the north yard he declares remain covered with snow for three months or more, and yet he has had perfect wintering. At this yard he used upward absorbents—no sealed cover.

Mr. Byer has two conditions that contribute to good wintering in his yard—namely (1), a cold atmosphere during which the snow does not melt as it does in Ohio, run in at the entrance, and then freeze; and (2) upward ventilation. We have a great many thaws in our climate. The snow becomes dense and soggy, and sometimes the ice hermetically seals the entrances. We use on the hives thin boards that are not sealed down. As others in our climate have similar conditions it would be a little dangerous to allow the statement to go out that bees in hives completely covered with snow are always safe. That depends on the climate and conditions. We have had many reports showing where colonies buried under snow died because either the entrances were sealed with ice or banked up with snow that had partially melted and frozen.

We have been in Canada during mid-

winter, and found the atmosphere is decidedly colder and dryer than south of the Great Lakes—at least south of Lake Erie. The snow is light and fluffy in northern Ontario, and such snow can cover hives to the depth of a foot or more, providing the climate is dry and cold.

A Look into 1916

THIS is not an ad. The advertisement appears on the back inside cover page; but by these paragraphs we hope to make a few further suggestions from an editorial point of view regarding our special numbers for 1916. Curiously coincident with the editors of a number of other magazines, we decided this year to give the main attention to matters commercial rather than professional. We are going to talk a lot about selling.

The first July issue is the special on advertising. We are gratified to announce that we have secured the promise of an article or articles from a man who is possibly the best authority on advertising honey in this country. He is the head of an advertising agency distinguished by unique achievement and unusual growth. Altho he has had charge of the only national advertising campaign ever carried out for honey, probably few beekeepers know him, simply because his attention has been toward selling and not producing. We allude to Mr. W. C. D'Arcy.

We shall also present articles on exhibits at fairs and food shows, newspaper and direct by mail advertising, and other means of publicity. We hope for this issue, as well as all the others, that honey-producers who have had experience with advertising in any form will state it for the benefit of their fellow beekeepers.

The marketing-honey number, the first August issue, will deal with matters of a similar nature, with the emphasis upon selling. From a dollars-and-cents point of view we hope to make this the most practical in 1916. We look for articles on local sales, whether by canvassers or thru stores, and distribution by jobbers. We expect to have some straight talk on co-operation as well.

The March 1 buildings number is sure to interest everybody. Send in the plan of your extracting-house or workshop, with a description accompanied by specifications and photographs, if possible. Labor-saving arrangements of equipment will be especially interesting.

The first May number is the special on out-apiaris. Large-scale beekeeping has

been featured before; but there is always so much new and valuable information coming up all the time that there are plenty of new things to be said about out-apiaries. If you have one, tell us so. Details on which we wish contributions are specified in a paragraph in advertisement elsewhere.

It may be that wax is a side line with you, very much aside. And yet there are profits in beeswax, especially for the man whose freights on comb and extracted honey are high. In fact, we have had several inquiries of late about whether it would be possible to run bees for wax primarily, and make honey a by-product. What do you think? And how would you go about it? This will be the meat of the June 1st number, the special on wax production.

Just as we have done in former years, we chose these special topics from suggestions which our readers have obligingly sent us during the past year. While a considerable number of articles are already on hand, there is plenty of room for more good ones.

Government Data on Wintering in the United States; Causes of Winter Losses.

Bulletin No. 325, of the United States Department of Agriculture, among other things, concerns itself with wintering. The data were secured from 650 honey-producers in 42 states, covering 80,000 colonies of bees. These reports came mainly from the best honey-producers; and the presumption is that the averages show up better than if returns were taken from beekeepers from all over the United States. Some interesting data have been secured; and among them, briefly summarized, are the following:

The average quantity of honey for stores reported in the hives at the beginning of winter is in excess of what is usually considered to be necessary to carry a colony from one honey-flow to another. As every up-to-date honey-producer will be on the safe side, he will put in more than enough. Those who report belong to this class. The figures show 32 lbs. per colony for the United States when 25 lbs. are usually considered enough.

We estimate that bees in the South require more stores than those in the North, for the simple reason that brood-rearing in some of the more southern places may go on every month in the year. But a study of the tables shows that there is but very little variation between the food supply, either north or south. This may be and

probably is accounted for by the fact that bees in the North are confined in their hives for a long period of time without flight. This causes more or less bowel disturbance, and toward spring a large consumption of stores, thus aggravating the trouble until dysentery pulls the colony down.

As would naturally be expected, the reports show that winter protection varies according to the latitude north or south.

Winter losses range from 15 to 20 per cent in the more northerly states, and from 5 to 15 in the more southern. The cause of winter losses is usually thought to be missing or worn-out queens. A considerable percentage of the reports failed to state the cause of death, and it is believed that the heaviest mortality is due to starvation.

In the line of honey-yields, the July 1st honey report indicates that the honey season had been late from one to three weeks over most of the country, due to the cold and generally wet weather. The average of surplus honey up to July 1, 1915, was estimated at 18.3 lbs. as against 20.7 for the preceding year. Taking the country as a whole, this amount, however, is only about 50 per cent of the total crop for the entire season, estimated up to Sept. 1. On that basis the average would be twice as large, or 36 and 40 lbs. respectively. The yield from the small apiaries, especially of the backlotter and of the up-to-date farmers would be higher than that from the large apiaries.

The northern states, with the exception of Illinois, Wisconsin, and Nebraska, show that a high proportion (from a half to two-thirds) of their production is in the form of comb honey, while in the South and West generally it is only from a third to one-half of all.

Reports show that 60 per cent of the honey removed from the hives is consumed locally. However, more than half is shipped out of Vermont, New York, Florida, Kentucky, Louisiana, Texas, Wyoming, Colorado, New Mexico, Arizona, Utah, Idaho, and California.

California is estimated to furnish about a fourth, and Texas one-eighth of practically all the extracted and comb honey produced in the United States. If the figures from all the producers could be secured we believe that the two states mentioned are credited full high.

Copies of the bulletin above referred to can be obtained of the Superintendent of Documents, Washington, D. C., for 5 cents.

An editorial in the second January issue will discuss data from this bulletin on honey imports and exports.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

VON MORALEC, a French apileryman, made the first drone-trap, according to *Deutsche Bienenzucht*, 172.

GRACE ALLEN, I like you—first rate—but I won't like your "favorite apiarian attitude," p. 968. True, it's as good as sitting on a "wiggly hive-cover," but why not take a decent seat?

J. E. CRANE advises, p. 986, that in a case of European foul brood the colony have a cessation of egg-laying for two or three weeks. Will not ten days do, leaving the colony stronger?

BEEN "rasslin'" with grip for nearly a month, and cough hardly any now. Thankful it didn't come two months later, for I want to get to that convention at Chicago, Feb. 22. You goin'? [Expect to.—Ed.]

F. J. LEE, p. 997, the editor has sized the thing up about right as to light in the cellar. My bees in cellar, having air the same as outdoors, will stand full light for weeks; but later on light is bad, and fastening in hives would be disastrous.

Now is a good time to ask your grocer to save you some cork-chips that come in kegs of grapes. Then to make the finest drinking-place for your bees, all you have to do next spring is to put water in a tub, pail, or half-barrel, and throw the cork upon it.

A. I. ROOT is asked, p. 1001, to preach sunshine for the babies. Sunshine outdoors is all right, but not in the house. Fashion dictates that the window-shade must be pulled down to just such a height, and a baby more or less is not to be considered when it gets in the way of fashion.

DR. NELSON has taken 280 pages to follow a young bee through its life in the egg. What an achievement it would be if it were as carefully followed through all the rest of its life, with all its goings, comings, and doings! Dr. Nelson has laid a grand foundation.

I SAY "amen" to A. I. Root's prayer, p. 911, that the president who comes after Wilson may be a praying man. But I wouldn't mind if the present incumbent would stay on the job for another four years, if he'd only agree to tackle the liquor problem with all his might.

W. P. ROOT, the man upon whom I depend to keep my punctuation straight in GLEANINGS, in his excellent summing-up of Bible mention of honey, p. 974, thinks

Jonathan ate a large quantity of honey. Jonathan testified, "I did certainly taste a little honey with the end of the rod that was in my hand." The mention of Christ's eating honey, Luke 24:42, does not appear in the American revision.

YES, Mr. Editor, I note that the other fellow of the floury name agrees with you that piping and quahking are the same, p. 993. I note also that both you and he avoid explaining how it is that notes of such unequal length *out* of the cell become of the same length *in* the cell. [So far as we are concerned, we did not know that we were "avoiding" any explanation. Perhaps we do not get your point.—Ed.]

DOUBLE CAPPING of sections (that is, a fresh layer of honey built over that already capped) is reported in the *British Bee Journal*, 413. I never had a case of that kind with sections, but have had it a good many times on brood-combs. The curious thing about it is that the bees don't seem to know enough to open the bottom capping; and unless the beekeeper uncaps it the bees may starve before they find the honey under it.

WESLEY FOSTER says of European foul brood, p. 972, "It has been my observation that transferring and requeening produces results while caging the queen has not." In this locality, in mild cases (I'm not sure about severe cases) caging produces just as good results as transferring, and leaves the colony stronger. [Is it not true that European foul brood that has run for a certain length of time loses its original virulence? If that is the case, would it not explain the difference between the experience of Wesley Foster and yourself?—Ed.]

MRS. ALLEN wants to know how many pounds of syrup will replace a given shortage of sealed honey, p. 969. A syrup of 5 pounds sugar and 2 pounds of water is about equivalent to 7 pounds of honey; so for every pound of honey lacking, feed 5/7 of a pound of sugar, no matter how much water is added. [Is it not possible that Mrs. Allen has raised the question whether a pound of thick syrup is equal to a pound of honey of the same density? Was it not yourself who made the statement something over a year ago that, pound for pound, honey will go further than syrup? In your statement above you almost imply that, pound for pound, they are one and the same. How about it?—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

But please, Mr. Editor, after my last paragraph, page 969, Dec. 1, you say that twenty pounds of sealed stores is advisable for northern wintering, and twenty-five or thirty for southern, and that is not what I was trying to elicit, but, rather, this: How many pounds of *syrup* (two measures of sugar to one of water) are required to make a certain number of pounds of *sealed stores*? If you found a hive lacking ten pounds of stores, would ten pounds of syrup do the work? In other words, will a pound of syrup make a pound of honey for wintering? (Why didn't I put it that way in the first place) Our judgment, based on nothing in particular, said no. To hives lacking ten pounds, we fed about fifteen pounds of this two-to-one syrup, on a vague "better-be-safe-than-sorry" proposition; but suppose one wanted to be accurate, how many pounds should he feed? [See answer to a Straw of Dr. Miller's in this issue. If in the fall a colony were lacking sufficient stores to carry them thru we would not hesitate to make up the deficiency by feeding. While a pound of sealed sugar syrup might not equal a pound of honey, it may be a better feed if the honey is of a poor quality. It is probable that a pound of good table honey like clover, basswood, and the like, will go further than a pound of sealed sugar stores, because the former contains some food elements that the latter does not.—Ed.]

FOR BEGINNERS.

Have you ever happened to hear of anything called the ventriculus? or anything else called the proventriculus—which you would very naturally, and quite correctly, infer was in front of the ventriculus? Well, there are such things, and most fascinating they are to study about. The more common name of the ventriculus is stomach, and of

the proventriculus is stomach-mouth; and it makes a wonderful story—how the nectar passes through the worker bee's oesophagus, down into her tiny honey-stomach, from there to be either emptied out into cells or held as reserve for her own nutrition. If the latter, how deftly it slips down into the real stomach just any time it is needed, perhaps even when the bee is in full flight. And then the polite, delicate way that the real stomach presses its sensitive little mouth up, right through the honey-stomach, to eject some of this partially digested food, or chyle, to feed the larvæ, leaving the nectar and pollen in the honey-stomach daintily undisturbed. Why! it is as interesting as a new novel, and far more thrilling and

beautiful. And do you know where a bee's heart is? Do study about these things. Every minute detail is startlingly perfect and thoroly worth while to know about. Even if you don't think it practical enough to be necessary, do it for the delight of it and the zest of it and the charm.

On page 624, Aug. 1, Mr. Gates mentions the occasional change in the flora of a given locality and the appearance of the new honey

sources. Dr. J. S. Ward, Tennessee state inspector, says that somewhere up the Cumberland River the beekeepers report the appearance in the last year or two of a new generous-yielding honey-plant whose name they do not know. It is a late-summer and early-fall bloomer, and Dr. Ward plans to go up there when it opens this year, to help establish its identity.

Surely Major Shallard's tragic accident arouses the sympathy of beekeepers this whole country over; and how plucky his letters sound—not a whine in them! J. D. Bailey's experience in the disastrous Louisiana storm was bad too. Our best wishes to both these gentlemen, and the hope of a more fortunate year to come.

Greetings

Happy New Year to you, friends,
Gleaners one and all,
Amateurs and veterans, beefolk great
and small—
East and west and south and north,
forest, field, and fen,
Happy New Year to you all, women-
folk and men!
Happy New Year to the kiddies with
their starry eyes!
Greetings to the editors, friendly folk
and wise!
Everybody, everywhere, here and over-
seas,
Happy New Year to you all—and also
to your bees!

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Another fine rain, December 4, came in time to save the filaree.

According to official reports there are now more than 15,000 colonies of bees in Imperial County.

There has not been a season for some years when the eucalyptus has shown such a profusion of bloom as it does this season, especially the bluegum (*Eucalyptus globulus*).

The supply of honey is becoming very limited in this part of the world, and prices are advancing a little. One buyer claims to be unable to find enough California honey to fill his orders. A recent sale of a 30-ton lot in Orange County at figures as high as 6 cents is a big improvement in prices offered heretofore. A part of this lot was carried over from 1914 on account of low prices. There is some credit due the beekeeper who owned it and stood for better prices, even if he did have to wait nearly a year and a half to win his point. A number of buyers have been scouring the country for honey, and in some sections, at least, have taken all they could get, at their prices. The market is sure to be cleared before another harvest.

Displayed on a large bill-board in this city is an advertisement of a corn syrup which is doubtless no better than the same kind of corn product that has been handed over counters for years. Hundreds of eyes have seen the word, the curiosity of many has been excited by this apparently new syrup, and will be satisfied only by the purchase of a trial order at least. One of the greatest ideas in advertising is to keep an article constantly before the public. If the colored cook that is paraded before the public in Cream of Wheat advertisements should disappear, the public would take it for granted that Cream of Wheat had ceased to be, and the sales would no doubt slump distressingly. If honey were paraded to the same extent in advertising, the sales would increase to an enormous extent. But where is the money to back such an extensive advertising campaign?

The mooted question of "Goldens" seems to have bobbed up again. Both the editor and Mr. Byer discuss it at some length in the Dec. 1st issue. My ideas have not

changed since I had my say in the Oct. 1st issue. I covered the ground pretty fully so far as my ideas were then concerned. Now comes Mr. Byer with the plea that they do not winter at all well, while Editor Root says, "and too many of them have been cross, very cross." Since my plea for the fair race in the Oct. 1st issue, I have received letters from as far north as the location of Mr. Byer, from men who assure me they will compare them with any bees of any kind, for any qualification.

I have bred extensively this season from a golden queen that was guaranteed in every respect and qualification. I have as yet no reason to question the guarantee; and as for crossness I can only say there has been no smoke used on this colony during the entire season, and not one sting has been suffered by any one. Last season I introduced both golden and three-banded, with no apparent difference in their qualities. I have never claimed the goldens were superior to the three-banded strain only in black brood (European foul brood) resistance; but I do claim there is no sound reason why there cannot be a strain the equal of any three-banded strain for other qualities. It is my opinion there are now several strains which have reached that point, and I have the assurance of several that they are superior in resistance to disease. As a matter of producing honey, the thorobred stock of any race have nothing on the common mixed race of mongrel breeds. Last season the best colony in my yard was the darkest in point of color.

If I were in a locality where there was no danger of "black brood" I would breed alone for quality, whether from a dark or a light race; but as it is, I cannot afford to take the risk. I believe the goldens are superior in resistance, and I expect to prove that the goldens are at least the equal of any race on earth. There are some strains of chickens which have been bred for show points so long that, as a commercial factor, they are very unprofitable. That has been the case in the past with the goldens; but the future will correct those mistakes. To a great extent it has been corrected; but the prejudice against them remains to be lived down. They must now pay the price of color. They should at least be given a fair and unprejudiced individual-strain test, for there is more than one strain of three-banders being unloaded on the public that have little merit to back their sales.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

THE HONEY MARKET.

If all the comb honey could be sorted in such a manner that the honey subject to early granulation could be marketed each year before Christmas time, and a good supply of the clear transparent non-candyng comb honey held for the spring trade, the market would be more stable. The trouble is that there is always the fear of not enough comb honey being produced to go around, so the buyers load up early on high-priced honey, buying for the whole season. If the crop is larger than estimated by the buyers, there are quite a few cars of honey that have to stand the slump in prices late in the season. If these cars of honey could be held until spring, just as good prices could be secured as for the early honey, provided it is not subject to granulation.

The year 1915 has passed, and in beedom a few signs point to progress made. The use of honey is being extended, and the beekeepers are realizing that practical honey publicity lies largely with them.

The "Eat Honey" sticker has won its way into favor with hundreds and thousands of beekeepers.

The perfecting of methods for shipping bees from the South is doubtless one of the most important elements that will have a large influence on future beekeeping.

In the West, the honey industry is growing by leaps despite the ruinous prices of California honey. Beekeepers are getting better organized for business. Idaho has a new association, and efforts are being made to start one in California. Success to them!

The last carload of Colorado comb honey in the producers' hands that I know of has just been sold, and will be shipped to Kansas. Prices secured for this honey are lower than most honey brought, but are a fair average for the last few years. I learn that \$2.65 for fancy, \$2.40 for No. 1, and \$2.20 for No. 2 were secured. This honey was produced in western Colorado, where the freight rate is higher to the East than from Colorado common points.

VARIATIONS ALLOWED BY NET-WEIGHT LAWS.

In a letter from Mr. Ernest Ryant, of Connecticut, to Mr. E. R. Root, and forwarded to me, I find the following: "I think the grading of honey as related by Wesley Foster on page 884, Nov. 1, will sooner or later get him into trouble. The selling of such sections by the section would lay the seller liable to prosecution in this

state. No variation over $\frac{1}{2}$ ounce is allowed—that is, if a section is marked 12 ounces it must weigh at least $11\frac{1}{2}$ ounces and not over $12\frac{1}{2}$ ounces, and the case must average at least 12 ounces."

Here in the West we are stamping our honey with the minimum net weight, and doubtless we are erring in thinking that, if we stamp a section "net weight not less than ten ounces," it will be all right if it weighs twelve or thirteen. So far none of us have gotten into trouble, but it is better to find out the regulations of the various states before we do. If GLEANINGS could give us the laws of the various states on these points it would help. We ought to be able to put up our comb honey so it would sell in any market.

EXTRA PROTECTION NOT NEEDED IN COLORADO.

Dr. Phillips states that additional protection, other than that provided by single-walled hives, is beneficial for bees throughout the United States. The majority of beekeepers with whom I have talked regarding this, disagree for their locations. The double-walled hives have been tested over a series of years, and bees kept in them have not wintered as well as in single-walled hives. The winter case has not been well tested here in the West, to my knowledge. Our beekeepers have demonstrated that normal colonies wintered on their summer stands winter almost perfectly.

Granted that bees wintered in a case containing four or eight come thru in better shape (which I have found no one willing to grant unqualifiedly), the majority say it will not pay for labor or expense.

The only time I can see where additional protection could pay is when we have a month of zero or near zero weather. This does not happen oftener than once in three years. We do lose some colonies at these times that would be saved if given more protection. But I do not think it will pay to go to the expense when we consider that, if all our colonies were wintered, the increase from swarming would soon overstock our locations. Some are overstocked now.

One beekeeper, who owns 800 colonies, told me he counted on 25 per cent loss each year, and that gave him enough empty hives for increase, so new hives did not have to be bought. This beekeeper is located where the winters are severe.

We should like to see some plan worked out that will meet our conditions. The arid conditions are not the same as in the East.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Generally speaking, we had a nice open fall, but with few days when bees could fly. About Nov. 15 we had a day or two when bees could have had a flight if they wished, but very few were in the air. While it always gives us a feeling of satisfaction to see the bees have a thoro flight late in November or early in December, yet actual wintering results seem to be but little different whether they have this choice or not, provided the stores are of good quality and the hives are heavy.

This reminds me of seeing in the Dec. 1st issue of *GLEANINGS*, page 969, the statement that in Ohio the editor considers 20 pounds of sealed stores, including combs, as sufficient for wintering in the North, while 25 or 30 pounds would be necessary for the South. As we are further north than Ohio, on the same basis of reckoning we should require even less honey than they do in Ohio. But I wonder where the producer here in Ontario lives who would trust his colonies outdoors to go into winter quarters with stores aggregating but 20 pounds, combs included. The most of us will double that allowance, and then have nothing left over by the time the flow starts the following June. Mr. Sibbald makes his ten-frame Langstroth hives to weigh 70 pounds without the cover, and many others insist on nearly as much.

I am convinced that, for our climate, an allowance of but 20 pounds, combs and all, would often result in starved colonies early in spring; and in almost every case, even if bees managed to pull through till early spring on these limited stores, their death would not be delayed much later. If bees can be trusted to come out all right in Ohio on the amount stated, then that state certainly has us beaten a long way on the question of stores necessary to carry colonies successfully thru the winter.

"When hives are completely covered with snow for several months it is enough to kill any bees," page 964, Dec. 1. I used to think so; but in the light of experience for the past few years I am forced to change my mind on this question. At our north yard, often referred to, we have a heavy snowfall as a rule; and the more snow there is over the hives the better we are satisfied, and this yard is never visited by us from late fall till early spring.

The cases containing the bees drift right

over at times and remain covered some seasons for three months or more, and yet we have so far had perfect wintering. Once I was at this yard when all cases were out of sight, and I got a shovel and dug down to the entrances of a few of the cases, and I would find a large air-space around the entrances where the snow had been melted by the heat of the bees. Of course we use a quilt over the frames—wouldn't think of having a board under such conditions. About ten or twelve inches of packing over this quilt, and then between the top of packing we want a few inches of space for air to circulate between the packing and the cover of the case.

With a board over frames allowing little or no upward ventilation—a small entrance and then all hives covered over with snow for a long while—that's an entirely different proposition. We cannot visit this out-yard during the winter, so we have adopted the former plan; and as the storms blow here in York County it is with considerable satisfaction that we anticipate even worse blizzards up north and have no fears of the bees suffering. If in a locality where snow is abundant, try this plan and cease worrying, and at the same time save yourself a lot of work in shoveling snow away from entrances all winter. [See editorial.]

The writer has just returned from spending a week in New York, after being at Syracuse with the New York State Association convention. While I gleaned much that I hope will be of interest for the future, time forbids making more than a mere mention of my visit just at present. Assuredly the New York state fellows—at least those around Syracuse—"get there" in more than one way. From what I could learn, I doubt if there is any other section in the United States or Canada that is as heavily stocked with big beekeepers and bees as Onondaga Co.

I had the privilege and pleasure of enjoying the hospitality of Mr. House. Mr. Kinyon and myself were unable to leave friend House's on account of a regular blizzard all day in which about a foot of snow fell. While Mr. House had intended to take us on an auto trip to visit various beekeepers—Mr. Doolittle among the number—this pleasure had to be given up; but, after all, what a "talk fest" we had all that day long—Mr. House, Irving Kinyon, and yours truly!

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

PROLIFICNESS OR LONGEVITY.

"Which do you consider preferable—a queen having extra prolificness, or the queen whose workers have the greatest longevity? Is it possible to combine the two in one mother bee?"

I believe it possible that a queen may be prolific, and her bees long-lived too; but Dame Nature has some peculiar plans of her own, and, when left to herself, she generally takes away something when she adds a great advantage to anything. So we can rarely expect her to put length of days and many children in the same hand, even when she is dealing with her most favored offspring, the bees. But most queens are given to "sporting a little;" and in this, Nature seems more ready to acquiesce with the bees than with many other things unless it is with poultry.

My belief is that we can combine longevity and prolificness with less nicety of work and trouble than was expended on producing bees with a lengthened tongue; but if we can't, longevity is well worth the effort. Under similar conditions in the hive and colony nearly all the bees would bring in about the same amount of nectar. The important factor is, what will they make of it? In answering this question it is well to remember that the colony of bees which gathers the largest surplus during the honey-flow, and consumes the smallest amount of this surplus in maintaining the colony between or after the nectar flows, is the most profitable one, and therefore the one to breed from. But in order to set about breeding up bees to their highest standard of excellence understandingly, we must know what qualities in the bees stand *first* in the make-up of a honey-gatherer.

In order that we may better understand matters, allow me to give something of the past that first called my attention to the value of longevity in bees. During the middle '90's one of our most successful comb-honey producers desired to exchange queens; and as I was always on the lookout for any chance to improve the bees I already had, we did so. I gave this queen my best care and attention; but the best she would do at brood-rearing was to the amount of about six Langstroth frames full. I was disappointed, as many of my queens would give to the amount of eight and nine frames practically full of brood. So I marked the colony as one whose queen

should be replaced with one more prolific. My time for superseding queens is when the flow of white honey is near its close; but when I came to this colony I found that it had stored and completed more sections than had any of the colonies having queens giving eight and nine frames of brood. This led me to keep this queen for another season.

The next season proved a repetition of the year before; and while her bees did not seem to start out to work any earlier in the morning, or work later at night, nor seemed to be doing a "rushing" business at any time, they kept steadily at it, with the work in the sections slowly getting ahead of those which made a far greater showing as to working numbers at the entrance. This queen lived to be nearly five years old, and her colony held the "banner" as to completed sections for four years: and from close observation, longevity of the worker bees was the only reason I could ascribe to account for their superiority. The third and fourth year I used her as a breeder to a great extent.

If six frames of her brood gave a working force equal to eight frames of another queen, then that colony has saved the labor, the honey, and the pollen necessary to rear the two extra frames of brood. The labor part is not often thought about. The less brood that bees are rearing, the more slowly they are aging, other things being equal; and this saving tends to lengthen still further their time of service as the bees which "pile the honey in." And this is not all. Long-lived bees have less brood in proportion to keep warm and care for; and the small amount of brood for the size of the hive tends to discourage swarming as much as anything I know of.

Longer-lived bees do not slack off brood-rearing so quickly as the working force is large in proportion to the brood, and so a smaller nectar-flow suffices to keep the queen laying to her full capacity. This leaves the colony in better condition to begin storing a surplus from any smaller flow that may occur. What does all this amount to? To produce a given maximum force of workers, less honey is needed, less pollen, less labor, less heat; consequently a colony attains its full strength earlier in the season, and more surely, no matter what the weather conditions. It is better supplied with stores than others shorter lived, and the stores stay there at less loss of bees.

GENERAL CORRESPONDENCE

EUROPEAN AND AMERICAN FOUL BROOD

Their Differences, History, and Methods of Treatment

BY OREL L. HERSHISER

There is no subject pertaining to apiculture that absorbs more attention of the apiarist than that of foul brood. In view of the rapid spread of the two types of the disease, especially the European variety, every provident beekeeper is eager to learn all there is to know of them. It has been said that the European type will eventually sweep the whole country; and no one who has had a season or two of experience with it will doubt the statement. To this may be added that the spread will continue with ever increasing ratio. The time is now at hand in many of the states and Canadian provinces when few beekeepers can feel secure from its appearance at almost any time in the breeding season. It is appropriate, therefore, that we diligently seek and digest all the information possible on this subject, to the end that we may counteract its baneful influence on our apicultural endeavors and emerge from its attacks victorious, with better bees and apiaries, with greater proficiency, and with increased production and profits. That all this may be accomplished has been proven by some of the apicultural *savants* who have blazed the way for us.

Of the two foul-brood diseases the European variety is perhaps the more to be dreaded because of its inexplicably rapid spread in the colony, through the apiary, to neighboring apiaries, and to new centers of infection; but American foul brood is said to be the more difficult to treat.

There are various means by which these diseases are disseminated. The observation by many bee-inspectors, that they are more prevalent in and about cities emphasizes the claim that they are conveyed in the honey shipped to the markets, the bees carrying to their hives the disease in the honey they gather from containers when the same are relegated to the scrap-heap or garbage-can. Honey-containers thrown from car-windows have undoubtedly carried the diseases into new centers. It has been carried by shipments of bees in full colonies and nuclei. It has been said that the disease has been conveyed by means of diseased honey used in the manufacture of food for queen-mailing cages.

Undoubtedly swarms often carry the dis-

ease; and as they have been known to travel several miles before arriving at the selected place of abode, the disease may be carried into a new center in this way. If a swarm issues from a diseased colony and occupies a hive where a colony had perished, the disease contained in the honey the swarm takes with it is immediately stored in the old comb, and serves as a starting-point for the disease. When a diseased colony becomes reduced in bees to the extent that it will succumb to robbers, all colonies that participate in the robbing will become infected, thus spreading the disease far and wide.

The above several means by which these diseases may be disseminated applies equally to both varieties; but the very rapid and almost simultaneous appearance of the European variety thru the colony, in so many colonies in the apiary, and likewise in many neighboring apiaries, in contradistinction to American foul brood, is a peculiarity of the European variety which investigators have thus far been unable to explain satisfactorily. It is thought by some careful observers, notably Mr. R. F. Holtermann, that the disease is carried on the feet and body of the bee to the flowers, and that when bees from other hives visit such flowers they in turn will carry the infection to their hives, thus spreading the disease to other apiaries perhaps miles away. This seems probable; but the theory would be more readily accepted were it not the fact that bees are more successfully treated, and that the disease, in resistant colonies, rapidly abates during a good honey-flow, just when, according to the theory, it would be spreading most rapidly. Still this would not be positive proof that the disease is not spread in this way. It is conceivable that, during a honey-flow, the small amount of contamination that would be so introduced into healthy colonies would be insufficient to make the disease noticeable immediately. It might make slow progress for a season or two; but in a colony that is susceptible, it would gain headway in an ever increasing ratio, and finally, when dead, if overlooked by the apiarist or beyond his control, there would occur one of those mysterious outbreaks that reach so many colonies

in the apiary and all the apiaries in the neighborhood at the same time.

Dr. C. C. Miller has a theory which accounts for the manner in which the disease is ordinarily continued in a diseased colony. It is that, "when a larva becomes diseased and dies, before it becomes putrid, the nurse bees suck its juices and feed them to the healthy larvæ, which in turn become diseased." The fact that the disease commences to abate when a honey-flow is on, at which time the larvæ are fed on uncontaminated nectar and pollen, instead of food that is used at times when no honey or pollen is being gathered, seems to support this theory.

Another theory may here be advanced, which is that the peculiar sour-smelling condition of European foul brood, before the dead larvæ become putrid, is attractive to the bees, and that they not only suck the juice from the dead and feed it to the healthy larvæ in their own hive, but that silent robbing may be a condition brought about, especially when the colony becomes depleted by the ravages of the disease by the liking of the bees for the peculiar flavor. In this way it may not only be carried from hive to hive in the same apiary, but from apiary to apiary over a radius extending several miles.

Those who have tried to get colonies of uniform bees of some particular race for exhibition purposes—Italian for example—where most of the bees in the neighborhood are of a different color, know how common it is for bees of one hive to gain entrance to and be accepted in another, even when the different races are in apiaries some distance apart. It is probable that bees become mixed to some extent in neighboring hives and apiaries to a far greater extent than is commonly supposed, and this when not robbing. How much more, then, would there be mixing of bees thru the several apiaries in any given neighborhood when the peculiar odor of European foul brood is present, if it is attractive to them. This silent-robbing theory is strengthened by the fact that often the stronger colonies will be

badly diseased while the weaker ones, having comparatively few field workers, and hence not in condition to engage in robbing, will not take the disease or will be the last to take it. If silent robbing is the cause of the rapid spread of the disease it offers an explanation as to why adjacent colonies, or those near each other, are most likely to be the ones infected rather than a uniform distribution of diseased colonies throughout the apiary.

Messrs. M. G. and C. P. Dadant have advanced the theory that the bacilli of European foul brood are inherent in the queen taken from an infected colony, and transmissible by her. If this is true we are wasting valuable time by employing the shaking and brushing methods, *a la* McEvoy, unless we requeen at the same time, regardless as to whether the stock is of the resistant type. How are we to reconcile this theory with the many cures that are claimed where the shaking or brushing treatment is practiced? and with Dr. Miller's treatment by caging the queen in her infected colony for a period of eight or ten days, and then releasing her? and with Dr. Miller's other treatment by brushing the bees and queen of an infected colony on to brood-combs that this colony had cleansed above an excluder during a period of 21 days? Dr. Miller reports success in most cases with both these treatments. May it be that, with resistant colonies, the bees prevent the disease from becoming noticeable? That larvæ that have inherited it from the queen are so promptly cleared out that it never becomes apparent, and that only in susceptible strains of bees would it gain headway? This point should be cleared up by further experiments, not only by individual beekeepers but by governmental investigators.

Kenmore, N. Y.

[This is the first of a series of four articles by Mr. Hershiser on the history and treatment of foul brood. In the next issue he will discuss Dr. Dzierzon's method of treatment.—ED.]

WINTER SCHOOL IN BEEKEEPING, MASSACHUSETTS AGRICULTURAL COLLEGE

BY DR. BURTON N. GATES,

Associate Professor of Beekeeping, Amherst, Mass.

The Massachusetts Agricultural College announces its annual Winter School for Beekeepers, which lasts ten weeks, commencing January 3, 1916, and closing March 10. This is one of twenty-eight

short courses carried on simultaneously, utilizing the strong agricultural faculty. It is possible for the students to arrange their work so as to secure several of the 28 courses offered.

Two lectures are given weekly.

The beekeeping course deals with fundamental and practical apiculture; its relation to horticulture—that is, the growing of field and market-garden crops; greenhouse vegetable production; cranberry culture, and fruit-raising. The following subjects, among others, will be included: The natural history and behavior of bees; races of bees; handling and manipulation of the stock; a discussion of queens and their importance; the subject of wintering, spring manipulation, and kindred topics; comb and extracted honey production; the care of apicultural products; diseases of bees and their treatment, together with a discussion of the tools and implements used in beekeeping. First-hand experience in all phases of the subject is emphasized, conditioned only by the season.

This course is usually largely attended. This college is particularly well equipped, both for the intensive and smaller beekeeper. The course comprises two lectures and one laboratory period weekly, with certain periods devoted to special lectures or excursions. Those interested in enrolling should address the Extension Service, Massachusetts Agricultural College, Amherst, at an early date, requesting an application

blank. Full printed information is available. The course is in charge of the writer, assisted by Mr. John L. Byard.

BEEKEEPERS' CONVENTION.

A convention is usually held annually. The 1916 convention is not yet fully planned. A special announcement will appear in this paper later. The date, however, is determined for March 14-16 inclusive. This forms the conclusion of the Winter School in Beekeeping. A number of prominent authorities will appear upon the program. Remember to set aside these dates and plan to attend.

TWO OTHER COURSES.

The Spring Beekeeping School, May 31 to June 14, 1916, inclusive, is an intensive school for practical beekeepers. An especially attractive course is offered this year. This school is held at Amherst once in three years. A special announcement will appear in this paper soon.

During the annual Summer School a course in beekeeping will be given beginning about the middle of July. This course is designed primarily for teachers and those not able to attend the more intensive course. Announcements will be issued in the spring.

Amherst, Mass.

Students are required to do laboratory work.

COLONIES IN EIGHT-FRAME HIVES

How to Operate Them so as to Get a Maximum of Results in Brood and Honey the old Double-decker Scheme of Years ago

BY C. P. HENRY

While most beemen advocate for this locality (southeastern Oklahoma) the eight-frame hive, it seems to me from practical experience that it is too small. It does not give sufficient room (after storing winter supplies) for an active queen to keep up a colony sufficiently strong through late fall and early spring. The result is a weak colony in the spring when the flow comes on.

Our main flow comes in June and July, and usually lasts from three to six weeks. It seems to me that a larger brood-nest would give the queen a chance to have a rousing colony to gather the nectar when it is to be gathered, instead of having first to rear the brood. The consequence is, when our colonies get strong the flow is about over.

As I have all eight-frames I am thinking of putting another regular body over them and taking three or four frames of brood from the bottom and place in the top chamber to force the bees to occupy this early

also. I believe any good queen is capable of filling ten or twelve frames with brood in an average season. Moreover, we have considerable warm weather through the winter months; and if the colony has plenty of stores I believe they will raise brood through a considerable part of the winter months. My bees are flying today, Nov. 25, nicely.

I should like to have your opinion along these lines as to whether you sanction my idea of dividing the combs as stated.

Hugo, Okla.

[The plan you refer to will work very nicely in your climate; and a modification of it can be used much further north. Some eighteen years ago we worked one yard of eight-frame hives on the double-story principle. As soon as the queen and bees comfortably filled the lower story, we put on an upper story, and in it we placed two or three frames of brood and bees from the lower hive, and filled the space below with

empty combs. Above we put an empty one in each side of the brood, and last of all a division-board. As soon as young bees began to hatch out and the bees needed more room empty combs or frames of foundation were added till the space in the super was filled. Sometimes the brood was spread by inserting an empty comb between two frames of brood.

Colonies so treated built up to good strength, and did much better work in storing either comb or extracted honey than colonies that had been confined to the eight-frame brood-nest through the breeding season. To keep a queen down in a hive that is too small for her is certainly a loss of bees. It is the strong colonies that get the honey, especially when the flow is light.

When we worked on the double-story plan, and ran for comb honey, we removed the upper story and crowded the sealed brood into the lower, and put on one or more section-supers, according to the strength of the colony. This is the plan that has been worked so successfully by Dr. Miller. The unsealed brood was given nuclei, and colonies that were not strong enough to fill even one eight-frame body.

In running for extracted honey we added upper stories, as we called them, until we had them four and even five high. A full

account of our experiments in that one yard will be found in this journal for August 1 and 15, 1897, and Feb. 15, May 1, June 1, July 1, and Aug. 1, 1898.

There is nothing to prevent working ten-frame hives on the same principle. If a good queen needs more than ten frames put on an upper story. The fact is, some of our most successful extracted-honey producers are operating their colonies in two-story hives. One man in particular, who secures a crop of honey every year whether his neighbors do or not, always runs his colonies in two stories. If a queen cannot furnish at least twelve frames of brood in the breeding season he substitutes one that will; and he gets a crop of honey providing there is any nectar in the blossoms.

You can carry out the same general plan in your climate and get the bees strong early in the season, because you do not have severely cold weather. We consider Oklahoma one of the best places in the United States to carry out this scheme. If your bees are all in eight-frame hives we would say it is the only way to secure strong colonies; and it is the only way to get a crop of honey. If you were running for comb honey we would simply remove the upper story at the proper time as already explained.—Ed.]

AN AGITATOR IN THE HIVE

BY ÆSOP

A beekeeper who claims to have found a way to get the honey and not the stings sent for me to look at his device. He told me how he intended to work it for all the honey he wanted, and leave some to sell; and as I found he had gotten hold of a new idea in beekeeping I took a photograph of his contrivance. I will say, however, that I do not advise its use except for those who are afraid of getting stung.

The device, as will be seen by the photograph, consists of a barrel set upon a stand high enough to allow a pail to be put under it to catch the honey as it runs out of the barrel. Thru the cover of the barrel runs a bent iron rod. To the bottom and along the sides of it, at intervals, are cross-pieces of iron with sharp edges to allow them to cut thru the comb inside the barrel and release the honey which flows to the bottom of the barrel thru a wire screen or strainer, and which is drawn off thru the faucet.

The iron rod, or pipe, as will be seen, is bent so as to allow it to be turned like a crank, as it takes considerable force to turn

the knives in the comb after the bees have built around it and sealed it in with propolis. The inside fixtures may be easily understood from the following diagram, from which the device can be made if it is wanted.

Combined hive and extractor—
the middleman cut out.

The bees fasten their combs to the inside of the barrel, and the revolving knives reach far enough to leave a space of six inches between them and the sides of the barrel so as not to cut the comb loose and allow it to fall and drown the bees, but to shave off the cappings and allow the honey to run down thru the strainer, where it is drawn off as needed.

The entrance for the bees being on the opposite side of the barrel from the faucet allows the operator to draw off the honey without disturbing them or he can close the entrance while he is taking the honey.

It may be closed at night after the bees are all in, when there is little danger of being stung except by working the device at the wrong time or in the wrong way.

Since there is no patent on the invention as yet, anybody is at liberty to make one for himself, and use it without being disturbed except by the bees and he will find all danger of being stung is eliminated; and while he does not get comb honey it is a fine way to secure strained honey that he is satisfied is not adulterated—simply turn the crank a few times and open the faucet until the bucket is full; and if you get stung it is your own fault.

ÆSOP.

[Talk about "Bee Hash" honey! Considering the mangled bees and brood, such honey ought to have a "rich" flavor; in fact, it ought to be the equal of any *strained* honey.—ED.]

A WELL-ORDERED BEEYARD

BY W. E. SEAMAN

This apiary is located about fifteen feet from the National Pike leading to St. Clairsville, Ohio, and is one of which any person should be proud, especially if other beeyards in this locality are to be taken into consideration. The yard is well kept. On one side is a row of linden trees; on the

other is a wide border of flowers of all descriptions, and at one end a fence covered with rambler roses. Mrs. Seabright gets the credit for the flowers, as she is an expert in this line. All through the yard posts have been set on which well-pruned grapevines are clinging, laden with fruit.

A yard of which any one should be proud.

Mr. Seabright aims to keep about forty colonies of bees, and these are arranged in four rows all facing the same direction.

Previous to taking up beekeeping Mr. Seabright was an expert blacksmith. He is still using a wagon built some forty years ago which is trimmed with hand-forged ironwork. It looks better than the wagons of today. He followed his trade until his health failed, and he was advised to take up some outside work. Thru the influence of his wife, who had some knowledge of beekeeping, he started on a small scale. Gradually he got the "bee fever" and went about the country buying up all the bees available to get the combs if for nothing else. He has now been in the business thirty-eight years, and says in all his experience he has no fixed rule for handling bees. He is a student of Moses Quinby.

Mr. Seabright has had a great many different styles of hives, but now uses an eleven L-frame chaff hive with a tall outside top rim. He built these hives in 1883 so he could handle two-pound sections. Recently he went thru some old discarded appliances and found some two-pound sections of honey twenty years old. He has tools of every description for use in the apiary. One thing worth mentioning is a steel bracket which he hangs on the inside on the rim of the hive in which he can place two or three frames.

It can be said that all Mr. Seabright makes is "on the square." He has a power saw and a chest full of forms for putting frames and sections together. He says, "If you have a hobby, have it right," which is good advice if the hobby is a paying one, as his has proven to be.

Wheeling, W. Va.

THE HABITS OF THE SKUNK

BY FRANK C. PELLETT

For several years I have been carrying on observations of the food habits of various wild creatures of more or less unsavory reputations. In some cases most uncomplimentary criticisms have fallen upon my head after the publication of the results of these investigations. The skunk has been of special interest, and the study of this animal has extended over several years, with perhaps three dozen individuals under observation. This animal is so generally condemned that it requires some courage to say a word in its defense.

Nearly every one has known of cases where chickens were destroyed by these animals, and, as a result, the common impression has grown up that skunks as a class are poultry-killing animals. On one occasion I confined a hen in a pen with two large skunks, and, altho they sniffed the bird, and it was apparently a source of great curiosity, they did not offer to injure it. I have at times released captive skunks on my grounds where poultry was easily available, and have done everything to learn the real food habits of these little animals. Some individuals have remained about the place for weeks at a time without disturbing the poultry in the least.

On one occasion some boys found a very young skunk, and, thinking to have some fun, wrapped it up carefully and gave it to a young lady, a daughter of a friend of mine. When she opened her package she was at a loss to know what disposition to make of the animal, but finally gave it to

the cat, thinking that she would kill it. The cat, however, took the little creature to her nest and reared it with her kittens. This animal remained with that family for more than a year, and never once showed the slightest inclination to disturb the poultry. As nearly as I can tell from my observation of the animals, both in confinement and unrestrained, not to exceed one in ten of

It requires considerable courage to say a word in his behalf.

them will form the poultry-killing habit. I feel very sure of my ground when I say that as large a percentage of the house cats are destructive to poultry as are the skunks. It would require altogether too much space to describe in detail the various experiences that we have had with the numerous skunks

here at our home. However, while occasionally one will form the poultry-killing habit, by far the greater number confine their food to small animals and insects.

While I have not made any special study as to the extent that bees enter into their diet, I should expect every skunk to eat bees freely if they chance to find them, for insects seem to be the natural and preferred food of the animals. So far as I can tell, they show little preference as to the kind of insects, but seek those which are most abundant and consequently easiest to obtain. Probably only occasionally does one learn how to get the bees from the hive by disturbing them. As the skunk feeds mostly at night when the bees are quiet, they would not be likely to find them in cool weather unless they had first chanced upon a hive when the bees were hanging out during warm nights. I can readily see that skunks are a serious pest in the beeyard in many localities. On the other hand, aside from the beekeeper, there is seldom serious cause of complaint. So few individuals become destructive in proportion to the whole number, that the good they do far overbalances their injury in the poultry-yard. I am familiar with the fact that, where one animal takes to killing chickens, it often happens that several others of the same family learn the same trick.

It is not a difficult matter for the poultryman to protect his chickens from possible attack; and the destruction of the large numbers of grasshoppers, crickets, mice, gophers, and other pests which make up the bulk of the food of the skunk would seem to make it worth his while to do so,

rather than to fight the pests after killing the skunk.

With the beekeeper it is a different matter, for it is not easy to protect his bees from attacks by the animals. Insects being the preferred food, he can expect a visit from every skunk that chances to pass the apiary. These animals are very skillful in catching insects, and one who has not observed them closely will be surprised at the facility with which they make a capture. Where one's apiary is in a compact form and on comparatively level ground it should not be difficult to fence out the animals with a small-mesh woven fence, altho it would be some expense.

Just at present some of these animals are living in our barn close to the hen-roost. Altho we see them frequently they are not very timid, and show no disposition to attack the poultry, which are housed in small buildings with roosts less than two feet from the ground.

Atlantic, Iowa.

[During this last year, for some reason skunks in this particular locality seemed to have been much more numerous than usual, and the reports of their depredations in different parts of the country lead us to believe that the condition is not local. Perhaps, as our correspondent intimates, the beekeepers suffer the most; but we have always supposed that poultrymen consider skunks as natural enemies on account of the loss of young chickens. Several years ago we shot a skunk after it had killed nine or ten little chickens by biting holes in the back of their heads.—ED.]

A HANDY QUEEN-CELL CAGE

BY JOHN H. ROSSER

For the past six months I have been working for A. H. Stephens, a 600-colony beekeeper living sixty miles or so from Brisbane and near the New South Wales border. When queen-rearing we tried a cell-cage after Dr. Miller's pattern with queen-excluder sides. (When we used wire-cloth sides our virgins were dark.) The queens from the new cage were good, but it was not as convenient to work with as we should have liked.

Mr. Stephens thought of trying a cage that would hang in a Langstroth frame, and whose divisions would be just deep enough for the queen to hatch in, and just wide enough for the cell to turn around. We used a tin slide for a cover, and found that

it killed a few queens. So we put a strip of calico under the slide—result, a perfect cage.

These are the dimensions: Length $16\frac{3}{8}$ inches, depth $1\frac{5}{8}$ inches, width $1\frac{1}{16}$ inches, with 26 divisions, each $\frac{1}{2}$ by $\frac{5}{8}$ inch in width. To make it, take a piece of queen-

W. H. Blackford, of Capay, Cal., started this yard in June, 1914, with one hundred three-frame nuclei. This June he increased to 238, buying 203 more.

excluding zinc of the right size, solder tin divisions on one side in the top; fold the excluder under these, making the bottom, and then fold up the rest of the zinc, making the other side. Solder this side to the divisions in a few places. Turn the top edges over to make a groove for the tin slide. Solder to each end of the cage a loop to hook over a hook made of a wire nail driven through the end-bar of the frame.

Crowd the bees of a six-frame nucleus on to two frames and this frame with cages. Put cells in against one wall, so as to leave as much room as possible to prevent queens being caught between the cell and wall, as a few are liable to be. Note the age of the cells in the queen-book. When the queens hatch, take the cage around to the nucleus hives and run the queens in with a very little smoke. If an odd queen gets out of a cage, remedy this by not using the division she gets out of. When the first cells are put in they may drop to the floor unless the sides of the cage are waxed.

We had varying results with the smoke method of queen introduction, but at our last experiments we had as many losses with cages as with the smoke. We still use the smoke method and follow the directions carefully, especially in regard to contracting the entrances for a few days.

We have found the method of queen-

rearing given by A. C. Miller a great success; but we have to start our cells in a queenless hive. I use his record-book; and for ease and simplicity in operation it is the best thing on the market. In queen-rearing we have a record of, first, the starter hive, showing just when we gave the cells and how many. An example of the other records follows:

QUEEN-REARER		CELL-MINDER	
March 24, 1 bar, 15 cells	March 28, 1 bar, 15 cells		
April 1, 1 bar, 16 cells	April 5, 1 bar, 16 cells		
HATCHING HIVE			
		April 1, top cage, 15 cells.	
		April 8, middle cage, 16 cells, etc.	

The cell-minder is used between queen-rearers, and the cell-cages when we are going full time with cages. We have but three of these. Our nuclei are four in a hive, on L. frames. Hives are numbered on one side, and nuclei numbers, 1, 2, 3, 4, etc., start from that side.

Here is an example of our nucleus record:

No. 1.					
1	2	3	4	brood	honey
13	F13	13	13	4 uns	
				3 s	

By 4 uns we mean "gave No. 4 in No. 1 nucleus 1 frame of unsealed brood;" 3s means "gave No. 3 in No. 1 nucleus 1 frame of sealed brood." F13 means queen failed to mate; 13, queen taken; and 13, given virgin on 13th.

Tambourine, Queensland, Australia.

LAYING WORKERS NOT CLEARED OUT BY SHAKING

Letting the Bees Fly in a Wire-cloth Cage in a Warm Room to Cleanse Them of Liquid Feces

BY MOODY BRENNEMAN

Late last summer I found one of my young swarms of bees queenless, and it already contained laying workers. I carried them (hive and all, after first placing another hive containing one frame of foundation on the stand), a distance from the apiary, and shook the bees all off the frames on the ground. This was done in the evening just before dark. After they had got back in the hive on the old stand I gave them a little syrup, closed the entrance, and left them there a day or two, after which I gave them several fresh empty combs with one comb containing eggs

each side of the comb; and upon close examination I found them covering quite a patch of sealed worker brood.

How do you account for those drone-capped cells at that time, as mentioned above? Now for the thing I wish to get at.

Knowing that such a small colony would never winter over I thought I would try an experiment. I made a two-frame observation hive, to one end of which I attached a small screen cage about 10 x 14 x 22 inches with a board floor and ends, the entrance of the hive opening into the cage. When the frame containing bees was put into this

hive, the bees having been robbed out, they were in a starving condition, some already showing signs of dysentery. I at once brought them with the cage in front of a window where they have been ever since—about two weeks and a half. They have had water, and a small feed of honey each day. Forty-eight hours after being brought in, the queen was laying. They now have some sealed brood; but the old bees (some at least) are not doing well. Each day there are more dead bees in the cage. They look very much like bees having paralysis, but have shown no nervousness as yet. Their

Another view of Lakeside Apiary, Apopka, Fla. See editorial "In the Shade of the Spanish Moss."

and larvæ, and opened the entrance. They built queen-cells. Shortly afterward, upon examining the brood-nest I found the queen-cells gone, and with every appearance of laying workers again—cells capped and being capped, with greatly raised cappings. I did not look long but thought of course the case was hopeless. Not having time to bother with them just then I took out all combs but the one containing brood, and closed the hive (not the entrance), and thus they were left till about the latter part of September, when, upon opening the hive, I found quite a bunch of bees hanging on

comb still contains pollen.

Now, what I wish to know is, would it be possible to have bees inside as above, and be kept in good health, or cannot the inside conditions be made right for them? There are always some of the bees that seem restless, and appear continually to want to get out of the cage, while others go calmly about their business.

Berne, Ind.

[The plan of shaking all the bees of a fertile-worker hive some distance from the old stand has been mentioned before. Sometimes it works, and sometimes it does not.

In your case it is evident that the laying workers came back to the old stand with the rest of the bees after you gave the old stand a frame of eggs and brood. They built cells from the good brood, and later on (you do not say how long after) you found the cells gone. The probabilities are that one of the cells matured and hatched a queen. She probably cleaned out the laying workers and assumed the maternal duties of the hive. One of the best ways to cure a laying-worker colony is to give it a ripe queen-cell, and that is practically what you did.

Attempts have been made before to let bees that are filled with liquid feces fly into

a large wire-cloth cage in a warm room during winter. They will discharge their feces, and some of them will go back into the hive. The high temperature and the general disturbance cause the queen to begin laying; but as a general thing most of the bees thus confined in the wire-cloth cage will worry themselves to death. They will die off one by one until all disappear. The only real remedy is warm weather when the bees can have access to all outdoors. New nectar and new pollen, if there are enough bees to take care of the eggs, will build up the colony; but the process is often slow, usually taking the whole season to build up, and too late to catch the honey-flow.—Ed.]

IOWA BEEKEEPERS INCORPORATE

BY F. C. SCRANTON

The Iowa Beekeepers' Association filed articles of incorporation, and adopted a constitution and by-laws at its fourth annual convention held in Des Moines in the Chamber of Commerce convention room Dec. 13, 14, and 15.

The following officers were elected for 1916: president, C. E. Bartholomew, Dept. Zoology, Iowa State College; vice-president, B. T. Bleasdale, Des Moines; secretary-treasurer, Hamlin B. Miller, Marshalltown, Ia.; directors, J. W. Schlenker, Ankeny, Ia., J. I. Danielson, Fairfield, Ia., and W. S. Pangburn, Center Junction, Ia.

Dr. Phillips, of Washington, D. C., gave an excellent talk on "Outdoor Wintering;" and on the evening of the 13th, in the absence of Mr. E. R. Root, who was to have given an illustrated lecture on "Beekeeping," but who, on account of sickness, was unable to attend, Dr. Phillips gave an illustrated lecture on "Beekeeping." In the absence of C. P. Dadant because of sickness in his family, Frank C. Pellett, state bee inspector, read Mr. Dadant's paper. L. A. Kenoyer, of the Iowa State College,

delivered an illustrated lecture on "Pollinization of Economic Plants." Prof. C. E. Bartholomew, of the Department of Zoology, Iowa State College, described a short and efficient method of producing the finest kind of honey vinegar.

The retiring secretary, S. W. Snyder, of the Snyder Bros.' Fruit and Nursery Co. of Center Point, Ia., was presented a fine rocking-chair as a token of esteem and appreciation for long and faithful service.

Upon departing for their homes many remarked that the meetings had been of great value to them, being packed with common-sense talks and discussions. A large number availed themselves of the use of the question-box arranged by Prof. Bartholomew. The questions were mailed to him in advance and then he chose competent men to answer them and printed the questions and the names of those answering them on the program.

The time and place of the next meeting was left for the board of directors to decide.

Des Moines, Iowa.

WISCONSIN BEEKEEPERS' CONVENTION

BY HARRY LATHROP

The annual convention of the Wisconsin Beekeepers' Association has come and gone. It was held, as advertised, at the Capitol in Madison, Dec. 9 and 10. Of the instructors and prominent beemen from other states who were advertised, only Dr. Phillips, of Washington, D. C., was present. The absence of E. R. Root was very noticeable, his

appearance being anxiously awaited during the first part of the meeting. The general attendance was better than it had been in many years. The convention was held in the Senate chamber, and extra chairs had to be brought in. With an increased attendance another year, a larger room will have to be provided.

Sixty were present at the Iowa convention of beekeepers.

The sessions were crowded with important papers and questions, and the interest was always intense; but the thing of greatest value, as we see it, was the paper by Dr. Phillips, on outdoor wintering of bees. Does it not seem remarkable that a young man like Dr. Phillips should go before old and experienced beekeepers and have them willingly and thankfully preserve the attitude of an A B C class? There is a reason: Dr. Phillips, with the aid of his associates and the means provided by the government, has been able to solve questions that could not be solved by individuals, no matter how willing or painstaking they were.

It now seems to the writer that beekeeping is almost to be revolutionized. We have been ready to make the claim that dysentery is a worse scourge than American foul brood. Think of the enormous drain on the industry through winter losses! We

have also been accustomed to figure winter losses as based on the number of colonies that die outright during winter; whereas we should have figured on depletion of colonies. Strong colonies in the fall that come out of winter quarters mere nuclei cannot be said to have wintered successfully. Dr. Phillips shows that, with proper wintering, there would be practically no dysentery in the colonies. Protection we must have, and it must be better than we have been providing, even if we are to keep not more than half the number of colonies. Dairy cows protected in winter as poorly as we have been protecting our bees would pay no income. What we lacked was conclusive evidence regarding proper wintering conditions. This Dr. Phillips has furnished; and if we don't follow instructions we may just as well turn our live stock out in a cold northern winter without protection.

Some years ago the writer wintered a

number of colonies in hives having an outer shell which provided four inches of dry packing on all sides, and as much on top as one wished. We usually placed about eight inches of dry leaves over the top super. Some of these hives produced good crops of honey for ten years at a stretch without swarming or dying out during that time. We wish to have bees again in such hives, but would place two colonies in one house and provide a space of six inches instead of four for dry packing. Would that be about right in my location?

One thing that has caused beekeepers to take too many risks in wintering has been the accidental or occasional wintering of colonies under very adverse conditions. We placed too much stress on these isolated cases and drew too much from them.

As an example of how tenacious of life a small colony of bees can be, in the spring of 1885 we bought some bees in hives that

had a deeper and shorter frame than the Langstroth. It was about like the Gallup frame. In transferring these combs the bottom part was cut off to the depth of a Langstroth frame to which we wished to transfer, and the strips of comb that were left on the frames contained a few cells of brood and a few eggs. The old hives were set back against the fence and let alone. A few bees gathered on the stubs of comb, and in due time each built queen-cells and hatched queens which were fertilized. The little colonies built some comb during the summer. The middle combs reached nearly to the bottom-boards, while the side combs were not larger than one's hand. The hives were allowed to remain where they were. No protection was given. They did not have even a quilt over the frames. The cover fitted only loosely, and I had no idea they would live after freezing weather came on. However, they both lived thru; and

The attendance at the Wisconsin convention

was better than it had been for many years.

the spring and summer of 1886 being one of the most favorable for beekeeping ever known in Wisconsin, they both built up and filled their hives with comb, brood, and honey. One cast a swarm which we failed to secure, not thinking that they were so far along. It is interesting to notice anything like this, but it sometimes leads to wrong conclusions.

At Madison Dr. Phillips spoke on the subject of outdoor wintering; but after hearing him one can readily see that the principles of outdoor and indoor wintering are the same. It is a question of proper insulation and the securing of certain conditions for the colony. The question of winter stores becomes far more simple when we understand that, with proper wintering conditions, bees consume very few stores in confinement and start no brood until the proper time.

So much for the Wisconsin convention. Now I would beg the privilege of a few

words for old friendship's sake. Some have asked why I do not write for the journals as I did once. The reason is that the pressure of other work so encroached on my beekeeping that I realized I was not up with the progress of the times. Nevertheless I did not lose interest, but constantly read what others write, and attend as many conventions as possible. Being still in the railroad employ I have an opportunity to attend meetings of railroad men which we hold at times for mutual benefit and instruction. In those gatherings I certainly meet a fine body of men, but my heart is with the beekeepers. I wonder that so few discover what they are losing by not attending the meeting.

I am unable to attend as many as I should like. I wanted to be at the Akron meeting, oh so much! but it was not possible. Then those informal meetings down at Bradentown—how I should like to be in on that deal!

Bridgeport, Wis.

HONEY - LABELS

BY JOSEPH TINSLEY

Beekeepers rarely take sufficient advantage of the art of displaying their produce to effect the best sales, as do the various trade firms of their specialties, such as fruits, syrups, etc. It is candidly admitted that a neat label on any article increases its charm, and gives it, particularly if a food, an appetizing appearance. The public gets absolutely tired of a label if it is of an uninteresting character, such as, for instance,

Pure Honey, or Honey from our own Bees, etc. A white label soon shows the dirt and dust in a shopkeeper's window. This state, I always think, reduces the value of the article in the public eye. Nothing tends to diminish the value of an article more than the presence of dust or dirt.

Get a good photograph of your apiary which will give the public an immediate interest. Send it to an engraving house to get a good half-tone engraving made, and at the same time the usual lettering put on such as "Pure Texas Honey from the Apiary of John Smith;" "Pure Raspberry Honey," or as the case may be.

I was spending a day with one of the most prominent beemen of Scotland, Major Maxwell, and could not resist taking a photo or two of his apiary. Later on, when Major M. was asking my opinion on honey-labels, I suggested that this beautiful view

A neat label always increases the charm of an article.

would make an ideal one. I took it to a lithographic artist, who lettered it, and got a half-tone made, which I reproduce. The same label can do also for cans. Another

point worthy of attention is that a similar block can be utilized by the beekeeper when his circulars are printed—note paper, bill-heads, envelopes, etc.

Stone, Staffs, England.

JOTTINGS ON BEE-YARD EFFICIENCY

BY E. E. STERNER

I have shade-boards on all my hives to protect the colonies from the hot sun. I believe that every hive ought to have a shade-board in winter as well as in summer.

In summer it keeps off the hot sun; in winter it keeps off the snow and prevents the cover from rotting.

In the illustration the pole I hold in my hand has an old lard-can attached. It is one of the best swarm-catchers in the world for a home apiary. I would not give ten cents for a manufactured swarm-catcher. They are too small in the first place, and they ought to be attached rigidly to the pole so they will not swing.

Hives should not rest upon the ground, but should stand about eight or nine inches above it, as these in the illustration do. What will you do with the bees that fall to the ground? A strong bee will fly up again,

and a weak or worn-out bee is no good anyway.

Grass ought to be kept cleaned away from around the hives. Why? Bee-moths

Hives should stand nearly a foot above ground.

as well as toads have their hiding-places. You never see a butterfly or toad around my apiary. I keep my hives above ground and cut down all long grass.

Wrightsville, Pa.

HIVES USED IN CENTRAL EUROPE

BY ERNEST TSCHUDIN

Bees are not particular about the kind or shape of their home, provided it affords sufficient shelter and room for building combs. This fact is confirmed by the many kinds of hives used. Almost every material fit for making receptacles has been used for hives — earthenware, basketwork, cork, straw, wood, etc. Of these materials straw has been the most popular for a long time in Germany, Austria, and Switzerland; and even now, after the frame hive has been known there for a lifetime, straw skeps are still in use to some extent.

In the majority of cases the skep owners are farmers who keep a few colonies and are satisfied to reap what they can get with

least trouble and fewest stings. Usually a specialist—a practical beekeeper—has to visit the skep owners in his neighborhood in early spring to cut out the surplus honey. I still remember such a scene I witnessed in childhood on my grandfather's farm in northern Switzerland. The skeps were taken from their shelves in the beehouse, and turned upside down. The bottom-board was lifted, smoke from the pipe was blown in, and the operation began. The skeps in question have a diameter of about 20 inches, and are about 12 inches high.

As the combs do not reach quite down to the bottom-board they remain undisturbed

when the latter is removed, and the combs may be examined with more or less ease. Supply-dealers even offer a comb speculum, a small mirror to be introduced between the combs for examining the cells; also various classes of introducing - cages, specially for skeps, are manufactured. The queen may be caught by drumming off the swarm, etc., which proves that the skep is rather handier than the common box hive, which, in the regions mentioned, is almost unknown. It should also be borne in mind that straw is one of the best insulating materials. But even the practical beekeeper, able to get every drop of nectar by careful management, would be at a loss, as too much honey is to be converted into wax, considering the good price that honey brings in Europe. Under normal circumstances few extensive beekeepers figure among the skeppists; but just here comes the exception. In the most productive honey region of Germany, the Luneburg heath-country, and in a part of Holland, the typical hive is a skep, Fig. 1, with entrance above.

The size and shape of the skeps in different regions vary greatly. Fig. 2 represents a variation—the Kanitz hive of eastern Prussia. It consists of two or more interchangeable bodies and separate straw cover. To avoid the combs being built to the cover,

Varieties of the skep.

top-bars (carriers) with comb starters are placed in the upper story.

A straw hive of peculiar shape, but adapted to the principle of the modern frame hive, is the "bogenstuelper" invented by Gravenhorst, who died in 1898. This hive contains twelve to sixteen frames, and is especially in favor in northern Germany. Fig. 3 will give the reader an idea of it. The other modern hives are, of course, made of wood.

At the convention of the German and Austrian beekeepers at Cologne in 1880 there was adopted a standard measure for the two countries.

and the following size of frames for the brood-room was declared as standard: 8 3/4 inches wide and 14 9/16 inches high; frames for honey-room half the height; dimensions of hive in accordance with beespaces. Fig. 4 shows a standard hive from the rear, the door being removed so that some of the empty frames are visible in the brood-room (a) and the honey-room (b). The frames hang in rabbeted cleats in a transverse

position; or, to understand it more clearly, imagine a Langstroth hive with firmly fixed cover, front entrance also closed, instead of which a new entrance is opened at the right side (being now the front), and the left side made removable (door, now the back end of the hive). That is, in short, the principle.

To operate the hive, one frame after another has to be taken out at the back, for which purpose special tongs are in general use. To put the frames in place again, they are simply pushed forward; and it is, therefore, indispensable that every frame be provided with a spacing-nail or a metal spacer, of which there are many kinds.

To American readers this system might seem impractical; but most beekeepers who are familiar with it are satisfied with the arrangement. On the other hand, one of those beekeepers once expressed to me his disgust for

hives to be treated from the top. "The whole colony is aroused when the cover is lifted," he said. Indeed, in a few points the system shows some conveniences—in the first place, its fitness for the bee-house.

Altho the hive was declared standard, the length was not prescribed. Usually it is made for 12 frames in every story.

A bee-house of primitive design. The fronts of the hives themselves form the side of the house.

In some regions the 1½-story hive is considered too small, and a hole is provided in the top, to be opened during a good flow when a special super is placed above. When accommodated in a modern bee-house this, however, is not possible, and then three-story or even four-story hives are preferred. In the latter case the upper rooms are also provided with an entrance; and after being separated from the lower story by a division-board one can lodge a second colony, for instance, in a poor season or during winter.

The door in the rear is either removable or moves on hinges. Then follows next in the newer hives a window (not seen in the figure), the frame of which exactly fits the interior of the hive, and that can be pushed forward when contracting the room. Sometimes the glass is replaced by wire cloth, which has the advantage of ventilation when, in summer, the back door is left open. Lately a space of an inch is observed between the hive-bottom and the bottom-bars; and in lieu of a division-board above the lower story only a beespace of ¼ inch is left.

The entrance is often guarded by a tin slide. One of the many different styles is shown in Fig. 5. For small entrances, a correspondingly small alighting-board is in favor (Fig. 6), one part of which can be put up to protect the entrance from wind or sun in winter.

In spite of the existence of a standard hive its adoption is not general, and never will be. After the same principle and disposition is made the hive of Baden (but

Fig. 11

A kiosk for a small number of colonies.

with larger frames). The Vienna hive differs little from the former. The Swiss hive has wider frames, etc.

This general principle (operation from the back and with transversal frames) is maintained in some other kinds of hives which differ more or less in other points. For example, the Alsatian hive (only one story, with special super to be put on top; the Suabian hive (two stories); the Thuringian hive, modified by Rev. Mr. Gerstung, can be manipulated from the top, etc.

However, contrary to the opinion of many beekeepers, some brethren of the fraternity found it an inconvenience to have the frames transversal with the opening, which idea, many years ago, gave birth to a new hive system usually called "page hive" (blaetterstock), as the frames are exposed from the side like the pages of a book, when opening the door at the rear. Thus the position of the frames is the same as in the American hive, but are supported at the hive bottom by two or three transversal iron bars. Fig. 7 gives a representative of this group, the Alberti hive, with the door removed. Staples that regulate the space between frames and between frames and front wall are driven into the latter. Corresponding staples are also driven into the door or a separate framework (with glass or canvas serving as a window) that must be put in place before closing the hive. Queen-excluder, division-board, etc., adapted to the construction, facilitate the management. A modification is the Dadant-Alberti hive (improved by the Swiss Rev. Mr. Streuli (frames wider than high). The Spuehler hive and the Reidenbach hive are other forms that belong to this group.

The American hives, or similar styles, are also known, and the new edition of a well-established treatise on beekeeping says,

Bee-house designed by Rev. Gerstung.

"The American system has found of late many followers also among our beekeepers." Undoubtedly this would be the case to a much greater extent if it were not for the fact that the traditional bee-house interferes somewhat with the operation of the American hive.

With the hives described, their long list is by no means exhausted; but they represent at least the most typical and important ones in use now. But why this diversity of hives? Amateurship has surely contributed a good deal to it; but it is also a vivid proof of the existence of a progressive beekeeper's spirit.

In France the hives with manipulation from the side are unknown, the most popular modern hive being there the Dadant-Blatt. In arrangement it is almost identical with the American hive except the size of frames (12 frames $10\frac{5}{8}$ inches high, and $16\frac{17}{32}$ long). Efforts have also been made to introduce among farmers the economical one-story hive invented by de Layens, a form of the Long Idea hive known in America, with 20 frames $12\frac{1}{4}$ in. high and $14\frac{9}{16}$ long. It is made single-walled, back and front, sides covered with a straw mat, Fig. 8.

Basel, Switzerland.

NOTES FROM GERMANY

BY J. A. HEBERLE, B.S.

CROP AND MARKET.

The honey crop in Germany this year is good to very good. I have not had a crop like it since 1905. The demand for honey

at a good price is equal to that in years with a short crop. In part, at least, this is due to the fact that no honey (or but little) is coming from Cuba and South America.

HONEY FOR THE SOLDIERS.

Large quantities of honey are given the soldiers, not only the convalescent in the hospitals and sanitoriums, but also to those in the field and trenches. This has also favorably influenced the general market. Liquid honey is sent to the front in tin tubes, in tin cans, and in cans with aluminum bottoms, and push-in cover, with the sides of pasteboard. Crystallized honey has also been sent in parchment paper, etc. The soldiers appreciate the honey very much. Bread and honey make a fair lunch compared to dry bread. Those poor men (friend and foe) in the trenches get their hot meals very irregularly or not at all, because the "field kitchen" can approach only under cover of darkness; and even at night it is perilous—sometimes impossible.

NEW OR OLD COMBS?

This question is much discussed at present. By men of experience, extreme views are advocated. Some hold that old combs are dangerous; that they contain disease germs; that a colony on old combs does not develop itself as rapidly as on new ones; that bees do not (or only rarely) swarm from old combs; that they do not build queen-cells readily, etc. Some say that often beginners have unusual success because the bees are building much and are on new combs; but later, when the combs get older, and the bees are not allowed to build freely, the former success is changed to failure.

Others with equal positiveness say that old combs are saturated with formic acid which would kill all disease germs(?). If such an old comb is taken out it spreads a delicate perfume, and this perfume pervades the hive of a healthy colony.

Usually extremes should be avoided in everything as well as in the case of combs. Some have recommended in the journals the renewal of the brood-nest every two, three, or four years. I think it is natural, and correct from the practical point of view, to let the bees build. The extent is influenced by the condition of the colony, the weather, and the locality, or, to be more explicit, by the pollen and nectar furnishing flora within the reach of the apiary. Some few beekeepers use only virgin combs in the extracting-super, believing that old combs color the honey and affect the aroma. I consider it very important to have only first-class worker combs in the brood-nest, and that it matters not so much whether brood has been reared in them for three or six years. I would not suppress, if I could, the rearing of drones; but would, if it were

practicable, have a few of the best queens furnish the drone eggs to the other colonies—at least to such as are, after careful consideration based on close observation booked at the time, found undesirable.

QUEENS MATED BY DRONES OF THE KEEPER'S CHOICE.

This should be the ambition of the ambitious beekeeper—consummation devoutly to be wished. All beekeepers seem to agree that, were it possible to mate the virgins of the choicest breeding with drones from a colony specially selected for the purpose, we would, in a very short time, have bees that would bring considerably more surplus—to be more definite, double the average. There would be greater uniformity. Nearly all colonies would be populous at the right time, few would swarm, and those that would swarm would do so at a time when it would least interfere with the purpose of the beekeeper. They would be very industrious, and easy to manage.

The first and most important care would be to give them sufficient room to store the surplus during the honey-flow to supplement the winter stores early in case they should be short, and provide ample protection in winter, and especially in the spring, against the inclemency of the weather. Such colonies a beekeeper could, with the same amount of exertion; manage double the number of colonies, and these would average at least twice the amount of surplus of today. That means that a beekeeper with such bees could secure four times as much surplus as at present. If beekeepers want more than that they should try another planet.

Even if the beekeeper should not reach the goal (control of mating) it may be that the conditions under which mating has taken place for uncounted centuries are a sufficient safeguard to exclude inferior males from taking part in the perpetuating of the race, and prevent deterioration.

If we heed the counsel eminent beekeepers have given us as a result of their extended experience and careful observation, we can at present improve our inferior half of the apiary by careful selection of the breeding material on hand that may have been purchased and has been found well adapted to the locality; but we must remember that the conditions under which, from the time the egg is laid until the fertilized queen is introduced to a full colony, especially until the cell is capped, are at least of equal if not superior influence in determining the quality of the young queen rather than her ancestry.

Kempton, Bavaria, Germany.

THE QUIN-COMPACTNESS HIVE—SUPERS BESIDE THE BROOD-CHAMBER

BY W. F. M'CREADY

A lame shoulder set me thinking of modifying the hive so its manipulation would not require lifting heavier than that done in handling combs of honey, and yet remain as satisfactory in most respects as the ordinary hive.

To place the brood-nest and supers in proper relation to each other appeared to be most important. Three supers were set side by side; but to add another in that arrangement seemed not sufficiently compact. Accordingly, two other supers were placed across the ends of the three.

Naturally the brood-nest should be the central one of the group, as there it would be furthest away from its enemies, robber bees, etc. In that position a super could be placed upon the top of the brood-nest and another up against its bottom side. These six supers so thoroly protect the brood-nest as to permit leaving it on its stand outside all winter.

But how pass the bees into the brood-chamber? The final method was to use three-eighths of an inch of almost the entire length of the bottom-board of the front super as a channel thru which the bees could pass from the outside directly into their brood-nest.

To admit the bees from the brood-nest to the supers, V. V. wire strips, cut to special size, were secured, and attached to openings made in the sides and ends of the brood-nest, practically as shown in Fig. 2.

Where one side of each super is removed, notice that frames are hung in the openings made in the sides and ends of the brood-nest, thereby giving that much additional comb area. If another such brood-nest is placed on top, and supers also ranged around it, eight frames nearly the full size of the sides and ends of a super will be added to the capacity of the two-story brood-nest.

On the lower left-hand corner of the edge of the front super may be seen a small vertical block. In use it fits into a corresponding cavity in the edge of the bottom of the left super. There are sets of these at all corners. They automatically lock the five supers together and prevent their being pulled apart. To make this fastening, two of the supers are placed against the brood-nest, and the other two are lowered one by one into position against it while the locking apparatus of one is engaging that of two others.

To remove a super, it is only necessary to lift it, automatically releasing it from the others.

With the improved hive there is no lifting of heavy supers of honey to set the bee-escape board under.

A string of bees. They hung from cover to bottom-board without touching the hive-body or super. Photographed by William Bair, of Odon, Ind.

It is only necessary to lift the super-cover and place a division-board containing a bee-escape at the side next to the brood-nest. Nor must one do heavy lifting in the removal of honey unless it is desired to take it all away by a single operation. In this case the super can be removed from its position, and an empty one put in its place.

FIG. 1.—The hive assembled.

At the beginning of the season last year, a colony which had just been robbed out, and probably a thousand or more of its bees killed, was placed in the improved hive, without any stores, and by the end of the season it had overtaken and excelled in all respects the best of other colonies in ordinary hives.

This season, to give it a different test, the first swarm was placed in an improved hive; and on the same day and for the next few following, swarms were put in ordinary hives, under otherwise similar conditions. The last time these swarm colonies were examined the one in the improved hive was found to have gained ten combs in honey production over the best of the others in the ordinary hives.

To summarize, this hive is: (1) The only single-walled hive having its brood-nest at the center, where it naturally should be. (2) It is the only one of great capacity, each part of which has its separate cover, etc.—the maximum of convenience with the minimum of disturbance in its manipulation. (3) It is the only one giving as much or more comb area in eighty-eight supers as is to be had in a hundred supers of other makes of the same size. (4) It is the only one in which ten supers can all abut directly on the brood-nest. (5) It is the only one in which, on account of all the surfaces of its six sides being used for abutting supers, is perfect in its compactness. (6) It is the only one which can be used to protect itself against cold weather during the winter. (7) It is the only one which goes a long way toward being completely robber-proof.

Before seeing the photographs of the hive, Mr. H. H. Root, managing editor of *GLEANINGS*, thought "the connection between the brood-chamber compartment and the supers is so slight that the bees might prefer to clog the brood-combs with honey

before entering any of the other compartments." Again, that "on cool nights they would desert the surplus apartment entirely."

Referring to Fig. 2, it will be seen that the connection is the reverse of slight, the openings in the sides and ends of the original brood-chamber being so extensive that only the margins are left to hold it together. I had thought about it somewhat as Mr. Root had; and therefore, not to discourage the bees, I gave them free access to only one of the supers, excluding them from the other three by means of division-boards with but a single bee-space aperture between them. But when I next opened the hive, I was surprised to find work being done vigorously in two or three combs of each of the four supers.

From the results of this hive during the two seasons, I think the idea that cool nights would affect it is erroneous. I once resided in a house which had one very large, low-ceiled room in it. During the winter the temperature in that room was always more equable than in other even much smaller rooms with high ceilings, the heating apparatus in the different rooms being similar. The improved hive may be compared to the low-ceiled room and the tiered-up ones to the high-ceiled. The long-channel entrance may also soften the air coming in. This can be readily appreciated by those who have been in tunnels of coal-banks, and noticed the total absence of atmospheric disturbance due to outside weather conditions.

FIG. 2.—The hive taken apart.

Mr. E. R. Root, editor, objected that: (1) "It would cost a good deal more to make a hive of equal capacity on this plan than it would on the tiering-up plan." I admit there would be the costs for the additional covers and bottoms; also for a few cents' worth of wire netting of worker-bee-size mesh with which to cover the openings in the sides and ends of the brood-nest. But I claim that these costs would be almost immediately repaid, over and over, in the added comb area of twelve or more per cent given to each super; in being able to manipulate each super separately with a maxi-

imum of convenience to the operator and minimum of disturbance to the rest of the colony in the other supers; and in the total absence of necessity for heavy lifting.

(2) "Your hive-stands would cost considerably more. In northern climates the stakes after they have been used will be moved around in all directions by the frosts or the freezing of the ground. The hives would have a tendency to pull apart."

Stakes were not used with the hive-stand; but provision had been made for legs for it, attached to its frame in such a manner that they would fold up against the latter, permitting of shipment of the light strong hive-stands in the flat in bales at small cost. When the legs of these hive-stands are set on bricks, the hives will not get out of alignment nor pull apart.

(3) "I doubt very much whether you would be able to get a queen which would be prolific enough to fill not only the four side supers but the brood-nest as well with bees. It is very seldom that we have a colony strong enough for anything of this kind (filling four extra supers with honey). I am afraid you would have all kinds of trouble with it in the North. You are contemplating four extra supers."

Replying to the last part of this first, if I get a good long season and a black-mangrove flow, I can fill a two-story brood-nest and ten supers placed against its six outside surfaces; altho I presume that generally the bees will be mostly clustered in the brood-nest and at the points of unfinished work. I anticipate no more trouble with the improved hive in the North than in the South. If supers are not lacking, the weather warm, and the colony strong, simply furnish the latter with brood-nest and four supers, and, when these are filled, provide more supers, as described elsewhere.

If the colony is not strong, nor the weather sufficiently warm, I would place close-fitting division-boards in the supers,

just outside the combs in which the bees were working, and thus provide them an ideal workshop in and around the brood-nest. If I were short of supers I would tack covers over the sides and ends of the brood-nest and start the colony in that alone. When more room is needed, one side or end could be uncovered, a super placed against it and the two held together on the hive-stand by means of a few nails driven into the latter at edges of the supers, and this plan followed until the five supers were there to be locked together by each other.

As I have not had experience in the production of comb honey, I suspect some of the methods would have to be considerably modified for that work.

Estero, Fla.

Bees removing dead stag beetle which they have dropped to the hive-stand in front of the bottom-board. Workers can be seen fanning, and drones sunning themselves. Photographed by Frank C. Pellett, Atlantic, Iowa.

WINTERING BEES IN VIRGINIA

BY FRANCES W. GRAVELY

After reading what Dr. Phillips has to say about the wintering of bees, and from the experience I have had along that line, I am under the impression that it will pay the beekeepers of Virginia to experiment to see whether it will pay them to continue to winter their bees in the old way—that is, just leave them to winter if they can. I know bees *can* lie wintered in Virginia without being protected; but I believe it

would more than pay the beekeepers to give their bees proper protection in winter. I ally the bees will be mostly clustered in other outdoor protection is the best for this locality; and I am expecting to give the Holtermann case a thoro test next winter.

In the fall of 1913 all of my bees were weak from making a heavy increase, and I wintered them in ten-frame hives on six combs with division-boards on each side,

and the space on each side filled with packing; and they came through the winter in fine order and built up to full colonies by the time our earliest flow began. But in the fall of 1914 my colonies were all very strong, and I gave them no protection at all. The following spring they came out weak, and were a long time in building up. I lost more than enough honey to pay for cases and packing. It was a mild winter at that.

The bee business has not made the progress in this section that it should. There are many bees scattered around on the farms, and they are kept in old log and box hives with but very little profit. It is hard to convince the farmers that, with the proper equipment and management, they can make money with their little apiaries. I am proud to say we have a few successful apiarists, and have prospects of having more.

There are many beginners. I am inclined to believe some of them will make a success. I hope so.

Those that are studying the business, and reading the bee journals, I think are making good headway; but there are some who think all they have to know is how to hive a swarm and take the honey from them when it is made. The consequences are they don't have much trouble in taking the honey.

There is no reason why Virginia should not be one of the leading states in the Union for the production of honey, as we have about a three months' honey season, and there is a large number of the best honey-yielding plants such as tupelo, locust, poplar, persimmon, sourwood, blackberry, and different kinds of clovers, and many other small plants which help a good deal.

Stockton, Va.

HEARTSEASE TURNS FAILURE INTO SUCCESS

BY W. S. WILLIAMS

Last fall I put up in winter quarters 83 colonies of bees which were unusually heavy from the fall bloom of aster and smartweed. When I went over them in April there were twenty-nine dead with from two to four combs of honey. The entire inside of the hives was plastered with stain. They still kept dying till reduced to twenty-six. All seemed weak until late. There were no swarms until the middle of June, and only about five until in July. They then got very strong, but did not go into the supers to any account until buckwheat bloom.

They then just rushed things and started swarming in earnest. Eighteen of the twenty-six that survived swarmed twice, and the second swarms were seemingly as large as the prime swarms. Never in all of my bee experience have I seen colonies build up

and overflow so quickly. They kept up the swarming until Sept. 2. They all filled up their brood-combs, and some which swarmed the last of August gave me one and two supers of the finest light honey I ever had.

It was all from smartweed or heartsease and aster. It was a wonderful crop. The cornfields and potato-ground were a mass of the heartsease. Some of the wheat-stubble fields produced a late crop of it on account of the wet season. I had a little over a ton of honey from the twenty-six, spring count, and increased up to sixty-five colonies. All are going into winter unusually heavy and strong.

This locality is getting to produce more honey from the fall bloom than from the summer season. Each fall seems to get better, and the honey is water-white and of a very pleasant flavor.

Julian, Pa.

A WINTER CASE OR HOUSE

BY L. M. AUTHAN

We winter our bees in long rows. We build a long house, six feet high, four and one-half feet wide, as long as is necessary to accommodate our colonies. The house has doors at each end.

We cover the top with cheap roofing-paper, and the sides with oiled paper. Holes are left in the sides corresponding to

the entrances of the hive. It is possible to make the house a double-decker if necessary. These sheds can be taken apart in 16-ft. sections, and moved whenever desired.

I throw old carpet or any packing material I happen to have over the bees inside, and they are nice and dry. Combs in colonies kept this way hardly ever sweat. Mois-

ture which is so bad for bees is never erected in the hives.

I find that bees kept this way come out much better in the spring than by any other plan of wintering. I leave parts of my bees in the house all summer, and find they do well.

I have worked with bees for thirty years, and find there is still much to learn. My own experience favors a compact hive of 12 x 12-inch frames. The colonies keep better and make more honey, one year with another.

Emlenton, Pa.

TICKLING THE PALATE OF A NATION

While national conventions of beekeepers and writers in the journals of apiculture have been insisting that something ought to be done to boost the sales of honey, it has already been done. While repeated suggestions and plans have been broached for getting articles about honey into the newspapers and magazines, lo! it has already come to pass. It is not too much to say that, at the present time, honey is getting more general unpaid publicity than any other food product.

The *Delineator*, a magazine with a circulation close to the million mark, published in its January, 1916, number three columns of recipes for the uses of honey in cooking. The January number was on sale December 10. The *Delineator* is one of the oldest woman's magazines in the world. It has been called "the most helpful and best loved of all magazines." If the National Beekeepers' Association had purchased this space to fill with matter of similar nature it would have cost about \$4000.

Three columns of recipes calling for honey will appear in the *Pictorial Review* for March, 1916, which is on sale Feb. 10. The circulation of this fifteen-cent woman's magazine is more than a million. The same amount of paid publicity for honey would have cost probably another four thousand.

American Cookery, probably the foremost culinary publication in this country, contained in December a recipe for a honey cake. *Good Housekeeping* for the same month has a recipe for "honey fluff." The *Cooking Club Magazine*, of Goshen, Ind., is reprinting the recipes for honey cookery which appeared in GLEANINGS for Oct. 1.

Farm magazines these days are making so many allusions to the use of honey in cooking that it is impossible to keep count of them all. The *Country Gentleman*, of Philadelphia, for December 4 had a note recommending the use of honey in this way. *Farm and Ranch*, published at Dallas, Tex., one of the largest papers of the Southwest, had two columns of honey recipes in their Dec. 11th issue. The *Alfalfa Journal*, of Sioux Falls, S. D., a progressive new paper

which has been mentioned in these columns before, is using from time to time some of the recipes of the Oct. 1st GLEANINGS. Each recipe is illustrated.

If the references to honey in farm magazines are hard to keep tab on, what shall we say of the daily press? Two or three examples are all there is room for. The *Cleveland Leader* for Sunday, Dec. 19, contained half a dozen honey recipes. The *Cleveland News* lately had one for Lebkuchen which requires honey. A few weeks ago the *Plain Dealer* of the same city had a number of honey recipes, as well as suggested menus of which honey was a part. A number of papers had recipes for Christmas candies. Almost invariably the editors included one or more requiring honey. Two weeks ago the Worcester (Mass.) *Telegram* printed two columns of reading-matter on honey, its nature, preparation for market, and distribution.

Domestic-science teachers in the public schools are turning to honey with enthusiasm. The qualities of superior texture and enduring freshness which honey imparts to cakes and cookies are esteemed by these instructors and explained to their pupils. Grocers, restaurateurs, and proprietors of delicatessens are finding honey increasingly popular with their patrons. The number of new honey preparations is increasing rapidly. Witness a new confection recently put out in Chicago, said to be made from honey by a secret process, yet nothing more than bars of granulated honey encased in chocolate.

Here and there progressive bakers are springing new honey foods on the public, and finding them highly popular. A baker in Medina, for example, made up a batch of honey cookies over an original recipe and sold them out the day they were made.

At last honey seems to be coming into its own. How long the welcome publicity it is now getting will last we cannot say; but there is every indication that it will continue to have its "place in the sun" on household pages, in cookery departments, and on grocery counters.

Heads of Grain From Different Fields

The Backlot Buzzer

The amateur who bought a hive of blacks last year to study their habits has learned more than he figured on. Anyway, he says he's mighty glad winter is here. They are all in the hive, and won't be out till spring.

Here's Orthodox Bee-story

Pelham Grenville Wodehouse, prominent writer of fiction, must have been a beekeeper. In his serial story, "Uneasy Money," now running in the *Saturday Evening Post*, he introduces Elizabeth Boyd, the heroine of the plot, as a beekeeper; and in the installment for Dec. 18 it turns out that Lord Dawlish, alias Mr. Chalmers, also at one time worked with bees.

The high-spirited Miss Boyd, resenting Chalmers' presence on her farm, plans to trap the young man in the apiary and get the bees to sting him badly. Part of the dialog follows.

"Elizabeth's irritation became painful. She resented his smile. She hung the smoker on the side of the hive.

"The stool, please, and the screwdriver."

"She seated herself beside the hive and began to loosen the outside section. Then taking the brood-frame by the projecting ends she pulled it out and handed it to her companion. She did it as one who plays an ace of trumps.

"Would you mind holding this, Mr. Chalmers?"

"The surface of the frame was black with what appeared at first sight to be a thick bubbling fluid of some sort, pouring viscously to and fro as if some hidden fire had been lighted beneath it. Only after a closer inspection was it apparent to the lay eye that this seeming fluid was in reality composed of mass upon mass of bees. They shoved and writhed and muttered and jostled, for all the world like a collection of home-seeking New Yorkers trying to

secure standing room on a subway express at half-past five in the afternoon."

She gets him to shake the bees.

"Lord Dawlish watched them go with a kindly interest.

"'It has always been a mystery to me,' he said, 'why they never seem to think of manhandling the Johnny who does that to them. They don't seem able to connect cause and effect. I suppose the only way they can figure it out is that the bottom has suddenly dropped out of everything, and they are so busy lighting out for home that they haven't time to go to the root of things. But it's a ticklish job for all that, if you're not used to it. I know when I first did it I shut my eyes and wondered whether they would bury my remains or cremate them.'

"'When you first did it?' Elizabeth was staring at him blankly. 'Have you done it before?'

Her voice shook. Bill met her gaze frankly.

"'Done it before? Rather! Thousands of times. You see, I spent a year on a bee-farm once, learning the business.'"

Simmins Starvation Introduction Successful

Replying to Mr. A. T. Rodman's article on page 896, Nov. 1, I wish to say that this plan of introducing is the old Simmins method, described in the A B C and X Y Z of Bee Culture.

I too had a great many failures in introducing this year. The cage plan was a failure, as was also the smoke method. Knowing of the Simmins method I decided to try it, and did, with great results. Mr. Rodman tells us in his article to be sure to introduce the queen after dark; but I killed old queens at noon and introduced by this method thirty minutes later. A flow of nectar was on from the aster, and this may account for my good luck. All of those introduced at noon were accepted.

Altho this is a good method for introducing, like all others we shall have some failures at times. I have never found a method that was infallible, and wish that I could. Better results were obtained this year with the Simmins method than by either cage or smoke method.

Morgan, Ky.

J. E. JORDAN.

Wintering in Texas, and Other Observations

When one reads so much about packing bees away for their winter nap it makes him smile to think he is not to be troubled that way down in Texas, where the bees fly very nearly every day in the year. Of course we have a day or two now and then when our bees have to stay in. I winter on the same stand from year to year.

I might say my bees are the very best three-banded Italians, the only kind of use for honey production in this section of country. Swarms? Yes, I think I had a swarm or so once while I was sick and could not give them proper attention.

My surplus is from horsemint and clover, although there are quite a number of other sources from which our bees draw. I raise my own queens, and think I get better results than trusting to let the bees take their own will about their mother.

There are very few bees about my yard, and it is a show to lots of folks to see the hive opened up and have the queen pointed out to them. A large majority want then to see the "king bee."

I use the standard eight-frame hive, and run them for chunk and extracted honey, and always have more orders than honey; yet I get a good surplus.

Nacogdoches, Texas.

W. S. CHADWICK.

What Would You Do in This Situation?

I had 150 colonies, spring count. I don't know how old a queen is in the lot except one or two. That doesn't speak well for a beekeeper, but that is the size of it, and what I want to do is to get on the right trail this coming season.

Our honey-flow starts here about the last week in June; but fruit-bloom comes about six weeks earlier, so there is a dearth between fruit-bloom and anything else, tho as a rule there are lots of swarms issuing during fruit-bloom. I am mentioning this so you will know conditions here.

Out of the 150 I have lost fifty, mostly from American foul brood, and I have brought all home, put them in a corral with a windbreak on the north, east, and west. I have rendered all the diseased combs and charred the hive-bodies, tops and bottoms. I have nearly a hundred nice extracting bodies with drawn comb, and several with full sheets of foundation. All are eight-frame hives.

Now, I want to buy one hundred queens next spring, and I want to know when is the best time to get them. What should be done—make nuclei or put them in the old colonies? I want at least fifty new colonies, and I also want a honey crop. As I said, I don't know which queens are old and which are young, and I should like some advice from the more experienced as to just what they would do.

Albuquerque, N. M.

R. E. PIFFLEY.

[Presumably you have about a hundred colonies left. There will probably be a further shrinkage of 15, leaving you 85. Twenty-five of this number, the weaker ones, should be devoted to increase, leaving a balance of 60 good colonies for the production of honey. It is not profitable, usually, to try to run for increase and honey from the same colony; and hence we would make the divisions as proposed. With the 25 you should be able to increase to 50; and if you have had some experience you can make an increase of 15 up to 50. Stimulative feeding should be practiced by feeding half a pint of syrup daily. Young queens should be supplied to the colonies split up into nuclei for the purpose of increase, but don't split to more than half—two colonies from one.

The 60 or 70 colonies run for honey should be made as strong as possible. Be sure to use only strong colonies, devoting all the weak ones or medium-strength colonies to increase. When a colony in an eight-frame hive is strong enough, put on an upper story and add combs and raise two or three frames of brood from below. If you run for extracted honey, you will tier up; but you should keep all brood below the second story: and as the season advances, confine it to the lower story by means of perforated zinc.

If you are sure your extracting combs are free from disease you can use them; but watch all colonies very closely where they are placed, as the disease may break out again.

Get your queens of some reliable breeder at the time you make increase, and introduce them to full colonies and nuclei, following closely the directions furnished by the queen-breeder. By contracting for a hundred queens you will be able to get a reduced price, altho the queens may be sent to you in lots of ten at a time. Don't divide until settled warm weather comes on. If you do it too soon you may lose a lot of good brood.—Ed.]

Aster Stores Candy Solid

Aster honey in this locality is not good winter feed. If capped over and well ripened it candies solid in the combs. If not capped, the sugar in the honey granulates and leaves a thin liquid in the cells which will sour and make the combs damp. It comes mostly from a small white aster about eighteen inches high which branches out a good deal.

BEEs EIGHT MILES FROM THE HIVES.

I believe the letters in late numbers of GLEANINGS regarding the distance bees will work from the hives do not reach the limit. When I began taking GLEANINGS in the eighties, a man on the coast of Washington wrote that he found his Italians eight miles from the hives. The bees were on an island a mile from the shore, the island five miles from the mainland, and the bees were found working in the swamps two miles from the beach. The owner of the bees had the only Italians in that part of the state.

At another time I read in GLEANINGS of a man in Wisconsin who followed a line of Italians seven miles and found them across a river in Minnesota. Again, a man in the northern part of New York followed a line of bees six miles and they went over a mountain to the tree.

When "Rambler" was keeping bees in California, near Redlands, he stated in GLEANINGS that his bees did a paying business working on the orange-orchards five miles from the hives.

I believe good Italians will work three and a half or four miles from home if they cannot get honey nearer.

New Hampton, N. Y.

E. D. HOWELL.

Simple Cure for Bee Paralysis

Paralysis has been the means of reducing our crop to a considerable extent in two or three of our yards for the last few years, gradually getting worse. At first we paid but little attention to it; but the number of colonies affected steadily grew, and the severity of the disease seemed to increase from year to year. We tried setting the hives up on stilts so that the affected bees would fall out and not return. Some have used a tin (five-gallon can or the like), to be buried just in front of the entrance with the top on a line level with the alighting-board. This caught the bees unable to fly; but this year we hit on a plan that seemed to be entirely satisfactory.

With the other plans the bottom-board has been left on, and the sick bees fall on that and not at once away from the combs. Our way now (and it has been entirely effective in curing every colony treated this year) is simply to remove the bottom-board from the hive; get an empty body, old box, or anything that will hold the hive and colony up a foot or so from the ground, and set the hive minus the bottom-board on it criss-cross or any way so that there is plenty of space for all infected bees and dirt to fall away. We tried this on a great many sick colonies this year without much faith; but the results were indeed surprising. From many of these such colonies as formerly we would expect but little if any surplus from, we harvested nearly a normal crop of honey. Of course they must be treated before the force is too badly gone. We left them in this condition until along about October 15, when ready to fix the yards up for winter.

It now remains to be seen if the disease reappears in the spring. If it does, this plan at least saved the crop of honey; and if it does as well each year it will be sufficient. What was the reason that we got honey from all those paralytic colonies?

It seems to be a disease that, to a certain extent, comes and goes, eases up for a time, and then grows worse again. We changed the queens in a few colonies, but also treated them as above, so the experiment was valueless so far as the requeening is concerned.

I don't know how general this disease is; but I do know that it has been the means of reducing our crops a good many thousands of pounds during the last few years. In this locality this is a thing that can not well be overlooked.

OUR HOMES

Editor

Give us this day our daily bread.—MATT. 6:11.

Behold they which are gorgeously appareled and live delicately are in kings' courts.—LUKE 7:25.

In all thy ways, acknowledge him, and he shall direct thy paths.—PROV. 3:6.

I believe it is generally understood that this first prayer implies that God may give us the chance or opportunity of *earning* our daily food by honest work, or the *means* wherewith to pay for the bread, earned by honest work; and as I pen these lines I am thinking of the thousands who are prevented from earning their "daily bread" by the cruel war. I am thinking of the thousands of helpless and innocent women and children who have had their homes, gardens, and fields despoiled, and of the suffering and hardship such as the world never knew before, through no possible fault of the sufferers. Again and again a prayer wells up in my heart, "How long, O Lord, must this injustice continue? and what are the lessons we are to learn by it? and wherein are thy people remiss that our prayers for peace are not answered?"

Just now, however, I have also something else in mind. The matter of daily bread, while we are at *home*, is a comparatively simple one compared with the problem while traveling. Mrs. Root and I travel but little since we are nearing eighty, except our spring and fall trips to and from our southern home. We usually go on a car made up by elderly people near our Ohio home, and the most of these good people carry their "daily bread" in lunch-baskets. We have done this considerably; but Mrs. Root is usually troubled more or less with car sickness, and at such times she says she cannot bear the sight nor even thought of food carried in a hot car, wrapped up and tied up. For this reason, mostly, we have of late years been going into the dining-car. As a rule we now have excellent service on all our roads, and at reasonable prices when we consider the expense of "spotless linen" and neat and artistic table service. Mrs. Root and I usually each make our selection and then "swap" to some extent for variety. On our last trip at dinner (or "lunch") Mrs. Root was fairly well served; but when my order came of "broiled trout," taken from "special dishes of today," I said to the waiter:

"Where is the bread and potatoes?"

"You didn't order any, sir."

"But, my good sir, are not bread and potatoes included in a 60-cent fish order?"

As he shook his head I said, "So there is a new regulation in regard to 'the high cost

of living,' is there? Here—give me the order." Then I penciled, "Bread, 10 cts.; potatoes, 15 cts.; but while he was gone for them I went over the bill of fare, and found in plain print, "Bread and potatoes included with all meat and fish orders."

As he returned I pointed it out to him.

Now, before any one has time to say, "This is a regular *darkey* trick," I want to tell you that this fellow was so nearly *white* he colored painfully while he took his pencil and marked "free" after the last two items, or at least I supposed he did; but when I came to pay the bill I found the "free" was only opposite the bread, 10 cts. Just one thing more:

Instead of a fair-sized trout for the 60 cts. there was only a small part of a fish, and that by no means first class—nothing like a ten-cent fish delivered in Bradentown.

I have given the full details of the above in order that we may discuss "daily bread" in traveling a little. First a lot of you will say I should have reported him to the head of the dining-car, and, may be I should. But who likes to be making "kicks" among a lot of nice people? I once witnessed a "racket" in a restaurant between a waiter and a customer. A third party who sat near asked how much was at stake in the dispute. When told it was only 25 cents he extended a coin and said, "Here! take this and let us have peace." He afterward said he would lose 25 cts. any time rather than get into a "jangle." Perhaps I should add that neither one would accept the quarter, but kept right on disputing. I believe it is pretty universally agreed that where you are only *personally* concerned it is right and proper to "resist not evil," as the dear Savior commanded; but when humanity is likely to suffer it is a different matter. If this waiter is following this as far as he is permitted, day after day, I did wrong in letting it pass.

Another matter comes in here. How could this waiter gain by the transaction? There must be gain for the waiter somewhere or they would not practice it. I have been told that at least on some dining-cars they purchase the supplies and have all they can get out of it. In California I saw a porter or waiter purchase a bag of grapefruit at a station for perhaps five or ten cents each, and afterward serve them at "half a grapefruit, 20 cts." If a customer ordered this, and nothing else, considering the table, napkin, table ware, etc., the price is all

right; but this has nothing to do with evading the printed bill of fare.

Some one else may suggest I should have "tipped" the waiter to start with, and then there would have been no tricks. Very likely; but I don't believe in tips, and a world of good people are back of me.

Mrs. Root suggests he took a look at my *old shoes* that I wear even in traveling, because they are easier, and concluded I was "hayseed," and wouldn't dare say a word, etc.

At this point in my story three things come into my mind. The first is our second text—"Behold, they which are gorgeously appareled, and live delicately, are in kings' courts."

The second is that I am told I was named by my grandmother after the prophet Amos. She was a devout Christian, and, most likely, prayed I might be like him. Commenting on a recent Sunday-school lesson the *Christian Herald* says:

It was good for Amos' preaching that he was a day laborer. Doubtless he often went to bed with the backache. His hands were calloused, and he wore old clothes. But he got far more out of day's labor than day's pay, as Christ's workmen disciples knew how to do.

The third is that, some years ago, the governor of Ohio called on a near relative to help on a commission of three for an important work for the State. He said he was not permitted to offer pay, except necessary expenses. When each of the three sent in items of expense, my relative had among expenses *thirty cents* for dinner in a great city. Said the clerk, "Why, hello! When the State of Ohio is to pay for your dinner, is *30 cents* all it costs?"

"I had a nice dinner, and everything I cared for. What did the other two pay for dinner?"

"Only \$1.50 each."

I don't exactly remember; but my impression is the two others had expensive liquors, and let *Ohio* pay the bill.*

As I have said, this was several years ago. May God be praised, things are different now.

Now, dear friends, I have something pleasanter to tell you about "daily bread in traveling." Had our train been on time we would have reached Bradentown Friday night, and Mrs. Root was impatient to get

* It is not the *men* only who, when called upon to do important work for the state, seem to think it the thing to run up a big bill. Recently a woman was sent to Columbus to take charge of some business for a few days. Her bill of expenses included room or rooms at something like \$5.00 a day, and she gave as an excuse that she supposed when our great state called on a woman they expected to give her the best lodging place to be found in the capital city.

hold of our cottage that had been vacant since last May. As we had a couple of hours in Jacksonville I was glad of a chance to call at the office of the Florida Anti-saloon League. I first interviewed (from the outside) the saloons on that long central street. The few that had not closed up seemed very quiet, and I saw notices of liquors sold only in "sealed packages." After some delay because the office had been moved, I stood before the open door of the new office. As it is nearly always "summer" in Jacksonville, doors are almost always open. Well, while I stood in the doorway feeling I hardly knew a single soul in that great city, a lady came forward with such a beaming smile I was forced to laugh outright as I said:

"Why, you don't know *me*?"

"Yes, I *do* know *you*," she replied, as she gave me her hand.

"Well, who am I, any way?"

"You are the great beeman of Medina, Ohio."*

Then we had a most friendly chat until the State superintendent, Mr. Crook, came in. He gave me full particulars of the great victory for Florida, and I could not but commend his wisdom when he said he was sure it was best to avoid as far as possible fights or lawsuits with the saloon element. The new law has been declared valid, and there seems a general disposition to submit to it all over the state.

Notwithstanding they told us at the ticket office we would get to Bradentown that night the conductor said we would have to stay in *Tampa* over night. Mrs. Root was disposed to be cross about it when told it would be toward Saturday noon before she could get to work "sweeping down the cobwebs," etc. I assured her it behooved us to wait and see if a kind Providence had not something good in store for us. Whenever I am in *Tampa* I try to call at the Crenshaw Bros.' seed-store to talk over dasheen and other new things for Florida. Last May I stayed so long there I almost had to run for over a mile to catch the train, and Mrs. Root objected to my going there this time for fear it would be Saturday *night* before we got "home."

As we stepped from the train after dark, strangers in a strange city, something impelled me to breathe a little prayer something like this:

"Lord, guide our erring footsteps."

I had planned getting a hotel near the station so I might get up very early and

* As she had seen me only once a few minutes three years ago it was a little surprising. She had, however, read these Home papers.

get a little time at the seed-store. I found just back of the station I should say fifteen or twenty rigs and runners for the different hotels. From the whole lot I singled one and asked for a nearby hotel. He replied he felt sure the lady would not be pleased with those near by, but that he would take us in his Ford auto to a nice clean place and bring us back by train time, all for a dollar. Mrs. Root suggested he certainly meant a dollar each.

"No, ma'am. I will give you a nice room, clean bed, and bring you back all for *one* dollar."

While we were on the way I ventured:

"I suppose you don't happen to be anywhere near the Crenshaw Seed Co.?"

At this question he and his companion both laughed as he replied:

"Why, my good sir, our hotel is right *over* the Crenshaw establishment, as you will see."

Although Mrs. Root and I have paid as much as \$1.50 *each* for staying over night at a hotel in traveling, I don't think we ever had a pleasanter room. Just outside is a spacious elevated porch or veranda running the whole length of two sides of the great building, and this porch contains a beautiful collection of semi-tropical plants and flowers in tubs and boxes. Just over the desk in the office I saw a notice: "Guests taken to meet any train for 15 cts." I tried to have him take pay, since he had entertained us so handsomely, and at such a low price, but he replied:

"Mr. Root. I *agreed* to take you both ways for the dollar; and what I have agreed to do I have always lived up to so far."

How is that for a hotel-keeper?

A word in closing: Was it not a little funny that, out of the fifteen or twenty runners, I should strike just *this one*? and funnier still (if you will excuse the expression) that his place should just *happen* to be where I particularly wanted to go? I had a nice visit with the manager of the seed-house before train time, and the little Ford got us around in ample time, and Mrs. Root got most of the "cobwebs" down before Sunday. Would it not be well for a lot of us to use my little prayer oftener—"Lord, direct our erring footsteps?" *In all thy ways acknowledge him, and he shall direct thy paths.*

BOOKER T. WASHINGTON

Their works do follow them.—REV. 11:13.

One of the pleasant things about living to a fair old age is the opportunity it affords

of noting the growth and development of the good and great men and women of the age. When the boy Edison started out near my own home I hunted the papers for everything that was said of him. It was the same with Booker T. Washington. Thru some correspondence I was soon in touch with him—sent him a copy of the A B C book, and made his school a life subscription to GLEANINGS. When his first book came out it was my privilege to give it a notice and a price with GLEANINGS that resulted in the sale, I think, of several hundred copies. No one, white or black, who reads the book can well avoid getting a new inspiration for education. Washington started an apiary, and, for aught I know, it is still a part of their institution. One funny thing about it was (and may be *is*), the colored *girls* took mostly to the bees, and we gave a photo, years ago, of the colored-girl beekeepers. I planned to make his institution a visit, but never got round to it, and now it is too late to see the man of whom we have heard so much. Below are two clippings from the Jacksonville *Times-Union* in regard to his recent death. The first is from the governor of Alabama.

HENDERSON LAUDS WASHINGTON.

MONTGOMERY, Ala., Nov. 15.—Governor Charles Henderson today issued the following official statement on the death of Booker T. Washington:

In the death of Booker T. Washington, the colored race has lost its greatest leader. He was a man of unusual force and executive ability, and in many respects rose above the environment of race. In my opinion his efforts toward the development of his race have been of greatest benefit to them and to the entire South. Born a slave, living a life of earnest endeavor, and at his death the chief executive of an institution of nation-wide reputation, created by his own brain and energy, demonstrates to the world the unbounded possibilities open to those whose purpose is to accomplish something and marks him as one of the able men of his time.

CHARLES HENDERSON.

BOOKER WASHINGTON.

Few men in the United States had stronger influence than Booker Washington, and we do not know of any one who used his influence more beneficially. There are ten million negroes in the United States, and the man who represented the best that was in this large number, and who had so much to do with cultivating the best that was in them, was, just from that alone, a power in American life. But Booker Washington had influence far beyond his own race. White men, north and south, held him in the highest honor. He will be greatly missed, but he has taught others who will follow in his footsteps.

We place Booker Washington first among the men of his race. Alexander Dumas probably had a reputation that could be better classed as worldwide. Toussaint L'Ouverture showed ability both as a general and a statesman. Maceo was the most successful general, with the possible exception of Gomez, in the war that resulted in the liberation of Cuba, and Fred Douglass was an orator of great reputation; but we rank Booker Washington above all these. Dumas was not counted as a negro at

all by the French, but he would have been so classed in the United States. He was a quadroon. Fred Douglass was a mulatto. Booker Washington lived with and for his race. Fred Douglass married white women.

Dr. Washington was a messenger of peace and good will between the races in the South. Naturally he was considering his own race, but the good feeling that he taught as necessary to the progress of the blacks operated to the benefit of the whites as well.

Only a few years before Booker Washington began to be known throughout the country no one attempted to lead the negro race except in antagonism to the whites of the South. He had no precedent for his gospel of good will, but he urged the negro to count the southern white man as his best friend. His public life extended through several decades, but not one expression was ever quoted from him that indicated any bitterness. Indeed, his whole life was an exhibition of his confidence in the southern white man, and his efforts with his own race were for their advancement in moral and industrial lines, and in these lines he relied largely on the help of the white man of the South, and his reliance was not misplaced.

Hundreds of thousands of negroes throughout the South will be better and more capable citizens of the communities in which they live on account of Dr. Washington's influence, and not one will be worse. The record is one of which both races in the South should be proud.

The above, at several points, touches on his characteristic humility—I might say "Christlike" humility. At one time in his religious experience he said in substance: "I have finally come to a point where I can thank God that I was born black; for how could I otherwise work for the elevation and development of the race unless I was *one of them*, and had shared from infamy their toil and hardships?"

Does it not remind one of Moses, and, later on, of Him who left his home in heaven, came down to earth, was "born of woman," became the carpenter's son—"a man of sorrows, and acquainted with grief," and finally, without complaint, gave up his life on the cross that *we might live*—yes, *more* than that—that *we, through him*, might have "everlasting life"?

THE MENACE AND ANTHONY COMSTOCK.

On page 911, Nov. 1, I made brief mention of the above; but from the *Sunday School Times* of Nov. 13 I find the *Menace* in three different issues has attacked the life and character of our departed friend. The *Times* answers seven distinct charges at length, and gives proof that every fair-minded reader must accept, not only that the charges are untrue, but that there is not a shadow of truth in any one of them. As an illustration I will just quote No. 5:

5. *The Menace* states that "The least of his offenses was that he permitted his aged parents to die in the almshouse, which is a matter of public record."

In regard to the *truth* of the above, I quote again from the *Times*:

5. The following interesting letter to the Editor from Mr. Comstock's widow, dated October 15, 1915, states the facts as to his parents:

"I am glad to bear testimony to the following facts regarding my late husband, Mr. Anthony Comstock, and his parents.

"His mother, whom he dearly loved, and from whom he learned the principles of pure religion and undefiled, died at her home when he was a boy ten years of age.

"Some years later his father went to England, and little was heard from him for some time. Becoming anxious for his welfare, Mr. Comstock asked a friend to find out about his father's circumstances. He learned that his father had married again, and that four children had been born, and that they were in straitened circumstances.

"Mr. Comstock at once sent money to bring them all over to this country. He took them into his own home and kept them there until I was so near a breakdown that it seemed advisable for him to rent a home for them elsewhere. He continued to support them all, despite his own limited income, until his father died, and then supported his stepmother and her children, assisted somewhat by her eldest son, till her death. One of these sons, Herbert, is a respected business man in Brooklyn. Mr. Comstock's generosity toward this branch of the family was continued until the time of his death."

The writer of the articles in the *Menace* said in his second article: "If you will show me that I am wrong, that any statement of mine is untrue, I will publicly retract and apologize, like any just man and gentleman." The *Sunday School Times* earnestly hopes that *The Menace* will give its many readers the facts as to Mr. Comstock that are here presented.*

Christian people everywhere will be glad to know that the continuance of the great work of the New York Society for the Suppression of Vice has been well provided for. Its offices are at 140 Nassau St., New York. Among its founders, builders, and present officers, co-workers of Mr. Comstock's who knew him intimately and loved and trusted him, appear such names as Robert R. McBurney, Welcome G. Hitchcock, Morris K. Jesup, Samuel Colgate, William E. Dodge, Jr., Cephas Brainerd, Kiliaen Van Rensselaer, William C. Beecher, and Josiah Strong. In 1912, at the fortieth anniversary of Mr. Comstock as secretary of the society, the officers of the society provided a larger executive force, including an associate secretary, Mr. John S. Sumner, who is now the acting secretary of the society. During the last three years the society has taken advanced steps, and in 1914 had an executive force of seven. The president, Mr. Fred E. Tasker, and one of the vice-presidents, James M. Buckley, D. D., issued a letter last month announcing these facts, and stating: "A few newspapers have expressed the opinion that dealers in bad books, prints, etc., upon learning of the death of Mr. Comstock, will attempt to be more active in their diabolical trades, not realizing that the society has been preparing to meet any emergency that might occur."

Readers of the *Times* may remember a personal word from its publisher, Philip E. Howard, in the issue of October 16, 1915. Mr. Howard, knowing about the hellish products that Comstock had fought for forty years, had once exclaimed to Mr. Comstock,

* My good friends, please notice in the above the gentle kindness and Christian courtesy, under most provoking circumstances, and this has always been characteristic of the *Sunday School Times*. The *Menace* has been coming to me for years, both here and in Medina, although I have never ordered it, or suggested exchange. First and last, it has always seemed to me unchristian.

"How have you managed to stand this sort of thing so long?"

The reply was characteristic. "Howard," he exclaimed, "I never could have stood it unless the Lord had just kept me through it all. I'd give almost anything to forget the stuff that I have to see. But somehow, you know, I have thought of myself as a man standing at the mouth of a sewer, saving boys and girls from falling in. It's that which has kept me up, and God's power alone can explain how I have been able to keep on."

A LONG LIFE AND A HAPPY LIFE.

I have always been much interested in those who have lived 100 years or more; but it never occurred to me until just now that we might have a symposium made up from the lives of many people who have acquired old age until the following letter came with a clipping from the *Oregonian*:

Mr. Root:—Here is an article from which I thought you might wish to copy an extract.

GEORGE ROGER CHUTE.

Reed College, Portland, Ore., Oct. 30.

Below is the clipping:

HUNDREDS OF AGED MEN AND WOMEN TELL WHAT TO DO AND WHAT TO AVOID IF YOU EXPECT TO APPROACH OR PASS THE CENTURY MARK.

Practically none of those who have lived to a ripe old age have ever indulged in tobacco, alcohol, or stimulants of any kind except in a small degree. There are only a small number of instances where persons after becoming old indulge at all in any stimulants.

Old persons depend very little on medicine and have never done so.

Most of the old persons were very fond of honey, and have always indulged themselves in it.

The old people, practically without exception, had a weakness for honey. But they did not eat much candy. Fruits, dairy products, vegetables, and honey were used mostly as edibles by the old people.

Comparatively few centenarians ever chewed or smoked tobacco or drank alcoholic liquors, and very few have been even moderate users of them.

Let me make a summary from some of the above. First, "get busy," and keep busy. Have something on hand to explore and develop every day of your life—something outdoors if possible. Keep pleasant. Love everybody, even your enemies. "Do good to those that hate you." Sleep before an open window, and have your face so near the side of the bed that the air you have breathed once will be very unlikely to be drawn back with the next breath. Shun stimulants of every sort, and, I might almost say, medicines of every sort. Get into the habit of thanking God every day, then "rejoice and be glad," even if everybody else looks sour and cross.

"GET BUSY," AND KEEP BUSY.

The following from the *Plain Dealer* voices my sentiments exactly. If this great teeming world does not interest and appeal to you, even if you are over 80, you are to be pitied.

KEEP INTERESTED; THAT'S SIR WILLIAM CROOKES' RULE FOR HEALTH AT 83.

At 83, Sir William Crookes, the scientist, says he does not feel any different from what he was at 40. As to how to keep fit, here is his dictum:

"A good deal of my own present feeling and position is due to the fact that I have always been working tolerably hard and always doing something I take a great interest in, and am enthusiastic about. That, I think, keeps one's mind healthy and in a good state, and tends to keep one going."

SHALL THE UNITED STATES INVEST MILLIONS IN ANTICIPATION OF WAR?

We take the following (by the author of "In His Steps") from the *Christian Herald* of Nov. 24:

PASTOR SHELDON ON PREPAREDNESS; AN OPEN LETTER TO THE PRESIDENT.

President Woodrow Wilson, Washington, D. C.

Mr. President:—In your speech in New York you are reported as saying: "If men differ with me in this vital matter, I shall ask them to make it clear how far and in what way they are interested in making the permanent interests of the country safe against disturbance."

I am one of those who differ with you very positively on your program of war preparation, and I believe the men of the West generally differ with you. You say, "No thoughtful man feels any panic haste in this matter. The country is not threatened from any quarter." She stands in friendly relation with all the world." If that is true, why all this military program for an enemy we do not possess? In the entire course of your speech you do not mention one single reason for an increased army and navy. You do not name one nation in the world that has any design to threaten or invade our country.

Mr. President, I have lived in the West over twenty-seven years, and within the last year have been in every western state, and faced over one million and a half of the people, and your program of militarism will meet with earnest and intelligent opposition from this part of the country. Much as I would wish, as a citizen who loves his country, to stand by the President in matters of vital concern, I for one cannot and will not uphold you and your advisers in this matter.

Mr. President, you advise men who differ with you "to make clear how far and in what way they are interested in making the permanent interests of the country safe from disturbance."

If the money you and your advisers declare is necessary for military preparation against an enemy you do not name, were to be used in the education of the people and the Christianizing of the world, we could put an end forever to the war-just of the world. If we took a small part of the people's money which your program will take from the people to buy powder, and put it into a campaign for national prohibition of the liquor traffic, we could prepare our country for a Christian program of conquest over other passions.

If we took the price of one battleship and put it into the building of good roads in one of our states, we could prepare our people for a happier and cleaner and saner life.

If we took a small part of the immense sums your program calls for in the enrichment of munition factories, and spent it in Christianizing Europe after the great war is over, we could once and forever remove even the needless fear of war which exists in this country.

Mr. President, the program you propose to the

people of this country to strengthen the military power of this republic is contrary to the spirit of Christianity. What would Jesus do? Can we imagine him at this crisis in the world's history calling on a nation to spend vast sums preparing itself for war by creating a great army and navy? It is not thinkable. We know what he would do. He would call on the people of this country to give at least a dollar apiece to preach and practice the gospel of justice and brotherhood here at home, and to take what battleships we have and load them with the best of our sons and daughters and send them around the world to evangelize the nation that will be ready for it as never before, and put an end to war by teaching and practicing the principles of the Prince of Peace.

Over against your program, we who differ with you place this program of preparedness. It is more practical than yours. It is the only program which will in the end bring about the brotherhood of man.

With voice and pen and all the influence I possess, I, as one American citizen, will oppose this program of militarism to the full extent of my power, for it represents not the spirit of the Master, the Prince of Peace, but the spirit of the old-world fear and distrust and hate which has kept alive through all the centuries that which the United States does not represent either by her traditions or by her history. After all these centuries of Jesus Christ, we should have learned the lesson which he has been trying to teach us: "They that use the sword shall perish by the sword."

I am very respect fully yours,

CHARLES M. SHELDON,
Central Congregational Church, Topeka, Kan.

At *present* I am ready to give a hearty amen to every word of the above. I *may* change my mind later, but I hardly think I shall.

HIGH-PRESSURE GARDENING

OUR FLORIDA GARDEN.

We reached our Florida home on Saturday, November 6, just before dinner time. Wesley was on hand to welcome us, as usual, but he had a sorry report to make about the garden. I think I was out in the garden before I even entered the house. Everybody agreed it had been the hottest and driest summer that even the "oldest inhabitant," etc., remembered.

"Why, Wesley, you don't mean our valuable stuff is *all* dead?"

"Pretty much, or ready to die."

Jaboticaba, avocado pears, feterita, dash-
een, our nice bed of strawberries, etc., and, to top it all, the most of the nice lot of young chickens I spent so much time in raising last winter were *stolen*. It did look dubious for a little while; but I have learned from years of experience that it's never best to be in haste to "imagine evil." There were *some* things the dry summer didn't seem to hurt much, and pre-eminently were the great weeds, higher than I could reach, all over my nicely fertilized beds. I soon found *one* jaboticaba was alive; and by getting away the trash I found all three of the avocados (that cost \$2.00 each) had started to sprout near the ground. The feterita, that is so highly recommended to stand drouth, seemed to be affected with some kind of blight; and as the birds had appropriated about all the grain as fast as it had ripened, it made the whole garden look sorry.

Sixty hens were back in their old places and seemed very well pleased with the new growth of plants all over their accustomed runs. After we found they were being stolen, they (the 60 remaining) were moved over to neighbor Rood's, and Wesley

brought them back the day before. The first day I think we got 4 eggs, but with my management they speedily came up to a dozen or 15, and at 45 cents a dozen they are now (November 23) paying their way and a little more.

In one spot where I left a little sickly roselle plant, that I had no idea would live, stood a great tree 10 feet high and 12 feet across, and loaded with "fruit."

"Why, Wesley, do you mean to say that *tree* is the little plant I tried so hard to save?"

"It is the very plant, Mr. Root, and we have a lot more. Just look away down there!"

I could hardly believe my eyes. When almost everything else seemed sick and discouraged my roselle was just booming. We picked a panful and found them not only as good as cranberries, but to *my* notion a *great deal better*. The cranberries have a tough skin that I have always thought indigestible, but nothing of the kind with the roselle. We carried panfuls all around to the neighbors, and they are selling at a pretty good rate up fown at 10 cts. per quart. After having them in great plenty at almost every meal for the last two weeks I am thanking God every day for this most luscious and healthful fruit.* Lest you may think roselle is only another of my "freaks," instead of a "great discovery" along the

* When I said at dinner, "Sue, I do believe this roselle makes the most delicious sauce I ever tasted," she replied, "Now, don't you go and put that in print, for you have said it so many times it will sound ridiculous."

Well, this is the day before Thanksgiving, and I am sure it is the right and proper thing to thank God for roselle; and if it *is* true that I discover some new thing to be thankful for almost every day of my life, is it really a bad habit to get into? What do *you*, dear reader, think about it?

line of "daily bread," I quote below from a government bulletin:

ROSELLE: ITS CULTURE AND USES.

The roselle plant is adapted for culture in the tropical and subtropical regions of the United States, and should be especially valuable in southern California, Florida, the tropical islands of the United States, and in the Canal Zone. It is used in the South very much as the cranberry is used in the North, and is especially valuable for the making of jellies.

The name in Florida, "Jamaica sorrel," is evidently an indication that the plant was introduced from Jamaica—at what date the writer has been unable to ascertain—but it was probably not extensively grown in Florida before 1887, as P. W. Reasoner does not refer to it. Harcourt does not speak of it.

In Florida, as in California, those who have tried the roselle have nothing but praise for the plant, and considerable interest in it is manifest; but its culture on a large scale has not yet, to the knowledge of the writer, been undertaken by any one.

The assumption by Royle that the name roselle is a corruption of the French word "oseille" (the equivalent of the English "sorrel") seems very probable. In the evolutionary stages the name has at different times been spelled "rouselle," "rozelle," and "rosella."

The fruit is seen at present in local markets only, and is sold by the quart. Its excellent qualities for making a sauce so closely imitating in flavor the cranberry as to deceive the very elect are not well known to the public or it would be a formidable rival in the South to that fruit, on which transportation charges are necessarily high owing to the great distance it must be transported. The crisp and juicy appearance of the roselle is diminished by being too long in the hands of the dealer, but this does not indicate deterioration of its useful qualities.

SUMMARY.

The roselle is an annual from the Old World tropics.

It is extremely sensitive to frosts, and can at present be grown for its fruit only in tropical and subtropical countries.

Being easily cultivated when the climate is favorable, the roselle should be in the garden of every family; and on account of its excellent qualities for making jellies, jams, etc., it is certain to become an important plant in the manufacture of those products.

The young stems also make good jelly. For such use the plant can be grown almost anywhere in the North or South.

By proper methods of breeding it is possible to obtain strains with larger calyces. Probably earlier-bearing races can also be obtained by careful selection of the earliest-flowering plants.

To save many inquiries as to where to get seed, I am going to do some free advertising by giving the advertisement as I found it in the *Florida Grower*:

Roselle—the lemonade plant, is a wonder; easy to grow; resists drouth; makes the finest jelly; its pods make a drink similar to lemonade. Send 15 cts. for seed and instructions. MRS. H. G. KAY, Route 1, Box 58, Pasadena, Cal.

My seed came from the above source.

When the weather is very wet there is apt to be trouble with mildew, but the past summer here seems to have just suited it.

The above illustrates that certain things

grow all right during the Florida summers, while there are many things that are sure to be failures.

Later.—When you cut up oranges for the table, put with them stewed roselle sauce, half and half. I like this better than any other combination sauce.

We have now for the first time grapefruit of our own growing; also oranges and tangerines, delicious papayas, pineapples, etc. Although our strawberry-bed died out, we got from neighbor Rood forty plants with a good lot of soil with each plant, and set them out so not a leaf has wilted. This is possible only when you can get good strong plants near by. We brought so much soil with each plant that the forty plants made quite a wheelbarrow load. These plants, with care, will probably be bearing in January. Over an inch of rain, scattered over three days, has made everything brighten up amazingly. We have an abundance of sweet potatoes and yams and Irish potatoes knee-high.

FANCY IRISH POTATOES—A NEW TRICK.

In one of our agricultural periodicals a writer advised thinning out the potatoes in a hill to a single stem, in order to get all large potatoes, evidently forgetting or ignoring that Terry's A B C of Potato Culture has for its main feature "cutting to one eye," and it has been advocated more or less for forty years. The above article advised throwing away the surplus sprouts, but right here comes in the "new trick."

Down here in Florida, and, in fact, in many other places, under some circumstances potatoes must be planted *whole*, because, if they are cut, even in halves, they are much more liable to rot, especially in cold wet weather. This is one reason why the seed potatoes in the market are all small. Well, my neighbor Ault makes a bed of three rows of potatoes. The middle row is planted first all to large potatoes. When these are just coming up he digs them up carefully and cuts them to one or two eyes, and fills the rows on each side. Every potato grows—no missing hills—and the potatoes all go right along almost as if they had never been disturbed, and *no rot*, for a potato never rots after it has started to grow. Is this too much bother? Possibly; but down here where sprouted *seed* potatoes cost \$2.25 per bushel, and choice *new* potatoes bring \$2.00 per bushel, the saving of seed and having a perfect stand is quite a figure. You will see by our book "What to Do and How to be Happy," etc., that I did the same thing by starting potatoes in the greenhouse *toward forty years ago*.

CASSAVA AND THE MANIOCA OF SOUTH
AFRICA

On page 471, June 1, and page 559, July 1, you will see that our good friend Thompson sent me some canes or cuttings which were planted here about May 1. I have before mentioned the wonderful growth of

cassava; but this manioea, while it looks exactly like our cassava, has a much larger leaf, a brighter green, and seems in every way a more hardy and thrifty plant than our Florida cassava. We have not yet tested it for table use; but it looks now as if it might prove an acquisition.

TEMPERANCE

"KANSAS HAS MORE INSANE IN 'STATE' HOSPITALS THAN WISCONSIN."

We clip the following from the *Christian Observer*:

Thirty-two counties in Kansas have abandoned their public farms. According to the latest report of the State Board of Control, 898 paupers were being cared for at county institutions.

The prison rate for the entire country is 121.4 per 100,000 of the population. In Kansas it is 91.1. North Dakota, another prohibition state, does better than that, with 63 per 100,000 inhabitants.

The per-capita liquor consumption in the whole country is \$21. In Kansas it is \$3.04. Kansas thus saves forty million dollars every year directly. The indirect gain is not subject to computation, but is certainly greater still.

Illiteracy is the lowest in the country except in one other state.

Forty-eight counties out of 105 did not send a prisoner to the penitentiary last year.

LIBERTY IN LYING.

It is well known to those who have looked into the matter that no dependence can be placed upon figures and illustrations used by the liquor people. Their literary methods well illustrate the truth of the familiar saying that figures do not lie, but liars will figure.

A sample of its method may be seen in the use made of statistics. The liquor interests have claimed that Kansas has more insane patients in its state hospitals than Wisconsin in proportion to population. That is true; but they omit to say that Wisconsin has, especially in its more populous counties, a system of *county* hospitals for the insane.

Do the liquor interests really believe that the open saloon would be a good thing for Kansas? Most emphatically they do not. I saw a liquor advertisement recently which claimed that the whiskey advertised brings "health, wealth, and happiness." Does any one believe that? Do the distillers of that whiskey themselves believe it?

When those opposed to prohibition point to the fact that, in the matter of laws protecting working women, Kansas is behind some other states, do they mean we should infer that the best way to protect the working women of Kansas is to go back to the open saloon?

When they seek, unsuccessfully, to prove that Kansas suffers by comparison with Wisconsin in the number of insane, do they seriously propose the open saloon as a cure for insanity?

"FROM BOOZE TO BUTTER"—"COWS OFFER CONSOLATION."

Kimball's Dairy Farmer for Nov. 1 contains a splendid article headed "From

Booze to Butter in Washington," from which we clip the closing paragraphs:

It is a well-known fact that the Bellingham brewery has specialized on pasteurizing and bottling milk, making cheese and ice cream since the town went dry. That the plant has been doing this on a losing scale is absurd to contemplate. Capital does not engage in turning out food products for fun, any more than it turns out beer for the humor there may be in it.

In founding a creamery establishment, buildings are the first essential. Steam-generating plants and refrigerating apparatus are necessary. An office equipment must be had. Teams and wagons and automobile trucks are needed. All these things are to be had in the brewery rendered useless through temperance legislation. The items represent the bulk of the cost in creamery construction. Therefore it is not plain why breweries cannot be profitably converted into creameries, especially when the surrounding country gives a portion, or all, of its attention to dairying. By diverting the money usually spent to advertise beer into channels that will develop dairying, the ultimate profit for the creamery should equal or exceed the profit derived from liquors. All that is needed is to get the milk-cans moving as fast as the beer-kegs moved under the old order of things.

Cows offer consolation to those few farmers who are displeased because of the dryness of their localities because of temperance legislation. Hop and barley growers can depend on cows and other live stock to consume all they raise, and a market via the brewery need not worry them. No people on earth is going to legislate creameries and dairies out of business. Therefore, to feel safe and secure, why not go in for something that will last, and not depend on the whims of humanity? Cows have saved many a farm from mortgage proceedings. They will save the breweries from the scrap-pile when the time comes, and that time is rapidly approaching. That's why the Bellingham Bay and Olympia brewing plants are meeting the situation now, before it is fully upon them, by getting into the milk, cheese, and butter business.

Dear friends of temperance, some of us have wondered why our earnest prayers have not been answered; but is it not a greater miracle to see breweries furnishing milk, butter, and cheese than to see "swords beaten into ploughshares, and spears into pruning-hooks"?

"GOD'S KINGDOM COMING."

No doubt you will be glad to know our county (Bell) went dry Nov. 13, 1915, by a majority of 505. I know A. I. Root will rejoice with us.

Belton, Tex.

E. D. TOWNSEND, Northstar, Mich.

Fine new-crop clover and basswood honey at 9 cts. in new 60-lb. cans with 3-in. screws. Also in gallons and smaller, for family and store trade. State quantity wanted. C. J. BALDRIDGE, Homestead Farm, Kendaia, N. Y.

FOR SALE.—Car honey, half extra-fine comb, half extracted, alfalfa, or car extracted. Small lots at \$8.00 per case of two 5-gal. cans; cases of 6 10-lb. pails, \$5.00; 12 5-lb. pails, \$5.40; all f. o. b. here.
E. F. ATWATER CO., Meridian, Ida.

FOR SALE.—Water-white alfalfa, white clover, amber alfalfa, and amber fall honey in 60-pound cans or smaller packages. Amber fall honey is of our own extracting, and can also be furnished in barrels. Write for sample of kind desired, and state quantity you can use. DADANT & SONS, Hamilton, Ill.

FOR SALE.—Amber extracted honey, well-ripened and mild-flavored, 6 cts. Honey-dew honey for baking or bee-food (cheaper than sugar) 5 cts. by the case; ten cases 4½; 25-case lots, 4 cts. per pound; two sixty-pound cans to the case; also have some fall comb honey for \$2.25 to \$2.75 per case of 24 sections.
H. G. QUIRIN, Bellevue, Ohio.

FOR SALE.—Finest quality of white-clover-basswood blend extracted honey in new 60-lb. cans. State how much you can use, and I will quote you price. L. S. GRIGGS, 711 Avon St., Flint, Mich.

RASPBERRY HONEY, all left on the hives until thoroly ripened. It is thick, rich, and delicious. This honey is put up in new 60-lb. tin cans. We have it in two grades—pure raspberry and raspberry blended with just enough buckwheat honey to color it. Price, the pure raspberry, \$6.00 a can; the raspberry and buckwheat blended, \$5.50 a can. In one-gallon cans by express, raspberry, \$1.50 a can; raspberry and buckwheat blended, \$1.40 a can. Sample of either kind by mail for 10 cts., which may be applied on an order for honey.

ELMER HUTCHINSON, Lake City, Mich.

H. C. CLEMONS, Boyd, Ky.

Convention Notices

The Washington State Beekeepers' Association will hold its 22d annual convention on Feb. 9, 10, 1916, in the court-house, North Yakima. We are looking forward to having a good time. It is one month later than usual, owing to an unavoidable delay.
J. B. RAMAGE, Pres.
North Yakima, Wash., Dec. 30.

MASSACHUSETTS CONVENTION.

The annual Massachusetts convention of beekeepers for 1916 will be held at Amherst, Mass., March 14 to 16, inclusive. This will form the conclusion of the winter school of beekeeping, but the program of the convention is not fully planned. A number of prominent authorities will appear upon the program.

SHORT COURSE FOR MICHIGAN BEEKEEPERS.

The Michigan Agricultural College, East Lansing, Michigan, announces a "Beekeeper's Week," March 13 to 18 inclusive. It is hoped that a large number of beekeepers will take advantage of this new course, so that it may become a regular feature. There are no fees, and no age limit. Women are as welcome as the men. All beekeepers desiring to obtain more knowledge of beekeeping should apply to the Department of Entomology, East Lansing, Michigan, for further particulars and program.

APICULTURE GIVEN AT THE MICHIGAN AGRICULTURAL COLLEGE.

1. A five-credit course, two lectures and one lab., elective to seniors only, with prerequisite entomology. Given during the fall term. Practice and theory.
 2. Two lectures a week, for eight weeks, given to the Horticultural short-course students in January and February.
 3. Two periods a day, lectures and practical, during the month of February, given to the Agricultural short-course students.
 4. Three lectures a day during "Round-up Week," Feb. 27, to March 4. These will be more general, and suitable for the farmer who has a few colonies, and wishes to care for them properly.
 5. A one-week course in beekeeping, given during the third week in March, known as "Beekeepers' Week." Outside speakers will address the students in this course, and it will be made as complete as possible in the time allowed. March 13 to 18, 1916.
 6. A long course for the students of the senior years is being considered, and announcements may be made later.
- F. ERIC MILLEN, Instructor in Beekeeping and State Inspector of Apiaries.

ON THE BOOKSHELF

Happy Hollow Farm

Unless one is prepared to become enthusiastic about farming perhaps he had better let alone "Happy Hollow Farm," by William R. Lighton. Mr. Lighton is the author of "Letters of an Old Farmer to His Son," which was reviewed recently in these col-

umns. He was formerly an Omaha newspaper man, and went into the farming business down among the Ozarks in Arkansas. This is the story of his experience.

The fact that the author was a writer by profession made the telling of the story easy, but he could never have imagined the buoyant enthusiasm that comes from a life earned from the soil. It is not a manual of farming, yet a book of vast practical usefulness, common sense, and advice, and delightful gaiety.

The man who hopes some day to own a farm of his own will read it, of course. The man who already owns a farm will see new joy in his work, and will more greatly appreciate his own usefulness by living over again with Mr. Lighton his adventures in freedom.

"Happy Hollow Farm," William R. Lighton, The George H. Doran Co., New York; 318 pages, 12 illustrations, \$1.25 net.

This Washer Must Pay for Itself

A MAN tried to sell me a horse once. He said it was a fine horse and had nothing the matter with it. I wanted a fine horse. But I didn't know anything about horses much. And I didn't know the man very well either. So I told him I wanted to try the horse for a month. He said, "All right, but pay me first, and I'll give you back your money if the horse isn't all right."

Well, I didn't like that. I was afraid the horse wasn't "all right," and that I might have to whistle for my money if I once parted with it. So I didn't buy the horse, altho I wanted it badly. Now this set me thinking.

You see I make Washing Machines—the "100 Gravity" Washer.

And I said to myself, lots of people may think about my Washing Machine as I thought about the horse, and about the man who owned it.

But I'll never know, because they wouldn't write and tell me. You see I sell my Washing Machines by mail. I have sold over half a million that way.

So, thought I, it is only fair enough to let people try my Washing Machines for a month, before they pay for them, just as I wanted to try the horse.

Now, I know what our "1900 Gravity" Washer will do. I know it will wash the clothes, without wearing or tearing them, in less than half the time they can be washed by hand or by any other machine.

I know it will wash a tubful of very dirty clothes in Six Minutes. I know no other machine ever invented can do that, without wearing out the clothes.

Our "1909 Gravity" Washer does the work so easy that a child can run it almost as well as a strong woman, and it doesn't wear the clothes, fray the edges, nor break buttons the way all other machines do.

It just drives soapy water clear thru the fibers of the clothes like a force pump might.

So, said I to myself, I will do with my "1900 Gravity" Washer what I wanted the man to do with the horse. Only I won't wait for people to ask me. I'll offer first, and I'll make good the offer every time.

Let me send you a "1900 Gravity" Washer on a month's free trial. I'll pay the freight out of my own pocket, and if you don't want the machine after you've used it a month, I'll take it back, and pay the freight too. Surely that is fair enough, isn't it?

Doesn't it prove that the "1900 Gravity" Washer must be all that I say it is?

And you can pay me out of what it saves for you. It will save its whole cost in a few months, in wear and tear on the clothes alone. And then it will save 50 cents to 75 cents a week over that in wash-woman's wages. If you keep the machine after the month's trial, I'll let you pay for it out of what it saves you. If it saves you 60 cents a week, send me 50 cents a week till paid for. I'll take that cheerfully, and I'll wait for my money until the machine itself earns the balance.

Drop me a line today, and let me send you a book about the "1900 Gravity" Washer that washes clothes in six minutes.

Address me this way—H. L. Barker, 1621 Court St., Binghamton, N. Y. If you live in Canada, address 1900 Washer Co., 357 Yonge St., Toronto, Ontario.

FREE Dr. Kellogg's Great Book Constipation

How to Fight It

A Limited Offer

For the next ten days we shall give a copy of Dr. Kellogg's remarkable book "Constipation—How to Fight It," with each one year subscription sent us for GOOD HEALTH.

GOOD HEALTH is the magazine which tells you how to keep from being sick and brings to you, in usable form, each month, facts about the very latest scientific methods of increasing your strength and energy, and protecting and preserving your health.

GOOD HEALTH teaches you how to save strength—how to make every ounce of energy count—how to ward off disease—how to eat for health—and how to breathe, exercise, rest, sleep, bathe, and otherwise care for yourself so you may keep young and vigorous for many years.

GOOD HEALTH also has a Question-box Department thru which its subscribers may secure free answers to as many health questions as they wish to ask. If your questions are personal, and demand immediate attention, they are answered at once direct by letter. If you ask about matters of general interest, not requiring immediate attention, answers are printed in the Question Box of the magazine. All such questions are answered by the medical specialists who help to edit GOOD HEALTH. The Editor-in-chief of GOOD HEALTH is

Dr. John Harvey Kellogg, M. D., LL. D.

For nearly forty years, Dr. Kellogg has been Superintendent of the Battle Creek Sanitarium. Here he has observed, treated, and prescribed for thousands of cases, including every ill to which human flesh is heir. Dr. Kellogg, therefore, writes from the standpoint of experience. He deals with facts—not theory.

GOOD HEALTH also numbers among its contributors the foremost medical minds of the country, including Dr. Winfield Scott Hall, of Northwestern University, Dr. J. N. Hurty, of the Indiana State Board of Health, Dr. L. A. DeVilbiss, of the Kansas State Board of Health, Dr. Luther H. Gulick, of the Board of Education of New York City, Prof. Irving Fisher, Ph.D., of Yale University, and many others equally well known.

GOOD HEALTH is not a magazine of fads and fancies. It teaches only good, sound, common sense. Any one who reads English intelligently can understand and follow GOOD HEALTH teachings.

Think of it! All these tremendous resources of health information at your command for only \$2.00 a year. And, in addition, you get Dr. Kellogg's famous book "Constipation" absolutely free.

"Constipation" is not a large book—only a little over 100 pages—but what it teaches makes it worth its weight in gold. It is yours free with a year's subscription to GOOD HEALTH for only \$2.00.

Use the coupon. Don't postpone acting on this opportunity to add a valuable book to your library, and, thru GOOD HEALTH to keep in touch with original sources of latest and best health information.

This offer is good for ten days on y. To get the benefit of it, you must act at once. Fill out the coupon and hail it now.

GOOD FOR TEN DAYS ONLY.

Good Health Publishing Co.,
1001 W. Main St., Battle Creek, Michigan.

Gentlemen:

I attach \$2.00 (send check, money order, bank draft, or a \$2.00 bill) for which enter my name as a subscriber to GOOD HEALTH for one year, and send me, as per your offer, a copy of Dr. Kellogg's book—"Constipation—How to Fight It," which I understand will be mailed to me postpaid and absolutely free.

"Hats Off to the New Management"

writes a Mission, Texas, customer

The old reliable line of Root's Beekeepers' Supplies with our new system of business management assures Texas beekeepers of service such as they have never before experienced.

Mr. B. I. Solomon, who is now in charge, has been with The A. I. Root Company for some years and knows their method of doing business.

We intend to carry a large and complete stock of supplies, and we also have our Weed foundation machines in shape to care for all orders promptly.

Give us an opportunity to convince you of our service.

Toepperwein & Mayfield Co.

Nolan and Cherry Sts.

San Antonio, Texas

A LOOK INTO 1916

Gleanings in Bee Culture

Long-headed men of affairs are enthusiastic over returning prosperity in business. Are you as a practical beekeeper prepared to take your share of larger profits? GLEANINGS IN BEE CULTURE for 1916 will emphasize practical sales methods for honey producers. Two numbers will be given over entirely to plans for pushing sales of honey. Experienced beekeepers look for a good year all around, and these special numbers will make it even more profitable.

In each of the numbers the respective subject will be given thorough treatment with articles, editorials, and departmental comment. The combined force of many men's experience will be focused upon these practical topics. As usual, we have selected the subjects to be featured from suggestions made by readers themselves.

Special Numbers for 1916

March 1—Buildings

Every beekeeper has or looks forward to having a workshop and extracting house. The first March number will discuss and illustrate plans, arrangements, and details of buildings which have proved satisfactory. If you intend to build you'll need this information. Interior equipment and devices for saving labor will receive attention.

May 1—Out-apiaries

This will interest the practical bee-man of large operations. There will be special articles on the let-alone plan of beekeeping; extensive or intensive—which? Look for pertinent matter on doing without detailed records for each colony, securing a location, arranging rentals, agreements, etc.—these and other important details of success on a large scale.

June 1—Wax Production

We found a man in Arizona who says it pays him to run his colonies for wax

alone. High freights take the profit from honey. The values in wax production, methods of extracting, rendering from old combs, marketing, and the uses of wax will get a hearing in June.

July 1—Advertising Honey

Talk about honey! That's the only way to sell it. What to say and what not to say will be the meat of this issue. Exhibits at fairs and food shows will be illustrated, newspaper and direct-by-mail advertising will be described, and other suggestions aired. Can you wait until July?

August 1—Marketing Honey

After advertising come the sales. Writers with something to say will discuss working up a local trade or selling thru wholesales or jobbers. You will not be kept in the dark about problems of transportation, trade marks, and construction of packages. Of course, co-operation, national and local, will have attention.

Are These not Worth Your Subscription?

Gleanings in Bee Culture, Medina, Ohio

Bay State Awl and Tool Set

Ten Tools

Tempered and polished tool steel blades; cutting tools sharpened. Polished hollow maple handle, with screw cap to contain blades. Polished steel screw chuck, jaws, and ferrule.

Length of Blade $2\frac{5}{8}$ inches; length of handle, $5\frac{3}{4}$ inches; total length with blade attached, $7\frac{3}{4}$ inches. Diameter at chuck, 11-16 inch.

This is just the kind of a set to take with one for emergencies when it is inconvenient to carry so many tools, as they all fit in the handle, and the tool in that way occupies little space but can readily be converted into ten different tools. Nothing handier for a pocket kit.

Bay State Awl and Tool Set

a Premium for NEW Subscriptions to "Gleanings"

Send us THREE NEW SUBSCRIPTIONS TO GLEANINGS
for six months each (25 cts. each), and one of these
Awl and Tool Sets will be mailed to you
postpaid as premium.

Canadian postage 15 cts. extra for each subscription.

Gleanings in Bee Culture, Medina, Ohio

THE IDEAL BEE-VEIL

Offentimes when out in the yard working with the bees one stoops over to pick out a frame, and, as usual, bees keep buzzing around his head, watching for a chance to sting. The cloth veil which is often used sticks to the face when one bends over, and gives the bees an opportunity to sting. The IDEAL BEE-VEIL is constructed of cloth of wire, there being a cord at the top of the veil used to pull the cloth around the crown of the hat. The lower part also has a cord which fastens around the waist. The wire on the IDEAL veil does not strike the face, and prevents the bees from stinging. It can be readily seen that a veil of this kind has the cloth veil far outdistanced for comfort and utility. Sparks from the smoker do not burn holes in the IDEALS as in the netting veil.

The veil is manufactured by us, and is recognized by the best and largest beekeepers as the most practical veil on the market.

Red Catalog, postpaid. "Simplified Beekeeping," postpaid. Dealers Everywhere.

Where the good beehives come from.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COLO., FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section is this grade must be stamped, "Net weight not less than 10 oz." The front section in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroughly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color, and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

INDIANAPOLIS.—This market is well supplied with honey, especially comb honey. With the approach of holidays the market usually shows a lack of vitality. No. 1 choice white comb is selling at \$3.75 to \$4.00 per case; No. 2 white comb, \$3.50 per case. Extracted honey is bringing 9 to 11 cts. We are offering 28 cts. cash or 30 in trade for good average wax delivered here.

Indianapolis, Dec. 18. WALTER S. POWDER.

ALBANY, SCHENECTADY.—There is but very little demand, and we look for a quiet market during January. The usual retrenchment, after the rush and gift-buying during the holidays may be expected. Lower prices will not induce buying, as merchants are taking account of stock, and add only what is necessary.

CHARLES MACCULLOUGH.

Albany, Schenectady, Dec. 22.

CHICAGO.—Trade in honey is quiet. Retailers having loaded up for the holiday season, there will not be much of a call before the middle of the coming month. Prices are without material change, ranging at 15 to 16 for the two highest grades; 12 to 13 for the ambers. Light-weight sections are preferred when well attached to the wood. White extracted ranges from 7 to 9, according to kind and condition; but very little of it is selling at over 8 cts. in a small way. Large lots can be bought at lower prices. Amber grades range at from 5 to 6, with some high-flavored and desirable lots at 7 cts. per lb. Beeswax brings 28 to 30.

Chicago, Ill., Dec. 18. R. A. BURNETT & CO.

ZANESVILLE.—Considering the proximity of the holidays, when usually the demand for honey begins to slacken, the market condition is fairly satisfactory, and the better grades are moving pretty well. Prices remain about as per previous quotations. Choice to fancy grades sell in single-case lots at \$4.00 to \$4.25; lighter weight and inferior grades correspondingly lower, with usual discount to the jobbing trade. Best grades of extracted are selling at 9 to 11, according to quantity, with the supply about balancing the demand. Twenty-eight cts. cash, thirty in trade, are ruling prices for wax as received first-hand from producers.

Zanesville, Dec. 20.

E. W. PEIRCE.

Honey reports continued on page 5.

Special Extra....Automobile Bargain

We offer our 4-cylinder 35-horse-power covered-top delivery automobile in perfect order. Cost \$1500; will sell for 750. Capacity 1500 lbs. Just the thing for a farmer, dairyman, or grocery delivery. If interested, write for more particulars, as the party buying will get a bargain.

The Fred W. Muth Co., 204 Walnut Street, Cincinnati, Ohio
"The Busy Bee Men"

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring besides saving 3 per cent

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the bee-keeper requires for the proper conduct of an apiary.

C. H. W. Weber & Company, Cincinnati, O.
2146 Central Avenue

The Prospect for 1916 is Very Good

It would be wise to be one of the beekeepers who are now ordering supplies for another season; besides, there is a discount for January of 3 per cent and February of 2 per cent. Send us a list of goods required and we shall be glad to quote you prices if you have no catalog. Catalog will be sent only on request. Our stock for season of 1916 is now here, and we can fill orders pretty promptly. We carry a full line here at Syracuse; and by ordering from here you will save time and freight. Goods will arrive in better condition on short hauls. Better make out a list before you forget it.

Honey reports continued from page 2.

ST. LOUIS.—There is no change in the honey market since our last quotations. The supply of both comb and extracted honey, while not large is quite sufficient for the present demand. We are still quoting white comb honey in 24 sections from \$3.50 to \$3.75; amber, \$2.75 to \$3.00; dark and inferior, less. Extracted honey in 60-lb. cans from 6 to 9, and in barrels from 5½ to 6½, according to quality. Beeswax is firm at 28½ for pure; inferior and impure, less.

R. HARTMANN PRODUCE CO.

Kind Words

GLEANINGS READ BY PRISON INMATES.

Our exchange list has grown to such an extent we were sure it needed revising, so we sent out a circular letter and a card to all exchanges on our list of which we were at all uncertain. All they have to do if they wish the exchange continued is to return the card we have sent, indicating that they are interested in GLEANINGS.

The card below is one which came from the *Star of Hope*, the paper published by the prisoners of Sing Sing Prison.

STAR OF HOPE, Inmates Sing Sing Prison, 354 Hunter St., Ossining, N. Y.

After the editorial office is done with the magazine we loan it to inmates interested in the subject; and after they have read it we send it successively to Auburn Prison, Great Meadow Prison, and Clinton Prison, where it is loaned to interested inmates until it is worn to shreds.

H. HUFFMAN BROWNE, Editor-in-Chief.

MAPLE SUGAR, BEES, POTATOES, AND "AX-HELVE."

A. I. Root's talks about maple syrup and sugar in *Our Homes* made me think it would, perhaps, be interesting to you to see how we make syrup and sugar each spring. I have made maple syrup about 40 springs out of my life of 53 years, and know it is just as healthy to make it as it is to eat it. I certainly enjoy both. My quarter-acre yielded 74 bushels of nice potatoes. This kind of potato was raised from seed of the Early Rose. They are the earliest potato I ever had. The bees did quite well this year in spite of cool rainy weather throughout the summer. I extracted 150 gallons, and had about 300 lbs. of comb honey from 35 swarms, spring count.

One of my side lines is hand-shaved ax-helves. This line goes well with beekeeping in my locality. One winter I made 82 dozen for the Wisconsin Timber and Land Co., of Mattoon. There are hundreds of acres of cutover lands in this locality where raspberries abound.

Mattoon, Wis.

A. V. POLLOCK.

KIND WORD FROM A SOUTH AMERICAN MISSIONARY.

Dear Bro. Root.—Your tract, "How to be Happy when People Abuse You," came to me with some sample tracts from California recently. I received a great blessing from the tract.

I should like to say I have known you since I was a little boy, as I grew up in Chippewa Lake, attended school in Medina, and saw your plant grow to the proportions it is now; and I know it is because you were true to God.

I learned to dance, play cards, smoke, etc., and would not yield my life to the Lord, although he called me many times.

On account of smoking I became so nervous I could not sleep at night—made one or two trips to Chippewa to end my life by my own hand. I was so nervous I could not do so, the Lord holding me because of prayer. I was saved May 10, 1900, since which time, excepting the first year, I have been preaching the gospel, six years of the time in South America.

The Lord has wonderfully blessed me, and given me many souls in this time, as my calling is that of an evangelist.

Let me say I always love to read your bee journal for the good religious articles you put in it; and I pray that God may wonderfully bless your last days.

When You Think of Bee Sup- plies, Think of Indianapolis

We Sell Root's Bee Supplies
---the Goods that Satisfies....

Indications just now are very favorable for a good season next year. A good season means an excessive demand for Root's goods at Root's prices. By ordering now you will receive your goods promptly, also save the cash discount for early orders, which is three per cent in January, and you can put them together in your spare time.

If you are interested, and it is your intention to order your supplies before goods are really needed, just try placing a trial order here. We are quite sure you will continue with us year after year. Some, of course, never buy supplies till after they are needed. But the men who are most successful are preparing *right now* for next season.

We allow you 30 cents a pound in trade for good average beeswax delivered here.

Finest extracted honey in five-gallon cans ready for immediate shipment. Write for quotations.

The Double-walled Massie Bee-hive

Surest Protection for Bees---Increased Supply of Honey---the Best Hive for any Climate

The Massie Hive for Comb or Extracted Honey

Furnished in the clearest of lumber, in either Cypress, White Pine, or red-wood; all brood and extracting frames are made from White Pine.

The Dovetailed Hive for Comb Honey

THE VENTILATED BOTTOM admits fresh air into the hive, lessening the chance for swarming, and gives renewed energy to the bees. It is also equipped with a feeder without extra cost. Fifty years in the bee-supply business has shown us that the MASSIE is THE VERY BEST HIVE, and testimonials to this effect are received daily from those who are using this hive.

Why not give us a trial order?
Satisfaction fully guaranteed.
Early Cash Order Discounts..

We are also extensive manufacturers of DOVE-TAILED HIVES and all other apiarian supplies. If you are in the market for supplies be sure to get our prices before buying elsewhere. We will mail our large illustrated catalog and SPECIAL price list to any one upon request.

KRETCHMER MFG. CO., 1000 3d St., Council Bluffs, Ia.

"Next Door to Everything"

reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business, distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

January cash orders are subject to a special discount of 3 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to prepare carefully the bees for winter, and anticipate all possible requirements.

NO. 2

EDITORIAL

Good Wintering at Medina

TODAY, Jan. 12, the bees at Medina are having a splendid flight. The temperature is up to 70, and the bees are flying as if they were out on a gala day in summer. Bees are wintering equally well in double-walled single hives and in the big quadruple winter cases. In some colonies brood-rearing has started. Notwithstanding the bees have been flying strong, scarcely a spot of dysentery can be found on the hives. Indications at the present time point to excellent wintering; and the government weather maps seem to indicate that our locality is no exception.

The Michigan Short Course

AFTER trying for two years to put thru his project of a short course for Michigan beekeepers, Prof. F. Eric Millen, of East Lansing, Mich., has succeeded and now announces a "Beekeepers' Week," March 13 to March 18, inclusive.

This is a new course, and is designed to meet the needs of a large number of beekeepers who have never had an opportunity to become acquainted with the newer and more profitable systems of management.

Seven or eight lectures will be given daily and expert beekeepers, including Mr. Morley Pettit, Provincial Apiarist, Ontario, will address the class. While it will not be possible to cover the whole field of beekeeping the fundamental principals will be thoroughly discussed. There are no fees and no age limit. The women are as welcome as the men. For particulars inquire of the Department of Entomology, East Lansing, Mich.; also Convention Notices elsewhere.

Bee-escapes

IN this issue there is some evidence showing the value of the double Porter escape, or two single escapes to a board. It is a little dangerous to put a single escape on a big colony during hot weather. We have

had one disastrous experience, and numerous reports showing that a single exit may become clogged. When bees are confined on a hot day in a super with no means of escape, there is danger, on account of the excessive heat generated, that the combs and honey will be melted down, and the bees smothered.

For these reasons the double-exit escape is coming more and more to the front. It is altogether unlikely that both exits will become clogged at the same time. And even if one should do so, the other opening will release the bees.

Quite a number are now favoring the ventilated escape-board having one or two Porter escapes in connection with the wire screen. The object of this is to provide ventilation, and keep the honey as warm as possible so it will extract more readily. But as E. F. Atwater, in this issue, says, the combs will not be as warm as when the bees themselves are on them. Herein the old method of shaking and brushing combs has a little the advantage.

Honey Bread—Not so you Could Notice it

OUT in Kansas they have a food commissioner who will not tolerate misrepresentation of a food by name or trademark, fanciful or otherwise. Butternut Bread, made in Chicago, when it comes into Kansas has to bear labels expressly stating that butternuts are not used in its manufacture.

Then the commissioner came to the "Honey Bread" people in Kansas City who had to confess that they use no honey in making up the dough. The only thing to do was to admit it on the label or find another name.

The decision of the food commissioner in the case of the Butternut Bread is rather curious, especially as it does not seem that any one would believe that butternuts actually are used in it; but the laughter at his "Honey Bread" decision was due to general

ignorance on the part of the public that honey is often an important ingredient in bread. The commissioner was right.

But then, isn't it to be regretted that honey is not more generally known as a delicious addition to a bread recipe? If it had been, the commissioner's action would not have been almost the national joke that it became.

The United Honey-producers' Association

THIS is an organization to "support a nation-wide system of teaching the food value of honey, and its uses in cooking, in the domestic-science departments of our public schools. It was started in Indiana, with B. F. Kindig, deputy inspector of Indiana, president, and George W. Williams, of Redkey, Ind., is secretary and treasurer. A vice-president will be chosen later from among the members of each state organization. These collectively will make up the national board of control, to determine the policies to be carried out. The dues are \$1.00 a year, plus one cent per colony above the first hundred colonies.

Mr. Williams, the secretary, is editor and owner of the *Booster*, a monthly journal devoted exclusively to the interests of honey-producers, but primarily to boost the price and sale of honey. We have already noticed this paper—see pages 431 and 739. *The Booster* appears to be still boosting, not only to increase the consumption of honey, but to boost the United Honey-producers of America.

It is announced that the new organization will make some of the "old fossils who have been running around in a ring for 25 years open their eyes when they wake up some of these mornings and see the United Honey-producers doing the things that they have been dreaming and talk, talk, talking about for a quarter of a century, and doing it in a way that will make them cuss themselves for not seeing how to do themselves."

It is indeed time that we were doing something besides talking and passing resolutions. The publishers of GLEANINGS have on their own initiative started a vigorous campaign of advertising honey. We would not dare to say how much we have expended; but if one knows what it costs to advertise in papers like the *Ladies' Home Journal*, he will know that the figures run clear up into the thousands. We gladly join with the United Honey-producers of America, and sincerely hope that they will succeed in putting honey in every family in the United States. They are going at it

right by getting the food value of honey before the domestic-science departments of our public schools.

Winter Weather up to January 3. How Bees are Wintering

WE have been going over our government maps, which we have been receiving since last spring, and find some rather interesting data concerning the weather over the United States as a whole. In our locality the winter started in rather early. We should have preferred to have two weeks more of warm weather before packing our bees; but it set in cold along toward the middle of November, and by December 1 it had set in for real winter.

A comparison of the weather maps for the last two months reveals the fact that it has been rather cold in the southern states, while on Dec. 28 10 degrees Fahr. starts north of Lake Huron, in Canada, continues thru Michigan, thru Chicago, to Springfield, Ill., thru Kansas, clear down south as far as Roswell, N. M., a little north of El Paso, and running a little north between Phoenix and Flagstaff, Arizona. Then the line turns sharply to the east, going thru Leadville, passing directly north up into Canada.

On different days it is really surprising to see how cold it has been in some of the southern states. Some of the cold was in a mere pocket covering a very small area in one state. For instance, on Dec. 27 there was a pocket of cold in southwest Utah near Modena. There was another pocket of zero weather around Rapid City. It was down to 30 and even 20 in Texas, and 30 in southern Georgia. On the day following the entire map was changed. The temperature went rapidly upward, but it went down below freezing in northern Florida.

Private letters from Florida indicate that it has been quite cold in that state, and the maps show it. While it has been rather cold in the southern states, the mercury has not been very low relatively in the northern states. In the lake regions, and directly south, it has seldom been lower than 30 degrees, with an occasional pocket of about 20 degrees. Apparently it has not been very cold in Canada; but occasionally we find some zero weather, and a little below zero; but these low marks are at least 100 miles north of Lake Superior.

There has been a large amount of wind; and when the temperature is not so very low there is apt to be a great deal more air stirring than when it is down to about zero. A temperature down to freezing, with a high wind, especially when it goes down to

20, is about as hard on unprotected bees as a zero atmosphere without wind. However, when colonies are well packed and screened by windbreaks, as they always ought to be, these high winds do no particular harm.

Taking the winter over the northern states for two months, so far it has been favorable for bees well packed and screened by windbreaks, but it has been a little hard on bees in single-walled hives out in the open.

It has been noted many times before that when a winter starts in cool and cold rather early as it did this winter that there is no likelihood of there being any severe cold during mid-winter. When, however, the fall is very mild and warm, and the weather continues clear up to Christmas, severe cold is likely to follow, as it did three years ago today, Jan. 5, 1913.

The weather maps also show that the lines of heat and cold this winter pay very little attention to the parallel lines of latitude. While it is true that the cold does not remain long in the southern states, yet this winter, on occasion, it has been just as cold in the extreme southern states as in the northern. For instance, on Jan. 3 it was 30 on the coast of Maine, and the same temperature in Texas, and a few miles north of Phoenix, Arizona; and Yuma, for instance, the hottest spot in the United States, had a temperature as low as 40. In southern Colorado it was down to zero.

According to the map there has not been a large amount of snow. There has been more precipitation in the southern states. There seems, however, to have been considerable snowfall in the regions just north of us in Canada.

The New or Old Bee-disease; Isle of Wight Disease and Bee Paralysis Probably the Same

ELSEWHERE in this issue, page 69, we publish a symposium of reports in response to our request on page 922 for a statement of experience detailing the amount of destruction caused by the new disease, its exact symptoms, and a cure, if any. We have received a good many responses, only a part of which we are able to publish; but those we do give are representative of some of those we do not publish.

The general evidence so far submitted would seem to lead to the belief that the Isle of Wight, or new disease, and the old bee paralysis of bygone days, of Florida and California, are one and the same. The differences, if any, we verily believe, can be

charged to environment and seasonal conditions. Let us compare the symptoms of bee paralysis, and then those of the malady that has shown itself in the Northwest and in the Mississippi Valley.

SYMPTOMS OF BEE PARALYSIS.

The disease seems to be confined mainly to the bees themselves. The first sign of it is a few black shiny bees, often with swollen abdomens, crawling around aimlessly in front of the hive entrances. A few scattered ones will be found in the hive. In the more advanced stages the whole colony seems to be demoralized, and the individuals will apparently be struggling against each other, and tugging at their own bodies, as if in distress. It is very seldom that we find bee paralysis in its advanced stages in the northern states; and when it does occur, not more than one or two colonies having it can be found in the yard.

Some twenty years ago bee paralysis was very destructive in Florida and California. The general symptoms were about the same as we have reported, except that whole apiaries wasted away. But in later years it, seems to have worn itself out, both in Florida and California.

A few years ago (1904) we began to hear about the Isle of Wight disease that spread all over England. At the time, it was observed that it was quite like our bee paralysis, and was so reported in GLEANINGS. Last summer we began to get reports of a similar if not the same malady, that was killing bees by the thousands in Oregon and Washington, and we heard of it also down in the Mississippi Valley and in parts of Texas. In some localities it appeared to be very serious. The reported symptoms did not, however, exactly tally with those of bee paralysis. The colonies simply wasted away until the brood began to die. The symptoms in the Northwest part of the country were about the same as in Isle of Wight disease in England. The bees would be seen crawling out in bunches around the entrances of the hives, not always shiny and black, apparently nothing the matter with them except that when they attempted to fly they could not. Some bees would lie on their backs. All of them showed more or less trembling of legs and wings. Some reported that the bees were black and shiny, and others said that they did see it. In this respect the malady in the Northwest was not quite the same as bee paralysis, and the difference between the two diseases could be accounted for by environment because there were several reasons that pointed to the same disease. Let us see what the points of similarity are:

1. As in the case of bee paralysis, so in the disease of the Northwest, some strains of bees are more resistant than others. Sometimes a change of queens brings about relief and often a cure.

2. Finely powdered sulphur sprinkled on the bees brought about relief and cure with the old bee paralysis of Florida and California, and it also seemed to afford relief and cure to the bees affected in the Northwest, down the Mississippi Valley, and in Texas.

3. An excess of moisture seems to favor both bee paralysis and Isle of Wight disease. Either would be more prevalent during a wet season such as we had last summer than during a dry one. In Great Britain, Florida, and in Washington and Oregon, there is an excess of moisture almost every season at certain times of the year. But the humidity is greater some seasons than others, and the virulence of the disease varies with the humidity present.

It will be noticed by the reports in the symposium that the disease apparently disappears when settled dry weather comes on. While we do not know positively, it would seem that a fungus of some sort is the disturbing cause. Whether the bees gather it with the pollen has not been proven. Fungus seems to develop better in a humid atmosphere than in a dry one.

The summer of 1915, especially the fore part of it, was the dampest and wettest we have known for years, and we have heard more of the disease similar to bee paralysis than we have heard before for many years. Moreover, it seems to follow in those portions of the country where there is a great amount of humidity; and it disappears just as soon as dry or settled warm weather comes on. It is quite clearly established that a moist climate, or an occasional wet season favors the propagation of this particular malady, whether we call it Isle of Wight disease or paralysis.

That it is destructive—fearfully so—when the conditions are right, is abundantly proven. One of the remedies is finely powdered sulphur blown over the combs and bees. But the only satisfactory relief is the drying-up of the weather. On this point, perhaps our British cousins may not agree with us; but we doubt very much whether they really know what a dry climate is. What to them would be dry would be only foggy to us.

Another fact seems to be that this new disease apparently wears itself out. After it has had a run for two or three years it will disappear. Twenty years ago Mr. O.

O. Poppleton reported it as very serious. When Dr. Phillips later on sent Mr. Demuth down to investigate he could find nothing of it. When we asked Mr. Poppleton what had become of it he said it had simply disappeared.

We have proved out to our own satisfaction that some strains of bees, especially some around Portland, will resist this Isle of Wight disease or bee paralysis much better than some other strains. The same disease has been rampant in Australia, and it was a very serious trouble there until the beekeepers developed a strain of Italians that were immune to it.

It will be remembered that Mr. F. R. Buehne, of Tooberae, Australia, imported some strains of yellow Italians from America. Everywhere these strains were introduced, bee paralysis broke out and made no end of trouble. He could not hold the disease in check until he had eliminated the imported strains entirely, and went back to his own stock that seemed to be immune.

From all we have so far learned we can draw no positive conclusions, yet the remedy seems to be to introduce strains that are immune to bee paralysis as far as possible in those parts of the country where the disease has held sway or where there is an excess of humidity, and use sulphur. The disease is sometimes imported thru the queen, because years ago there was no such thing as bee paralysis; and when a territory is once cleaned up, humidity alone will not bring it on.

Mr. Poppleton, besides having discovered that powdered sulphur will give relief to an affected colony, also learned that the combs and the bees themselves are not a source of infection to a healthy colony; but the treatment that he found to be the most effective was to form as many nuclei from strong healthy stocks as there were colonies to be treated. As soon as the nuclei had young laying queens he gave to each, as fast as possible, one or two frames of old capped brood from each of the paralytic colonies. He continued to give them brood in this way until the brood from affected colonies was used up.

At the present time we are not assuming that any theory we have advanced, to the effect that the two diseases are one and the same, are absolute and final. We desire to get more reports in order that we may make further comparison; but it is our belief, but only a belief, that the slight differences between the Isle of Wight disease and the old-fashioned bee paralysis can be easily explained by environment and the condition of the season.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

BULK comb honey looks good when those Texas chaps talk about it; but why has it never gone in the North? We might know more about it if some enthusiast who has made it a success in the South should move north and try it on our markets.

"CLOVER pollen seems to be the only pollen which is covered with honey, and the honey sealed over," says G. M. Doolittle, p. 927. That's new to me; but I've no doubt he is correct, as usual, at least for clover regions. But I do know that in pollen left over from the previous year I do not recall that I've ever seen any but dark brown, like clover pollen. I suspect there's more pollen from clover than from all other plants combined; and the other pollens being used as fast as gathered, clover is the only kind left to be sealed.

So much is said about Italians for European foul brood that there is danger a beginner may think all he has to do is to keep Italians and defy the European enemy. Italians have the disease as well as others, only they are a *help* in its treatment. [You are exactly right, Dr. Miller; but the tendency of late among beekeepers is to think that an immune strain of Italians is all that is required. In the first place, no one can know when a strain is immune; and in the second place, when they are immune, additional treatment is necessary.—Ed.]

YE Editor guesses bees go for nectar as far as they can see, p. 965. My guess is smell. No matter how slight the breeze, bees always approach a basswood on the lee side, although they can *see* as well from either side. Then I'm skeptical about their seeing a patch of clover two miles away. [You may be right. One thing in favor of your theory is that an obstruction would shut off an odor-carrying breeze the same as it would shut off a view of the thing itself. The suggestion has been made that the bee has a telescopic sight as well as a microscopic. The small simple eyes may be telescopic, and the compound or big eyes on each side of the head may be for near or close work.—Ed.]

ACCORDING to what you say, Mr. Editor, p. 1011, the average beekeeper of large experience leaves the dummy out of either eight or ten frame hives. Well, as I there said, "I'm not entirely certain it isn't an improvement." Let's figure: With $1\frac{3}{8}$

spacing, and combs $\frac{7}{8}$ thick where occupied with brood there will be $\frac{1}{2}$ inch between combs, and a space of $\frac{13}{16}$ at each side. Accumulation of glue will in time take up $\frac{1}{4}$ inch, as you say, and then the space at each side will be $\frac{11}{16}$. If $\frac{8}{16}$ is the right space for bees between combs, $\frac{11}{16}$ would seem none too much for the outside blanket of bees. I think I'll try leaving out the dummy. How about ten-frame hives $14\frac{1}{4}$ inches wide? When everything is new there will be just $\frac{1}{2}$ inch at each side. With an accumulation of $\frac{1}{4}$ inch of glue that space will be $\frac{3}{8}$, and with more glue it will be still less. Seems that outside space should be more than the inside ones, rather than less.

"I AM satisfied that fifty degrees is too high a temperature for successful wintering," converses Doolittle, p. 1015. Likely true in most cellars, where the air is close. But it doesn't seem to do much harm in my cellar, where the door is more or less open, and air about as pure as outdoors. At any rate, the temperature often stands at 50 or more, and the bees winter well. I wonder if purity of air isn't more important than temperature. [This question of temperature, as you say, is one that is largely dependent on the amount of fresh air. When there is no ventilation, or but very little, the nearer the thermometer shows 45 Fahr. the better. But with sufficient ventilation the temperature may go up to 50 or even higher without any serious results. In our best indoor wintering-cellar the temperature ranges from 45 to 65—most of the time about 50. We have a dry cellar with a large amount of ventilation. The bees in this cellar would scarcely fly out on the cellar bottom; and on Feb. 15 we were often able to go across the floor without stepping on a bee.]

If anything we prefer a temperature of 50, and ventilation, to a temperature of 40 to 45 with *little* ventilation. We have proved, to our own satisfaction at least, that with a perfectly pure air the temperature may go up to 60 and stay there for days; but, of course, we prefer it about 50. At 50 to 55 the bees begin breeding. This does no harm toward the latter part of winter, but it is too much of a good thing during the fore part or middle of winter. We have looked into a good many bee-cellars; and the conditions we have found all over the North are borne out by our own experience in our own cellar with plenty of ventilation.—Ed.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

Bees were flying freely about here as late as Nov. 28, and even working on fall-blooming dandelions.

* * *

It seems to me I never heard so much piping or quahking of queens as I have this fall.

* * *

On page 986, Dec. 1, first column, the strange statement is made that, if a colony of bees has European foul brood, it should "be broken up or *disturbed*." *Destroyed* would sound better.

* * *

Most of our bees are being wintered, as usual, out of doors. But we put 108 colonies in the cellar Nov. 30 and Dec. 1. The temperature since they were put in has ranged at 50 degrees, and bees are as quiet as one could ask.

* * *

Directions are given, page 739, Sept. 15, as to where to set bees in a city lot so as not to cause trouble. This is well; but it is equally important to be careful what kind of bees you set out in a city lot. The average black colony will make ten times the trouble an average Italian colony will. Italian bees rarely molest unless molested.

* * *

Mr. Byer inquires, page 970, Dec. 1, if clover out of season yields much honey. That has been our experience this year. It was also true fifty years ago this season. Moses Quinby stated, more than fifty years ago, that in some years it would yield nearly all summer, but as a rule neither white nor alsike clover seems to yield much honey after July.

* * *

In reply to Dr. Miller's question, page 789, Oct. 1, I will say that when our bees have sections filled with foundation within $\frac{1}{4}$ inch of the bottom, and on a good colony, and honey coming in freely, we have little trouble about the combs being built down to the bottom; but without these conditions foundation fastened to the bottom appeared to be gnawed away, and not as well secured as we had expected.

* * *

The statement is made, page 797, Oct. 1, that "just as water goes direct into the blood, so does honey, leaving no residue. It is assimilated at once, and changed to energy." I believe this fact of vastly greater

importance than we have been accustomed to think. Dr. Miller calls attention to this on page 800. If, when wearied or exhausted from any cause, we take a tablespoonful of honey dissolved in a cup of warm water, we may find ourselves in much better condition later than if we were to take solid food.

* * *

I went out a few weeks ago with my right-hand man to look over a hundred colonies of bees. Suspicious that robbing might develop, he brought along a hand sprayer and a little kerosene. Sure enough, we had fairly got started when robbing began. A little spray of kerosene soon put the robbers to flight; and by the use of it, spraying a few hives ahead of where we had at work we were able to work with as little trouble from robbers as in midsummer when honey is most abundant. It is better than carbolic acid—cheaper, and less trouble—best thing I ever tried.

* * *

That bulletin No. 695, "The Fundamental Principles of Good Wintering," by Dr. E. F. Phillips, is sound and timely, both as to packing, protection from wind, and strength of colonies. But where little honey is gathered after July we have many colonies that are not strong. What about them? Shall we break them up or unite them that all may be strong? We have found that such winter very well if the brood-chamber is reduced to three, four, or five combs, and well packed, notwithstanding the severity of our northern New England winters. A small room does not require as large a stove to keep it warm as a large one.

* * *

Dr. Miller inquires, page 835, Oct. 15, how many swarms I lose by running in virgin queens to full colonies. Well, doctor. "I don't know." We sometimes lose a swarm when a young queen is given a full colony, but I believe not nearly so often as where a queen-cell is given them, or one is left in a hive after it has cast a swarm. We run these virgins in mostly to hives that have prepared to swarm, and from which we have removed the old queen; and the secret of success seems to be to introduce a virgin just after the swarming fever has subsided, or in two weeks from the time they would naturally have swarmed if left to themselves. If much earlier they may swarm; and if very much later they may not accept such a queen.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

VALUES IN STORE FOR 1916.

We are promised a lot of good things in GLEANINGS during the current year, with special numbers on special topics. Just such treats as the special numbers have proven to be in the past are enjoyed by the readers. This is shown by the appreciation of them so heartily expressed in favor of each special issue that has been published. And we cannot but hope that the forthcoming numbers will be better than ever. Even those beekeepers who are more successful in any one or all of the subjects to be treated during this year, who are progressive enough to realize that one never gets too old to learn, welcome them. The less experienced should not fail to get them.

THE DAY OF THE SPECIALIST.

Just as in many other lines of work and business the day of the specialist beekeeper is coming. It absolutely must come before beekeeping will be put on a sound business basis. The trouble at the present time is that there are too many beekeepers of the smaller type who are a detriment to the industry. We have long heard of the great harm they do in marketing their product at ruinously low prices, and too often offering honey of such inferior quality. Both of these alone are detrimental.

Some of our larger producers have had to suffer considerably as a consequence of the operations of these "one-horse beekeepers," as they are commonly termed. The lower prices set by them affect the larger producer quite materially when the difference of even one cent a pound less on a large output may mean a loss of the profits over cost of production. A difference of two cents a pound on an output of 50,000 pounds of honey means a loss of the neat little sum of \$1000, otherwise a nice little income. Even half that sum, occasioned by a difference of only one cent a pound, may mean the loss of what might have been the actual income for the year.

Here in Texas at the present time, as for a number of years, we are handicapped by those beekeepers who produce a lot of honey and lack the ability to market it properly. The result is that they keep the honey on hand a long time. It granulates more or less, and they begin to offer it at a ridiculously low price. Then it arrives in granulated condition and proves a drug on the market, the dealer not buying any better

honey until he has eventually gotten rid of "the stuff I have on hand." This state of affairs is especially bad with a product like bulk comb honey.

But there is no reason why this should give any ground for objection to the production of this commodity, even for the winter and following spring trade; for we have certainly solved that problem. Even at this time of the year we are filling orders for bulk comb honey; and from the repeat orders we get every week or so from a large number of our customers we have proof enough that it sells like "hot cakes." But we are equipped to pack the beautiful white comb honey in the containers and fill up with properly heated extracted honey, as we get orders for it. This enables us to get out an absolutely fresh "pack" that appeals to the customer, and of which there is nothing nicer during the cold-weather months. That is the reason for its ready sale and the cause of the many repeated orders. It is altogether a different product from that sent out by too many of our beekeepers when they happen to get an order which they fill with the partly granulated old pack honey.

This is only one illustration to show the advantage the specialist has over the beekeeper who is not able to equip himself properly to meet these demands. There are quite a number of others. I am rather optimistic in the belief that the day is here when the larger beekeepers will have to equip themselves better, and when the number of smaller producing beekeepers will begin to wane. Of course, this need not necessarily include the small beekeeper who keeps only a few colonies for his own use, and gets perhaps a little honey to sell when the crop is more favorable.

GREAT NEED OF ORGANIZATION.

Have the Texas beekeepers lost interest, or why is it that there is so little stir among them of late years? There was a time when we boasted of eight beekeepers' associations of considerable size, whereas there is not one good-sized beekeepers' association in Texas today. My twelve years' connection as secretary-treasurer of the Texas Beekeepers' Association and similar connections of late years gave me an opportunity to keep in close touch with matters of this kind.

Why has this change come about? Is it not time that we wake up and begin to stir

at least as we used to, if we cannot do better? Is it not much more necessary to take a deeper interest in apicultural matters today than years ago? And is it not time that some of us were making a start in this direction? In my conversations recently with other beekeepers I found that even the most common subjects of the day could not be discussed because of the fact that "the other fellow" did not any longer subscribe for any of the bee journals, and consequently had not read the subjects mentioned in any of them. This is a sad state of affairs and needs remedying. It is difficult in this age of wide-awakedness and organized effort to strive alone, each individual for himself. It will not only prove lonesome wandering but expensive in the end.

It is true that our more experienced beekeepers have not fallen away from the usual order of things, and many new ones have embarked along the right lines. I am not casting any reflection on any of them; but I often boil over with enthusiasm when I see the great things that could be accomplished. At the same time, it is just as often that there is a boiling over of just the very opposite of enthusiasm. The possession of either of these will prompt outbursts of the above nature.

It is also true that we have a larger number of county beekeepers' associations than we have ever had before; but their effort is too local in nature, and not far-reaching enough. We need bigger organizations to undertake greater fields of work than we now have; and it is to be hoped that the coming year will bring us better results in this direction.

* * *

NEW SIZES OF BULK-COMB-HONEY PACKAGES.

Texas has enjoyed a standard of various sizes of packages for bulk comb honey for many years. The regular two 60-lb. square cans to a case, with eight-inch screw cap openings to the can, headed the list. Next in order came the case of ten 12-lb. friction-top pails, followed by ten 6-lb. pails to a case, and another of twenty 3-lb. cans. Before these became standard sizes for the Texas product there was a large assortment of other sizes, and much confusion. This standardization of packages relieved the situation, and resulted in a uniformity of price lists made out in the order of packages as given above.

During the last two years there has been a demand for our bulk comb honey in the regular sizes of syrup-pails, the 5 and 10 lb. friction-top pails. This demand has increased to such an extent that these sizes

have almost supplanted the standard honey sizes. It was still necessary, however, to carry all sizes in stock in order to be able to fill orders for any of the older sizes as well as the new. This created again the same confusion that previously obtained—too many different sizes of packages necessitating the carrying in stock of a much larger supply of cans than necessary. It also brought about all sorts of combinations of orders, and too frequently delay on account of one or the other size in stock becoming exhausted.

An effort will be made by a number of the foremost beekeepers and honey-dealers to eliminate the unnecessary sizes for the 1916 season. It is a fact that the special sizes of honey-pails of 12 lbs. and 6 lbs. are higher in cost of manufacture in comparison to the 10-lb. and 5-lb. syrup-pails. The former require a special size of tin in their making, while the latter are a standard for syrups, made in enormous quantities; and if adopted for honey in place of the former they can be obtained at much less cost to the beekeeper.

Recently I took the matter up with some of our jobbers who handle enormous quantities of honey. Their immediate answer was in favor of the change. One of these concerns preferred, however, before deciding definitely, to investigate, and consequently dictated a letter to a number of their traveling honey-salesmen as follows:

The following are some of the replies received:

HONEY.

Dear Sir:—With opening of next spring campaign on honey, try to sell everything in 10-lb. and 5-lb. buckets, packed, say, 6/10 and 12/5 to the case.

Please advise on bottom of this letter if this will be satisfactory to your trade.

SALES DEPARTMENT.

"The 6/10 and 12/5 are the best sellers; will want a few 2/60's."

"In my opinion the above will be much better than the old pack."

"Yes, they prefer it."

"Yes, O. K."

"This will be O. K. I like it better."

"Trade likes these sizes much better."

"I think this will suit the majority of the trade, but believe we should have some 3-lb. pails also."

This information is exceedingly valuable. It comes from men who know how to sell honey, and who know the trade and what it wants. The result will be that the honey-dealers will demand and the producers will have to furnish in the new schedule of sizes. These will undoubtedly be the two 60-lb. square cans to the case; six 10-lb. friction-top, twelve 5-lb. friction-top pails, and possibly the retaining of the twenty 3-lb. cans or the adoption of the smaller 2½-lb. syrup size in their place also.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

PRESERVING FRAMES OF COMB.

"Having sold quite a share of my bees I have on hand more combs than I am liable to use before August, 1916. I feel that it would be better to preserve these combs than to melt them for wax

and then buy foundation to replace them when I want combs again, as most of them are nice and straight. But during the spring and summer months I have had poor success in keeping such combs from the larva of the wax-moth. How may this difficulty be overcome?"

Straight all-worker comb, built true in frames, is of greater value by far than the wax will bring which can be gotten from them, to say nothing about the cost of rendering. Experienced beekeepers think it very profitable to purchase comb foundation at the rate of ten cents for enough to fill a Langstroth frame, besides the cost of transporting it and the labor of putting it into the frames. So I have considered such L. frames of comb worth at least twelve cents each. But the wax that can be gotten from such a comb will not bring, as a rule, more than five or six cents. Therefore I have always made it a point to preserve all the spare combs I had for future use.

Combs on which the bees die during winter and early spring can be kept by placing them over strong colonies during the latter part of May and June, so that the bees, but not the queen, can have access to them. In this way they can be kept for any increase that may be desired, and used for colonies set apart for extracted honey. This plan has also an advantage by way of keeping down the swarming fever liable to occur with strong colonies too early, and will more often than otherwise stop all swarming entirely, if these combs are allowed to remain till the surplus flow of nectar from clover is fully begun and the sections on.

Another effective way is to hang the combs up to the light and air with a space of $1\frac{1}{2}$ to 2 inches between them. For convenience in practicing this plan, when I built my shop and honey-room I placed the joists overhead so as to admit the top-bar of a frame crosswise, then by nailing common lath near the lower edge of neighboring joists, each space made a convenient place for keeping all frames of comb not occupied by the bees, the ends of the top-bars or arms resting on the lath. However, with combs not toughened with the cocoons

of many generations of brood, or where the brood has not reached parts of the comb near the upper corners of the frames, the light seems to have a deteriorating effect upon the wax, causing it to become brittle and crumble when thus left more than a season or two.

Where it is desired to keep combs for an indefinite period I have found the following to be the best way: Exposed to cold in which the mercury touches zero or below, everything of the wax-moth nature has to succumb and die. Therefore, if the mature female moth can be kept from such combs ever afterward they will be in perfect condition, even should ten or fifteen years elapse. After the combs have been thus frozen, lay two thicknesses of newspaper upon a level and out-of-the-way place on the floor of any building, setting a hive of these combs thereon; and after covering the hive with two thicknesses of the paper, put another hive of combs covered with paper on that, and so continue the operation until the pile is of the desired height, when the top hive should be protected with paper and a close-fitting cover. As these combs are packed close together and so tightly enclosed, they must be reasonably dry, and put away only in a dry place.

It is important, also, that they be not allowed to stay in any place after the zero freezing (and warm weather comes on before they are packed) where the millers have an opportunity to deposit their eggs on them. As all of our older beekeepers know, the female moth or miller which produces the eggs from which the larvæ hatch is furnished with a long ovipositor which she can insert in almost any crack or small opening—something which she can very easily find between almost any two hives which have been used for a little when one is set upon another. I would not say that these two thicknesses of paper close every crack or cranny, but for some reason the miller seems to shun them.

Whether the paper is repulsive, or because the paper extending outward from the hives all around two inches or so does not allow her to take a position to use her ovipositor, thin paper seems proof against her eggs. Tarred roofing-paper might be a certain insurance that, should there be any warping, or from any other unforeseen cause, worms should get in any one hive, they would be impeded from spreading to other hives in either direction.

GENERAL CORRESPONDENCE

WINTERING BEES IN A QUADRUPLE WINTER CASE AT MEDINA

BY E. R. ROOT

In our issue for Jan. 1, a year ago, we showed a method of packing four colonies in a case that we were using. This year we have made some changes, making the case larger and deeper, and at the same time providing a larger housing from the entrance of the hive to the outside of the case. See front cover design. Instead of a four-inch packing around the hive we have

The space occupied by four ten-frame dovetailed hives is $32\frac{1}{2}$ by 40. In the matter of the depth of the cases we decided to make it so we could put in two-story colonics if necessary. The depth, 25 inches, would not leave room for packing on top of double-deckers; but few such were packed. In a few instances where colonies were so strong we could not very well crowd them

FIG. 1.—The bottom of the winter case covered with three inches of planer-shavings. Note the entrance slots and the three $\frac{3}{8}$ -inch auger-holes just above.

now six inches. Dr. Phillips, from experiments at Washington, found that with any thing less than six inches of packing there would be a radiation of heat from the cluster; so we made our cases large enough so that the inside dimensions are 45 x 52 x 25 inches deep.

down into one story, we decided to try these colonies alongside of single-story ones in the same case. This room for an extra story leaves a space of 9 inches on top of a single story of packing, and this is about right.

In deciding on the amount of packing we consulted Dr. Phillips; and it is his opinion

FIG. 2.—The housing inside of the winter case that connects the entrance of the hives with the entrances of the case. Note that the space is large to prevent clogging with dead bees.

FIG. 3.—Looking on the entrances of two hives in one of the packing-cases. In the picture the hives are shown with the three-eighths side of the bottom up. It was our intention to put the deeper side ($\frac{7}{8}$ inch) up, to give more room for the accumulation of dead bees under the frames. There were a few hives packed with the narrow entrance, and our artist happened to get one of these groups.

that it does no harm to err on the side of getting too much. Six inches around the hives, eight to ten on top, and three or four under, would make a case that would give sufficient packing for most localities, altho he was free to say that in more northern locations, especially Canada, six inches might not be enough. But in the colder climates there is usually plenty of snow; and snow packed around the hives makes a good insulator providing the entrances are not closed by ice.

In order to provide packing under the hives, and to prevent the entrances from getting out of alignment with the openings in the sides of the cases, some cleats or supports must be provided of sufficient height to provide the amount of packing. Last year we used only $2\frac{1}{2}$ inches; but this year we are using 3 inches. In Figs. 1 and 2 can be seen the supports or parallel cleats that run lengthwise of the bottom-board or floor of the large packing-case. On these the hives rest, and also the board reaching from the projection of the bottom-board to the slots forming the entrances of the case itself. Over this board that closes the gap between the bottom-board extension and the outside entrance is placed a housing, so constructed that it fits the bottom-board projections, making a space of two inches deep. We made the space deeper this year to provide for the accumulation of dead bees that would otherwise close the space entirely. Just above the horizontal slot of the winter case will be seen three $\frac{3}{8}$ auger-holes—see Fig. 1. The purpose of these is to afford entrances and ventilation in case the lower horizontal slot is closed by the accumulation of dead bees. This is Mr. Holtermann's idea, and in the light of our

experience last winter we believe it to be good; in fact, it might be the means of saving not one but many good colonies.

In Fig. 3 we are looking down on the fronts of a pair of hives with the bottom-boards abutting up against the floor that reaches to the front of the case. This picture was taken before the roof or horizontal part covering the runway from hive to case was put in place.

The spaces over the entrances must be very carefully and completely closed so the packing material will not filter down and close up the entranceway from the hive proper to the entrance of the case itself.

In Fig. 4 we show a view of the floor before cleats were put in position.

In Fig. 5 we show four hives placed end to end and side by side, as we placed them last year on the floor of the case, and before the sides and ends were put on. Last year we used the supporting-cleats cross-wise of the floor. This year we ran them lengthwise as seen in Figs. 1 and 2. The latter arrangement is an improvement in that it keeps the runways between the hives

FIG. 4.—Floor for four-hive winter case.

and the ends of the case in better alignment. Last winter we had some trouble with the outside entrances not matching with the inclosed housing to the entrances

of the hives. This ing the cleats run year we have provided against this by making lengthwise, and by providing stops or cleats nailed on the bottom inside edge of the rim or case itself. These projections rest on the bottom or floor so that the case itself will not slip down, bringing the outer entrances out of alignment with the inside.

In Fig. 5 will be seen a bale of pine shavings. These can be secured, where one has neglected to gather together a lot of dry leaves, at about 25

cents a bale at a livery stable. It takes about a bale and a half to pack four hives. The expense is not great, because the shavings can be used over and over again, winter after winter.

Our winter case is made so we can take it apart in panels and pack it in the flat to

FIG. 5.—The four hives in position, the regular covers removed, leaving only the super covers, so that the hives may be close together. (This picture shows our former construction.)

shavings back in the case, and then places the case at the outer edge of the yard, to stay there for the season. The four hives removed are put back in the same position, but ten or twelve inches apart to afford convenience in handling the bees during the summer. Mr. Holtermann says that where

one takes down his cases every season he loses his packing material and enormously increases the labor of packing and unpacking; and there is no reason why one should take down the cases unless he desires to remove them to an out-
yard. The idea of winter cases is to keep them in one place, year in and year out, using them as a sort of windbreak around the apiary during summer.

FIG. 6.—An automatic screwdriver for putting in the screws at the corners of the case.

save room; but we prefer to put it together with common wood screws as shown in Fig. 6, with the idea of leaving them together year in and year out at the yard where they are used.

It is Mr. Holtermann's plan to leave these cases assembled. In unpacking he removes the cover, turning it upside down. He shovels the shavings on top on to the cover, lifts the four hives off, piles the

In the front cover picture there are shown nearly fifty packing cases of the Holtermann type. At three of our outyards there were no windbreaks, and as protection from wind is very important—as much so as packing—we decided to haul the bees home and pack at the home yard where we have ample windbreaks in the form of factory buildings and evergreens. We consider a good windbreak next to packing.

EUROPEAN AND AMERICAN FOUL BROOD

Their Differences, History, and Methods of Treatment

BY OREL L. HERSHISER

Continued from page 12 last issue.

A few historical facts may be of interest as a means of comparing the description and treatment of foul-brood diseases, given and practiced by investigators and experimenters of 35 to 50 years ago, with that of recent times.

Dr. Dzierzon records in the English edition of his work, "Rational Beekeeping," this prefatory statement in reference to foul brood: "Since the appearance of the first edition . . . we have further been successful in discovering the nature and the cause of foul brood . . . and almost simultaneously have discovered an infallible cure for it in salicylic acid." Salicylic acid as a remedy for foul brood was first brought to public notice in the papers communicated to the meetings of German beekeepers at Strasburg and Breslau, and published in the last numbers of the *Eichstadt Bienenzeitung*, the organ of the German beekeepers for 1875 and 1876.

As the salicylic-acid treatment seems to have been recommended subsequent to the time when the treatments by dequeening, decombing, and driving of the bees into a new hive were known; and as Dr. Dzierzon states that, since the appearance of his first edition of *Rational Beekeeping*, they had discovered the nature, cause, and treatment, with salicylic acid, of foul brood, we may reasonably place the discovery of such treatments by dequeening, decombing, and driving the bees into new hives at a period subsequent to 1861, the date of the appearance of *Rational Beekeeping*, and prior to 1875, when the salicylic-acid treatment was first brought to public notice.

DR. DZIERZON'S DESCRIPTION AND TREATMENT OF FOUL BROOD.

"An infallible symptom of the presence of foul brood is the discovery of dead, dried-up, shriveled larvæ or nymphs in separate cells among healthy brood. These dead larvæ have passed into a pap-like or tough mass, and later on into a grayish-brown or quite black crust on the floor of the lower surface of the cells. If the majority of the cells are in that condition the infection took place some time ago, and the evil has already become very great. Because a stock with foul brood generally ventilates considerably, the evil may be recognized in hives with immovable combs by an unpleasant smell proceeding from the entrance. The smell is similar to that of putrid glue

or meat. As the bees take the trouble to bring out separate larvæ that have not yet entirely rotted, such will be found sometimes on the floor of the hives affected. The bees take the trouble partially to remove to the outside the blackish-brown crust forming finally from the rotten matter. There are, therefore, found on the floor a dark-colored dust and entire skins torn off, which, when rubbed down between the fingers, give off the same unpleasant smell. In spring, when other stocks are already diligently building, the foul-broody do not generally make any preparation for it; at most they will do so only when they are fairly strong, and unusually good pasture sets in. If the combs are examined, the sealed brood is never found *en masse*, but standing in isolated, irregular patches. To be thoroly satisfied, a piece of brood-comb must be cut or torn out; and if it shows cells with the matter described above, foul brood is certainly present.

FOUL BROOD IS OF TWO KINDS.

"There is one kind that is mild and curable, and another kind malignant and incurable. Both kinds are, however, contagious.

"The curable occurs in this way: More of the larvæ die still unsealed, while they are still curled up at the bottom of the cell, rotting and drying up to a gray crust that may be removed with tolerable ease. The brood which does not die before sealing mostly attains to perfection, and it is only exceptionally that individual foul-brood cells are met with sealed.*

"This is exactly reversed in the malignant kind of foul brood. In this the larvæ do not generally die before they have raised themselves from the bottom of the cell, have been sealed, and begun to change into nymphs. The rotten matter is, therefore, not found on the cell floor, but on the lower cell wall. It is brownish and tough, and dries up to a firm black crust, both in consequence of the heat prevailing in the hive, and of a small opening bitten in the depressed cover. This matter the bees are not able to remove; and when they are in some strength they can at most get rid of it by entirely biting down the tainted cells and making fresh ones."†

* There will be noticed what has in recent years been designated as European foul brood.—O. L. H.
† This describes what we now designate as American foul brood.—O. L. H.

TREATMENT OF THE CURABLE KIND AS
DESCRIBED BY DR. DZIERZON.

"To put a stop to the evil immediately, catch the queen without delay as soon as any foul-brood cells have been observed. In spring and early summer she may be advantageously used for making an artificial swarm. If bees are added to her from healthy stocks we may be sure of having a healthy stock; but if bees were given to her out of her own or other foul-broody stocks, the swarm must be left in a transport hive, sieve, or the like, twenty-four to forty-eight hours before it is put into its hive, and the queen must be kept caged here for some days so that brood may not be deposited nor brood-food prepared before the bees have used up all the honey and food taken with them out of their parent stocks, and have expended it in comb-building.

"Because there is now no more brood deposited in the stocks robbed of queens, none can die or go bad; and till a young queen is reared, fertilized, and has begun to lay eggs again, the bees will have gained time, if they are still tolerably strong, to purify the brood-nest completely. They may be assisted in this by cutting the comb so close that the bees are able to cover it thickly. The new generation will then generally thrive quite well, and the stock be brought back to health again. There would be a greater certainty of this if the entire previous comb, as soon as it becomes empty of brood, were cut out, and the entire stock were driven into a new hive."

COMPARISON OF THE DR. DZIERZON, THE
ALEXANDER, AND THE DR. MILLER TREAT-
MENTS OF EUROPEAN FOUL BROOD.

The primary Dr. Dzierzon treatment consists in depriving the colony of its queen and allowing it to rear another requiring 10 to 11 days to hatch and 7 to 10 days more to become fertile and commence laying, leaving the colony without a laying queen for a period of from 17 to 21 days,

during which time the colony will purify the combs and hive of disease.

The Alexander treatment consists in depriving the colony of its queen; nine days thereafter destroying all queen-cells that may be built, or any virgin queens that may have hatched; and on the 20th day after dequeening, and not sooner, giving a ripe queen-cell or virgin just hatched from vigorous stock, leaving the colony without a laying queen for a period of at least 27 days, during which time the colony will purify the combs and hive of disease.

The primary Dr. Miller treatment consists in caging the queen with her colony for a period of 8 to 10 days; then releasing her to her colony, the 8 or 10 days' time being considered sufficient for the colony to purify the combs and hives of disease.

Mr. Alexander increased the time thought necessary to accomplish the cleansing of the combs and hive, over that found necessary by Dr. Dzierzon, by about 10 days; and Dr. Miller decreased that time by about 10 days. It is obvious that the treatment that accomplishes the result sought in the lesser number of days is to be preferred. If it should be established that the disease is inherent in the queen, as has been announced by Messrs. M. G. and C. P. Dadant, then would the Dr. Miller treatment fail unless the confinement of the queen for the 8 or 10 days would also purify her of disease *bacilli*.

To quote again from Dzierzon: "The curable kind (European foul brood) may occur of itself, under certain conditions of ingathering, especially when the bees are working on billberries and pines,* and sometimes disappears again of itself when the conditions have changed."

Kenmore, N. Y.

[This is the second of a series of four articles by Mr. Hershiser on the history and treatment of foul brood. In the first February number he will discuss methods of treatment under various conditions.—Ed.]

A MALIHINI IN THE HAWAIIAN ISLANDS

BY LESLIE BURR

October 12, 1915, is a red-letter day on my calendar, for it was on that day that I first saw the Hawaiian Islands, and at the same time discovered a new name for myself. It happened this way—the new name. I was standing on the corner of Fort and Beretania streets, examining the fire-station and the sidewalk, both of which are made of blocks of lava, and was observing the Hawaiians, the Chinese, and the little ki-

mono-draped Japanese women as they glided past. Some native Hawaiian children with schoolbooks under their arms passed by.

One of the children, a boy of about

* The mysterious way in which European foul brood spreads puzzled the beekeepers of 50 years ago. It is unlikely, however, that the germs of disease would be gathered from forage unless they were distributed to the same by bees from diseased colonies.

Part of Tamagawa's apiary.

twelve years of age, remarked to the other children, "Malihini," and at the same time indicated me. It was a simple thing, perhaps, yet I had been classified, identified, and named.

The city is a mass of vegetation; but most of the trees are old friends, and almost all of them are trees that were imported here. The royal palm is everywhere, perhaps not quite as beautiful as in Cuba; then there is the royal poinciana, the mango, the monkey-pod, and the algaroba. The last is the most common tree in the city. The first algaroba was brought to the island of Oahu by Father Bachelot in 1826. The original tree is still alive, and is to be found on Fort Street near Beretania. For the benefit of the Texas and New Mexico beekeepers I will state that the algaroba is nothing more nor less than their old friend mesquite.

The first apiary, or, for that matter, the first colony of bees that I saw after my arrival at Honolulu, was the apiary of L. Tamagawa, at Diamond Head. I had taken the Waikiki Street car to the end of the car line, and had then started to walk around Diamond Head. This is the crater of an extinct volcano. It is about seven or eight hundred feet high, and its base on one side is in the ocean. After leaving the street-car I had walked about two blocks when I heard the hum of bees; and, looking over the fence to my left, I saw an apiary of some seventy colonies of bees on the base of the crater.

I at once lost interest in my contemplated walk around Diamond Head, and went in to investigate the apiary. - It proved to be the apiary of L. Tamagawa, a Japanese. He is an energetic fellow about thirty-five years of age. He was born in Japan, and came to the Hawaiian Islands when a boy. He has been an apiarist for some four years, having purchased his apiary from another Japanese who was returning to Japan.

He showed me a copy of the 1913 edition of the A B C, and seemed very proud of its possession. He admitted, however, that he found it very hard to read and understand. The reason is, I suppose, that he was not familiar with any Japanese words that are the equivalent of the English apicultural terms. Then, too, I noticed that he appeared to be better able to understand writing in Japanese than English, as he kept all his accounts in that language. Even the records or notations on his hives were in Japanese, and I had quite an interesting time having him translate into English what the Japanese characters meant that I found on the hives. His records, while crude, still showed every indication that he had a good knowledge of the elements of practical bee culture.

One matter that does not bother Tamagawa is keeping down grass and weeds in his apiary. The particular place where the bees are located is composed of volcanic ash of such a nature that grass and weeds are unable to obtain a foothold or nutriment. The only plant that seemed to be able to

live was the algaroba, or mesquite, as it is called in Texas. From their appearance I should judge that the algaroba was having as hard a time there in that apiary to exist as the mesquite has in some of the desert regions along the Mexican border.

There was one pest, however, and the method used to combat it was new to me. That pest was ants. The way they were combated was by making a framework of 2 x 4 lumber, the same size as a bottom-board. In this frame four holes three quarters of an inch in depth were bored with an inch auger. In each hole a very large nail or spike was driven, and on the heads of these spikes the hive was set. The spike was then coated with oil, and the hole at the base of the spike was filled with crude oil. Tamagawa informed me that it was a sufficient protection against the ants.

The surplus honey is secured from the algaroba. Both comb and extracted are produced.

Tamagawa has a wife, who is a very comely Japanese woman, and two beautiful children.

Tamagawa looking over the colony. Record printed in Japanese on the side of the hive.

As I watched the mother playing with the two little children under a bread-fruit tree in the yard, I could not help thinking that L. Tamagawa must be a happy fellow; and remember that gray hairs are creeping in among the brown on the crown of my head. But then, otherwise I should not be a malihini interviewing a Japanese beekeeper on the Island of Oahu.

Honolulu, T. I.

THE CHICAGO AND NORTHWESTERN MEETING

BY J. L. GRAFF

One of the striking utterances at the annual convention of the Chicago and Northwestern Beekeepers' Association was that of President N. E. France, of Wisconsin, who said that European foul brood had been a blessing in disguise. He spoke from his experience in wide travel among beekeepers in his own state. The presence of the disease had aroused apiarists to the necessity of understanding it and to prevent its recurrence. He said he knew bee-men who had said, "I am glad I had it. I'll know how to take care of it in the future."

A year ago, when Mr. France was at the meeting, he said that within three years there would be no European disease in Wisconsin. He said that his people would be

clear of it today had it not been for the lack of co-operation, and the failure to report cases. Some time ago he asked apiarists whom he knew as beekeepers to give him the names of five neighbors who kept bees. This resulted in his getting 1500 names. They were beekeepers, some of them keeping bees in only a small way, whom he had never known before. Seventy of the fifteen hundred had foul brood in their apiaries. It is the man who has a few bees, and because he has so few he thinks it isn't worth while to report the presence of the disease, who causes the trouble. Were it not for this fact, Mr. France said, his prediction of last year would have come true by this time, or in but a little while longer.

There was but a small attendance at the meeting this year. Old-timers have dropped out, and young blood has not shown up as strong as desired. Secretary Bruner said that when he took the position last year he had a list of 150 members. He undertook to round them up, but was able to find only twenty members who could be depended on to attend a meeting. The others, in most part, were either dead or had moved away.

Despite this discouraging report there was much life in the meeting, and committees have been appointed and are to work up a plan by which it is hoped to make this old association take on the life of olden times. It is proposed to encourage membership and attendance at meetings by adopting the Michigan plan of awarding medals for fine exhibits of honey and honey products at future meetings.

It was also resolved to get a line on those who are promoting the work of domestic science and carrying on cooking demonstrations in schools, to the end that honey may be recommended as pure food, listed along with numerous other articles as desirable and healthy food for the human family. A committee was appointed to see the heads of instruction of state and city, to the end that the product of the bee may get a fair

show in the schools along with other pure foods.

The beekeepers also passed a resolution asking the state fair officials of Illinois to provide a separate and adequate building for the use of the beekeepers of the state so that demonstrations in the use of honey as a food may be properly made, and the honey-producers thus get a fair advertisement.

One of the members said that he had succeeded in getting his neighbors to take up the work of beekeeping by inviting them to witness his own operations.

One of the beemen of the Fox Valley, in Illinois, said that it is a mistake that the associations do not hold meetings more frequently. His own local association held a meeting every two weeks when important business made it necessary or desirable.

The Chicago-Northwestern Association voted to sever affiliation with the National, but decided again to affiliate with the Illinois State Association.

Officers were elected as follows: President, N. E. France, Wisconsin; vice-president, E. S. Miller, Valparaiso, Ind.; secretary and treasurer, J. C. Bull, Valparaiso, Ind.; delegate to Illinois State meeting, J. C. Bull, Valparaiso.

Chicago, Ill.

WINTERING BEES IN SUPERS

BY JOHN E. ROEBLING

I did not wish to imply in my article, page 863, Oct. 15, and as mentioned by Grace Allen, p. 969, Dec. 1, that twenty frames with honey scattered around in each is an ideal winter brood-nest. Our plan is to fix up for winter late in the fall, after the first cold spell of heavy frosts, at which time the bees will have formed their winter nest. Then on some cold day when the thermometer registers slightly above freezing we start in and take off all the supers, both comb and extracted, note amount of winter stores, and location of brood-nest.

The comb-supers will be free of bees at this time, and also do away with all trouble from robbers. If we note the bees have located the winter nest in the extracting-supers immediately above the brood-body, and this super seems to be light of stores, with nothing below, we get another super containing some stores, enough combined with the two to carry them safely thru the winter, and place it under the one containing the brood-nest. This plan has always succeeded well with us.

I much prefer, however, to find the bees prepared to winter in a super containing an abundance of stores, and then take one of the empty supers, or nearly empty, and place underneath for the queen to get busy with in the spring. I believe this to be the ideal condition for wintering, at least in this locality, as they breed up fast and come out strong. My theory is that it is much dryer and warmer in the upper super than it would be if this super were placed direct on the bottom-board, surrounded by snow, water, and ice the greater part of the winter.

Some of the brood-nests run for comb honey are very heavy, practically honey-bound; hence very little headway will be made in the spring for lack of room. Many of these are treated to a set of the extra extracting-supers underneath, and will produce a surprising number of bees early in the season. Shallow-frame supers are also used, above and below. This plan also does away with opening of the hives to put on supers too early in the spring. Sometimes

the weather changes and turns very cold, and much damage is done by the chilling of brood. I find it bad practice to open the hives much before drones are beginning to fly freely and honey coming in, as the bees are inclined to be cross otherwise, and sometimes the queens disappear, the latter frequently where clipping is done too early in the season.

We cover with the regular escape-board, deep side down. This enables the bees to cross from frame to frame, and they will never be found dead in the spring with honey in the adjoining frames. We place the packing on this board, burlap sacks and newspapers, and use the A-shaped cover, shingled. This makes an ideal cover, with good ventilation in summer, and always

perfectly dry. The covers are heavy and will not blow off.

I do not like the idea of opening the hives so late in the season; but it enables us to work fast, and there is no fear of robbers getting the upper hand. We try to choose a day when the bees will take a flight during the warmer part.

If any of your readers are troubled with skunks I have found it a very good plan to place a pane of window glass on the alighting-board. This will cast a reflection from the stars and sky, as one passes by; and these night prowlers fight shy of anything that apparently moves which they do not understand. They are said to be easily trapped, but I have not found it so.

Cincinnati, Ohio.

SOME UNCOMMON HIVES

BY E. G. CARR

Not the least interesting of the things which enter into the bee inspector's life are the different types of hives which he sees—not alone the nail-keg and grocery-store box, but also the home-made hives upon which has been put much care, labor, and considerable expense. These statements apply with special emphasis to New Jersey, since there are so many beekeepers in this

state from foreign lands, and it is the rule for these to cling to the ideas of the mother country. It is seldom they do not make considerable effort to provide a good home for the bees.

Perhaps the oddest type from the viewpoint of the American beekeeper is the Polish hive shown in the illustration. This is made similar in appearance to a cup-

board, and it houses three to eight colonies or families. The hive in the picture is made for eight colonies and is owned by Mr. R. Kohlos, of Woodbury, N. J. In the illustration showing the rear of the hive is seen Mrs. Kohlos, who is a very able bee-woman.

It will be noticed that the frames of this odd hive are crosswise of the entrance, and either hang on metal rabbets or fit into the grooves in the hive-sides, and are removed from the back of the hive. It is, of course, necessary in getting at a particular frame to remove all frames in front of it.

The Polish hive is similar to a cupboard.

Mrs. Kohlos is an able beekeeper.

Sometimes there is a small portable rack in which the frames are hung as removed, and a pincers-like tool is used in removing them.

It is pleasant to know that the Kohlos are not satisfied with this type of hive as compared with the modern frame hive, and

Two-story hive made from a section of a tree-trunk.

propose to change all the colonies to the latter type as soon as convenient.

The next illustration is a general view of this interesting apiary, which contains, besides the Polish hive, a battery of eight hives in a row, and all built together somewhat after the fashion of the original Langstroth hive.

Another curious hive contains two colonies, and is on the back-opening Polish style, with movable frames, but is made from a section of tree-trunk.

New Egypt, N. J.

THE SMOKE VS. THE CAGE METHOD OF INTRODUCING QUEENS

BY A. C. MILLER

Editor Gleanings:—I note what you say in the Oct. 15th GLEANINGS concerning the distress or smoke method of queen introduction. I am surprised at your results, for so many find it successful. Even were it not better than the cage method, I should continue to use it, for a failure is known the same or the next day, while by the cage method it sometimes is a week before the queen is out, and a day or two more before

we know she is safe. Either you have a different operator or there is carelessness in creating the condition of distress.

This year, Nov. 6, I dequeened some twenty colonies of hybrids, and ran in the new queens. Breeding had been stopped for some time, and it was none too easy to find the old queens; but it was all done, and new queens in within three-quarters of an hour. Every queen was accepted. I

The interesting Kohlos apiary.

knew it before I left the yard an hour later, and was sure of it on an inspection made later.

I do not recommend requeening so late; but I had the queens, and the very late and mild season led me to make the experiment.

A veteran beekeeper near by tried to put in eight queens from the same lot into just the same sort of bees. He used the cage method, and lost seven out of the eight.

Providence, R. I.

[We have just been interviewing our men who work in the yards, all of whom, without an exception, we have had for a number of years. On further inquiry we found that the reason they do not use the smoke method is because it takes more time than the cage plan. The former must be carried out very carefully, and, finally, the queen must be put through a contracted entrance. Sometimes they get away from the operator. The men say they can introduce by the cage method more rapidly, especially when there is a large number to be intro-

duced. Furthermore, the smoke method will not answer in the case of nuclei, either with the babies or with the larger ones.

We introduce hundreds of queens at a time, and the cage method is invariably used with all our colonies.

If the directions are followed, the smoke method, barring an occasional queen that gets away from the operator, is quite reliable, and will probably introduce a larger percentage than the cage plan; but by the latter plan our loss probably does not exceed one per cent; and the time consumed in introducing a hundred queens by the smoke plan will more than offset the value of one queen.

There is one thing sure, and that is, the directions for introducing by the smoke plan must be followed out to the letter. Right here is the difficulty with some beginners. If they are a little timid in handling a queen they may let her get loose. For the average beginner we believe that the average candy-cage plan is the safer.—Ed.]

ONTARIO BEEKEEPERS' ANNUAL MEETING

BY MORLEY PETTIT, SEC.

The annual meeting of the Ontario Beekeepers' Association held recently in Toronto was a record-breaker in point of attendance, two hundred beekeepers being present. President Byer, discussing heavy winter losses of 1914-15, attributed them to

inferior stores and the poor breeding season of the fall of 1914. Demand for honey is good.

Morley Pettit, secretary-treasurer, reported a membership of 1130 and a balance on hand of \$234. A large number of members

were buying queens co-operatively thru the association.

Dr. E. F. Phillips, F. W. L. Sladen, and Prof. L. Caesar delivered addresses. F. W. Krouse, of Guelph, was elected president, and James Armstrong, of Selkirk, and W. W. Webster, of Little Britain, first and second vice-president, respectively. Morley Pettit continues as secretary-treasurer.

An attempt will be made to increase the

fine against spraying trees during fruit-bloom from \$25 to \$100. The provincial apiarist has been requested to conduct experiments to find the effect on bees of sweetened poisons for the destruction of grasshoppers and field-pests. The Dominion Government will be petitioned to take measures to prevent the importation of bees from diseased districts.

Guelph, Ont.

PROBLEMS OF MARKETING GET ATTENTION OF INDIANA BEE-KEEPERS

How to sell honey was the chief topic of discussion at the convention of the Indiana State Beekeepers' Association held at Indianapolis December 10 and 11. Wallace Buchanan, representing the postmaster of Indianapolis, talked on "Honey by Parcels Post." The Farm to Table movement, he said, is growing, and its success is all a matter of proper packing.

"Instead of packing honey 24 sections to the case, why not pack it 3 or 6, or just the way the average family would want it? Comb-honey cartons can be made to hold three sections at 2 cents each carton, or for six sections at 3 cents for each carton. The total cost of container and postage shows that it pays to ship one pound by mail.

"If it pays a man in Boston to ship his cod and mackerel all over the United States by mail; if it pays in Los Angeles to ship nut kernels all over the United States, why can't the beekeepers market honey by the same plan? Simply advertise, and make the buyers know where it can be obtained."

George W. Williams, secretary of the association, read a paper. "One Promising Outlet for Dark Honey." He said, among other things, "The karo people are pushing their product, and the honey people are not. You will see karo attractively displayed on half a million shelves and its posters on ten thousand billboards. In the meantime honey is not seen on the shelves, no pictures appear in the windows, no publicity in the papers, and the beekeeper sits tight, doing nothing and keeping eloquently silent.

"The beekeepers' associations should take steps to have the value of honey as a staple food, and especially the value of the darker grades in cooking, taught in the domestic-science departments of the public schools."

Miss Emma Piel told how she met outside competition. "I believed that to put my honey in glasses was the best advertising I could do. I heard compliments of all kinds for my honey. People stopped me on the street, and said they had found my honey fine. I had no trouble in selling my honey this year in larger quantities."

B. F. Kindig believes in saying things right out. "The distribution of Indiana honey is extremely poor. We find one market where you can sell honey if you only mention it, and others where you can hardly give it away. There is a tendency on the part of beekeepers to stampede the large markets. Too many think they must sell the honey as soon as they get it off the hives. Their surplus might be moved with a very little advertising. There is a poor quality of salesmanship among the beekeepers of this state."

The opening address was given by Mason J. Niblack, president of the Association. He read a paper by C. P. Dadant on out-apiaries. Miss Emma Baylor, of the state department of public instruction, asked the beekeepers to furnish free literature on the food value of honey for distribution to the students of the domestic-science departments throughout the state. Prof. D. A. Rothrock read a paper on aster honey.

FEEDING DRY SUGAR

BY W. J. SHEPPARD

I have noticed that very little reference has been made in the bee journals during the last few years to feeding with moist sugar, or "dry-sugar feeding," as it used to be called. I conclude, therefore, that it must have fallen into disuse somewhat.

The past season here was a very poor one. After an unusually fine, dry, and warm February, March, and April, the three succeeding months turned wet with low temperatures prevailing all through. Consequently very little nectar was available

for the bees, and in June a good many colonies were actually on the verge of starvation, and ran down in strength. Feeding, therefore, became absolutely necessary.

Under these circumstances, and as I am away from home a good deal, I decided to feed with moist sugar. I had some nuclei in which the queens had stopped laying; but very soon after the bees got on to the "dry sugar" there was quite a transformation. The queens started laying again in earnest, and the frames were soon full of brood once more.

The feeder hangs like an ordinary frame. It is easily and cheaply made by nailing a thin piece of board on either side of an ordinary Langstroth frame after first cutting out the top-bar, excepting about an inch and a half at either end. The sugar can then be put into the feeder at the top and pressed down tight, and it will hold three or four pounds. A loose piece of thin wood can be fitted in the top in place of the top-bar that is cut away, leaving, of

course, a bee space under for the bees to enter. This will keep the quilt in its proper place so that it will not drop into the feeder and prevent the bees getting in.

The advantages of dry-sugar feeding consist in the stimulating effect it has on the bees, as apparently they are not able to take it fast enough to store it in the combs, so that it is practically all used for feeding the brood. Also, after a feeder has been filled and given to the bees it will not require much attention, as it will not need replenishing for a long time, if at all. The best sugar to use is a moist cane sugar with a fine grain such as Porto Rico.

I feel convinced that, for this province, where in normal seasons we generally get a wet June, dry-sugar feeding will be very suitable, as it will be the means of keeping colonies up to full strength so as to be ready for the main honey-flow in July. Filled with sawdust or cork dust, these feeders make good dummies for winter packing.

Nelson, B. C.

1915 WITH THE WIRE ESCAPE-BOARD

BY A. J. KNOX

The difficulties of brushing bees from the combs in the production of extracted honey have led many beekeepers to turn eagerly to any device that promised a measure of relief from existing troubles.

Since the general adoption of the Italian bee it has become harder to shake the combs clean. A slight jar previous to the shake causes them to stick fast. When the wire escape-board appeared I decided to try it, and to that end made fifty boards. In some of them I put the regular double-end Porter escape, set in the center of a strip of wood running across it. In others I put two single escapes on this strip, one at each side. In yet others the double escapes were simply soldered into a hole cut in the center of the wire, without any wood running across.

In use I did not find any appreciable difference in the time taken to clean the bees out of the supers by any of the methods of attachment or positions of escapes in the boards. I did find it made much difference whether the escape-board was put next to the brood-chamber or under the second or third super. When next to the brood-chamber it took from two to four days to clear out the bees; under the second super, from thirty-six to forty-eight hours. Placed under the third super, the bees would usually all leave in twelve hours.

One obstacle in the use of escapes is found in the brace-comb that is frequently built between the supers. If there is perfect uniformity in the bee-space clearance over the frames, there is not so much trouble; but taking outfits generally, there is quite a percentage liable to this drawback. In this connection the new two-piece board put out by Morley Pettit, the provincial apiarist, is quite an advantage. The board is really two boards, meeting in the center, and having a single Porter escape in each section.

One end of the hive is pried up, and one section of the board slid in. Then the opposite end is treated likewise, the boards meeting in the center. By this method considerable brace-comb can be squeezed thru, and the boards are very convenient and pleasant to put on. On the other hand they cost more money, and are more bulky to haul around to outyards. The boards are successful in retaining the heat of the honey, and make extracting lose most of its terrors, especially after the flow.

Sometimes, however, it is difficult to know just where you will be obliged to extract first; and by the time you find out, the delay necessary for their use can't be afforded. They also involve an extra trip to the outyard, and the time required to put them on is considerable. In a well-equipped

The lament of the drones.

apiary, abundantly supplied with supers, they are a delight to use, but have no place in a hurry-up job where supers are short.

Where thin nectar has been stored in supers, and the wire escape put on before it is ripened, the heat of the colony and the evaporation process going on below does not seem to ripen it properly.

After the rains, the bees in this locality stored some thin nectar from a second bloom of white clover. The buckwheat was

out; and to keep it from mixing, and allow the thin clover to ripen up, a wire escape-board was put under the top, or second super containing the thin stuff. This was left on the hives for a couple of weeks: Result, the only sour honey I ever had, and I am glad there was only 200 lbs. of it. It looks as if the presence of the bees on the honey were necessary to the proper ripening of it.

Orono, Ont.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sightings among the Bees

BY H. H. ROOT

During the last year we have been accumulating quite a number of pictures that we have taken of various subjects pertaining to bees, only a few of which have appeared on these pages. I propose to take up in a series of articles one or two subjects at a time, presenting the pictures and letting them tell largely their own story. We all like to look at pictures. If this were not true the motion-picture shows would not be so successful.

Twenty years ago, only an occasional beekeeper owned a camera. Now a very large number own cameras or kodaks, and the resulting half-tone engravings on the pages of bee-journals are a great improve-

ment over the invariable zinc etching from a pen-drawing, or wood engraving characteristic of the time before the kodak, or hand camera, revolutionized picture-taking.

We are asked so many questions on photography that perhaps a few general remarks, first, concerning our equipment, may not be out of place.

For picture-making about home we prefer glass plates rather than films. They cost but little over half as much, are somewhat more convenient to handle, and they may be obtained in a variety of emulsions suitable for all classes of work. There is no one all-around plate suitable for all kinds of pictures. We use Seed 23 plate

for copying, and frequently for landscape views, such as apiaries, etc. For general quick work about the apiary showing operations, etc., the Seed 27 is better, which has the same speed as the film ordinarily used in kodaks. For photographing live bees on flowers, or on combs, a faster plate is necessary. The Seed 30 may be used, which is about twice as fast, but we prefer the Seed Graflex, which has a speed about four times as fast as the No. 27. In other words, if a picture could be taken in $1/25$ of a second with the No. 27 plate, or with kodak film, $1/100$ of a second would be ample exposure if the Graflex plate were used. Taking life-size pictures of live bees requires an exposure as short as $1/100$ of a second, or even $1/300$ of a second. Therefore, extremely rapid plates are required. Such fast plates as the Seed Graflex require a little more careful handling in the dark-room in order to prevent fogging, but are otherwise developed the same as any negative.

For photographing honey, or for obtaining the correct tone values that show the right amount of contrast between certain colors, Panchromatic plates must be used. We use either the Wratten or the Standard Panchromatic plates for such work. Frequently a "filter" must also be used over the lens during the exposure. In a later article, illustrations will be used showing the correct and incorrect tone values of honey in glass.

The "worker" bee.

A bee with a load, too busy to dodge a loiterer, unconcernedly climbs over.

In making prints we use Azo paper, Grade F, which is a white glossy paper. We use three different contrasts—the Soft, the Hard, and the Hard X; the Soft for harsh contrasty negatives; the Hard for medium negatives, and the Hard X for thin negatives lacking in contrast. Many prints submitted to us by beekeepers are unsuitable for half-tone reproduction. In such cases, if the picture seems to warrant we send for the negative, and in almost every instance we find that, by using the proper paper, a much better result can be secured. If the negative is all that it should be, the Soft paper will produce the best results; but many negatives are so lacking in contrast that a harder paper is necessary in printing.

Even when the photograph is clear and distinct, the half-tone reproduction may not be all that is desired. The illustration of the drones on the preceding page is from the same photograph as the illustration accompanying Mrs. Allen's poem in the November 1st issue, "The Lament of the Drones." The first engraving was too small, and was not a very good engraving at that.

PHOTOGRAPHING LIVE BEES AT CLOSE RANGE.

Last summer I had photographed bees working on different kinds of blossoms, and had been having, therefore, an excellent opportunity to notice the feverish yet joyful motion of the bees collecting pollen, like the nervous yet enthusiastic ways of a man possessed with the get-rich-quick idea. I had also secured pictures of bees with loads of pollen on their legs, and I wanted to get one showing the business-like rush of a pollen-laden bee into the hive. But, to my surprise, I found the rush so truly business-like that catching it with even a fast plate and a quick-working shutter was not easy. I finally did secure an exposure that show-

Queen poking her head into cell to see if it is polished ready for a new egg.

Queen laying. Note the circle of bees around her in mute adoration.

ed the bee rushing in with pollen, but it was not quite up to my expectations.

In making these photographs I observed incoming bees absent-mindedly climbing over any loiterers on the alighting-board, that did not happen to get out of the way soon enough. It was exactly like two people meeting each other on a narrow sidewalk, and both dodging back and forth until one in disgust gets clear off and allows the other to pass, only the disgusted bee carrying the load calmly climbed over the offender—too busy to stop and go around—and then hurried into the hive without looking back, as much as to say, "There, perhaps that fool youngster will know enough to keep out of the way next time."

The illustration shows the *busy* bee just half way over the *lazy* one. Just watch the alighting-board some day next spring when the air is warm and the soft maples are in blossom, and see if you can not imagine the same conversation.

The next illustration shows a scene familiar to every beekeeper—a queen with her head poked down into a cell momentarily to see if it is ready for an egg while the surrounding bees wait almost breathlessly; and at the right the same queen with her abdomen down in a cell in the characteristic position of laying, the admiring bees meanwhile standing about with their heads toward her, some of them caressing her.

To be continued

THAT NEW BEE DISEASE IN THE WEST. THE SYMPTOMS. IS THERE A CURE FOR IT?

The Isle of Wight Disease in England a Terrible Scourge

BY W. HERROD-HEMPSALL

[On pages 784 and 922 we asked for reports giving the exact symptoms of the new bee disease that has killed so many thousands of adult bees in the West and particularly in the Northwest. We received a good many letters; but among the number are two from England that refer to what is known as the Isle of Wight disease, and which is possibly the same thing that has been causing trouble in our own country. In this symposium we give first the letters from England and then the others, from the United States. Editorial comment will appear in the regular editorial department.—Ed.]

I have watched very closely the various articles which have appeared in GLEANINGS on the great loss of bees in the various parts of America. I therefore feel constrained to write and warn American beekeepers of their danger. From the accounts, I am quite certain that the loss of bees is occasioned by *Microsporidiosis*,

otherwise Isle of Wight disease. The Americans, to comfort themselves, are making the same mistake that was made in this country when it first broke out—that is, attributing it to sprays of various kinds. In this country we have had beekeepers go so far as to say that loss was caused by the tar spraying of roads. Let there be no

mistake. Everything has been tried in this country as a cure, without success up to the present. Therefore the only means of checking or eradicating the disease is to destroy at once any colony showing the well-known symptoms. If this had been done in Great Britain at the first, the terrific loss which we have sustained would not have occurred. Our most practical and thoro beekeepers are helpless in the face of this disease. When an apiary is attacked, the owner is in the same position as a man whose house is on fire and no water available to put it out within a couple of miles. The disease is not unknown in America. I am speaking from memory as to the date of issue in GLEANINGS, but think it was in 1885 when some one wrote a letter descrip-

tive of a mysterious outbreak of disease in the Utah Valley where thousands of colonies were lost. That letter might have been a descriptive one written by a Britisher on the symptoms of Isle of Wight disease in his apiary. Knowing as I do the serious consequences of this disease, as I have experienced in my own apiary, where all the 126 colonies were lost, I again urge upon my American brother beekeepers to destroy ruthlessly all affected colonies and their combs; thoroly disinfect the hive, not only for their own sake, but also for the sake of their neighbor beekeepers, as robbing and the soiling with excreta of the drinking-place are the chief sources of contamination.

London, England.

THE NEW BEE-DISEASE NOT AFFECTING THE BROOD

BY C. H. BOCOCK

I have been much interested in accounts that have from time to time appeared in GLEANINGS of wholesale mortality among bees in the United States, and particularly so in that on page 784, Oct. 1. Bees hopping about in the grass, and collecting in bunches on the ground, is what occurs in cases of *Microsporidiosis* (the so-called Isle of Wight disease), which is yearly making larger and larger inroads into the number of stocks in Great Britain, until a bee threatens to become a *rara avis*. Incidentally I may mention that my own losses have been 260 colonies.

If the disease around Seattle is *Microsporidiosis*, Prof. Kincaid is either in error or has been incorrectly reported in saying that the bees' heads are full of spores. *Nosema* spores occur only in the gut and the gut-contents of infected bees.

In regard to the dead brood, I agree with you. Altho larvæ may be, and are, infected with *Nosema apis* at an early stage of their existence, there is no microscopic evidence of disease, and the death of the brood is to be attributed to the adult bees of the colony being so diminished in numbers, and the survivors so unhealthy, that they are no longer able to feed the larvæ or maintain the temperature of the brood-nest. Taking away all brood and feeding the bees frequently effects a temporary improvement, but a temporary improvement only. *Nosema* is still present in the gut, and the colo-

ny ultimately succumbs—usually during the following winter.

The reluctance of sick bees to put up a fight in defense of their stores has been a very marked feature here this autumn—stocks suffering only slightly from the disease and strong in numbers allowing wasps to carry off their honey with scarcely a protest. One consolation is that the wasps carry away the germs of disease, and themselves perish.

If any one in America whose apiary is suffering from a scourge like that described as raging around Seattle, Wash., would send me bees for microscopic examination, packed in such a way that they reach me alive, they would be gratefully received; and if you could put me in communication with any one whose apiary is so affected I should be doubly grateful. I suppose that, during the winter months which are now upon us, it would be impossible to avoid the bees perishing on the journey, and dead bees would be of no use for diagnosis. The bees sent should be taken from the hive. Crawlers picked up off the ground should on no account be sent, as these would inevitably perish *en route* at any period of the year. But during the warmer months I should think that it would be quite possible to get bees thru in good condition.

I should be pleased to report to the senders of bees the results of the examination.

The Elms, Ashley, Newmarket, England.

THAT WESTERN BEE - DISEASE; THE SULPHUR TREATMENT HELPFUL

BY M. W. HARVEY

[Mr. Harvey has in the neighborhood of 700 colonies of bees. He was the subject of an article by Wesley Foster, April 1, 1914, in his series "Beemen I have Known."—Ed.]

I had six cases of the new western bee disease in one yard and one in another, the yards being three miles apart.

The first to show the disease was my ten-dollar golden breeder and two of her daughters. I treated them with sulphur, and the trouble was checked. I continued to treat them for two months with sulphur every two days; and when settled warm weather came it disappeared. They then built up and made two supers of honey around.

The other queens were one leather Italian, one black and two hybrid. So it seems that the disease is no respecter of race. They were treated with sulphur for about a month twice a week, and the disease seemed checked; but when I stopped treatment in a week or ten days the bees would start dying as badly as ever. Then I tried a physic, but I suppose I did not get it strong enough, as it had no apparent effect. So I returned to the sulphur treatment, and kept it up until the main honey-flow commenced. Up to that time the two hybrid colonies were getting strong, and the bees had about quit dying. They had three and four frames of brood, and plenty of bees to cover the brood; so I left them alone for three weeks,

and concluded they were safe to take care of themselves; but what was my surprise when I went back to them at the end of the three weeks to find one dead and the other with queen and a handful of bees!

The leather Italian and black colonies got so weak by honey-flow time that I killed the queens, gave each three frames of sealed brood and young bees; then I gave a golden queen to each. At the end of the season of 1915 they were as good as the best colony in my yards.

My conclusion is that it is a bad case of paralysis. The actions of my bees were the same as described by Mr. Ladd, of Oregon, in GLEANINGS for Nov. 15, p. 922.

I hardly think that weather conditions have anything to do with it, as my bees are at Reno, Nevada, and we had a cold late spring lasting until June 16; but the disease lasted into July after hot dry weather had come.

I feel sure it is the same disease that weakened the bees so badly in Mason Valley, Nevada, in 1914, that the honey crop was practically lost, tho I did not hear of the disease appearing there this year. But if it makes me another visit I will find a cure or kill the bees trying.

Sebastopol, Cal.

THE NEW BEE-DISEASE IN TEXAS; BAD WEATHER ONE OF THE CAUSES

BY ALFRED L. HARTL

Four years ago in the spring my bees bred up nicely, and at the approach of the spring honey-flow they were very strong. Just at the opening of the flow we had considerable cool and rainy weather which kept the bees in their hives for about two weeks. After a few days of this weather I noticed considerable dead bees at the entrance of a few colonies, but didn't pay any attention to it. Next day I again went among the bees in my home apiary, and found that all the colonies in the apiary were affected. Of course some were worse than others, so I at once examined the colonies and not only found that the bees were dying but also the brood. In a few colonies the entire brood was rotten, and so of course I felt as if I were sitting in hot water. I then sent a sample of brood to Washington, D. C., and then went to my four other apiaries and

found the very same disease there. Some colonies had handfuls of dead bees at the entrances and lots of dead brood, so I started to treat them as for American foul brood, but without any good results. The brood in the new combs was just as rotten as in the original combs.

Then I received an answer from Washington, saying it was sac brood. It seems to me when a colony is badly affected with this malady it loses its energy, and consequently most of the brood will be starved, which will rot in the combs till clear sunshine comes.

I don't think there is another disease that can cripple an apiary in a few days as this does, for the bees die by the thousands, and hardly any brood will hatch. Of my five apiaries (560 colonies) I lost 13 colonies outright, and got no surplus from three

apiaries, and only a small crop from the other two apiaries.

The symptoms are not the same as for bee paralysis. The bees tremble but very little, and are not as shiny, and but few are swollen. In fact, some bees that look healthy in every way run out of the entrance, but are unable to fly, fall off the alighting-board, and crawl away.

After trying different treatments without any results I have come to the conclusion

that the only cure is settled warm weather for a few days. I positively know cool rainy weather causes its appearance, for the next two seasons whenever we had several days of weather that confined our bees to the hives the disease would reappear. Fortunately, the last two seasons I haven't had a trace of the disease, altho it still gives me the chills when the weather is favorable for its appearance.

Elmendorf, Texas.

TREATING BEE PARALYSIS IN WASHINGTON

BY MRS. A. A. GOOD

I do not think the old or new disease that has been so bad in western Washington this year is in my apiary. From the description I have read in the journals at different times I think my bees have paralysis. The first I saw of it was in 1911 in a colony whose queen was raised from an egg of a queen I got from Texas. Every year since then, except this year, I have bought one or two queens from the East, and in nearly every colony where I have queens raised from the eastern queens the disease has appeared, and once a year afterward it broke out in the colony where I had put the eastern queen. I have never had it in my native bees. I say "native" because my bees are descendants of bees taken from the woods. They are not black bees. They are as good-looking Italians as any that were hatched from the eggs of the Italian queens I bought, except the golden.

When the disease first starts there appear a number of small black shiny bees with their wings slightly spread, and some of them trembling. Then there will be bees

with distended bodies, some trembling, and some stupid; and, if let alone, the colony will dwindle away. I cure it by killing the queen and giving them sealed brood and a queen-cell from a healthy colony. I have tried introducing a queen, but have never been successful in getting one accepted in a diseased colony.

The spring of 1915 was the best one in my apiary that I have seen in my seven years of beekeeping. The bees built up well and stored some honey in April. Then it came off dry. By June they had used up all their stores in brood-rearing, and in July I had to feed a number of colonies or they would have starved. I have often wondered if hunger and poor honey did not have something to do with this new disease.

There was a two-weeks honey-flow in August, and the most they gathered was honey-dew off the leaves of the alders, and that is all they have in their hives now; but our winters are mild, and I hope the bees will come out all right in the spring.

Lakewood, Wash.

A SUCCESSFUL SULPHUR TREATMENT OF NOSEMA APIS

BY O. S. DAVIS

The bees about here have *Nosema apis*, Isle of Wight disease, just plain paralysis, or something, all right. I have seen a hundred colonies at one time in our apiaries affected; that is, the bees were sick, crawling over the ground in all directions, and dying everywhere. Some colonies were very much worse than others, and our best colonies were often the worst affected. Some of the bees were shaking as with the palsy, others were slick and shiny, some had distended abdomens, and some had a pinched-up appearance. Queens became affected

and soon died. In a few hives the brood died—from chilling, I think.

We tried sulphur according to the A B C and X Y Z—*i. e.*, we took the brood away and sulphured the bees thoroly. They generally died. Then a neighbor beekeeper told us to put sulphur on the alighting-board, but it did not work very well. So we got a sulphur-machine that my brother uses to blow flowers of sulphur over the grapevines to fight mildew. This machine blows a fine spray of sulphur with considerable force right into the mouth of the hive. We treat-

ed the whole apiary about twice a week with a sulphur bath.

Some colonies responded to the treatment quickly. Others were not visibly affected for two weeks or more. Two or three died. Some colonies took backsets and had to be treated over again. At present (Nov. 26) the apiary of 305 colonies seems all well, but we expect to have to fight the disease again next spring. We don't fear the malady as we did at first. I believe it to consist of a fungous growth on the outside of the bees similar to mildew on the grapes. The sulphur spray does not kill the brood—at least not much of it—unless used more freely than necessary.

Use sulphur often and with discretion, and I believe the disease can be cured every time. The time to spray first is when the first diseased colony is discovered.

In regard to this disease I have arrived at some conclusions by intuition or imitation in watching the farmers fight pests of all kinds—mildew, red-spider, and the like. They blow sulphur among the branches and leaves of the trees when the heat of the sun ranges between 90 and 110 degrees. It is claimed, and I believe it is true, that the sun cooks a kind of sulphurous gas out of the diffused sulphur that means death to these parasitic plants, bugs, lice, mites, mange, itch, ticks, etc.

I notice that the sulphur spray in the

hives, and all over the bee-yard for that matter, seems to do more good during the hotter parts of the day and very little or no good when the temperature is cool (below 80°). We blew the sulphur all over the ground, hives, and dead bees. The apiary smelled like his Satanic Majesty's proverbial palace; and I tell you the disease began to disappear at once. Now please don't imagine that it takes a barrel of sulphur, for we did not use ten pounds. I dare say we wasted part of that.

We need some special machine for the purpose of putting the sulphur in the hives, or possibly a different-shaped nozzle to attach to the machine we already have. This is strapped on a man's back and worked by a hand lever. But the builder designed it for sulphuring vines and trees, and not hives. When we blew the sulphur on the brood we could see minute grains of sulphur in the cells. We killed the brood, and the bees were very reluctant even to clean out and use the combs for any purpose. Still, the light fine sulphuring did no harm that we could discover. Our bees began to build up and get strong right away.

We have increased from fourteen weak, rundown, poverty-stricken colonies to 305 good colonies, and have 560 combs of honey to feed them upon if times get hard with the bees next May or June.

Selma, Cal.

THE SULPHUR CURE EFFECTIVE

BY WASHINGTON D. KEYES

Early in the spring of 1914 I ordered a pound of bees with queen; put them in a hive with drawn combs, and as soon as the brood was three-fourths developed a large portion was attacked, and turned, first pink, then brown, and finally black on the sides of the head, and died. They were cut out of the cells and thrown out on the ground; and when the young bees began to hatch out many of them could not fly, and fell on the ground, crawling around as if they were crazy or blind. This kept up all summer,

and the colony remained weak; but late in the fall I bought powdered sulphur, sprinkled it in the entrance, and on the alighting-board. I took off the cover and sprinkled the sulphur on the tops of the frames and between them; covered the hive up, and in a short time the disease disappeared. The colony came thru in good shape this spring, and is one of the best colonies in my yard—perfectly healthy, strong, and industrious.

Wilkesburg, Pa.

WET COOL WEATHER FAVORABLE FOR THE DEVELOPMENT OF THE DISEASE; GOOD WEATHER A CURE

BY E. J. LADD

In looking over my records I find that bee paralysis, or *Nosema apis*, has never shown up but that, on a *corresponding date, weather conditions were bad*. For instance, in 1915, when at its worst, a record shows

continued rain for weeks, and tomatoes and potatoes blighting. In 1912 I find hives A, V, E showing paralysis, weather condition bad, *potatoes blighting*. In 1908 I find hives 10-a, 12B, and G all showed slight

paralysis; weather bad for a long time. In 1912, all recovered when good weather returned; the same in 1908, but very slowly. I now find in each of those hives eastern Italian queens had been introduced the year previous. In 1907 I lost one by paralysis, weather bad. You by this time must have got the idea this paralysis, or *Nosema apis*, is, beyond doubt, brought about by weather conditions, and by *that alone*. Some, evidently, are more resistant; but I'll bet you that *wherever* it showed up you will find that weather conditions were bad, which, if long continued, would get the bees to a fare-you-well. Two original eastern queens are here today, in hives full of healthy

brood. *Early in the season they lost their colonies when the weather was bad; but when the weather became good, trouble disappeared.* Everything was all right, and is yet. It was a costly season—not a pound of surplus. I just finished feeding the whole apiary. Isn't it possible that *Nosema apis* is a severe and malignant type of paralysis brought about by adverse weather conditions? Bad weather is prevalent in Isle of Wight too.

Fungous growth attacks insects. Isn't it possible that either *Nosema apis* or paralysis is a fungous growth attacking bees when weather conditions are right?

Portland, Oregon.

ARE BREEDERS OF UNTESTED QUEENS GUILTY OF SENDING OUT A MAJORITY OF THEIR STOCK UNTESTED?

BY L. E. WEBB

Editor Gleanings:—If you will pardon a lengthy communication, there are a few things which certainly need a little jacking up in the journals in the interest of the small beekeeper, or, rather, in his protection in regard to queens. I want to give you my experience this year, which has proven conclusively that the average small beekeeper ordering "untested queens" is merely ordering hybrids.

Last year I ordered eight untested Italian queens from several breeders, and not a single one was purely mated. A percentage like that shows to me that breeders are sending out queens that they *know* are improperly mated, under a reduced price as untested.

I had eight this year and three last year, and not a single pure queen in the eleven. In the meantime I have the only Italian bees in this section, being surrounded by blacks; and this year I mated ten queens, and eight mated pure and two cross. That being my percentage, it certainly looks as if a man ordering as many as eight in a season ought to get a few pure ones, any way; so it is evident to me that many of those queens are known to be improperly mated.

Now, the journals do not take up this matter strongly enough—probably for fear of hurting some one's reputation or feelings, and in the meantime hundreds of small beekeepers are suffering for it.

I know and you know that if you were to get eight queens in a season from big breeders, even the untested, you would get a part pure, any way, or any other big beeman would; but it is the little fellow who needs

only a few, and whose dissatisfaction can't amount to much, inasmuch as he isn't well enough known to use any influence, and could get no voice thru the journals; or, if so, it would be censored down to where it wouldn't have the straight-from-the-shoulder effect; and it is the very ones who palm off these inferior queens under pretense of untested that get large amounts of publicity and who contribute articles, get free advertising in a way, etc., thru the journals, and the little fellow gets it in the neck if, perchance, he happens to be impressed with the talk in some articles and invests in queens.

It is high time some sort of strenuous campaign were commenced in behalf of the beginners, as, of course, they mean the future business.

There are plenty of men caught who never say anything, and of whom you do not hear; and it seems to me that if a man sees an advertisement in GLEANINGS or any bee-magazine, when ordering even an untested queen, he should at least have a chance at getting a purely mated one, and not one that failed for the tested class.

Of course, a thing like that can't be proven; but common sense tells us that, out of a given number of queens, some would be mated properly, or, in other words, if breeders mated as in my case eight queens before getting a pure one, then tested queens would be pretty scarce.

It is apparently a small matter, and yet the very business itself rests on it; and, aside from my experience, I can name a beekeeper who secured twelve "tested" queens, four of which proved to be hybrids.

Of course, a breeder can't guarantee a really untested queen; but this practice of testing them and finding them mixed, and then sending out as untested, should be lit hard; and now ask yourself the question, under any reasonable circumstances, is a man due to get (in two seasons) eleven queens without getting a few purely mated ones?

Morgantown, N. C.

[This seems like a severe arraignment of one or two and possibly more queen-breeders. Perhaps our correspondent happened to get a very bad lot; but he should not happen to get *many* such bad lots. We cannot believe the charge can be laid against the majority of our queen-breeders. As a matter of fact, we know there are some queen-breeders in this country whose untested stock will run from 99 to 100 per cent pure. There may be others who are more careless, and allow their mating-yards to be in localities where there are many black bees. This is neither fair nor square. If we know it we will not accept advertising from such people.

It goes without saying, that a large percentage of untested queens should be pure—not less than 75 per cent. Anything short of that ought to be replaced until the proper percentage is reached.

After all, it is a case of the survival of the fittest. The queen-breeder who continues to send out mismated for untested, or scrubs, will not get any repeat orders, and it will be only by extensive advertising that he will be able to get any new business.

Such extensive advertising unsupported by repeat orders will leave him no profit, and he will be forced out of the game. It follows that the man who has been in the field for years, and gets repeat orders year after year, will have his locality so thoroly Italianized that there will be no blacks in the vicinity.

We shall be glad to hear from others as to the untested queens they have received, and the percentage of pure matings. If any of our advertisers are in the habit of placing their mating-yards where there are many black bees, we shall feel compelled to reject their advertising of untested stock as soon as we know it.

Perhaps the solution of the difficulty would be to advertise only warranted stock; but that would open a way to fraud on the part of the customer. He could claim that many of the warranted queens sent him were impure, and ask for a replacement whether the facts warrant it or not. After all, it seems fair to sell untested stock with the understanding that at least 75 per cent of it shall show up pure; tested for exactly what they are, and so on up to the select tested and extra select, and breeders and extra breeders.

Last year we purchased from a prominent queen-breeder 100 untested queens, as we were short of stock at the time—that is to say, our own colonies were becoming queenless. We put them in the hives, and every one of those colonies showed up pure mating, notwithstanding the queens had been sold to fill orders.—Ed.]

BEE CULTURE AND HONEY-MARKET CONDITIONS IN LOUISIANA

BY J. F. ARCHDEKIN

At first it was hard to credit the stories that were told me about the possibilities of beekeeping in this section. Being from Missouri I had to be shown; but the showing has confirmed the stories.

This locality is swampy; and a southern swamp has to be seen and felt to be appreciated. Almost every conceivable kind of tree, bush, and flower grows in them, and they contain an immense assortment of insect, bird, and animal life, ranging from the almost microscopic redbug, or chigger, which makes itself felt continuously, to alligators twenty feet long. It is a naturalist's paradise; and mosquitoes! they are simply terrific. In fact, I never saw so many kinds of insects in my life.

Bees are plentiful, bee-trees being exceedingly numerous. Owing to the favor-

able conditions a bee-tree is permanent when once established, and will exist for years if left undisturbed. People are constantly telling me about bee-trees they have known of for years. Just the other day a man mentioned a tree he found eight years ago. I myself saw two trees cut for bees, not over sixty feet apart. Conditions here are very favorable to bee life, there being absolutely no disease with mild winters, and a continuous honey-flow lasting seven months of the year. The wild bees swarm, and during the spring flow wild swarms are seen almost daily.

In spite of all this, bee culture has been neglected to a great extent in this state. While there are extensive apiaries, here and there, over the state, they are comparatively recent in establishment, as it is only in late

years that the industry has been given much attention. Beekeeping is now in process of development as an occupation; and in the future this state is going to rank well to the front in honey production.

In this section there are a few progressive beemen, and a lot who are not. There is one apiary of probably two hundred colonies near me, all in box hives. Those who are progressive are mostly beginners, so that experienced beemen are scarce.

The country has in past times enjoyed some measure of prosperity; but all that has disappeared, and the people are now very poor. Nearly all of the best people have left, so that large tracts of once productive land are abandoned. The principal crop is cotton; but the farmers have planted one crop after another of it without doing anything to replace the fertility taken from the soil. Consequently cotton farming is not profitable any more. I have been talking alfalfa and red and sweet clover to them; but the seed costs 20 cts. a pound, and they balk at that. Wheat will do well, but the farmers are not progressive enough to take up any new crop. In fact, the only people who are prosperous are beekeepers.

The honey market here is very poor. At one time last summer the finest tupelo honey sold in New Orleans at wholesale at 42 cts. a gallon. There are several causes for this condition. In past years all the honey marketed was taken from bee-trees and box hives. The comb containing bees, brood,

and honey was mashed up and strained, and the product characterized on the market as wild Washita honey. From all accounts it was a villainous compound, and prejudiced the dealers against all honey offered them. Even yet they make no distinction in price, and don't know the difference between extracted honey and this other stuff—I mean the dealers in New Orleans.

Another trouble with the commission dealers is that they have been accustomed to holding up the consignor of cotton or any other commodity, and they are inclined to follow up this policy in handling honey.

On the other hand, they claim that the European war is causing the market to be so low. No doubt it is causing much honey to be sent here from South America and the West Indies that formerly went to Europe. This condition will be only temporary, and will, no doubt, disappear soon after the close of the war. I don't see how the producers of this honey can break even at the present prices, after paying transportation charges, commission, and storage.

The southerners do not eat honey to any extent, and consequently there is no local demand for it; and it must be sent to the northern states for consumption.

This is probably the main reason for the market being so dull. I am fortunate in having a market in my home state for my honey, and have not been forced to sacrifice any of our crop.

Bordlonville, La.

ANNUAL MEETING OF WESTERN NEW YORK BEEKEEPERS

BY WILLIAM F. VOLLMER, SECRETARY

The annual meeting of the Western New York Honey-producers' Association was held at the American Hotel, Akron, N. Y., Dec. 14, 1915. It was very well attended considering the weather conditions. Many more would have attended had there not been so much snow.

After reports of the secretary, treasurer, and delegates to the state association were read and accepted, a suggested constitution was read and adopted. As the weather for two years has been bad on the day of meeting it was decided to hold it in November instead of December as before. Several of the speakers were unable to be present on account of the weather and other reasons.

We had Mr. J. Roy Lincoln, of Niagara Falls, with us, who told of his method of making increase, which was 100 per cent perfect. His method, very condensed, is as follows:

When bees are strong enough to swarm naturally, place all the brood except one frame and queen above the supers above an excluder. When cells are started this top story or nucleus is set off on a new stand, provided the stock was satisfactory for raising queens from. If not, a desirable cell or queen may be given to this nucleus or nuclei, as the case may be. After the honey crop is taken off twenty-four hours, exchange the nucleus and the parent hive. The latter is generally overflowing with bees at this time.

The flying bees or old bees seem to get added vigor by having a young queen in the hive, and seem to work harder and wear themselves out getting the nucleus stocked with brood. This means young bees for winter, which we must have to have a fair measure of success. Thus both colonies are in the pink of condition, with young bees

and plenty of stores. It is rather important, in exchanging, that the bees be not excited, as that might cause trouble in their uniting.

Several members seemed to think that sweet clover has a great promise in store for those who take advantage of the opportunity it gives. The secretary told of the different ways of disposing of the honey crop; namely, by jobber, wholesaler, retail

grocer, and direct to the consumer. He said that he thought the greatest good for all concerned was by the direct-to-the-consumer plan. In many cases this is impossible. Mr. D. C. Hubbard, of Wyoming, told of his views of marketing. Several other questions were brought out and discussed, after which the meeting adjourned. All reported having had a fine time.

Akron, N. Y.

THE HANDY ESCAPE-BOARD

BY E. F. ATWATER

The writer was long skeptical in regard to the bee-escape, but for some years has been a convert to its use for removing comb honey from the hives. We formerly made a practice of putting three to six supers above each escape, but found that there is likely to be some fighting when supers containing many bees from several colonies are piled above a single escape-board. Too often the escape will be clogged with dead bees, and the supers will not be free from bees when we wish to load them on the wagons for hauling home.

When the supers are from one colony it is usually safe to put as many as necessary above a single escape. Possibly some of the clogging has been due to death of some of the bees from suffocation.

The chief objection to the Porter escape, in the past, has been that it was not made double, like its European imitation, so as to allow more bees to pass, and cut in two the liability of clogging; but the new double Porter escape solves the difficulty and is very satisfactory. We had heretofore used the escape but little for removing extracted honey from the hives, but are now satisfied, after trial, that where it is possible to be at a yard several hours, or over night, before beginning to extract, it will pay well in several ways to use the escapes in order to provide all the supers of honey that can be extracted in the morning. This is especially important here in the West, with its cool nights and mornings. When brushing and shaking bees from the combs for the morning run, the bees become greatly aroused, which is not very agreeable to the help or to neighbors.

Afternoons there is usually no difficulty, and it remains to be seen whether it is worth while to use the escapes for the afternoon run, altho our helpers have formed a decided opinion in the affirmative.

When removing comb honey we prefer to remove all burr-comb from the supers before putting them above the escapes.

In our practice I usually go along the rows, examine the comb-honey supers, and stand on end at the rear of the hive all supers ready for removal. Another man follows and scrapes off all burr-comb (worse and more of it here in the West), while a third man puts them above escapes and sees that all are tight and lids closely fitted to prevent robbing.

For taking off extracted honey we believe that the "new" ventilated escape-board, made chiefly of wire screen, is quite an improvement; but it is a mistake to suppose that the honey from supers so removed will be nearly as warm as when the bees are brushed from the combs. It is the actual contact with the warm bodies of the bees that is the chief factor in keeping the combs warm. When using the escape beneath two bodies of extracting combs crowded with bees it is particularly desirable that the escape be doubled—that is, that it have two sets of springs.

The idea of the ventilated escape-board is not so new as might be supposed. The old La Reese escape embodied that feature, and in actual use it is second only to the Porter.

We have several uses for the ventilated escape-boards, and find them so useful that we shall make many more of them.

For moving bees, in weather not too hot, and where circumstances make open moving undesirable, simply tack a ventilated escape-board on top of the hive, or one above and one below.

We carry a few of them with us at every trip with the wagon; then if we find a foul colony a screen is tacked above, the hive stapled ready for moving, and the entrance closed. We leave the ventilator open. Then the last thing we do at that yard is to close the ventilator and load the diseased colony on the wagon, when it goes home, where it can be watched and treated safely.

When the swarming season comes, there are several plans involving their use. A

method which has always worked well with us is as follows:

For extracted honey, take out the escape and put in its place a piece of queen-excluding metal. Find the queen in the colony which you fear may swarm, and set her, with the frame of bees on which she was found, after destroying all queen-cells, if any, into a new hive-body. In the place of the frame removed, put an empty comb into which you have poured some water. Put the escape-board over the old colony in place of the lid and nail a strip of lath over the entrance. Now put your new hive, containing the queen and her frame of bees and brood, on the escape-board, and fill out the hive either with worker combs or with frames filled with full sheets of foundation.

There must be an entrance to the upper body. This we provide by opening the

ventilator which we have in all bodies, but may be provided by shoving the upper hive forward, then laying a strip at the rear. In ten days you may take away the lower hive of brood, which has been well cared for by just enough bees returning thru the zinc. If you wish increase, set off the lower hive and give them a queen. The brood is all sealed, as in the Alexander plan. Or the brood may be divided among nuclei which you wish to build up.

If no increase is desired, the hive of brood may be left below until all bees have hatched; or at any time after ten days from treatment it may be put above for an extracting-super, after destroying cells, if any. A few colonies may prepare to swarm a second time, when the process may be repeated to advantage.

Meridian, Idaho.

LAYING WORKERS CAUGHT; A LOT OF 'EM

BY M. JOHNSTONE

Mr. Chadwick, on page 837, Oct. 15, states that he has never seen a bee known as a laying worker. In the same note he expresses a doubt as to plurality of laying workers, and also doubts that any one knows. Now, I wish to take issue with him right there. There is also the biological issue, as Mr. Chadwick, page 841, of the same issue, states his disbelief of a developed drone without fertilization. As to the latter point I cannot see that there could be a possibility of fertilization where there is a multiplicity of laying workers. In fact, my experience leads me to believe that practically every laying worker in a bad case of a colony developing laying workers is likely to possess the power to lay.

To the end that every one interested (and what lover of insect life is not?) may observe the phenomena for himself, let me relate what I saw. The science of bee life was new to me, and one day I observed in a small nucleus a number of eggs in several cells. I could find no queen. I searched every comb carefully for her, and in the process of searching I observed that some cells contained a large number of eggs. I devoted the afternoon of that July day to observation of that colony.

I don't know just how the inspiration came, but it struck me that the laying worker or workers being short of room might lay again in the same cells were the eggs removed. I did so with a pin, emptying several cells. Then the comb was replaced. I lifted it gently out in possibly ten minutes (I am not sure of the time),

when, lo! I caught a bee in the act of laying. I crushed her and removed the eggs and replaced the comb. After a short time I gently removed the comb again and caught several laying again. Again the same result was obtained—a third time.

I certainly saw these, and reported so in GLEANINGS at the time. I believe, also, that any one sufficiently interested could perform the same experiment with the same result.

I am writing this to induce others to try it next season, and I hope they will report success or failure.

Given a bad case of laying workers, remove the eggs from several cells; return gently; remove in ten or fifteen minutes, and the laying workers may be caught in the act. Of one thing I am certain—you will never forget the appearance of those discovered in the act.

Cayuga, Ont.

[There is probably not one beekeeper in a thousand who has ever actually seen a laying worker. Unless one neglects his bees there probably will not be found a colony of laying workers in the apiary. When a colony is queenless for a month or so, it may or may not develop a case of laying workers. With regard to the question whether there are more than one or two laying workers to a colony, that question was settled long ago. In back numbers of GLEANINGS, and, in fact, in the *American Bee Journal*, there is any amount of proof to show that if there is one laying worker in a hive there may be many of them.—ED.]

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Make your own hives if you will, but don't try to make one out of a grocery-box with a meat-saw and a claw hammer.

Winter Pictures

BY GRACE ALLEN

Gray clouds that creep across the sky;
 Grim icebergs haunting northern seas;
 A far-off war where countless die
 And men in mountain passes freeze;
 The city streets, a frosty glare
 Where huddled poor folk cough and wheeze;
 The country, desolate and bare,
 Where winds may stalk it as they please;
 And while they howl—a dismal choir—
 Within a cottage hid by trees,
 A man sits by a glowing fire,
 Reading a book on bees!

Wintering on Two Sets of Combs

I have wintered my colonies with two sets of combs ever since I kept bees. I use ten and fourteen L. frame hives, some single and some double-walled. I put a zinc sieve under the single-walled hives to let the dead bees and dirt drop out of the combs. I want little honey in the bottom combs, and I want six combs of solid honey or an equivalent amount in the upper hive.

I pack dry empty combs as tightly as I can against the side of the hive. Then I

lay three or four half-inch strips across the top of the combs to give the bees a passage between the combs; put the matting from tea-chests over them, put a box on top that telescopes over the top of the hives an inch, and fill it with six inches or more of dry leaves or planer shavings. Dry wheat chaff is the best packing material I have ever used, but I cannot get it here.

Where the entrance is the full width of the hive I stop up the middle, leaving about 2½ inches at each end open, and put boards in front of the entrance so that light cannot get in to call out the bees while it is still too cold for them to fly.

My top-bars are ¾ inch thick by ⅞ inch wide. I think the thick top-bars would not be suitable to winter bees in double-story hives. In cold weather the bees would not move up thru the narrow opening between the frames over the amount of wood they would have to cross.

New Hampton, N. Y. E. D. Howell.

The True Boneset

Gleanings for Oct. 15 contained some excellent illustrations of wild flowers noted as honey producers. One, called boneset (*Eupatorium perfoliatum*), is not boneset, *Eupatorium perfoliatum*, but is another species of *eupatorium*. Here it completely covers all closely grazed pastures, lying on wet black lands, and is an important honey-plant some seasons.

Boneset grows only in the vicinity of springs, in sandy stray spots; has but few flowers, and bees do not seem to work much on it. The stems of boneset seem to come thru the leaves like the red honeysuckle. The leaf has no petiole. For reference I refer you to Lloyd library, Cincinnati, Ohio, which I believe is the most complete collection of botanical and allied subjects in existence.

Elk City, Kan. Dr. J. T. Blank.

[Mr. Crane has called attention to this in his department.—Ed.]

Introducing Queens: Are They Known by Their Odor?

In an editorial headed "The Smoke Method of Queen Introduction Not Always Successful," in the first September number, you say "Oversmoking or undersmoking will lead to failure." I believe you are wrong. You might easily fail by not smoking enough, but not by smoking too much.

I have smoked the bees in a particularly savage colony until half of them were on the floor in a state of stupor, and the queen with them for all I knew, but she turned up laying all right. The bees were none the worse, so far as I could see.

I always use plenty of smoke. I have used this method for thirty years, with one

variation: I do not run the queen in at the entrance, but drop her among the bees at the top of the hive. Then I am sure that she is right in the thick of the bees and smoke.

I have just been thru a lot of hives that had queens given them by the smoke method, and the queens are all laying—not one failure. I think any failures you have had were caused by not giving enough smoke.

Major Shallard.

South Woodburn, N. S. W., Aus.

Carrying Hives in a Touring Car

I have used my five-passenger automobile to carry empty hives, combs, etc. I have four leather straps made with buckles, the straps of the right length to fasten two hives on each running-board.

I next remove the back-seat cushion, setting two hives crosswise on the seat. Then by removing the foot-rest I set two hives lengthwise on the floor, and then tier the four hives as high as I think best. By running a rope around them it makes quite a compact pile.

If you follow this plan and want a neat-looking load leave the back curtain and the top on the machine. If one does not have an old car on which a special body can be fitted, a new car can be used in this way for carrying quite a load. I can carry 22 to 28 hives, by using all the room except the driver's seat.

Colo, Iowa.

D. E. Lhommedieu.

Winter Protection in Virginia

It began snowing here Dec. 11, and the snow was 18 inches deep in less than fifteen hours; then it cleared up and turned warmer, but not warm enough for the bees to fly. On the 13th the wind blew hard and cold, and I noticed a few dead bees in front of one of my hives, and the next day I found more dead ones, and among them was the queen. I took the cover off, thinking all of the bees were dead, and was surprised to find a nice cluster of bees right over the entrance, and they seemed to be in a normal condition. The cluster was a good-sized one, as it covered the ends of six frames, and they had a large quantity of stores. I have been noticing a restlessness about this colony all the fall and winter. I haven't any of my bees packed, but have sacks between the double telescope cover.

Do you think it would be profitable to pack bees in winter cases in this locality? What do you think was the trouble with this one colony?

Stockton, Va.

Francis W. Gravely.

[In localities similar to this it has been customary to provide no extra packing except what could be inserted outside the combs. It is impossible to give a definite answer as to the advisability of winter cases. They might prove an economical in-

vestment one year and an expense another year if the extra labor is considered.

These bees coming out may have been old ones that could not live any way. Or the stores may have been to blame. This, however, would hardly explain the death of the queen. We are inclined to believe that the death of the queen was incidental, and not connected with the disturbance.—Ed.]

Bees Dying Off by Handfuls during Mid-winter

My dear Mr. Root:—My bees are dying off by the handfuls. Can you tell me what is the matter and what I should do? I am wintering them outdoors in single hives, but where the wind does not strike them. The hives are new, and my bees are kept dry. I left plenty of honey for them to winter on, I thought.

How do you feed bees in winter?

Clintonville, Ohio. E. W. Mendenhall.

[We can't imagine what can be the trouble unless your colonies went into winter quarters too weak. In the fall there should be at least eight or nine frames well covered with bees, and, better, the full ten frames. It is possible that last fall the queen died, and the colonies got weaker and weaker, and the cold wind that has been blowing has possibly been too much for them, and so they are dying by the handfuls. If there are no young bees in the previous fall the old bees would begin to die off very rapidly.]

It would do no good to feed them now, and the only thing we can suggest is that you take the bees as they are into your cellar, making the cellar dark. This may be the means of saving them. If you have two or three colonies that are weak unite them together after you get them into the cellar.—Ed.]

Long Cases for Wintering a Row of Hives Not Practical

Information has been requested in regard to winter packing-cases; and altho you ask from those having experience with both kinds I make bold to state my experience, altho I have used only the two long kinds. Some 35 years ago, when lumber and packing were cheap, I used to pack all my bees; but I simply could not keep house and have any more than three hives in one box. When I had four, five, or more hives side by side in one box the way the inside colonies butchered one another in the spring was simply scandalous. I even painted large blotches of different-colored paint over the entrances. This helped somewhat, but did not cure the evil entirely. I sawed all my long boxes in two, so there would be no more than three hives in a box.

I consider two hives well packed worth as much as three hives wintered in the cellar.

West de Pere, Wis.

Paul Scheuring.

[This confirms our statement made on page 921, Nov. 15th issue.—Ed.]

A. I. Root

OUR HOMES

Editor

The land was corrupted by reason of the swarm of flies.—EXODUS 8:24.

CREATION; HOW MUCH OF IT IS STILL GOING ON?

Ever since GLEANINGS was started there has been more or less speculation in regard to the honeybee. Were they originally made just as they are now, or have there been changes? Let me digress a little.

I suppose every one of our readers has been annoyed more or less by the common housefly. When you are especially busy, perhaps writing, a mischievous fly will alight on your hand or perhaps on your nose. You impatiently brush him away, but he comes right back and then you have the same thing enacted over and over again until you lose your patience and make up your mind to kill that particular fly if you can, so as to have a little peace. May be you are running an automobile, or having something to do with it. Perhaps you are stopped in the road away from home somewhere. You are obliged to pull a complicated machine apart more or less. It may be a hot day, the sweat dropping from the end of your nose as you stoop over to twist yourself into a tiresome attitude to get at a defective point. Just at the critical moment a fly gets close to your eye. With greasy fingers you try to drive it away; but it persists in coming back. It would seem that flies do this just to be contrary and because they delight in pestering anybody at a time when he especially does not want to be annoyed by a fly or anything else. We have all heard people talk about "saucy flies;" and they really do seem to enjoy bothering one when they find out they can do so. Now, may be I am uncharitable in regard to flies; but I have not got through yet. They seem to have learned just how far they can go and not get hurt. If you attempt to strike them, unless you are very quick, and circumstances are favorable, a bright frolicsome fly will laugh at your clumsy effort. How does it know, or how does it learn to escape almost any blow you can give it with your hand? It cannot have had a very long time to learn by experience. In fact, I am not sure but the fly would behave much the same way the very day it learns to use its wings. It is not human beings alone that it annoys. Every farmer knows how flies at certain times of the year pester his horses and cattle. Of course the horse and cow can brush the fly away with their bushy tail, and they can bite too; but I think the fly dodges and escapes. Now to my point:

For a few summers past, not only the city but the town and country have been waging war on flies; and the number has decreased, I think, everywhere most perceptibly. Some inventive genius, I do not know who or where, has given us the little "fly-flipper," and I have several times thanked God for it, and for the good man (or woman) who invented it. By the way, it occurs to me that something was said in the bee-journals years ago about a wire-cloth paddle instead of a wooden paddle to knock down an angry bee that keeps following one all over the premises. Can any of the veterans tell us anything about it? Over in our home (and it does not matter whether the home is in Medina or Florida) it is a rare thing to see a fly buzzing anywhere in our well-screened rooms. Mrs. Root has the credit for that, at least mostly. Well, at my table in our big office, flies trouble me so much when working on my correspondence that I have been obliged to use sticky fly-paper. This also has been a great boon to humanity. But this summer I have not used any sticky fly-paper at all. I have a very light neat fly-flipper; and now if a fly ventures to get on my hand or face or bald head, I hit it a clip. At first the fly begins his old antics of dodging and then coming back, but when I get hold of the flipper I "get him." At the first clip the fly seems greatly surprised and astonished. I think I have acquired some skill—yes, skill even in my old age, in killing flies just as they approach my table. A very little clip lays a fly out. It takes some time, I admit; but when I am busy reading letters a little exercise does me good. I have got so I can swat a fly every time, even before it gets to work at its old antics, because it does not consider that I now have a new invention to circumvent it. The dodging scheme that he has used, and acquired such skill and proficiency in using, is now knocked out, and the fly cannot understand it. Now for my point:

How many years or centuries has the fly been in learning to dodge a human hand? And while I am about it I might as well ask how many years and even centuries has it taken the *bee* to learn the trade of making the beautiful honeycomb? And will the fly eventually learn to dodge the fly-flipper as it has heretofore dodged the human hand?

Do not plants as well as insects modify their habits by what we may call ages of experience?

Bananas do not bear any seed. May be you have heard bananas never grow from seed; yet growing bananas is one of the greatest industries in the world. We are told that the banana stopped bearing seed because people kept propagating from suckers. As nobody made any use of the seed, if it ever had any seed, it stopped yielding it. In the same way we have a seedless orange, or almost seedless, and other plants have been following along. Now, will the fly learn after a little to dodge the wire-cloth weapon as it dodges a folded newspaper or a flat stick? Who can tell?*

In waging war against redbugs, mosquitoes, and infectious diseases, such as the foot-and-mouth disease, and I might go on indefinitely, it may behoove us to look into this matter a little more than we have done. In other words, did the honeybee come from the hand of the loving Creator with all its wondrous skill? or have centuries of practice, and, you may say, the "survival of the fittest," had something to do with it? And then, again, did this mischievous fly possess the same skill from the creation down to the present time, or did it *gradually* learn the trade of dodging so it might keep on annoying at a time when we wish so *vehemently* he were at the other end of the earth?

My impression is, in closing, that the great Father has for the best of reasons ordained and planned that we should turn in and *help* wherever it is possible to make things better in this busy world of ours.

"THE GREAT ARMY OF THE UNEMPLOYED."

On page 780, Sept. 15, I have some kind words to say in regard to a tramp, or at least one whom the world would call a tramp. I think now it may be well to tell another experience. A few mornings ago a tolerably well-dressed and able-bodied man came to Mrs. Root saying he wanted something to eat. She told him to go into the lumber-yard, that they would give him work and then he could buy what he needed. She did this because I had told her not to give tramps food. Well, because he said he

* How many ages or centuries does it require for the fly to acquire the skill necessary to evade the flipper? And, again, do flies and bees remember or inherit the piled-up experience of their ancestors? Do you and I, dear reader, occasionally have glimpses of things our fathers and mothers learned before we were born? Some years ago I visited Waterbury, Ct., and I found there a few old gray-headed people who could tell me where my father passed his boyhood days; and as I looked over the surroundings and tried to recall what he had told me of his boyhood, it almost seemed as if away back in the past I recalled glimpses of the landscape and surroundings; and yet it was the first time in my life that I ever visited the place.

could not very well work without something to eat she gave him a fair meal. He asked for coffee; but she told him we used postum cereal, and he said that would do all right. Instead of going to the lumber-yard, however, he went to my daughter's, next door, and asked if he could not have some *real* coffee, making complaint about the cereal coffee. Not knowing he had had a fair breakfast she gave him something more. Then he asked if he could not do some work for her. She told him he might mow the lawn; but when he asked how much pay he was to have she told him a man came around once a week and mowed it for 25 cents. He replied that *he* was not going to mow any big lawn like that for 25 cents, and then he put off. After he had bothered two busy women, and had eaten two breakfasts without charge, he was not willing to work for the regular market price. I "scolded" both of the women for encouraging and putting a premium on the whole tramp business.

Now here is something *so sensible* that I have about decided to have a lot of slips printed; and when somebody writes me a letter about "the great army of the unemployed" I will send them this clipping by way of reply. Read it, and see if it does not just about "hit the nail on the head."

CHATS WITH THE BOYS.

Not enough of him to go round.

I hired two boys. One tried to see how much he could do, and everybody wanted him. There was not enough of him to supply the demand. He was kind and helpful every way, always cheerful, and ready for any job. He is now getting \$1200 a year.

The other fellow tried to see how little he could do. If I sent him to the field to work, he would find a berry-patch and spend a good deal of time there, or loiter under the bushes and try hard to see how little he could do, and now he is hunting for jobs, and the jobs always shy at the sight of him.

I have an old friend about my own age who started out to make his way in the world along in the 50's of the last century. Money was scarce, and work was hard to find, but A. J. gathered himself together and started out. Now, there is a good deal of a boy when he gathers all in and takes the whole of himself along. Healthy, strong, willing, cheerful, honest, with plenty of gumption and common sense, he makes quite a combination, and he is bound to win. A boy mourns because he has no money when nine-tenths of his capital is vested in *himself*.

Well, A. J. started out. He had \$5 which he had earned by the hardest work. He heard of a job which he could have in about ten days. But if he went to the hotel his \$5 would not last long, so he struck out for the country. He approached a good-looking farmhouse and asked if he could stay over Sunday. "No, sir, this ain't a hotel and we don't keep tramps."

"But I can pay for my board."

"Well, go in and see wife."

He went in and saw a poor over-worked woman and asked if he could stay over Sunday.

"Why, yes, I will try."

The woman had her hands full, and a squalling,

dirty-faced laly was very much in evidence. Having a little candy in his pocket, he picked up the little fellow and quieted him, and soon was on the best of terms with him. The mother started out to get some wood.

"Oh! let me go," he said; and he brought in two good armfuls. When milking-time came she took two pails out to milk.

"Here," said he, "let me have one. I am a good miller."

And so he was on the alert to help all he could. Monday came, and there was corn to hoe, and work in the garden along with the chores, and with outdoor work and helping the overworked woman, he made himself useful all the while.

When the next Monday morning came he asked the man, "How much do I owe you?" and the man pulled out a \$2.50 goldpiece and said, "I owe you so much, and would like to hire you for a year.—*Independent Farmer.*"

POULTRY DEPARTMENT

MY CHRISTMAS PRESENT.

Of all the Christmas presents I have received in over 70 years I do not recall any that gave me more real pleasure than the one I am going to tell you about. It came so entirely unsuspected, it was really one of my "happy surprises." No one of my many friends sent it, for, in fact, not a soul on earth knew anything about it or had a finger in the work of getting it up until it was presented to my astonished gaze when I was all alone out in the Florida woods. I did not even know that long days and weeks were at work getting it up for my especial joy and delight until the finished and complete creation was handed over to me—shall I not say direct from the hand of the kind and loving heavenly Father?

I have already mentioned a Rhode Island Red hen, blind in one eye, that laid right along a year ago thru November, December, and January, when the Leghorns and Buttereups were moulting and when eggs were 50 cts. or more. Well, I set quite a few of her eggs, and therefore found a dozen or more young pullets, pictures of their mother, when I reached here in November. Sure enough, like the mother they have been almost all laying clear up to Christmas, and, like the mother also, not one wanted to sit until December 14 (altho I was very anxious for some chicks to study and care for as soon as possible) and another on the 23d.

One morning I caught a glimpse of a soft fluffy red hen (or yellow, rather), rushing about for corn and water, with her feathers ruffled up and clucking; but supposing it was the sitting hen of the 14th I thought little about it until I found said sitting hen on her nest with no indication of having been off that morning. Once, later, I got a glimpse of her; but she was off in the woods before I could keep her in sight. I said to Wesley, "We must hunt that hen, for she might have more eggs than she could cover."

We both spent quite a little time, but had to give it up, and I concluded she was

only "making believe" she was "broody," as pullets sometimes do.

Well, on Monday morning, Dec. 27, I went out in the woods alone, thinking I might catch her coming off to feed, and I *did* catch her; but imagine my astonishment when I saw around her a perfect "swarm" of fluffy downy yellow chicks. The morning sunshine came thru the evergreen-trees and shrubbery, and there she stood, a proud and stately mother with her inquisitive brood scattered around her. I tried to count them, but they rushed about in the sunshine at such a rate that I was really unable to decide whether there were 16 or 17; and, to tell the truth, as I write we haven't decided even yet. I made 17 several times; but Mrs. Root declares that her accurate "auditing" shows only 16. Wesley and I finally located the nest and found three infertile eggs, so she must have laid 20 eggs (or 19?) before deciding to sit. From the activity and looks of the chicks she must have hatched them on Christmas day, and neither she nor the chicks had had anything to eat except what she scratched up in the woods for the lot, until the third day. They are now on a "bread-and-milk" diet, located right near our bedroom window, and we are going to try hard to keep the "happy family" entire.

By the way, there are quite a few "chicken men" (and women), as I happen to know, who read GLEANINGS. Well, may we not thank God that there is a place in the United States where (when we are getting old) we can go and see a hen steal her nest, sit on twenty eggs, and hatch 17 (or even 16) at *Christmas time*?

POULTRY-KEEPING IN FLORIDA.

The letter below explains itself:

Mr. Root.—We (our party) take the liberty of enclosing some questions touching the poultry business in Florida. Some of us expect to go down soon. We know that you are well conversant with the situation and that you are a Christian, and

hence give us, as far as you know, some reliable advice.

J. H. PARKER.

Magnetic Springs, O., Nov. 16.

Is there a demand for crate-fed poultry in Florida?

There is usually a very good demand, especially during Thanksgiving time and the holidays. My neighbor, Mr. Abbott, told me of selling fat *old hens* for over a dollar each, and they were not "crate-fattened" either. I think he delivered them at the large hotels.

What variety of poultry seems best adapted to Florida? Our idea is more particularly for egg production.

As you know, all the great egg-farms use Leghorns, both north and south; but I think a change is coming. Some time ago I got a few Rhode Island Reds so as to have some hens that would sit. Well, when the Leghorns did not lay at all, say in November and December, I had one blind "red hen" that laid, without wanting to sit, all through November, December, and January. I have now quite a few of her chicks, and they are giving me fifty-cent eggs, just like the mother.

Take a laying hen, put her in Florida, then take her to Medina, O., at which place will it cost more to keep her?

If you shut her up in both places it will cost more in Florida on account of the higher price of grain. If, however, you give her the run of the woods, as I do, it would take *less* grain here in Florida, for in Ohio she could not find feed in the woods in winter as she does here.

What do you think of a White Indian Runner duck-farm for Florida?

I am sorry to tell you that Florida people care little for ducks or duck eggs. When hens' eggs are forty or fifty cents, duck eggs sell very well at a little less: but in the spring no one seems to want them. Duck eggs are larger, and ducks lay right through moulting time, and I like them just as well as hens' eggs, especially when the ducks are *grain fed*. But people *will* have their notions.

Is there any good reliable poultry concern on the west coast of Florida from which one could buy reliable stock?

The best I can do is to submit the two advertisements below, which I clip from the *Florida Grower*, published at Tampa:

Single-comb White Leghorn and Rhode Island Red yearling hens, pullets, and cockerels, at \$1 each. Jersey Stock Farm, Trilby, Fla.

Single-comb White Leghorns. Pure bred, and mated for highest egg production. A year's test; the trap-nest the judge; then the best, then matings. Matings with records up to 245. Day-old chicks and eggs for hatching. None better. Wm. B. Moore & Son, Olga, Fla.

I know nothing of the parties above. You might also write Crenshaw brothers, at

Tampa, who deal in poultry-supplies considerably.

Do you consider Florida a good place to start a poultry-farm? and would you advise around and about Bradentown for the same?

Around Bradentown is a very good place while eggs are worth 50 cts. a dozen, as they are now, December; but last April they were down to 15 cts. for a short time, and not wanted at even that price. As yet, there is little or no "cold storage" for eggs (if I am correct) in any part of Florida.

What are the best things to grow for feed stuff for one's poultry in Florida, assuming that one has six or seven acres?

Dasheen, cassava, turnips, radishes, cabbage, lettuce, oats, and rye, to be fed green, and no end of other things. See back numbers of our journal.

What is a good thing to go with poultry in Florida?

I would grow potatoes, at least so long as you can swap a bushel of potatoes for a 100-lb. sack of corn. Raising green stuff for the fowls saves grain, and helps the egg yield.

Do you think that there is more profit in the raising of poultry in Florida than in Ohio?

That is hard to answer. If you feed grain, it always costs more in Florida than in Ohio; but a great part of the year *eggs* bring more here than in Ohio. Again, as I have already said, there is a big saving down here in the way of buildings, brooders, etc. Altho others down here may differ, I would and do raise chickens without any lamp-heated brooders.

In starting an egg-farm would you buy in Florida or in the North? By this we mean the stock to start with.

I would buy here to save expensive transportation unless it would be a few choice fowls and eggs so as to work into a good strain.

Is it possible to keep down the lice, insects, etc., in Florida?

This is easily done. If the roosts, nests, etc., are sprayed a few times a year, and the droppings are swept up daily, and carried away, we rarely find a trace of poultry insects, or parasites of any kind.

Is there any particular kind of house that you advise for poultry in Florida? We allude more particularly to a laying-house—an expensive house to start with. We aim to keep 500 laying hens later on, or part ducks—that is, Indian Runners and part hens, such as may seem best.

In southern Florida I would almost say, "The *less* house, the better;" in fact, I was at first quite successful with all of my poultry roosting in trees. There were some objections, however. Big owls sometimes take grown fowls out of the trees; and when you want them it *may* take a very

long ladder to get them. Besides, when we do have a bad storm, the chickens seem to prefer a shelter. Our five houses now have a good roof of shingles or roofing-paper; but the walls are mostly only poultry-netting, and even then the poultry prefer the trees during very warm weather. A lot of money is worse than wasted all over Florida in tight houses.

Do you advise the yard or colony plan for Florida?

If you want eggs, give them as big a run as you can. Our Ohio experiment station has just put out a leaflet showing not only more eggs but a considerable saving in feed by giving a wide range. Down here a piece of wild land seems to suit the chickens. We give an average of 100 fowls a run of three acres of trees, bushes, or weeds.

HIGH-PRESSURE GARDENING

APPLE-GROWING IN THE GREAT NORTHWEST,
WITH SOME KIND WORDS SPRINKLED IN
HERE AND THERE.

Our good friend Peter Henderson made quite a sensation years ago by writing a book called "Gardening for Profit." Later on he gave us another book called "Gardening for Pleasure." The two books have had a great run, and are selling yet to a considerable extent. The good brother who sends us the article below recommends "gardening" with a *four-horse team* and an appropriate cultivator, and he rather makes light of "gardening with a hoe." When he gets to be seventy or eighty years old he may have more respect for the humble occupation of gardening with a hoe.

BREWSTER FLAT, THE ONLY SPOT IN WASHINGTON
WHERE WE TAKE SWEEPSTAKE PRIZES ON APPLES.

Dear Mr. Root:—Another year has rolled around, and it still finds us on good mother Earth, and still living in the land of plenty and peace, the United States of America. You, undoubtedly, would thank God for this peace blessing, while I would thank also our President for his kind but forcible answers that "turn away wrath."

We are a long distance from each other—you in the South, where it must be warm, while I am in the great Northwest where it ought to be cold, and is cold. This morning it was two below zero, with about a foot of snow. In the mountains, eight miles away, it was ten below. This at this time is not much difference; but later it is generally twenty to thirty degrees colder in the mountains than here.

This is certainly an apple country, and the only pest we have to bother us is the ticks. If they once get on us, and begin to set in their prongs, they stay; and if pulled off they leave these prongs in the flesh, making a spot that itches awfully. But when we begin to feel one starting in on us a little turpentine, kerosene, or grease rubbed on the spot will kill the tick; and when dead it will let loose. They get on the horses; and if let alone until they develop they become as large as half an inch in diameter, filled with blood that they suck from the body. I understand that California has us beat "forty ways" in the abundance of ticks.

Over on the other side of the mountains, at Seattle and on, it seldom freezes, so by going some 70 or 80 miles west we must have nearly as warm and pleasant weather as you do in Florida. Here we have abundance of snow in winter, and rather dry in July and August; but at other times we have rain enough to grow an abundance of crops.

The great cry here is for irrigation-ditches, and we have them too. Millions of money are spent to

get water on to the land, and, of course, it is fine to be able to water when needed. But the land and crops are abused by use of *too much* water. This is because of people not using good judgment in irrigating. The overhead system is going to be the popular one, because then all parts of the land get the same quantity of water, and the land does not have to be leveled.

I noticed a letter in GLEANINGS some time ago from a Socialist. I thought he was very ungentlemanly and was lacking the gentle spirit now characteristic of the greatest nation on earth. Covetousness is the desire of the ignorant and indolent. The men who want nothing but what they earn are the very bone and sinew of this nation. They see opportunities on every hand, and simply say to themselves, "We do not want our neighbors' house or wealth, but are able to go out and earn a house or wealth just like my neighbor's or better." This principle shows equality, and a generosity that is progressive. But the man who advocates division of wealth and its comforts does not understand the true principles of manhood, and is drifting into the parasite stage; and if we all would drift along that line we should become more helpless than our next best associates, the animals. The true American type of man will never call for a division of wealth, but will assert himself and take another spot on the broad acres of the United States, and there dig out a comfortable fortune too. The true American type of manhood would scorn a division of wealth as an insult. But the man who would take a division of a neighbor's goods would set an example that, if all indulged in, would make us a beggar nation.

You, Mr. Root, are setting one of the best examples of industry. You at the age of 75 are doing more good hard work than all the great army of hoboes in this nation. You dig in the garden, supplying not only yourself with luscious fruit, but hand them around to the neighbors. You *keep busy*. You find plenty of work, and you always will as long as you live. Industry is the making of this nation. Let every hobo, those that would call for a division of wealth, look to you in your industry and be inspired both of God and for the good of humanity. With the example you are setting, if followed out by every one in our land of plenty, not one person in this peaceful nation of ours would be in want. They would all be in comfortable homes, and plenty to eat and to wear. They would all be law-abiding citizens, and not be in the way of others. The man that would suggest a division of such industry should begin to think how they could most humbly apologize.

The few members of our human family are not great because of their religion or wealth, but because of good and wise deeds done for humanity.

To keep well depends on how we treat ourselves. We are really our own doctor. Eating the right kind of food and the right quantity with variations will keep us well all the time. Working or playing

must be indulged in for exercise, but must be indulged in only to correspond with our physical strength. Many a man has shortened his life by overdoing.

It "makes me tired" to hear you speak of that hoe. I never could do anything with a hoe; but when it came to cultivating crops with horses, I was and am strictly "on the job." I am inclosing you a cut of my four-horse apple-orchard cultivator that will do more work than a thousand men with hoes day after day. I have orchards of my own, and do lots of contracting to grow orchards for non-residents. This year I handled alone 195 acres. We cultivate these orchards ten times in five months. This would make 1950 acres to cultivate once over, or at the rate of 17 acres per day for 130 days in the 5 months. As my capacity is 20 to 25 acres per day, you can readily see that I would have some spare time to rest besides the rest on Sundays. Not only cultivating the ground, but I must drive within one to three inches of the trees every time I pass a tree, and not bark it. There are about 100 trees per acre. Here are four horses trained so perfectly that it is possible to do just such close work. I can take a weed out from close to a tree with this monster cultivator as easily as you can with your "little hoe." With cultivators made for the purpose, corn, potatoes, and all garden stuff, if planted in rows the right distance apart, can be cultivated more perfectly than even you, Mr. Root, could possibly do it with the hoe. Not only better work is done, but a thousand times as much more work is done, with a larger crop. Not one bit of hand hoeing for me. Give me the grand noble horses hitched to a good cultivator, and it is simply play to raise any kind of crop on good soil. My horses are so trained that I could send them over the field without me to drive them, occasionally, and the work would be done just the same. But soon they would miss the tension on the lines, and become lost. These horses are a part of myself to a certain extent. They come at my call, and call me when they want water and feed. When turned out in the pasture for a day or so, and they do not see me, when I go after them they are as tickled to see me as a dog is his master. This cultivator cuts as wide as ten to twelve feet, and requires four-horse power. I am doing two men's work.

Brewster, Wash., Dec. 14. V. W. CLOUGH.

TILE DRAINS, AND TILE MADE OF CEMENT IN PLACE OF CLAY

In the closing chapter of our book on tile drainage I made mention of the bad results down in Florida that came from home-made tiles made of cement and sand. This question has come up several times, and I have been told that well-made cement tiles answer all purposes, and stand all kinds of weather here in the North. However, I am just in receipt of a bulletin the heading of which reads as follows:

DURABILITY OF CEMENT DRAIN TILE IN ALKALI SOILS.

The closing remarks of this bulletin are as follows:

Drain tile manufactured in a manner as described for cement mixtures not leaner than one part cement to three parts of aggregate are apparently unaffected structurally when exposed for one year in operating drains in very concentrated alkali soils, similar to any of those included in the investigation.

Drain tile made from cement mixtures leaner than 1 part cement to 3 parts of aggregate should

not be used in localities where the character of the alkali and concentration is similar to that found at the site of the experimental drains at Grand Junction, Colo., Montrose, Colo., and Garland, Wyo.

Drain tile manufactured in the manner described of 1 part cement to 4 parts of aggregate, the leanest mixture used, is apparently unaffected structurally by exposure for one year in an operating drain in concentrated alkali soils similar to those found at Fort Shaw, Mont.; Sunnyside, Washington; Yuma, Arizona, and Roswell, N. M.

Other than the above, no very general conclusions should be drawn from this investigation until the results of further tests are obtained. It is anticipated that this report will be amended from time to time as the results are obtainable.

The department would be pleased to receive information concerning the behavior of the concrete exposed to concentrated alkali soil which may come to the attention of engineers or others interested in the use of concrete under these conditions.

Washington, D. C., July 12, 1915.

You will notice that in the above no mention is made of Florida soils; and so far as I am aware we have no alkali there to trouble us; but for some unknown reason all the cement tiles in our neighborhood, in Manatee County, have dissolved or rotted out sooner or later. Mine were mostly gone inside of a year. But I think that Mr. Rood's, or at least the most of them, did fairly good service for two or three years; and it is very likely that neither his tiles nor mine were made as strong in cement as mentioned.

"EFFICIENCY" (AND ECONOMY) THE "SLO- GAN."

We clip the following most sensible suggestions from *The Friend*, published away off in Honolulu:

WAR AND FOOD.

Reports from Germany tell the news that, because of the cutting of supplies from abroad, the nation's men of science have been compelled to give attention to the food problem in a way never before demanded. In consequence, new sources of food and the entire question of the amount and character of sustenance are being gone into with German thoroughness made all the more effective by the very pressing demands of the hunger situation. Out of this will come information of exceeding value to the world. In every wide-awake nation today there are numbers of people who are revising their habits of eating and drinking. Stimulants are being thrown to the bats and moles; tobacco and other narcotics are being discarded; meat consumption is being radically curtailed, and a regimen in accord with the demands of health and highest efficiency is eagerly sought. One of the greatest blessings which the war will confer, therefore, will come to these enthusiasts for being at one's best from Germany after the exhaustive study and experimentation now being conducted shall have crystallized into scientific knowledge. All who believe that extravagance in eating and drinking are marks of the beast in human nature, and directly prevent one's highest development, will hail these results with enthusiasm. Economy in food is the great demand of our day and nation, and it is good to think that this war, if it had to come, will help men to live more healthfully as well as more brotherly.

HEALTH NOTES

PHYSICAL CULTURE—SOMETHING IN FAVOR OF IT, EVEN FOR FARMERS.

In your potato book you say a few things to the effect that physical culture is unnecessary with farm work. I worked on a farm from the age of 12 to 16 (am still there), and at that time I could not do things that others stronger than I could. I took up physical culture, and in one or two years I was their equal, and in a few things stronger.

JOHN H. ROSSEK.

Tambourine, Queensland, Aus.

My good friend, I think that what you allude to is where I spoke of lifting a bushel of potatoes to pour them into a sack that was hung on a wheelbarrow, etc. That kind of exercise seemed to bring almost every muscle of my body into play more or less; and by the time I had sacked several hundred bushels in that way I had gained in weight, and you may be sure I gained in appetite. At the present time I find it a benefit to go through a part of my physical-culture exercises every morning just before taking my bath. As soon as I am out of bed I swing my arms until I am warmed up enough so I do not mind taking a bath in moderately cool water.

WOMEN DOCTORS FOR WOMEN.

Mr. Root:—You say on p. 519, July 1, 1914, "No doctor is qualified to treat husbands and wives until he is a married man himself. . . Perhaps I had better modify it by saying that any doctor 25 years old should be married, and should have some children. . . . I would suggest that his wife go with him, especially when he has women patients." To all of which I devoutly say *amen!* But why not go one better, and advocate women doctors for women? Do you know that, in my opinion, men doctors for women is one of the most disgusting things we could have, and one of the most debasing things for the women. Do you know that women being treated (and young girls too) at our public hospitals are exposed to the gaze of a body of *male students*? Could you imagine any treatment which would destroy her natural modesty quicker? I have even heard (and I have no reason to doubt it) that at one hospital in Sydney women are confined on a warm slab in the presence of a large class of students. Can you imagine the feelings of these poor creatures at the time of their greatest tribulation being subjected to this treatment? I am told that this is unavoidable, as the students must learn; but in my humble opinion they need not be male students.

Then, again, the percentage of bad immoral men in the medical profession is just as great as in any other walk of life; and the amount of harm done in family life is very great. Why run the risk of this at all when women doctors can do the work just as well? If you helped the cause of the women doctors it would help very materially to further this very necessary reform.

MAJOR SHALLARD.

Many thanks, my good friend, for your very excellent and kind suggestion. It is probably true—at least at the present time

—that our most able and efficient physicians are men; but there is no reason, as I see it, why a woman doctor, when she has charge of a critical case, should not call in an able male physician to consult with. Your suggestion (and how true it is!) that our doctors should be the most moral men—next to the clergy, in fact—reminds me there are quite a few who do not hesitate to use their position as a means to commit foul crime. During my short life I have known one or two cases where the family physician broke up a family; and I have come in touch, also, with doctors who gave the vilest counsel and advice to young men and boys, that one can well imagine. As an illustration, the family physician, one whose office is to lead the way to health, is too often a user of both alcoholic stimulants and tobacco. The papers of late have been declaring most vehemently that no drunken man, or, for that matter, *drinking* man, should presume to run an automobile. But what is an automobile compared with the human form? Think of a surgeon, with his keen lance, *taking* a drink before he undertakes an operation!

COUGH MEDICINES—A CAUTION.

When we gave a list of recipes for cough medicines made of honey in our issue for Oct. 1, the recipes were first submitted to a competent physician. He replied that there was nothing in them that would probably do any harm, but did not commit himself any further. I now notice that one recipe calls for lobelia. When I first began to go to school I was troubled every winter more or less with severe coughing-spells. They not only disturbed me, but sometimes they threatened to disturb the whole school. I think our family physician told my mother to give me at such times a little lobelia tea, sweetening it enough to be pleasant to take. When the cough was on I would take just enough lobelia to make me begin to feel a little sick at my stomach. The cough then would let up. Later on I carried lobelia pods in my pocket and would chew a small fragment when the cough began to trouble me. Below are some valuable suggestions, and a caution in the use of the much advertised "cough lozenges."

MEDICINE TO ASSIST PUBLIC SPEAKING.

The honey-in-cooking number had under Health Notes a pretty strong article against patent medicines; but in its list of recipes there were eight or nine for cough medicines. It looks as if the idea was that cough medicine is a sort of medicine that

does no harm. That isn't true. My father was a clergyman. Hoarseness used to interfere sometimes with his voice in the pulpit. He took cough lozenges to clear his throat, and he carried them into the pulpit. After years, when he was beginning to be dissatisfied with the working of the lozenges, a man sent him circulars and samples of a other kind that delighted my father by their efficiency. He bought them by the big box, and had them for a family medicine. At length his voice got so that he could not depend on it even with that help, and he felt it necessary to consult a doctor in the matter. The doctor told him that he had been ruining his throat with cough lozenges—first the milder sort, till those got him into a condition where they no longer took effect, then the stronger until they had about finished the job. His only chance, the doctor said, was to give up lozenges of any sort. By following that advice father's throat got back strength enough so that he went a few years more, and rounded out a good length of service; but when he did break down it was his throat that went first. *Moral*.—What is true of medicines in general is true of cough medicines.

I do not mean to decry the legitimate use of medicine. In many diseases there is some symptom which interferes with nature's work of curing the disease, so that if you knock out the symptom with a drug it leaves nature a better chance to work; and a cough is very apt to be such a symptom. Also there are cases where nature's curing is not enough without some help; for example, the lockjaw microbe cannot live long in a man's body. It always dies before the man does, so that in a sense the germ-killing power of the human blood has successfully cured the disease; but the microbe leaves in the blood so much of a strychnine-like poison that the man dies of that; so he has little chance of life unless you can either give him a dose that will kill the microbe quicker than the blood kills it, or else give him an antidote for that poison. So drugs have their proper use, though the best doctors are apt to be those who trust most to the self-curing power of the body. But I doubt if there is any exception to the rule that it is dangerous to make *habitual* use of any medicine, great or small, without the more or less continuous oversight of a competent doctor.

As to those recipes for cough medicines, I should think it safe to guess that the ones which contained least of medicinal ingredients would do least harm. Chambers' Encyclopedia gives a list of two or three dozen cures for cold that are used by different people, and then says, "There is no doubt that colds do get well under all these treatments;" but it thinks most of those colds would have got well quite as well without the treatment.

Some folks, sad to say, are so in the habit of dosing that they feel more as if they were going to get well if they are "taking something;" so it does them good to give them something that has a reputation but has no medicinal qualities, such as sarsaparilla or ginseng. Honey with something to make it taste bitter ought to be good for such. As to any possible medicinal effect of the honey itself, a medicinal quality that is not strong enough to keep the article from being wholesome as daily food is not strong enough to worry over.

The case is different with antiseptics to hasten the cure of external sores, wounds, etc. Such can do no harm to the constitution unless very badly misused. Honey ought to be an efficient mild antiseptic under any circumstances where it would not get diluted by watery discharges; but such circumstances would be comparatively rare, so without doubt the propolis salve that was recommended a few months ago would do better service in general.

STEVEN T. BYINGTON.

Ballard Vale, Mass., Oct. 14.

The suggestion in the above, that even if a drug *does* effect a cure for that particular trouble, there is much danger that it may do harm somewhere else in the system, resulting in proving the truth of the old adage that the remedy may be worse than the disease. And I heartily indorse the sentiment about the habitual use of *any* medicine being dangerous; and I am glad to see the statement that "sarsaparilla" and "ginseng" really have no medicinal qualities, and I think the list might be greatly extended.

OVEREATING, ESPECIALLY FOR ELDERLY PEOPLE.

We clip the following from the *Scientific American*:

In conclusion let me warn you of the dangers of overeating. Most of us eat too much. We would do well to follow the advice of the great English physician, George Cheyne: "Every wise man, after fifty, ought to begin to lessen at least the quantity of his aliment; and if he would continue free of great and dangerous distempers, and preserve his senses and faculties clear to the last, he ought every seven years to go on abating gradually and sensibly, and at last descend out of life as he ascended into it, even into the child's diet." In short, why do men over forty break down? Indulging their appetites!

Amen to the above. Especially let me put additional emphasis on the fact that as we grow older, and begin gradually to let up on both physical and mental work, we should let up on our eating—especially on eating solid and substantial food toward the close of the day; and as we go down to our second childhood let us by all means adopt the author's idea.

Just a word in regard to the matter of sleep. The first days and even months of childhood are largely devoted to sleep; but as we get older there seems to be less need of it. Now, when our faculties begin to be impaired by age my experience is that we need sleep oftener. Occasionally I do some work in the garden, or possibly somewhere else, by which I get pretty well tired out. At such times I can neither work nor even read intelligently. But a twenty-minute rest and good sound sleep gives me all the vigor and strength of both body and mind that I have in the early morning. In this way we cannot only take care of ourselves, but lend a helping hand to the good people around us, not only when we are up to eighty but even ninety.

In recommending sleep, please do not get the notion that I advise anybody of any age to mope around lazily. Sleep only when you are tired out and fatigued by some sort of work.

Engine Power costs less -NOW

By using 1916 Model WITTE ENGINES

Gasoline, Kerosene Gas, Distillate.

Buy Direct; Cash or Easy Terms

Stationary engines, 2, 3, 4, 6, 8, 12, 16 and 22 H.P., less than \$17.50 per horse-power. 6 H.P. only \$37.75, F. O. B. Factory. Portable engines and Saw-Rig outfits proportionally low. Proven highest quality for 23 years. Before you arrange to try any engine, at any price, read my free book, "How to Judge Engines." Paint Without Oil

Remarkable Discovery That Cuts
Down the Cost of Paint Seventy-
Five Per Cent

A Free Trial Package is Mailed to Everyone
Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powdripaint. It comes in the form of a dry powder and all that is required is cold water to make a paint weather proof, fire proof, and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 11 North Street, Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

QUEENS OF QUALITY

The editor of *The Beekeepers' Review* and his sons have 1100 colonies of bees worked for extracted honey. With all those bees working with equal advantage, all having the same care and attention, they have an opportunity unexcelled to ascertain without a reasonable doubt colonies desirable as breeders from a honey-producer's standpoint. Likely, never in the history of beekeeping was there a better opportunity to test out the honey-getting strain of bees than this. Think of it, 1100 colonies with equal show, and a dozen of those colonies storing 250 to 275 pounds of surplus honey, this last poor season (with us), while the average of the entire 1100 being not more than 40 pounds per colony. We have sent two of our best breeding queens (their colonies producing 275 pounds surplus each, during the season of 1915) to John M. Davis, and two to Ben C. Davis, both of Spring Hill, Tenn., and they will breed queens for the *Review* during the season of 1916 from those four superior honey-gathering breeding queens. Those young queens will be mated with their thoroughbred drones. Our stock is of the three-banded strain of Italians; also that of John M. Davis; while Ben C. Davis breeds that disease-resisting strain of goldens that is becoming so popular.

By this time you are likely thinking that your strain of bees may be improved some by the addition of this superior strain of *Review* queens, and how you can secure one or more of those superior honey-gathering queens as a breeder. We will tell you. They will be sold to none except *Review* subscribers. If you are a paid-in-advance subscriber to the *Review* for 1916, we will mail you one of the daughters of those famous queens in June for a dollar. If not a subscriber to the *Review* for 1916, send \$1.75 for a year's subscription to the *Review*, and one of those famous queens. Those queens are well worth two dollars each compared to the price usually charged for ordinary queens, but we are not trying to make money out of this proposition, only we are anxious to have every subscriber of GLEANINGS a subscriber to the *Review*, and we are taking this way to accomplish the object. A few of the very first orders for queens that we receive can be mailed in May, but the majority will not be mailed until June. Orders filled in rotation. Have your order booked early and avoid disappointment. Address with remittance

THE BEEKEEPERS' REVIEW, Northstar, Michigan.

ON THE BOOKSHELF

The Rockefeller Foundation

We have just received the Annual Report of this society for 1914. It has 214 pages, and is probably the most remarkable report of the kind ever issued, especially as the association is the carrying-out of the plans of one man, and that, too, on a scale so stupendous that perhaps no government on earth would dare attempt it.

In all the large continents of the globe are to be found vast areas where the inhabitants are nearly all afflicted with some endemic malady, which, although not immediately fatal, still renders the subject of attack a pitiable wreck, transmitting the trouble to others. One of the most notable cases of this kind is known as the hookworm disease of the South. It is an intestinal trouble caused by the presence of the hookworm, which causes an enormous swelling of the abdomen, and general prostration. It is caused by the lack of proper sewerage, and going barefoot in the infected soil. The report says:

"The Commission has found more than two million people in the Southern States to be infected with the disease, involving vast suffering, partial arrest of physical, mental, and normal growth, great loss of life, and noticeable decrease in economic efficiency over vast regions."

The report adds that over half a million persons have been treated, and that a diagnosis of the disease can be made with ease and certainty, and that it can be readily cured and easily prevented.

The association in question, for the support of which Mr. John D. Rockefeller has alone contributed the enormous sum of one hundred million dollars, now proposes to grapple these various diseases in all quarters of the globe in the same way our government took hold of the yellow fever in Cuba and a multitude of epidemic diseases in the Canal Zone, and virtually wiped out the last vestige of them.

The results accomplished almost stagger belief; and as these evils are the immediate result of appalling filth, it is likely that, with an increasing degree of intelligence in those benighted districts, especially in Egypt and India, and a dying-out of religious customs which tend so directly to the spread of these loathsome diseases, the duration of human life will soon be doubled in length and trebled in sweetness.

The Rockefeller Foundation, while working on independent lines (for it is independent) yet seems to affiliate readily with all governmental efforts along parallel lines.

We of this country need not repress a patriotic pride in seeing our men of capital and technical skill sending out the X-ray of hope and comfort to the millions of afflicted ones in all climes, and literally trying to "lift up the fallen," against whom the bars of hope have so long been fastened. And with this increase in bodily vigor we may be sure a higher mental and spiritual mode of life will be sought for and found in all nations.

We see no price attached to the book in question; but it can probably be had for a nominal sum by sending to The Rockefeller Foundation, 61 Broadway, New York.

You can have your beeswax made into *best quality* foundation; also the wax from old combs or slumgum. We get it all out. On shares or very cheap for cash. New factory. Old liberal terms. Cheapest and handiest transportation for all Northern beekeepers. You always get your own wax back.
J. J. ANGUS, 434 Fulton St., Grand Haven, Mich.

Convention Notices

MASSACHUSETTS CONVENTION.

The annual Massachusetts convention of beekeepers for 1916 will be held at Amherst, Mass., March 14 to 16, inclusive. This will form the conclusion of the winter school of beekeeping, but the program of the convention is not fully planned. A number of prominent authorities will appear upon the program.

MONTANA MEETING.

The Montana State Beekeepers' Association will hold its annual convention in Billings, Mont., Jan. 20, 21, 22, in the basement of the Parnly Billings Library. All meetings will begin promptly at 9 A. M. and 2 P. M. respectively. An interesting and instructive program will be carried out. All beekeepers of the state, whether members of the association or not, are invited to attend the convention and take part in the discussion and the question-box. One session will be held in conjunction with the Montana State Horticulturists' Association, which meets in the city at the same time, at which topics of mutual interest will be discussed. Rates of fare will apply if a railway receipt or certificate is asked for when purchasing a single-fare ticket from your local agent and presenting it to the association secretary upon your arrival at the convention.
PERCY F. KOLB, Sec.

Billings, Mont., Dec. 16.

FREE ONTARIO SHORT COURSE IN BEEKEEPING.

The sixth annual short course in apiculture of the Ontario Agricultural College will be given at Guelph, Ont., January 11 to 22, 1916. It is the purpose of this course to give the underlying principles of bee nature, a knowledge of which is essential to successful bee management. The course is valuable to beekeepers of all degrees of practical experience. It is absolutely free, the only condition being that students reach the college in time for registration at the president's office, Monday, Jan. 10, and attend lectures regularly thereafter. Railroads give reduced rates of fare to persons traveling to take the course.

The instruction will consist of lectures by Morley Pettit, Provincial Apiarist; F. E. Millen, lecturer in apiculture in Michigan Agricultural College, and other authorities. These will be illustrated by lantern slides, and in many cases by the actual objects under discussion.

The Agricultural College will gladly send further information to persons thinking of taking the work.

ADVANCE PROGRAM OF NATIONAL BEEKEEPERS' ASSOCIATION CONVENTION TO BE HELD IN CHICAGO, FEBRUARY 22—24.

PAPERS AND ADDRESSES PROMISED.

- Use and misuse of prime swarms, Grant Anderson, San Benito, Tex.
- Advertising and selling ripe honey, R. M. Spencer, Ventura, Cal.
- Beekeeping in Utah, M. A. Gill, Hyrum, Utah.
- Teaching value of honey in our public schools, Geo. W. Williams, Redkey, Ind.
- Insuring honest values to queen buyers, Kenneth Hawkins, Plainfield, Ill.
- Extending the use of honey in cooking, E. H. Bruner, Chicago, Ill.
- Possibilities and limitations of inspection, Frank C. Pellett, Atlantic, Iowa.
- Establishing a trade name, E. R. Root, Medina, O.
- Some beekeepers of Canada and their apiaries (with stereopticon slides), Morley Pettit, Guelph, Ontario.

- Importance of bees in pollinating economic plants, L. H. Pammel, Ames, Iowa.
- Out-Apiaries, C. F. Dadant, Hamilton, Ill.
- The depressed honey market, J. E. Pleasants, Orange, Cal.
- Beekeeping improvement thru agricultural school-work, Francis Jager, St. Paul, Minn.
- Papers (subjects later)—Grover Matthews, Finn, Ida.; J. H. Stoneman, Blackfoot, Ida.; D. C. Polhemus, Lamar, Col.

IDAHO-OREGON PRODUCERS ELECT.

The annual stockholders' meeting of the Idaho-Oregon Honey Producers' Association was held at Ontario, Oregon, December 7 and 8, and the following officers elected:

- C. E. Dibble, president; J. M. Stark, vice-president; P. S. Farrell, secretary-treasurer.
- The following were elected Directors for the coming year: C. E. Dibble, Payette district; J. M. Stark, Middleton district; C. W. Nelson, Yale district; P. R. Randall, Nampa district; H. M. West, Parma district; J. F. Weaver, Ontario district; Homer Cheney, New Plymouth district.

One member in each district was appointed to take up the use of honey in cooking with his local domestic-science teacher, and a committee will be appointed to take up the same subject at our next school convention.
P. S. FARRELL, Sec.

TRADE NOTES

CATALOG FOR 1916.

We have completed printing the first run of our 1916 catalog, and will mail a copy to any one on request. It will be several weeks before we reach all the names on our list, so that, if you would like to get one before we reach you in the regular list, send a request on a postal, and it will be promptly mailed.

BEESWAX MARKET.

While there has been no noticeable change in the beeswax market of late, we will from this date, till further notice, pay 28 cents cash, 30 in trade, delivered at Medina, for good average wax. Price paid at our California branches will be 2 cents a pound less.

SWEET-CLOVER SEED.

Those having a surplus stock of white-sweet-clover seed, hulled or unhulled, which they desire to sell are asked to submit a sample, stating quantity, and the price asked. While there has been a good crop of seed, a great deal is still in the hands of producers because the market price has been much lower than for several years past.

SECOND-HAND FOUNDATION MILLS.

We have to offer the following list of foundation machines which have been used but are in fair condition. In many cases they will answer as well as a new machine where you have only a moderate output. Send for samples of any mill in the list which may interest you.

No. 0147, 2½ x 6 hexagonal thin-super mill in good condition. Price \$12.00.

No. 0153, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.

No. 0156, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.

No. 165, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.

No. 0183, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.

No. 0214, 2½ x 10 hexagonal light medium-brood mill in poor condition; rolls quite badly pitted; will make fair foundation. Price \$13.00.

No. 0222, 2½ x 6 hexagonal thin-super mill in extra good condition. Price \$14.00.

No. 0225, 2½ x 12 hexagonal medium-brood mill in excellent condition; nearly new. Price \$25.00.

No. 0236, 2½ x 10 hexagonal medium-brood mill in fair condition; a few bruised cells. Price \$18.00.

No. 0227, 2½ x 10 hexagonal medium-brood mill; a new machine which does not test up to our present high standard, but a bargain at \$30.00.

No. 0238, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$22.00.

No. 0230, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.

No. 231, 2½ x 10 hexagonal medium-brood mill in fairly good condition. Price \$20.00.

No. 0232, 2½ x 10 hexagonal medium-brood mill; not very good cells; somewhat bruised. Price \$15.

No. 0233, 2½ x 10 hexagonal medium-brood mill in poor condition; cells bruised. Price \$14.00.

No. 0234, 2½ x 6 extra-thin-super mill in very good condition. Price \$12.00.

No. 0235, 2½ x 10 hexagonal light-brood mill in good condition. Price \$22.00.

No. 0236, 2½ x 6 extra-thin-super mill in good condition. Price \$12.00.

No. 0237, 2½ x 6 thin-super mill in fair condition. Price \$10.00.

No. 0238, 2½ x 6 thin-super mill in fair condition. Price \$10.00.

No. 0239, 2½ x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.

No. 0240, 2½ x 10 medium-brood mill, hexagonal cell in fair condition. Price \$17.00.

No. 0241, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.

No. 0242, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

No. 0243, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

No. 0244, 2 x 10 round-cell medium-brood mill in good condition. Price \$14.00.

THE A. I. ROOT CO., Medina, Ohio.

This Washer Must Pay for Itself

A MAN tried to sell me a horse once. He said it was a fine horse and had nothing the matter with it. I wanted a fine horse. But I didn't know anything about horses much. And I didn't know the man very well either.

So I told him I wanted to try the horse for a month. He said, "All right, but pay me first, and I'll give you back your money if the horse isn't all right."

Well, I didn't like that. I was afraid the horse wasn't "all right," and that I might have to whistle for my money if I once parted with it. So I didn't buy the horse, although I wanted it badly. Now this set me thinking.

You see I make Washing Machines—the "1900 Gravity" Washer.

And I said to myself, lots of people may think about my Washing Machine as I thought about the horse, and about the man who owned it.

But I'll never know, because they wouldn't write and tell me. You see I sell my Washing Machines by mail. I have sold over half a million that way.

So, thought I, it is only fair enough to let people try my Washing Machines for a month, before they pay for them, just as I wanted to try the horse.

Now, I know what our "1900 Gravity" Washer will do. I know it will wash the clothes, without wearing or tearing them, in less than half the time they can be washed by hand or by any other machine.

I know it will wash a tubful of very dirty clothes in Six Minutes. I know no other machine ever invented can do that, without wearing out the clothes.

Our "1900 Gravity" Washer does the work so easy that a child can run it almost as well as a strong woman, and it doesn't wear the clothes, fray the edges nor break buttons the way all other machines do.

It just drives soapy water clear thru the fibers of the clothes like a force pump might.

So, said I to myself, I will do with my "1900 Gravity" Washer what I wanted the man to do with the horse. Only I won't wait for people to ask me. I'll offer first, and I'll make good the offer every time.

Let me send you a "1900 Gravity" Washer on a month's free trial. I'll pay the freight out of my own pocket, and if you don't want the machine after you've used it a month, I'll take it back, and pay the freight too. Surely that is fair enough, isn't it? Doesn't it prove that the "1900 Gravity" Washer must be all that I say it is?

And you can pay me out of what it saves for you. It will save its whole cost in a few months, in wear and tear on the clothes alone. And then it will save 50 cents to 75 cents a week over that in wash-woman's wages. If you keep the machine after the month's trial, I'll let you pay for it out of what it saves you. If it saves you 60 cents a week, send me 50 cents a week till paid for. I'll take that cheerfully, and I'll wait for my money until the machine itself earns the balance.

Drop me a line today, and let me send you a book about the "1900 Gravity" Washer that washes clothes in six minutes.

Address me this way—H. L. Barker, 1620 Court St., Binghamton, N. Y. If you live in Canada, address 1900 Washer Co., 357 Yonge St., Toronto, Ont.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Geo. L. Emerson, Manager, 948 East Second St.

Where the Weed foundation-machines are making perfect non-sag foundation. Send us your wax to be made into foundation. We buy wax too.

Root Redwood Hives.—A sample hive body with cover and bottom KD, \$1.00. Quantity prices on application. We cut hive parts to order.

New machinery for manufacturing hives and frames has been added. Extractors are now shipped "knocked-down" from the factory at Medina.

The A. I. Root Co., San Francisco, Cal.

245 Mission Street

We have moved. Office and warehouse in the same building.
Write for catalog and send us your list of wants.

“Hats Off to the New Management”

writes a Mission, Texas, customer

The old reliable line of Root's Beekeepers' Supplies with our new system of business management assures Texas beekeepers of service such as they have never before experienced.

Mr. B. I. Solomon, who is now in charge, has been with The A. I. Root Company for some years and knows their method of doing business.

We intend to carry a large and complete stock of supplies, and we also have our Weed foundation machines in shape to care for all orders promptly.

Give us an opportunity to convince you of our service.

\$1000 COLD CASH for Beemen

Make a CLEAN Fortune from UNCLEAR Millions

New - - Brilliant - - Scientific Invention

Solves mighty home problems. People everywhere are waiting for it—wonder why it was never invented before. Supplies enormous demand. Covers new field. Just out—just introduced. Tremendous rapid sale staggers country. Remarkable demonstrations going on everywhere. Agents happy—banking enormous profits daily. **\$80.00 clear in 2 days—one man's record.** Mighty opportunity for you to get the mighty dollar. Failure impossible.

No Experience Required

Territory free, but going fast—worth fortune—get yours today. Write now. Don't lose by waiting. Win by immediate action—without risk, obligation, or cost—the very chance you have been looking for.

Hailed as a Great Blessing to Humanity

Clean homes demand clean shoes. Dirty shoes with their load of dirt, mud, or snow have been the bane of every woman's life. Women for ages have been slaving to keep the house clean, but it is no longer necessary to endure the hardship imposed by dirty shoes. The time has come when people can and will **"wipe their feet before entering."** This problem is solved—this longed-for and enjoyable condition is now a happy reality for all. Once again man's inventive genius has conquered and lifted a great burden from women's shoulders.

Every family wants Grab's Automatic Foot Scraper on their doorstep. Replaces unsightly, unsanitary, crude door mat. Mud, dirt, dust, snow, dirt of all kinds, removed in a jiffy. Works like magic—sells like "sixty."

(Ramsey, of Mont., writes: "Only 45 families in town—have sold all.") A positive pleasure for any one to use—a source of never-ending comfort to the household, to all who value cleanliness.

It
Sells for
Only
\$1.00

Grab's Scientific Shoe Scraper

Truly a mechanical and scientific wonder. Automatically removes mud, dirt, dust, snow, from shoe in one operation. Cleans sides, sole, heel. For men, women, children. Automatically adjusts itself to any size shoe—any shape. Attaches quickly to any doorstep or other handy place without screws, nuts, bolts. Neat, attractive, always ready to use. *Rotates for sweeping.* Handsomely enameled. Saves drudgery, time, money, shoes—saves carpets, floors. Mechanical wonder. Weighs less than 3 pounds. Very compact, strong, easy to carry. Has 7 new patented features not found in any other scraper—10 steel blades—10 dirt outlets—twin adjustable and removable brushes—compound springs. Can't clog—practically self-cleaning. Guaranteed satisfactory or money refunded.

Means less dirt—less work—less drudgery—less shoes to buy—longer life to rugs, carpets, floors—better health. Over half million in daily use. It appeals to everybody. High grade, unquestionable merit, something with class, practical and durable value, unique, odd, and pleasing to the eye. Sells on sight. No forcing, no salesman's tricks or deception necessary. Simply tell the truth—that's all. You have nothing to learn—nothing to set up—no dirty work to do. Seeing dispels all doubts, settles all questions, a sale results. So easy because it solves a mighty home problem, costs so little, does so much, is not a luxury, but an actual necessity. Every person who sees it wants one. (J. Rowan, Mont., writes: "Six dozen received. All sold, and more. Find them easy sellers, as they fill a long-felt want.") This invention is right for the public, right for you. The price of \$1.00 retail is insignificant, everybody can afford it, everybody recognizes immediately its great practical value, can see at a glance that it saves labor, drudgery, health, worry, time, carpets, floors. You have no competition. There is nothing else like it. What others have done you can do, but do your part—get started today.

Read These Amazing Cash Records

Walters, Tex., made \$25 first day; never sold goods before. Arnold, N. D., orders one, then 2 gross; sold 160 in 2 days. Hagen, Tex., sold 100 in 2 days. Webb, Pa., averaged 10 sales per hour. O'Connell, Mont., 25 first day. Mike Bock, Minn., 30 first day. Mrs. Windsor, Mo., "Ship 6 dozen more. First 3 dozen all gone. Have orders for 75 more." G. Pauscher, Minn., "Ship 5 dozen. Sold 36 first morning." G. Froom, Iowa, "I sold 30 first hour."

Hundreds like these—many doing better. You, too, can have money in abundance. Just get started. Quit the shirt-sleeve wages—stop worrying with goods that everybody has or nobody wants. Get Grab's. It's new, wonderful, irresistible.

Write . . . for free catalog and exclusive agency. Better still, send order, naming territory. Satisfaction guaranteed—you can't lose. Investigate anyhow. . . . Today It costs nothing—leads to your success and certain prosperity. Address

Gleanings in Bee Culture

How to Secure these Wonderful Plants---Free!

The wonderful Progressive Everbearing Strawberry Plants are becoming immensely popular. No wonder! You set them out in May and enjoy fine berries during the following summer and fall. No long wait for this crop! Progressive Everbearing Strawberries take the risk out of Strawberry growing, too. The plants are much harder than the common varieties. Ordinary spring frosts will not hurt them. Even if a heavy freeze does kill the early spring bloom, in 30 days they will bloom again.

Thru a special contract with a grower of National reputation, The Farming Business is able to furnish to you FREE these wonderful

Progressive Everbearing Strawberry Plants

or, if you prefer, Fall-bearing Strawberry Seeds—the true hybridized sort, and also plants of the ever-popular Chesapeake variety. All strains are pure. The progressive plants will actually grow and fruit as described. A test patch of a square rod was set in May, 1914. Just 83 days after, the owner began gathering a fine crop, which continued till late October, aggregating 74¾ quarts. The great Chesapeake variety needs no introduction. The Fall-bearing Seeds afford a most interesting way to grow Strawberries. These plants and seeds are scarce this year, and prices will be high, where they are obtainable at all. Act now and insure yours.

Our Plan

NO. 1.—Send \$1 (stamps accepted) for Farming Business—one year—52 big issues—and we will send in addition 12 healthy Progressive Ever-bearing Strawberry Plants this spring, just at the right time to set. Postage prepaid.

NO. 2.—Send one yearly subscription to The Farming Business, together with \$1 (stamps accepted), and in addition to the paper we will mail you one packet of true hybridized Fall-bearing Strawberry Seeds. This will give you about 500 plants.

NO. 3.—Send \$2 (stamps accepted) for The Farming Business—2 years, 104 big issues—and we will send in addition 12 Progressive plants and also 25 plants of the popular Chesapeake variety.

You need The Farming Business in your home. It is practical, helpful, progressive, cheery. A great paper for the busy farmer and the entire family. The Vegetable Growers' Magazine Section alone is worth the subscription price. It will pay you to accept one of our liberal offers. If already a subscriber your paper will be continued for an extra year—or two. Accept today to make sure of your free berry plants or seeds.

The Farming Business

THE IDEAL BEE-VEIL

Oftentimes when out in the yard working with the bees one stoops over to pick out a frame, and, as usual, bees keep buzzing around his head, watching for a chance to sting. The cloth veil which is often used sticks to the face when one bends over, and gives the bees an opportunity to sting. The IDEAL BEE-VEIL is constructed of cloth of wire, there being a cord at the top of the veil used to pull the cloth around the crown of the hat. The lower part also has a cord which fastens around the waist. The wire on the IDEAL veil does not strike the face, and prevents the bees from stinging. It can be readily seen that a veil of this kind has the cloth veil far outdistanced for comfort and utility. Sparks from the smoker do not burn holes in the IDEALS as in the netting veil.

The veil is manufactured by us, and is recognized by the best and largest beekeepers as the most practical veil on the market.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL., FEBRUARY 6, 1915.

COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight. All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH

1. *Extra Fancy*.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2*.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

NEW YORK.—The market is very inactive, both on comb and extracted honey, and large buyers are few and far between. Prices rule about the same as in our last report.

New York, Jan. 22. HILDRETH & SEGELKEN.

INDIANAPOLIS.—Trade has not been very active in comb honey during the past three weeks; however, the demand for extracted is fairly satisfactory. Choice No. 1 white comb honey is selling at \$3.75 to \$4.00 per case, and \$3.50 per case for No. 2. Finest grades of extracted are selling at 9½ to 11, according to quantity. For beeswax we are paying 28 cts. cash or 30 in trade, delivered.

Indianapolis, Jan. 20. WALTER S. POWDER.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: Fancy white, per case of 24 sections, \$3.15; No. 1 per case, \$2.93; No. 2 per case, \$2.70. White extracted, per lb., 8½ to 8¾; light amber, 8 to 8¾; amber, 7 to 8. We pay 25 cts. per lb. in cash and 27 cts. per lb. in trade for clean yellow beeswax delivered to us here at Denver.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, Jan. 22.

ST. LOUIS.—There is no change since our last quotations, and our honey market is still very dull and slow, with stocks ample for all demands. We are quoting white comb honey, 24 sections to the case, at \$3.25 to \$3.50 per case; amber, from \$2.50 to \$3.00 per case; extracted in 60-lb. cans, 5 to 8½; southern amber extracted, in barrels, from 5 to 6, according to quality. Beeswax is firm at 28½ for pure; impure and inferior, less.

R. HARTMANN PRODUCE CO.
St. Louis, Jan. 21.

KANSAS CITY.—The supply of both comb and extracted honey is large, and the demand very light—especially on extracted. We quote No. 1 white comb honey, 24-section cases, at \$3.10 to \$3.25. Some sales of No. 1 comb have been made at \$3.00. No. 2 white comb honey, 24-section cases, bring \$2.75 to \$3.00; No. 1 amber ditto, \$3.00; No. 2 ditto, \$2.50 to \$2.75; extracted white, per pound, 7½ to 8; ditto amber, light, 6½ to 7; ditto, dark, 5½ to 6. Beeswax, No. 1, brings 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.
Kansas City, Mo., Jan. 17.

We are in the Market to buy both comb and extracted honey. Write us what you have to offer, naming your best prices delivered. Every time an interesting price is named us, we buy, and remit the day shipment arrives.

Ship Us Your Old Comb We render it into wax, and pay market price.

Select Bred Three-banded Italian Queens

After 20 Years of Select Breeding We have Bees in Quality Second to None

Price List of Our Queens

Tested	\$1.25 or \$1.15 per 100	Untested75 cts. or \$70.00 per 100
Select Tested	1.50 or 1.25 per 100	Select Untested90 cts. or 85.00 per 100

Price List of Our Swarms of Bees in Packages

1 lb.	1 to 50, \$1.25 each; ...50 to 100, \$1.20 each; ...100 to 500, \$1.15 each
2 lbs.	1 to 50, \$2.35 each; ...50 to 100, \$2.30 each; ...100 to 500, \$2.25 each

If queens are wanted, add price as according to price list.

Our select colonies used for breeding purposes, larva, and select drones, are those of the highest standard, the choice of over 1000 hustling, honey-producing colonies of pure Italian bees. These select colonies are located in our queen-yard at such a distance from all other bees as to assure pure mating, and thus effective use of our select drones. The larva used in grafting is as small as can be seen and handled, having just come out of the egg. All cells are drawn and nourished in strong ten-frame colonies just running over with young bees. Thus we are able to produce large, long-lived and hardy queens, which give workers unexcelled for honey production.

Our capacity is 6000 queens and 5000 pounds of bees a year, or 50 queens and 100 1-lb. swarms a day. All queens warranted purely mated or are replaced free of charge.

Safe arrival and satisfaction we guarantee or we refund your money.

We have no disease, and foul brood has never been known in our community.

Book your order now; only a small cash payment required.

M. C. BERRY & CO., Hayneville, Alabama -- Successors to Brown & Berry

Largest shippers of young pure Italian bees in the South.

QUEENS OF QUALITY

The editor of *The Beekeepers' Review* and his sons have 1100 colonies of bees worked for extracted honey. With all those bees working with equal advantage, all having the same care and attention, they have an opportunity unexcelled to ascertain without a reasonable doubt colonies desirable as breeders from a honey-producers' standpoint. Likely, never in the history of beekeeping was there a better opportunity to test out the honey-getting strain of bees than this. Think of it, 1100 colonies with equal show, and a dozen of those colonies storing 250 to 275 pounds of surplus honey this last poor season (with us), while the average of the entire 1100 being not more than 40 pounds per colony. We have sent two of our best breeding queens (their colonies producing 275 pounds surplus each, during the season of 1915) to John M. Davis, and two to Ben C. Davis, both of Spring Hill, Tenn., and they will breed queens for the *Review* during the season of 1916 from those four superior honey-gathering breeding queens. Those young queens will be mated with their thoroughbred drones. Our stock is of the three-banded strain of Italians; also that of John M. Davis; while Ben C. Davis breeds that disease-resisting strain of goldens that is becoming so popular.

By this time you are likely thinking that your strain of bees may be improved some by the addition of this superior strain of *Review* queens, and how you can secure one or more of those superior honey-gathering queens as a breeder. We will tell you. They will be sold to none except *Review* subscribers. If you are a paid-in-advance subscriber to the *Review* for 1916, we will mail you one of the daughters of those famous queens in June for a dollar. If not a subscriber to the *Review* for 1916, send \$1.75 for a year's subscription to the *Review*, and one of those famous queens. These queens are well worth two dollars each compared to the price usually charged for ordinary queens, but we are not trying to make money out of this proposition, only we are anxious to have every subscriber to *GLEANINGS* a subscriber to the *Review*, and we are taking this way to accomplish the object. A few of the very first orders for queens that we receive can be mailed in May, but the majority will not be mailed until June. Orders filled in rotation. Have your order booked early and avoid disappointment. Address with remittance

Honey reports continued from page 2.

CHICAGO.—There are very few sales of honey being made at this time, and under these conditions it is difficult to quote prices. The weather at this writing is about zero, and comb honey will not bear shipment without being injured more or less.

Chicago, Jan. 17. R. A. BURNETT & Co.

NEW YORK.—Clover, comb, No. 1 to fancy, 13 to 14; ditto, lower grades, 11 to 12; clover, extracted, 7 to 8; buckwheat, extracted, 6 to 7; California, extracted, 6 to 8; Southern, extracted, per gallon, 50 to 75; West Indian, extracted, per gallon, 50 to 53.

New York, Jan. 22.

CINCINNATI.—Very little honey is selling at present. We quote No. 1 comb at \$3.75 to \$4.00; No. 2 at \$3.50 to \$3.75; white clover extracted in cans, 7 and 9; amber in barrels, 5½ to 7, according to quality and quantity. For choice bright yellow beeswax we are paying 28 cts. per lb. delivered.

Cincinnati, Jan. 20. THE FRED W. MUTH Co.

ALBANY AND SCHENECTADY.—There is little call for either comb or extracted; and from the many inquiries in regard to the condition of our market from producers, we judge there is still a large quantity of honey in their hands unsold, especially light extracted and amber. There is some demand for buckwheat. There may be an improvement later. January is not the best month in which to sell honey.

CHAS. MACCULLOCH.

Albany and Schenectady, Jan. 25.

ZANESVILLE.—The post-holiday lull is affecting somewhat the demand for honey, tho the market shows no material change as regards prices. In small lots the better grades of white comb bring around \$4.00 per case, jobbers receiving customary discount from prices to the retail trade. White extracted we quote at 9 to 11 cts., according to quantity. Producers receive for beeswax 28 cts. cash, 30 in exchange for merchandise.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powdripaint. It comes in the form of a dry powder and all that is required is cold water to make a paint weather proof, fire proof, and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 11 North Street, Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

SWEET CLOVER \$5.50 PER BU.

White Blossoms. Biggest bargain in unhulled Sweet Clover this season. Have scarified hulled seed at low prices. Wonderful money-maker. Best paying crop on the Farm today. Builds up worn out land rapidly and produces heavy, money-making crops while doing it. Splendid pasture and hay; inoculates your land for Alfalfa. Keep up with the times. Investigate. It will pay you to get our free samples and prices and big Profit Sharing exclusive Field and Grass Seed Guide. It's free. AMERICAN MUTUAL SEED Co., Dept. 966, 43rd and Roby St., Chicago, Ill.

1916--Advance Lewis Bee-supply News--1916

THE NEW LEWIS CATALOG this season, like BARNUM'S CIRCUS, is better, bigger, and grander than ever.

As a progressive beekeeper, you read the bee-journals, all the bee-books you can get, and attend the conventions, BUT—

IF you do not get the LEWIS CATALOG FOR 1916 you are neglecting a liberal bee education. In no other form can you get so much good, meaty knowledge about bee fixtures, apparatus, tools, and whatnot as you can right in the LEWIS CATALOG—and the pity of it is, the man who does not avail himself of this opportunity passes up that which he may have for the asking—for it is free.

Send Right Now for a New Lewis Catalog

Here are Only a Few of the Distinctive Features Contained in It.

- Our NEW METAL-BOUND DIVISION-BOARD in the full-depth size is to be found illustrated, described, and listed.
- A very good tool in the shape of a KNIFE FOR SCRAPING AND CLEANING FILLED SECTIONS is illustrated, described, and listed.
- A WOVEN WOOD-AND-WIRE CHEST, which is a low cost article with many uses, is illustrated, and described.
- One page is given over to the RAUCHFUSS FOUNDATION CUTTING-BOX, a practical little outfit for the beekeeper.
- Two other articles, a SECTION-HOLDER NAILING-FORM and FRAME WEDGE DRIVER are offered.
- Two whole pages of INSTRUCTIONS TO BEEKEEPERS BY C. P. DADANT will be found interesting to the old beekeepers as well as the new.
- One page devoted to the PROSPECTIVE BEEKEEPER is very interesting, and many new thoughts are presented.

SWEET - CLOVER SEED

Quick Germination

Get our "Scarified" Sweet-clover Seed, which will germinate from 85 to 95 per cent the first year, and thus insure you a good stand right from the start. By sowing our seed you will save money, as it takes only about half as much scarified to sow an acre as ordinary hulled seed.

Prices	1 lb.	10 lb.	30 lb.	100 lb.	60 lb. a bu.	5 bu. a bu.	10 bu. a bu.	Lbs. per acre
Unhulled White, re-cleaned	\$0.25	\$2.00	\$5.10	\$16.00		\$4.80	\$4.50	25 to 30
Hulled White, re-cleaned and scarified .	0.30	2.75	6.75	22.50	\$13.50	13.00	12.50	6 to 10
Hulled Yellow, re-cleaned and scarified (<i>Melilotus Officinalis</i>)	0.20	1.80	5.10	17.00	10.20	9.50	9.00	8 to 12

When seed is wanted by parcel post, be sure to include postage. Bags will be included in the weight in parcel-post shipments.

Please Note—All of our seed is thoroly cleaned. The scarifying process usually breaks some of the seeds, and we remove all broken seeds. This is an important saving to you. Samples on application.

Dadant & Sons, Hamilton, Illinois

YELLOW SWEET CLOVER.—Many people fail to recognize the value of the biennial yellow sweet clover as a honey-plant. The fact that it blooms two weeks earlier than the white variety makes it especially valuable to the beekeeper. Be sure, however, to get the biennial variety as quoted above.

FEBRUARY 1, 1916

NO. 3

EDITORIAL

REPORTS from our California readers indicate good rains thus far. One letter written January 14 gives the rainfall to date as over 15 inches, nearly 6 inches more than last year at the same time.

WE must beg the indulgence of our readers a little longer till we can catch up in our printing department. One thing after another has come in upon us, and these, together with the yearly index, have kept us behind. We are running almost night and day, and hope to be caught up by another issue or two.

The 1916 Spelling in Gleanings

AMONG the new year's resolutions we put into practice for this year is a typographical one. As our discriminating readers have noticed, we have discarded a few of the old and prolix forms of spelling which have come down to us from Saxon days without any real reason for their being.

In short we have adopted the list of ten words picked out by the National Educational Association as worthy of simpler spelling. The following are the words: thru, thruout, thoro, thoroly, tho, altho, prolog, program, catalog, and decalog. The old forms for which these are substituted are familiar to every one.

This list has been adopted by some of the best magazines in this country. Among farm papers, *Successful Farming* made the change just recently. So you see, far from being faddists, we are simply falling in with progressive journalism.

The Lament of Job

OUR old friend Holtermann is "all in the dumps" over European foul brood. (See page 116). Like the Job of olden times, to whom he compares himself, he has friends who only increase his distress. He wants to know if there is any one who has been able to stamp out absolutely European foul

brood after it had gotten a hold in an apiary. He is not interested in the fellow who claims he has cured it but yet never got entirely rid of it. How about Dr. Miller? Is there not some one (if not the venerable doctor) who can give our friend a crumb of comfort? While there are some who have an utter contempt for American foul brood, there are others who care no more for European foul brood than they do for a case or two of bee paralysis or laying workers.

Verily we believe that our correspondent is seeing only the dark clouds and not the silver lining that breaks into a nearly clear sky.

Care of Comb Honey during Winter Months; How to Prevent Granulation

EMPHASIS cannot be laid too strongly on the importance of keeping comb honey at a temperature as warm as the living-room. It is almost equally important that it be maintained uniform. A temperature down to 65 that is uniform is not as favorable to granulation as a temperature of 75 during week days, and then going down to 40 or 50 during Sunday when everybody is gone from the warehouse or store. Comb honey that has started to granulate can be checked by keeping it at a uniform temperature of 80 or 85. At the last-named point, however, there is some danger of the combs sagging and leaking.

We are satisfied that a majority of stores and warehouses where comb honey is kept have variable temperatures — sometimes down to 50 and even 45. A large number of honey-buyers do not realize the importance of keeping comb honey uniformly warm while in storage, and they will pay for it dearly before next spring.

Where natural gas is cheap the temperature can be controlled very nicely. A soft-coal fire or a wood fire is too irregular. A gas-stove or a stove burning hard coal will usually maintain a temperature of somewhere about 75; but when the weather outside warms up, the fire should be reduced.

A temperature of 85, dropping down to 70, back and forth, is not as favorable to anti-granulation as one of 75 maintained day in and day out every hour of the day.

A New-old Cure for European Foul Brood

WE would call particular attention to the article by Timberline Riggs, on page 102, on the new cure for European foul brood. While at first sight it might seem as if the cure were new, yet in view of the fact that it involves the fundamental principles used in the treatment of this disease, the cure is really old.

We have had talks with the New York State inspectors, who have had more experience with European foul brood than perhaps any others. We have heard them, time and time again, urge the importance of vigorous Italian stock, and keeping all colonies strong; and not only strong, but in a prosperous condition, and that means, of course, feeding if they are not liberally supplied with stores.

Mr. Riggs speaks of contracting the space occupied by nuclei. From conversation with inspectors we are of the opinion that it is unwise to fuss with anything but strong colonies. In this he differs from the accepted practice in the cure of the disease.

The Net-weight Law Effective within 24 States as well as in Interstate Business

A NUMBER of the different states have passed net-weight laws to conform to the federal net-weight regulation. Where there is no law operative in any state, it is not necessary that comb-honey producers, for example, mark the exact net weight or minimum net weight on their sections. But as 24 states have passed such laws it is important for us to know which ones they are. We wrote, therefore, to the Department of Commerce, of the Bureau of Standards, Washington, D. C., and received the following from the director:

Dear Sir:—This list is not presumed to be complete, as the session laws for the past two years have not been examined carefully except in the cases of a few states. We are anxious to bring this information up to date, but the press of other work has prevented us from doing so.

S. W. Slatton, Director.

Washington, D. C., Dec. 18

List of states having laws which require packages containing commodities to be marked with the net contents.

Arizona, 1913.—Foods: A large number of foods and classes being enumerated, but there is no gen-

eral statement. California, 1913.—“Provisions . . . apply to foodstuffs and stuffs intended to be used or prepared for use as food for human beings,” or eaten or drunk by human beings. Connecticut, 1911.—Food only. Florida, 1911.—Food only. Georgia, 1913.—Food only. Indiana, 1913.—All commodities to be sold by weight or measure, except commodities customarily sold by numerical count, or in gross, or in packages so marked as to indicate contents. Iowa, 1913.—“All dry commodities weighing ten ounces or more, except drugs, section comb honey, and those specified in section nine” (relating to berries). Louisiana, 1914.—Food only. Maine, 1913.—Food only. Massachusetts, 1914.—Food only. Michigan, 1913.—Food only. Montana, 1913.—“Any commodity or article of merchandise in a package or container.” Not applicable to packages selling for ten cents or less. Nebraska, 1913.—Certain food products only, some exceptions; statute does not include all food. Nevada, 1911.—“Any commodity or article of merchandise.” New Hampshire, 1913.—Food. North Dakota, 1907.—Food and beverages. New York, 1913.—All commodities except those for which special containers are provided. Pennsylvania, 1913.—All commodities. South Dakota, 1911.—Food. Tennessee, 1913.—Food. Utah, 1915.—Foods. West Virginia, 1915.—All commodities. Wisconsin, 1913.—Foods. Wyoming, 1911.—Foods.

Bureau of Standards, Dec., 1915.

In view of the fact that one's honey may be shipped outside of the state in which he resides, and be sold, we will suppose, where there is no net-weight law, such shipper would be liable to Uncle Sam. Whether a state has a net-weight law or not, it is always wise and safe to mark the net weight on every section.

Shall we Clip One or Both Wings of our Queens?

MR. D. D. STOVER, of the Stover Apiaries Co., Mayhew, Miss., seeing our article in the A B C and X Y Z of Bee Culture, wherein we recommend clipping *both* wings from *one* side of a queen, writes that he clips only the large wing on one side, leaving the smaller one under it intact. He has found it, he says, just as effective in preventing the flight of a queen as to clip both wings. Moreover, it does not mar the appearance of the little lady, and at the same time it makes it easier to pick her up.

We replied by saying that we were of the opinion that the one-wing plan would still leave the queen able to fly possibly a yard or more from the hive, and thus get lost. Mr. Stover came back by saying that, if the large wing is clipped close to the body, there will be no danger of the queen flying at all.

We finally referred the matter to Dr. Miller, who has had a very large experience on queen-clipping. His reply is so valuable that we are glad to give it to our readers:

A good many times it has happened that, when clipping a queen, I have taken off only

the large wing on one side. Such a queen is more easily caught, her beauty is practically unmarred, and I think she can fly no better than a queen with two wings clipped. But when I find a queen of that kind she is immediately caught and the small wing taken off. The mere fact that her beauty is practically unmarred condemns utterly the one-wing plan, at least for my use; for unless I can get a good square look at the one-winged queen I cannot tell whether she is clipped or not; whereas if both wings are clipped I can spot her with the least glance as she dodges around a corner. For one who cares much for the appearance of a queen and a little for the time spent in looking for her, the one-wing plan may be all right.

The last argument of Dr. Miller, that clipping both wings enables one to tell at a glance whether the queen is clipped or not, is a clincher. It might take two or three good square looks to determine whether a queen on the Stover plan has been clipped. It very often happens in the height of the season, when colonies are strong, that one glimpse is about all one will get of her majesty, so it is not altogether a question of looks but one of saving time when time is most valuable.

How to Keep Bees Fresh and in a Normal Condition at Expositions

IN the initial article in this issue, by Prof. George A. Coleman, an interesting fact is brought out; namely, that an observatory hive can be placed inside of an exposition building having an entranceway thru an ascending tunnel 7 feet from the hive itself to the outside wall of the building. When we were visiting Prof. Coleman at the University last winter he raised the question whether bees could be made to go thru a long passageway. We told him we knew it had been done; but when he stated it was necessary to have a tunnel 7 feet long and 10 feet above the ground we had some misgivings.

The fact that the bees used this long runway as a means of exit and actually swarmed out of it is interesting and valuable, as it will solve the problem of live bees on exhibit at expositions and agricultural fairs. It also emphasizes the importance of making arrangements in advance to have the exhibition of bees and bee-appliances next to the outside wall of the building. When the exhibit is centrally located, the observatory hive must have fresh bees every four or five days; and even then they will be uneasy, crawling up and down the glass, seeking a means of exit. This nervousness or uneasiness causes an abnor-

mal condition, giving the public the idea that bees are generally on a constant run and excited, when the very reverse is true.

It is also interesting to note that the bees flew over the heads of thousands upon thousands of sightseers for months at a time, and no one was stung.

A Winter Case with Inner as well as Outer Walls for Holding Four Regulation Single-walled Hives

ONE of our subscribers, Mr. S. K. Best, of Youngstown, O., writes that he has seen nothing in GLEANINGS relative to a double-walled winter case for holding four hives. By this he means a case made up of matched house-siding for the outer wall, and cheap lumber for the inner wall, the space between the two walls being packed with straw or other material. In order to facilitate removal of the four hives set down in the inner compartment he would have a 1½-inch space for clearance which would really result in a dead-air space between the hives proper and the inner walls of the case. The four hives are each to be covered with an eight-inch cushion. Of course suitable provision has to be made for providing entranceways thru the packing and to the inner hives.

The advantage of this arrangement, Mr. Best thinks, would be that a given number of colonies could be put into winter quarters and taken out in less time than where the packing material had to be shoveled out of the cases until the hives could be uncovered so that they could be removed.

There is no use in trying to dodge the fact that the quadruple case of the Holtermann type involves a great amount of labor in packing and unpacking. The packing material must be handled over and over again at each operation.

One thing in favor of the plan proposed by Mr. Best is that some labor will be saved, but not much. By the Holtermann plan, from 300 to 400 colonies can be packed in a day by two men. The labor of unpacking and removing the packing would be about the same. Perhaps Mr. Best's plan would save half of that time. But suppose it saves three-fourths; the relative difference in the cost of packing and unpacking per colony would not be large. On the other hand, the double-walled cases would be considerably more expensive because an extra wall would have to be provided. Then there would be an objection to the dead-air space between the hives and the inner walls of the case. Cold air would be pretty sure to percolate thru the entranceway into the dead-air

space. While, of course, it is supposed to go into the hive itself, yet if it leaks and travels all around the four hives, a considerable portion of the benefit of the packing would be lost.

The large quadruple cases of the generally accepted type are expensive enough; and it is our opinion that it would actually cost more in the aggregate to make the cases with an inner as well as an outer wall. As a matter of fact, there is no advantage in the inner wall after the bees are packed, because the wall of the hive itself is sufficient. There is nothing like having the packing come in direct contact with the hives themselves. There is then no opportunity for circulating currents around the hives.

The Number of Colonies Needed to Pollinate Properly a Citrus Orchard

ON page 1000 of our issue for December 1st we made the statement in reply to Mr. Paul J. Davis, Glenn, Cal., that a much smaller number of bees are required to pollinate a citrus orchard, either in California or Florida, than an apple, peach, pear, or cherry orchard in the North. We have used the estimate of about a colony to the acre in our northern orchards, and this number in numerous recorded instances appears to have been sufficient to secure record-breaking crops of fruit. Considering the fact that there are only two or three days out of the whole blossoming time when the bees can mingle pollen, and sometimes not over two or three hours, it is apparent that we need many more bees in the North than in the South, where the blossoming time extends over two or three months, and where the weather is always favorable except for occasional rains. We are reminded that E. G. Baldwin, of Stetson University, Deland, Fla., who wrote an article on Florida beekeeping for one of the Florida papers, estimated that five colonies are needed to the acre in a citrus grove. See GLEANINGS, page 216, March 15th issue. He may be right; but if one colony per acre of trees in the North will do the work it would seem that one-tenth of that number would be sufficient in a southern grove. We have gone thru a large number of citrus groves in Florida and in California, and asked the proprietors if they had any bees there.

"None whatever."

"Are there not some in your locality?"

"Not that we know of."

And yet the significant fact was they were securing good crops of fruit. We have generally told these people that there

were more bees in their localities than they supposed, and have never yet failed to find bees on the blossoms in orchards where it was claimed there were no bees. These bees were probably wild, or in the hands of some person unknown to the owners of the grove, and yet the number was sufficient to do the work because the yields were good.

As nearly as we can estimate, one or two colonies could, in some localities, some seasons, take care of a hundred acres of citrus groves. Of course it would be advisable to have many more.

If we are wrong in our estimate of the number of bees required in citrus groves, it is important that we be corrected as speedily as possible in the interest of more and better fruit. The question of how many bees are needed in fruit orchards is being agitated not a little. We should be glad to get expressions from our friends—particularly from Prof. Baldwin, who has given the matter not a little study.

Later.—Since writing the foregoing the following has come to hand:

Lack of Pollination in Orange-groves

THE following clipping from the *Hemet News*, Hemet, California, was sent in by a correspondent. As we believe it states an absolute truth we are glad to place it before our readers.

BEES IN ORANGE-GROVES.

Otto Lowentrou, deputy county clerk and long-time orange-grower, says in the *Riverside Press*:

"I believe that one of the chief causes why many of the Riverside orange-groves have gone back is because we no longer have bees here. It will be remembered," he said, "that when it was found necessary to prop the heavily laden orange-trees all thru the valley, bees were kept at many points thru the city. Then an ordinance against beekeeping in the city was passed, and orchardists who had kept bees as a profitable side line sold their apiaries. We have been told that the orange-blossoms are self-pollinating; but until there is actual proof of this fact it would seem the part of wisdom to keep the bees inside the city. I do not believe that all orange blossoms pollinize themselves, and I feel sure that an investigation would show that our decreased orange crops are due in no small measure to the fact that bees no longer draw their honey store from our orange blossoms."

While we have said before that orange-groves do not need as many bees per acre as apple-orchards in the North, yet when there are no bees present it is very plain why the yield per acre drops down as stated in this clipping.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

I AM quoted in *Bienen-Vater*, p. 180, as saying in GLEANINGS that there is no buckwheat in America. That was heather (Heide), friend Richter, I was talking about. Plenty of buckwheat here.

GRACE ALLEN, p. 6, I don't believe a pound of two-to-one syrup equals a pound of honey for wintering. About 1.07 pounds comes nearer to it; but a little extra must be added to pay for evaporating out the extra water. Make syrup $2\frac{1}{2}$ to 1, and there will be no extra water.

RIETSCHKE foundation-presses are used by the thousand in Europe, beekeepers making their own foundation. But it's expensive business. Franz Richter once told about a beautiful lot, faultlessly made, but it took $2\frac{2}{3}$ times as much wax as for the same number of sheets of Weed foundation.

To get a label to stay on a five-pound pail is not easy. A good thing is to have the paper long enough to reach around the pail and lap over, with the label printed twice upon it. [If you get the right kind of prepared paste the label will adhere to tin. We have no trouble of that kind; but it is not an easy thing to make up a paste that will do it.—ED.]

SWISS beekeepers claim a near approach to non-swarmer bees (black bees), and reports seem to warrant the claim. Of 293 reporting for the past season, 203 have had no swarm, 74 few, and 16 many swarms. Nor is this different from reports for a number of years past.—*Schweiz. Bztg.*, 424. I believe non-swarmer bees are just as possible as non-sitting hens.

ACCORDING to *Leipziger Bienenzeitung*, p. 173, I tried for years to secure larger bees by having them reared in drone-cells. No, Pastor Fleischmann, I never tried the experiment. But I did get bees from Florida so large that their worker-cells were as large as ordinary drone-cells. How they were secured I don't know. And I don't know whether they were worth more than bees of usual size.

C. JUNGLEISCH reports, *L'Apiculteur*, 75, that he made a super from the boards of an old hive. It was well glued inside, and he planed and painted it outside. Blisters formed under the paint; and on trying to flatten them with his fingers he found they were filled with water. He reluctantly concluded it was better in summer to have

supers without paint, and still more important for hives in winter.

THAT diagram, p. 1010. Please don't fail to note that item of "undetermined matter," 3.68 per cent, or one in every 27 parts. Those things—iron, phosphoric acid, etc., are not found in sugar, and so they give to honey a value as food that is not found in sugar. Indeed, in some cases they make honey an invaluable medicine. Some day cane sugar will be considered a rather poor substitute for honey as an article of food for the human family—also for the bee family.

"Two men with a rope can carry bees in so that they will hardly know that they have been moved," p. 1015. Two men did better than that here, Dec. 4. With never a veil or a glove, each one picked up a hive, hugged it to his bosom, took it into cellar and set it in place, doing the job in just half the time they could have done it with a rope. But they were eight-frame hives; and if Doolittle says I'd be better off with larger hives, I'm not going to have any argument with him.

JUNG-KLAUS, the brilliant Sammal Korb man, quotes in *Deutsche Imker*, p. 184, a paragraph about my enthusiasm and record crop and then says that if it is true that 100 kilograms average per colony of comb honey is possible only in America, and there only by taking away all honey at the time of harvest, and then systematically feeding back—sugar. Guess again, friend Jung-Klaus. No man in Europe is more bitterly opposed than I am to sugar-feeding—have not fed a grain for years. Besides, as it was all comb honey you can see I could take it only from the supers, leaving the stores in the brood-chamber untouched. He further thinks that all my enthusiasm is for the "almighty dollar," and that a genuine bee-enthusiast will suffer ten years of failure and still carry in his heart enthusiasm for the little bee. True enough; but does it follow that success would kill such a man's enthusiasm? Even if that be true, I've had difficulties enough to keep my enthusiasm alive. At the end of my first eleven years of beekeeping, after having first and last bought quite a number of colonies, at one time having had 50 colonies, all I had to show for my eleven years of effort was two colonies! and I've had plenty of failures since then. Don't you think, Jung-Klaus, you can afford to credit me with a little enthusiasm? Just a little, please.

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

January came in with a retinue of flying bees, buzzing flies, broody hens, and dandelions in bloom. This morning, Jan. 12, it was too warm outside, even hatless and coatless, to frolic comfortably with our strenuously playful kitten who runs when you chase and chases when you run. But this afternoon something broke in a storm, and a cold wave is now reported on the way. Warm mild weather it has been so far, yet damp and unseasonable, bringing colds and grip to countless people and causing the bees to consume their stores pretty fast. Morning after morning they have been out at eight o'clock, working up an appetite for breakfast. They seem to be wintering all right, if you can call this wintering. So far they have not worn themselves out generating heat, that's sure. But we should not like to face a long, lingering, chilly spring, with depleted stores.

We have been glad in each of our frequent winter rains that all our hives are tipped pretty well forward.

* * *

Use 5/7 of a pound of sugar for each pound of honey lacking, when feeding sugar syrup in the fall, Dr. Miller says, which is what I wanted to get. Mr. Bruce Anderson has recently sent me a newspaper report of the work in North Carolina of Mr. E. G. Carr, one of the Federal bee experts, and in it Mr. Carr recommends feeding one full pound of sugar for each pound of honey lacking in the fall. Perhaps Mr. Carr was taking into account the point raised by the editor, that, pound for pound, the sealed syrup stores may not be of equal value to sealed honey stores. [See Mr. Byer's comment in his department, this issue.—Ed.]

In this report of Mr. Carr's work I was also interested to note that he advises requeening every second August, and also packing hives into winter cases in the fall, even here in the South. If the winter losses in the South are from 5 to 15 per cent, as Bulletin 325 estimates, perhaps better winter protection will do away with a large part of this, and being sure of queens in the fall eliminate most of the rest.

* * *

The new hive arrangement on p. 30, Jan. 1, interested me a lot. I feel as tho Mr. McCready has rather "beat me to it," as I had already decided that some day I should startle the beekeeping world with some bril-

liant plan of my own to do quite away with lifting. I have gravely considered this placing of hives alongside one another, also of tiering up on one end of the Long Idea hive; and then there are various other promising combinations still too vague to put on paper, but very superior, as one's own unformed ideas always are. I like some things in Mr. McCready's hive, and some things I don't. It looks unnecessarily spread out somehow, and seems like a more awkward arrangement than the simple long hive of Mr. Poppleton. I should think, too, that it would be more difficult working with the bees in the brood-chamber if the operator has to reach across a side super. ("Side super" sounds a bit contradictory, doesn't it? One might call them "wings," perhaps.) On the other hand, this arrangement makes use of equipment already on hand. Then, too, the snug way that the brood-chamber is tucked away in the center looks as tho it must have advantages. I can't help thinking that, while winter cases with their generous packing may bring about splendid results, there ought to be some less expensive way to accomplish the same thing—less expensive and easier too. Perhaps Mr. McCready is on the right line.

* * *

Another person that "beat me to it" is Mr. Pelham Grenville Wodehouse, according to the notice on page 35, Jan. 1, where mention is made of a serial story running in the *Saturday Evening Post* with a beekeeper conspicuous in it. Now, if Mr. McCready has evolved my effort-saving hive, and Mr. Wodehouse has written my story putting the beekeeper into literature, what, pray, is there left for me to do?

Oh heart of mine, we'll sing!
And Life's fair cup of gold
We'll fill as full of winey song
As it will hold!

A song of flashing bees
With swift, ecstatic wings
And dauntless mood that flies afar
And sings.

A magic-hearted song,
A song of big desire,
Of wonder and of witchery
And fire.

A yearning song and wild,
Whose haunting music streams
Across tired hearts, and brings them back
Their dreams.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

See here, Dr. Miller; I am a bit surprised at what you tell Grace Allen as to amount of syrup equivalent to a pound of honey sealed in the comb. I thought that was pretty well settled some time ago. Up here 5/7 of a pound of sugar will not equal a pound of sealed honey, and a general average of experiments has shown us that it takes a full pound of sugar made into syrup to give the bees the equivalent of a pound of honey. This is for winter stores. I have no data, and know of no way of obtaining any to test the matter for any other season of the year. [See Dr. Miller's second "straw," this issue. —Ed.]

Here in this part of Ontario we have had a nice moderate winter to date, Jan. 19, with but little snow. As beekeepers, if we were looking for any cause to complain, the lack of snow would be the only thing offering for an excuse, as we have had no extreme cold yet, and bees appear to be wintering nicely. During the next four weeks we are apt to have our very cold weather; and during that period we like to see a good blanket of the "beautiful" over the clover and around the hives. For our latitude, abundance of snow is a normal condition for our winter season. When we lack this covering of nature, something is bound to suffer more or less.

For a long time I have been of the opinion that Wesley Foster was a pretty good sort of chap, altho I never have had the pleasure of meeting him. Just at present I have a much higher opinion of him than I have ever had before just because I read that letter from his honored father on page 1044, Dec. 15, relative to the question of taking human life, even as a matter of self-defense. The sentiments expressed in that letter are exactly the views held by myself, and I never have been able to reconcile the teachings of Jesus Christ as given in the Sermon on the Mount and in many other places with the view taken by thousands of his professed followers, that under certain conditions we may kill our fellow-men.

While on this topic I wish to give my hearty approval of an extract from the sermon printed on page 1043, relative to the claim made by some that the present war shows the collapse of Christianity. "It

is not the collapse of the Christianity that Jesus taught, but it is the collapse of the Christianity that the church has taught."

In the matter of advertising honey, and especially in getting it placed in high-class hotels and other like places, I called the attention a short time ago to the fact that honey is not popular because so many people actually do not know how to handle honey at the table. Just a short time ago I was talking to the manager of one of our best hotels in Toronto, and he mentioned this matter, saying that honey would be unpopular in the high-class hotels until some plan could be devised to give an individual service. At present nearly all preserves, jams, etc., as well as the soft varieties of cheese, are served in this manner, small jars with large necks being used, the manufacturers of the different foods putting it up at their factories. It seems to me that the cost of putting up honey in this way would be prohibitive for hotel use, altho it could, no doubt, be arranged for dining-car service where such high prices are charged the patrons. It is a problem worth investigating, for one who travels much knows that very few menus of our good hotels include honey.

RABBIT SPACING.

As the editor says on page 1098, self-spacing by hive-rabbits was tried many years ago. One of the first movable-frame hives sold here in Ontario, and called the "Thomas" hive, had this feature. But very few are in use today by the large producers. A notable exception to this, however, was the late Wm. McEvoy, who, if I am correct, used rabbits for self-spacing, and doubtless his sons who now run the business use the same style of hive. Judging by all the hives of this pattern that I came across while at inspection work, there would not be much danger of the frames jumping out of these rabbits of the hives if they were being moved, as they were mostly glued good and tight with propolis. But this would not be the case in Mr. McEvoy's apiaries, as they are very particular in their beework, and all excess of propolis would be removed. From the fact that so good an apiarist as Mr. McEvoy used these hives altogether, perhaps the principle of rabbit spacing has some virtues that have been overlooked by others who have tried them.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

WINTERING AND PROSPECTS.

Nineteen fifteen ended up with a precipitation above normal of nearly four inches. The mountains are well supplied with fallen snow, and prospects are good for sufficient moisture for the coming year.

Alfalfa is in excellent condition, and sweet clover is unusually abundant and thrifty.

The bees so far have wintered well, considering the amount of poorly ripened honey in the hives. They gathered honey clear into November; and as this honey could not be thoroly ripened, it is likely to cause trouble later on.

THE NATIONAL CONVENTION.

The beekeepers who attend the National convention in Chicago will be assured of a rare treat. Problems of national importance will be handled. There will not be the detailed business to be transacted this year so common in years past. We should have a feast of good things. Prof. Jager (it is hoped) will show us how to clean sections. Mr. R. A. Burnett will discuss the comb-honey situation from the dealer's standpoint. Editors Root, Dadant, and Townsend will discuss subjects they are expert in. We shall have the commercial aspects of beekeeping well represented.

There will be much valuable discussion, and we will have a banquet.

The Hotel Sherman, Chicago, is the place where our convention will be held, and a live convention is assured.

Come, and contribute your bit to the convention.

IDAHO WINTERING EXPERIMENTS.

Mr. Jos. J. Anderson's wintering experiments as described by him (page 1016, Dec. 15) are very interesting and instructive. A few things might be said in this connection that will add more light to the subject. In a footnote to Mr. Anderson's article Editor Root mentions that Idaho weather is similar to that of Ohio, but that the climate is drier. I take it that Idaho has about the same snowfall and cold weather, but a drier climate than Ohio. If this is the case, as seems true, Idaho has a damper winter than Colorado, Wyoming, Utah, Nevada, and Arizona. From my observation, dampness is far more fatal to bees than cold. This applies whether the cold is external to the hive or inside of it.

One thing that would be interesting to know is what the loss would have been had Mr. Anderson wintered one hundred of his

colonies on their summer stands with no protection. Mr. Anderson says, "With young and vigorous queens, a hive full of young bees, and ample stores, the battle is half won." Give me these conditions in Colorado, and the wintering battle is ninety-five per cent won. This subject is of intense interest to me personally, as I am wintering nine hundred colonies in Idaho for their first winter. They are packed in straw, except the fronts, and the straw is covered over with tar paper to keep out the snow and moisture. Eight hundred colonies of mine are wintering in Colorado with no protection whatever. Colorado and Idaho are different.

SPRAYING AND BEEKEEPING.

The spraying of fruit-trees and the alleged destruction of bees is a complex subject. In no case where investigations and experiments have been carried on has the work been sufficiently thoro to get at any tangible results. In California, the published results of experiments there performed are at once convincing to those who have passed thru spraying troubles, that the experiments did not duplicate the proper conditions. The published facts regarding the experiments in Australia (page 994, Dec. 1, 1915) are so very meager that it is surprising scientific investigators would attach any importance to them. The number of colonies is not stated, the acreage in bloom within two miles of the apiary in relation to the acreage sprayed is not given, and doubtless was not even considered. The information given is so very meager that such conclusions are valueless. Those of us who have lived in commercial-fruit districts and seen thousands of colonies destroyed in the thousands of acres of orchards, cover crops growing under every acre of trees (almost), realize the importance of this subject. We have seen thousands of colonies saved by being moved two and a half to three miles from the orchards. Honey crops have been saved by moving. It is so well established among hundreds of our Colorado beekeepers that bees cannot exist in commercial-fruit districts that a man who does not move his bees when spraying begins is placed in the same class with the man who allows foul brood to destroy his colonies when he knows how to cure the disease. And another thing, our experiment-station men are not trying to prove a self-evident condition false by a few half-planned, poorly conducted experiments.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

MEETING OF THE CALIFORNIA STATE BEEKEEPERS' ASSOCIATION.

A meeting of the California State Beekeepers' Association was held at the Y. M. C. A. building in Los Angeles, December 28, 29.

The question of whether it was the regular annual meeting or a "called" meeting remains undecided, there being a conflict of opinion on that point. This will be anything but a full report; for to give a full report with the feelings engendered would offend some who are now prominent in the work, tho to follow the usual course and say all was peace and enthusiasm would be handling the truth somewhat ruthlessly. To follow the undercurrents would make a report bristling with things not pertaining altogether to beekeeping. So I will confine my report to the proceedings as nearly as possible as shown on the surface, for the benefit of the great majority of beekeepers who were not present.

The meeting was called to order by Prof. Willis Lynch.

An invocation was offered by Mr. Albert Miller, of the Y. M. C. A.

After the address of welcome and response, the business of the meeting was called for. Here the first fire was drawn. President-elect W. H. Allen took the ground that no business could be presented, the regular annual meeting having been held in San Francisco in August, and that no business should now be transacted. The chair ruled against this contention; an appeal was made to the house, the house sustaining the chair. The program was then resumed.

The secretary's report was read and accepted.

Delegates from county clubs made reports, county inspectors following. Inspectors' reports were favorable, showing disease well under control, improved conditions prevailing in most sections.

"Possibilities of foreign markets" by Hon. S. S. Knabenshue (former consul-general to Ireland and China), was then heard. Mr. Knabenshue gave a fine talk.

The different strains of resistant stock, by Prof. Geo. A. Coleman, of the State University, was then heard. The best part of this was the announcement that the University had acquired the use of an island several miles out in San Francisco Bay on which the establishment of a bee hospital is to be undertaken, the object being to study disease, its cure, test disease-resisting strains, and make a study in general of the

bee with an idea of assisting the industry, keeping careful records of all experiments, and compiling valuable data for the future.

Practical wax-rendering by T. O. Andrews was interesting and instructive.

M. C. Richter gave a paper on marketing, giving a volume of export figures, which was altogether an instructive paper.

The exhibit committee thru Prof. Willis Lynch made a detailed report, which showed that, outside of donations from Stanislaus County and the A. I. Root Co., the exhibit might be better known as a private exhibit of Prof. Lynch rather than an association affair. An indebtedness of nearly \$1100 was shown. There had been some opposition to assuming this indebtedness, a resolution having already been passed to disclaim any expense of an exhibit. Prof. Lynch presented his report in a manner that showed that, to disclaim the expense after the secretary had admitted that Prof. Lynch had been told to go ahead with the exhibit, meant the repudiation of debt by the association. The report was finally accepted by a vote, after which Prof. Lynch, in one of the fairest talks ever heard in an association meeting, agreed to accept \$212 as payment in full, this amount representing the actual cash paid out of his personal funds into the exhibit, but not the expense of travel, five months' time of his son in charge of the exhibit, and numerous smaller considerations.

"The Western Honey Bee; Its Fraternal Status and Its Financial Straits" was the topic of the editor, J. D. Bixby. His report, while showing the journal at a point where it might be expected to pay its way in the future, still showed an indebtedness of \$214 printers' bill and \$199.90 editor's salary. Inasmuch as the editor had tendered a conditional resignation, making it obligatory on the association to provide funds to continue the paper or accept his resignation, some way must be found to finance the journal or cease its publication. The Consolidated Honey-producers of California agreed to take the paper over and assume all indebtedness. In the future the State Association will not own or publish a journal, but the *Western Honey Bee* will remain the official organ of the association.

The farewell address of President Lynch virtually closed the business of the meeting; and while many dangerous points had been faced that seemed would cause a rupture, all ended in harmony and good will, save, to be sure, some mental reservations.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

LIQUEFYING GRANULATED HONEY.

"The honey I extracted last summer is all candied hard; and while some of my customers seem to like it that way, the majority of them prefer it in the liquid form. Please tell me the required heat, and how to proceed."

The recipe which was given me some thirty years ago, at about the time extracted honey came before the public, was this: "Set the vessel containing candied honey on the back part of the stove where it is a little warmer than you can comfortably hold the hand, allowing it to remain there till the honey is all liquefied." With only a small quantity, this answers very well unless you forget all about the honey, build a big fire, and allow it to stay there till it reaches the boiling-point or nearly so. Where this is done, the honey not only changes color but the flavor is also very much impaired, especially for one who likes the delicate flavor contained in nice clover or basswood honey. Too much heat is always injurious, both as to color and flavor. We may consider 212° F. as the boiling-point of water; but honey brought to that degree of heat would be ruined; and therefore it is not safe to set granulated honey on the stove-top or its oven if the honey is to be marketed, since such heat is an unknown quantity. Moreover, the bottom of the honey in any receptacle where liquefied by dry heat may go above 212 degrees while the top is still in the candied form. For this reason I would not advise the novice to try the dry-heat plan save for a small amount used at home.

What is called here the "wet plan" is generally preferable for all purposes. This plan generally calls for the "wash-boiler," tho any open dish of suitable size is good. Some put pieces of brick or iron in on the bottom of the boiler to set the vessels containing the candied honey on; but those claiming to know say that wooden strips crowded in so they will not float are preferable, as such will not convey the heat to any part of the honey more rapidly than will the water in the heating-up process.

Having the strips fitted in, the vessel of honey is to be set on these, and cold water poured in by means of a long-spouted funnel till the water comes up around the vessels as far as the honey is inside. It is important that the heating be gradual, for the reason that the process of melting can-

died honey must be rather slow, as it is a poor conductor of heat. If the heating is rapid, that at the sides of the containing vessel would be melted and might be injured before that at the center was little more than warmed. This would be especially true if the vessel were of considerable size. If thru rapid heating the temperature at the sides of such a vessel goes above the highest point of safety, and is maintained at that point until the honey is all reduced, damage is likely to occur, altho the temperature at the center of the mass of honey may have hardly approximated the danger-point. I generally take from three to three and a half hours in bringing the honey to a temperature of 135 degrees, and rarely allow it to get above 150. An oil-stove is preferable to either wood or coal in that the flame can be rased or lowered at will, and thus a temperature of from 140 to 145 be kept as long as it is desired to have every part of the honey reach the same temperature. Basswood and clover honey readily liquefy, and become as clear as when first extracted, at a temperature of 145; but I am told that other honeys, like alfalfa, seem to need a higher temperature to bring them back to their original clear and limpid condition, at least a temperature of 160 being needed.

I find that an injury begins with clover and basswood honeys if they are allowed to stay any length of time much above 165; but as these honeys liquefy readily at a temperature of 135 to 145 the difference between the melting-point and the danger-point is so wide that there is no necessity for running any risk.

Some claim that if honey is put in glass cans and sealed up while hot it will not granulate again, and by this claim many a lot of honey has been injured, both in flavor and color, in that the term "hot" conveys to the average mind near or quite the boiling-point. True, if honey is brought to or above 212 degrees it will rarely granulate again; but the price of such honey will depreciate from one-fourth to no sale at all with most consumers of extracted honey, to say nothing of the injury which comes to the market by putting such before the people. I find that any honey which is liable to granulate will granulate again if only heated so as to liquefy it; but it does not granulate quite as quickly after heating as it did at first nor as quickly after each heating as it did after the one before.

GENERAL CORRESPONDENCE

EXTENSION WORK IN APICULTURE AT THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION

BY PROF. GEO. A. COLEMAN, UNIVERSITY OF CALIFORNIA

Perhaps there is no one subject in all the realm of nature-study upon which the general public so much needs enlightenment as that of the habits, natural history, and anatomy of the honeybee. This is especially true when we consider the very close relationship existing between the bees and the agricultural and horticultural interests of man.

That there is a surprising lack of knowledge of even the most common facts now known in regard to the development of the workers, drones, and queen, and the general economy of the hive, may seem surprising, considering the number of journals devoted to apiculture, and the number of books published in which these topics are discussed. You would not doubt this, however, if you had to find answers for the thousand and one questions which the author has had propounded to him during the past eight months by people who really ought to know better. The most surprising thing to them seems to be that the bees are actually able to go out from the hive, gather the nectar and pollen from the flowers on the exposition grounds, and return to their own domicile without getting lost. As one lady expressed it, "Why, I should think you would be afraid you would lose them all;" and another, "Oh! you don't mean to say that they really go outside of this building and find their way back thru that tiny hole in the wall?" and when assured that such was the case, "Why, how really wonderful!" Then every one, adults and children, even the babies, are always anxious to have the queen pointed out to them; and on the rare occasions when her royal personage permits the operation of egg-laying to be witnessed, the favored few who witness it are simply entranced. The drone is usually taken as a huge joke, and becomes at once the butt of ridicule. The many operations of the workers in wax-secretion, cell-building, caring for the young, gathering and storing of the nectar and pollen, when explained, become so absorbing to a great many that they come around every time they visit the grounds "just to see how the bees are getting on."

Realizing that the Panama-Pacific exposition would offer exceptional opportunities for an exhibit of this kind, and for instruc-

tion in the matter of handling bees in the schoolroom as well as in the apiary, the author planned and has carried on successfully during the entire exposition period an exhibit, accompanied by demonstrations and lectures, which I believe is unique of its kind. It may be interesting, therefore, for you to know something about the manner of arranging this exhibit, apparatus used, and the results.

The "Observation Beehive Exhibit," as it is known in the catalog of the Panama-Pacific exposition, was organized primarily for the purpose of instructing the general public, and particularly teachers in the public schools, as well as pupils, concerning the habits, natural history, and methods of handling the honeybee.

The exhibit was placed in the Palace of Education, on floor space adjoining an outside wall, and occupied a space of 12x20 feet. The space next the wall, and extending out six feet, was divided up into three compartments, 5 x 6 ft. by 9 feet high, and a small office, which were enclosed separately with wire screen to confine the bees when they were being placed in the observation hives, or manipulated in any way. The space outside these wire cages was occupied by a table two feet wide by ten feet in length, upon which was placed all the best books, journals, circulars, and bulletins on apiculture, all wired down so they could not be misplaced but could be readily consulted. The exhibit also included a modern hive for comb-honey production complete, all the apparatus for the extraction of honey and wax, including an A. I. Root automatic reversible extractor, and all of the small apparatus and tools necessary in a modern apiary. On wall space at the end were placed two large charts illustrating, by means of paper models and drawings, bulletins of the United States Department, the anatomy of the queen, drone, and worker, the manner of secreting wax, collecting pollen, etc.—also some models of the honeybee, done in "modelen" by the pupils in the second grade of the LeConte Public School in Berkeley, which were particularly good.

The *special feature* of the exhibit, however, were the observation hives containing the live bees at work. There were three of

Exhibit of observation hives at the Panama-Pacific Exposition, in charge of Prof. Geo. A. Coleman. Note that the bees have to travel thru long tubes to reach the outside.

these hives, two of my own design and construction, and one of the eight-frame Root observation hives, one being placed in each of the three compartments, and containing respectively colonies of each of the three standard races—Carniolan, Caucasian, and Italian, in order to illustrate the characteristics and markings of each of these races of bees. These colonies were placed in the hives in April, and supported themselves thruout the exposition period of eight months, with no feeding except a very little at the beginning. The manner of connecting the hives with the wall and outside is very interesting as showing what bees will do when necessary. In order to have their entrance raised above the heads of the people entering one of the main doors of the building which was just adjoining the exhibit, it was necessary to place the entrance holes in the wall ten feet above the ground, leaving a distance of some seven feet between the hives and the wall entrance on the inside. This distance was bridged, and connection with the hive and wall entrance made by the use of wooden tubes, one by three inches in diameter by eight feet or more in length, and placed at an elevation of 75 to 85 degrees, with glass slides for observation placed at a distance of about three feet from the hive entrance. I have found no trouble in this arrangement, the bees going and coming thru this long tube as a matter of course, and removing dead bees and other debris from the bottom of the hive, carrying it all out thru the long tube to the outside. These hives were left open for observation for six to eight hours daily, after gradually getting them used to the light, which troubled them slightly at first, by leaving them open a short time every day at the beginning until they became so accustomed to the light that it did not seem to interfere with their work in the least.

This, I believe, is largely a departure from the methods of conducting exhibits at former expositions and many fairs, where they have consisted mainly of spectacular demonstrations of handling the bees with the naked hands, having them cluster on the naked skin, etc.—a method which has justly been condemned because it has caused trouble on several occasions, and at best gives people a wrong impression of the real habits of the bees and of the proper precautions to be taken in handling them. It has resulted, also, in a distinct antagonism on the part of exposition officials against such exhibits. For this reason the officials of the Panama-Pacific exposition at first refused permission to allow live bees

to be placed in the exhibit—even the director of exhibits, Mr. F. J. V. Skiff, expressing his disapproval of the plan, making it necessary to do a little missionary work and instruct the said officials, and, indeed, the entire board of directors, in the ways of the humble honeybee before the proper permission could be obtained. I count it, therefore, as one of the greatest victories won by this exhibit, that, thru the entire exposition period, there has not been one complaint from visitors or officials as to any annoyance from the bees, and they have had the entire freedom of the grounds, flying within a few feet of hundreds of people daily, including the throwing of four swarms which were duly hived in the most approved manner in the presence of the admiring multitudes. It also demonstrates the fact that the bees can be placed in the schoolroom, as also the exact manner of doing it, and kept there constantly under observation without any danger of annoyance to teachers or pupils, allowing the children to study their habits daily under normal conditions of non-excitement, a condition in which they are much more likely to retain the facts they learn than when they are under the nervous strain of something very startling. This fact has been abundantly demonstrated by the daily visits of hundreds of schoolchildren at the exhibit, and by their manifesting the most intense interest while there.

In connection with the exhibit, I have, since the first of April, given weekly lectures illustrated with a large number of stereopticon slides, of an hour's duration, on Saturday afternoons, in the Palace of Education Theater No. 1, consisting of a series of four lectures as follows: The Natural History and Anatomy of the Honeybee; The Handling of Bees; The Management of an Apiary; The Composition and Uses of Honey and Beeswax.

The attendance and interest manifested in these lectures was very gratifying. Starting with a handful of people, the attendance rapidly increased until I had the theater, which seats 150 people, packed, some standing in all the aisles and on the platform at every lecture. In this way I reached many thousand people.

The attendance at the exhibit was steady from the beginning, and counts made at different times showed an average of about fifty people per hour thru the busy hours of the day, which would mean several hundred every day, and many thousands for the entire exposition period. On the days when the schoolchildren visited the grounds we were simply overrun.

The exhibit was run entirely with volunteer help, consisting of students who were taking our course in apiculture at the university, and other people interested in the study of bees. Mr. A. C. Earl, a real-estate man, but a lover of bees, gave three half-days a week to it. Mr. E. H. Mosher, Principal of Emerson Public School in Berkeley, devoted considerable time to it simply because he was interested from the schoolroom point of view, and was much pleased with the results. Among those especially interested, I may also mention Mr. Augustus Downing, Assistant Commissioner of Education in the State of New York, who has expressed himself to me as very desirous of introducing the system into the

public schools of New York. The exhibit was also visited by many of the prominent beekeepers of the United States and other countries, all expressing themselves as much pleased with it. Mr. E. R. Root, editor of *GLEANINGS*, has taken a special interest in it, and my thanks are due him for kindly assistance in connection with it.

The exhibit has also afforded a good opportunity for handing out literature regarding our courses in apiculture, bulletins, etc., and of securing a large list of names and addresses of people interested in bees.

The exhibit was awarded a gold medal by the International Jury of Awards.

A NEW CURE FOR EUROPEAN FOUL BROOD

BY TIMBERLINE RIGGS

In attempting to treat any disease one must first understand as fully as possible the nature and cause of the trouble itself. Without taking up too much space I shall, therefore, give a few of my views concerning European foul brood. If necessary I believe I can find facts to support these views.

Very near all of us have some theory or belief as to the method by which European foul brood spreads in a yard. I believe the most common theory, and the one which to me seemed most reasonable, is that it is communicated mainly by drifting nurse bees, the infection being contained in the food they prepare for the brood. As I understand the disease, in an infected apiary practically every colony is continually exposed to infection—of course to a greater or less extent, those with the most vitality being able to withstand it, and those with insufficient strength contracting the disease. The fact that many colonies, particularly the strong ones, are able to clean up European foul brood without any treatment would seem to support this.

In order for the disease to get a start, our bees must in some manner become weakened in vitality. Of course some stocks are naturally of low vitality; but any stock may become weakened temporarily. A knowledge of European foul brood and the habits of the honeybee, I believe, give us the following facts:

In the spring, colonies come out of the winter weak in numbers, and depleted in stores and vitality—in fact, at about the lowest ebb of the season. Nature at this time supplies them with the instinct for

brood-rearing, possibly, more strongly than at any other time. Under this impulse the bees raise all the brood they possibly can gather stores for, keep warm, and take care of, spreading themselves to the absolute limit of their brood-rearing capacity, of course the weather compelling them to keep no larger brood-nest than they can keep warm. With a very large brood-nest, such as is supplied in modern apiaries, almost invariably this period of brood-rearing must last longer than with a smaller breeding-room.

At this time it is quite reasonable to suppose that the bees do not feed their brood a bit more lavishly than is absolutely necessary. The honeybee is extremely provident and economical except in times of prosperity. With all the brood they can care for, and in a slight dearth of pollen or nectar, it is quite possible a lot of brood does not get all it really needs for its best development. This, it seems to me, *must* result in lowered vitality. We get inferior development and vitality in any of our domestic or other animals if neglected as to food or other necessities at any time during the period of its growth, and my experience tells me it is the same with bees.

Coincidentally you will find that it is at practically this very time that European foul brood does its worst damage. You will also find that increase or any weak colony at any period when the bees are spreading their brood as much as possible is quite subject to the disease. A colony that has reached its capacity for brood-rearing when there is an abundance of nurse-bees to take care of the brood seldom shows the disease

unless there is very little food coming in, when they are just as liable to starve their brood as a weaker colony. In my experience strong colonies never succumb to the disease when there is plenty of food coming in.

I have never heard of a case of European foul brood found in bees taken from trees. Has any one else? Yet these same bees transferred into a modern roomy hive in an infected locality quickly contract the disease. Bees in a tree, left to their own devices, generally have quite a small brood-nest; for if the cavity is large, surplus room is quickly taken up with surplus stores, and in the spring there is seldom more room than that supplied by winter consumption. As a consequence the period of extensive brood-rearing is much shorter, and the bees reach the swarming condition earlier. In other words, the chance of any brood being neglected is reduced to a minimum. How else can the immunity to European foul brood found in trees be explained than that they do not get a chance to spread their brood like other bees, resulting in more or less partial starvation and weakened vitality?

My explanation of my method of treatment of this disease is quite simple; but before giving it I wish to state that I do not claim that it is a proven cure or even proven experience to hold good in all localities and under all conditions. With my bees and local conditions it works so well that I consider it a cure. However, I have never handled black bees, nor have I ever experienced in my apiary European foul brood in its most virulent form, nor do I believe any one is liable to with good Italian bees. Possibly my method may not work with black bees or a different locality. I should hate to try to cure it with poor bees. The experience of others may contradict rather than support this article. I give it for what it is worth.

SIMPLY CROWD THEM!

Now for the cure: In the treatment of a colony or nucleus, no matter of what strength, take away every bit of room the bees are not fully occupying, or a little more, and then contract the hive down till the bees are *crowded*, using a division-board if necessary. They must not have unoccupied room if they are reduced to even one comb. If nectar is coming in, that's all that is necessary. If it is not, apply a stimulative feeder. I have not found it necessary to dequeen, altho if the case is bad it is liable to be because the stock is poor, and for this reason I would requeen the worst cases.

Their only fault may be an overtendency to spread brood.

In swarming time this is liable to result in swarming. Frankly, I do not use it much at this time, but unite all of the worst cases, making rousing colonies of them, dequeen, and feed as by the usual method of treating disease. However, with me I consider this treatment almost an annihilation of my investment, and only the worst cases are so treated—not as a cure, but to prevent the spread of the disease. However, I have very few bad cases—almost none in which the disease would overcome the bees if I cared to let them wait before treating. I must, however, admit that spring months in this locality are much more favorable than in most. Prior to swarming time, and while colonies are not yet strong, they may be more or less crowded, if necessary. In deciding whether a colony will stand this treatment, there is room for quite a bit of judgment and knowledge of the humor of bees and what they will probably do.

Sooner or later bees treated by this method will require more room. Do not give a colony super room until it can occupy and have use for it; and in giving nuclei additional brood-nest, never use drawn combs. Use full sheets of foundation and put it on the outside, at least with diseased nuclei, never spreading the brood. Your nuclei, you will find, will build up almost or quite as fast in the long run as if you had given them abundance of room.

In regard to brood-spreading, to me it has always seemed that bees do best where they were not given too much room, and they seem to make the room themselves just as soon as they really need it. I have never yet practiced brood-spreading where I knew that I derived any benefit from it. On the other hand, many times I know it has cost me money. There may be times when there is a profit in it, but I do not know when it is. Most beginners always make the mistake of giving too much room to their bees, and simply tingle with a burning desire to spread brood as soon as there is any to spread. I believe this is the most common and costly mistake beginners make, for verily it keeps the bees in a state of absolute discouragement and demoralization.

Of course, where one or two men are looking after six or eight yards of 500 to 1000 colonies of bees one occasionally has to give more room than the bees really ought to have, for in this case the item of labor is supposed to counterbalance any loss of crops. But where proper attention can be spared, I consider the giving of room

Algoroba-trees growing on the lowlands near the sea, on the lee shore of the Island of Oahu.

one of the fine points of judgment in the ordinary apiary manipulations.

Here is another thing I have found out: The strain of bees themselves is at least half the battle with European foul brood, for quite frequently a good Italian stock will clean it up of their own accord. I much prefer the leather-colored Italians, for I have noticed that the yellowest bees

are often most subject to disease. This crowding of brood, forcing the bees to feed and care for the larvæ more lavishly, is, of course, given only as treatment for European foul brood. I know of nothing but starvation, shaking, and destruction of combs for the treatment of American foul brood, altho for me it has very few terrors. Overton, Nev. [See editorial.]

HONEY-PLANTS ON THE ISLAND OF OAHU, AS SEEN BY A MALIHINI

BY LESLIE BURR

There is but one honey-plant on the island of Oahu—that is, but one worthy of the name. There are numerous plants that yield honey. Some of them yield profusely, but they do not count in the crop. When the royal palm is in bloom it is alive with bees; but the royal palm blossoms only once or twice during the year, and each tree has its own individual time for blooming. Besides, it is planted only as an ornament, and is found only where planted, and that is principally in the city of Honolulu. That lantana grows everywhere—that is, when given an opportunity. It yields some nectar.

Then there are cocoanuts, dates, and other palms that yield some honey whenever they happen to be in bloom. Sugar-cane, when attacked by the cane-borers, secretes juice very copiously, and the bees step in and keep it from going to waste. Millions of dollars have been lost to the cane-planters of the islands by reason of the cane-borer, and the beekeeper seems to have been the only person to profit. This cane-juice honey is not an article that can be placed on the market for home consumption—not even if it is sought for by the bakers. In the past, prior to the war in Europe, it went to Ger-

many. That gathered last season by reason of the war still remains unsold. It is at the present time in storage, and will probably remain there until the end of the war.

The only real honest-to-goodness honey, worthy of the name, is that gathered from the algaroba-tree. The native name is "kiawa." In the United States, along the Mexican border, it is called "mesquite;" in the Spanish countries it is called "algaroba," and the botanical name is *Prosopis juliflora*.

The first algaroba was brought to the Hawaiian Islands by father Bachelot in 1826. He was given the seed at the Royal Gardens in Paris. The seed was given to him there with the seeds of several other plants—several that were thought suited to the conditions existing in the islands. It is not known just how the seed got to Paris; but the supposition is that it came from South America. From the original seed brought by father Bachelot there is still one tree alive. It stands on Fort Street of Honolulu.

Of all the trees on the island, the algaroba is considered the most valuable. Following its introduction it spread like wild-fire, and thrived under every condition it met. And there are many conditions that exist in but few places. At one place the annual rainfall may be over a hundred inches, while at a distance of a few miles the fall will average but a few inches. The cause of this varied rainfall is the mountains, which have the effect of spilling the rain out of the atmosphere, causing it to precipitate near the mountain-peaks.

Stock was the agent that distributed the

seed. Cattle are very fond of the seed-pods; and since the introduction of the algaroba the pods have been one of the principal stock foods. The seeds, however, are very hard, and are not digested unless they have been ground, and so were distributed. Wherever the seeds were dropped they grew as readily as any weed. Low land, whether wet or dry, seemed to be exactly suited to the algaroba. In fact, any kind of land on which a tree could grow seemed to be all that was asked. In some places they grow in dense thickets, in other places they are tall trees over three feet in diameter. Every piece of land on which it is possible for a tree to grow, if not dominated by the hand of man, is dominated by the algaroba.

The trees reach a height of fifty feet; have small pale-yellow flowers in cylindrical spikes, abruptly bi-pinnated leaves, having from six to thirty pairs of leaflets. The pods are gray, sickle-shaped, and from five to seven inches long. The trunks of the trees are not, as a rule, well formed, being either crooked or gnarled; but the foliage is beautiful. The wood is the best fuel to be found on the island; and as the growth of the tree is rapid it is possible to grow it for that purpose. The wood is used for other purposes than fuel, being very hard, with a beautiful color and grain.

The algaroba blooms during the summer months; yields nectar in a copious manner, which is of good flavor, color, and body; and it is the only good surplus honey obtained on the island.

Honolulu, T. H.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sightings among the Bees

BY H. H. ROOT

Every season we get a lot of reports from beginners, telling of the bees of some colonies being very large while those of other colonies are small. Frequently we receive samples of large and small bees. Of course, there is sometimes a difference in the size of bees in different colonies. But in the great majority of instances the difference in the size of the workers is due to the difference in the size of the abdomen, depending upon whether they are distended or contracted. Bees that have been feeding heavily, or those whose abdomens are swollen because of an overcharged condition of the intestines, look very different from

other bees whose blunt contracted appearance makes them look very much smaller.

The first illustration shows two worker bees, both of which are distended, the one at the left rather more than the one at the right. Altho both looked large there was an actual difference of about 1/16 of an inch in their length.

The second illustration shows a worker bee with a distended abdomen, then a worker with a contracted abdomen, and, last, an old shiny bee—from all appearances a robber. These bees were all taken from the same colony at the same time. So far as head, legs, and thorax were concerned they

Two bees with distended abdomens, making them look large, almost like a queen. Photographed on Seed 23 plate; time, one minute.

were substantially the same size; but the difference in the entire length, including the abdomen, was very marked indeed. The black shiny bee at the right looks more like a diminutive drone than worker on account of the round blunt appearance of the abdomen. The bee itself, however, did not look quite so blunt as represented by the photograph, for the tip of the abdomen was turned down somewhat so that it did not show plainly.

SOME INTERESTING MALFORMATIONS.

In one hive we found several very curious-looking bees running about on the alighting-board. They were not making any attempt to fly, especially the one in particular which had no wings. The illus-

tration shows three cripples that were alive and apparently well when found. How long they would have been permitted to remain in the hive is hard to say. Some of them were so badly twisted that they had to turn around and look backward when they wanted to walk ahead.

There were no moths in the hive, no burrowing-moth larvæ thru the combs—nothing of the kind could be found to have mutilated the bees. We found these bees, however, just after a cold rainy spell when the sun and clouds seemed to be quarreling to see which could be boss the longer. The temperature, moreover, was alternately hot and cold. Perhaps the rather peculiar and unsettled conditions caused the queen to start more brood than the nurse bees could

Different sizes of worker bees from the same colony. Note that the abdomen of the first bee is longer than the wings, while that of the second bee is shorter than the wings. The third bee was an old shiny one—perhaps a robber. Photographed on Seed 23 plate; time, one minute.

Some curious examples of malformation. These bees were alive when found, running about the hive as cheerfully as any bees. Note that none of them have a full outfit of wings, and all of them are badly twisted and deformed.

care for, so that some of the brood was badly neglected—at any rate, the bee in the center, for instance, which, instead of having four wings, had only about half of one. It did not have the appearance of having had even the stub of the three other wings. It seemed to have matured without them. Perhaps a sudden turn in the weather arrested development, even tho these bees in the larval stage might have been well supplied with food.

The bees in these illustrations were not photographed alive, but were killed first by being placed under water for fifteen or twenty minutes, and then dried and sub-

jected to the fumes of hydrocyanic gas for about ten minutes. I have tried many ways of killing bees, but none that result so well as this plan. Bees kept under water even for several hours often have an annoying habit of coming to life again and crawling about just when you are ready to photograph them. If they are left under water ten or twelve hours they “stay dead;” but, strangely enough, they take on a rather water-soaked appearance in spite of all that can be done. If they are placed in the gas alive they curl up and get into such unnatural positions that it is impossible to make them look lifelike.

THE DISTRESS (OR SMOKE) METHOD OF INTRODUCING; WHY MEN FAIL

BY ARTHUR C. MILLER

The following letter introduces the article:

“I follow Mr. Miller’s method up to letting the queen run in at the entrance. Previous to smoking, a regular bee-escape board is placed over the cone to receive the queen. The colony, of course, is in one hive-body. Then I proceed to smoke *a la* Miller. Perhaps I had better say this bee-escape board is made air-tight. A tight-fitting plug (a block with a larger piece of tin nailed on to it) is inserted in the hole and all weighted down.

“I had a small flat wire cage, $1\frac{1}{2} \times 1\frac{3}{8}$ inches, which is open at one end. Into this I put the queen. I think that, if the queen is put into this cage without any attendants for twenty to thirty minutes previous to introducing, it will add the excellent features of the starvation method.

“Remove the plug from the bee-escape. Send in a good puff or two of smoke: Put the caged queen into this hole on the top

of the frames and close up the hole. In ten minutes give a small entrance (one inch); an hour or so later, the full entrance.

“Mr. Miller says the frames should be $\frac{7}{8}$ inch above the bottom-board (page 370, 1913). While I believe this is necessary to distribute the smoke, I believe it is almost equal to the mistake he cites on page 511, July 1, 1914, of introducing the queen to a full-sized hive, and not filling up the empty space to prevent the queen wandering into it. If the queen goes directly on to frames, well and good; if not, I believe there will be trouble. Hence this method of putting the queen directly on top of the frames.”

St. Louis, Mo.

J. H. FISBECK.

Mr. Fisbeck’s use of an escape-board in queen introduction is a very convenient arrangement, and has been used by quite a number of people. It is particularly good where one’s hives have only a small or shallow entrance, as it makes possible the prop-

er smoking of the colony. But the fasting which he recommends in addition is quite unnecessary.

The so-called smoke method of queen introduction has now had several seasons' trial, and, like every other method of practical bee culture, has given varying results in different hands.

Beekeeping is far from a fixed science. The bees are a living organism governed by certain laws, reacting to external conditions, always reacting the same to the same conditions; but if the conditions vary, the reactions vary also.

Two persons attempt a certain method; one succeeds, the other fails. They wonder at the results, but do not see the cause. They may be assured, however, that the conditions were different. And until all beekeepers become past masters in the art of reading bee actions and analyzing conditions, we may expect wide variations in the results of the same methods in different hands. The best that can be done will be to explain and emphasize the conditions essential to the successful carrying-out of a method, and then leave each individual to work out his own salvation.

It is somewhat unfortunate that the method of queen introduction so closely identified with my name should have been called the "smoke method," for there have been several methods called by that name, and not a few of the older beekeepers confuse the new with the old. The old was a system of smoking the colony more or less and letting the queen run in, generally at the top; but closing of the entrance was *not* a part of that old practice.

The new plan is more properly called the "distress method," for by confining the bees in a smoke-filled chamber, and preventing their obtaining any relief by ventilation, a condition of distress is created which enables us to do as we please with them.

Thru the courtesy of Mr. Morley Pettit I have been enabled to see the reports of the various Canadian experimenters with this method as well as the many letters sent to me, and also the published reports; also at every convention I am asked many questions concerning it. From all this evidence I have been able to get a pretty clear idea of the causes of failure by different persons, but the successes far outnumber the failures, tho we might not think so from published reports; for so long as matters go smoothly the operators do not hasten to inform the press. Every little while, by a letter or at a convention, I learn of some big operator who has adopted the plan and of many a lesser light who uses it. For the

new comers, and those who are not familiar with the "distress method," let me repeat the instructions and then speak of some of the causes for failure.

A queenless colony has the entrance to its hive nearly closed, say all but an inch. Into this space a cloud of smoke is blown until the bees roar; then this space is quickly closed. In about a quarter of a minute a queen is run in and the space reclosed. In ten minutes more the inch space is opened and the bees allowed to ventilate slowly. That is the sum and substance of the method.

Here are some of the qualifying conditions: First, the hive must be smoke-tight. Open corners, warped covers, cracked floors, etc., are conditions fatal to success with this method. All possible chance of ventilation must be prevented. Second, the smoke must be such as to create the greatest distress and the least danger, and that sort of smoke is the thick white choky kind. Third, enough smoke must be driven in to fill the chamber so completely that no bee will fail to feel it. Fourth, the smoke and bees should be confined for ten to fifteen minutes, and then relief given slowly as by opening only an inch of the entrance. If the whole of the entrance is opened at once the bees may pour out in a mass and sometimes the queen with them. They soon quiet down, even with only the inch outlet, and when quiet the entrance may be fully opened.

Failure has been reported where introduction was tried on a small nucleus—two or three frames—in a full-sized body. The cause is usually insufficient or thin hot smoke or both. Other failure reports have to do with attempts to introduce queens to big colonies occupying two stories or having supers on. It is very poor beekeeping that calls for changing queens under such conditions. It is much like swapping horses while crossing a stream. When colonies are as big as that, or are at work in supers, for gracious sake let them alone! They are doing well and working for you, so don't queer the job by butting in. Plan to do the requeening at such time as little or no honey is coming in, and when the stock is comparatively small. In the northern United States and Canada, August or September will be found to be the most advantageous plan.

If conditions compel the introduction to big colonies during the harvest it is only necessary to be sure the whole hive, supers and all, are filled with smoke, and that no cracks let it leak out; then the queen will be as safe as when put into a smaller colony.

But it is tough on the beekeeper and tougher on his bees.

Where a hive does not fit quite evenly to the floor, or a very *slight* crack is open between the cover and the hive, it is not always necessary to plug them up—just be sure the smoke is thick and white, and give a little more of it.

The best test is the tone of the bees' "roar." It is quickly learned, and the trained ear will instantly detect any undue subsidence, and more smoke will be given. I have several times noticed the sudden lowering of the "roar," and, on looking around, discovered smoke being blown from some unsuspected crack.

Create the distress; see that it is continued for about ten minutes, and you never need worry as to the safety of the queen.

As to the manner of running in the queen, use the handiest way—that which is easiest for you. If working with queens from one's own yard, taking them by the wings and tucking them in at the entrance, followed by a puff of smoke before closing the small space, is easy for all who are accustomed to handling queens. Sometimes it is easier to push the cover back at one corner, drive the bees back with more smoke, drop the queen in, followed by smoke, and close the cover. Putting the queen into a wire tube and holding the finger over the open end until the tube is pushed in at the entrance is another way. The escape-board on top as given by Mr. Fisbeck affords a very convenient place to drop in the queen or to put in an *opened* cage.

When running in a queen from a mailing-cage the end is opened and the cage is pushed in under the frames, and queen and attendants allowed to run in. My entrances are all an inch high so I can do that; and, by the way, if you see the attendants being

thrown out soon after you open the entrance you may be sure you did not give smoke enough, and that your queen is in danger. Pour in more smoke—thick and white, remember—and reclose the entrance for another ten minutes, at the same time making sure there is no leak by which the bees may drive out the smoke or obtain fresh air.

I find several advantages in the distress method over any other I know of. There is no long queenlessness of the colony, for the new queen may be run in at once on removing the old one, the only exception being where a colony has been badly overhauled in finding the old one. Under such circumstances, it is better to wait a few hours or over night.

Another advantage is the lack of any need of looking up queen-cells, as when a colony has been long queenless. If, however, it has been so long without a queen that a virgin may have hatched it will be necessary to find and remove her. And if a man must, he may safely introduce a queen by this method to a colony with laying workers, but it is a piece of poor beekeeping. Better add such a colony to one with a good queen, giving her the run of both chambers for a couple of weeks, then separate and give a queen to the queenless part.

Finally, the method yields the highest per cent of success. I lose less than one per cent of all queens introduced, and I can almost always trace such loss to insufficient smoke or some chance for ventilation.

In conclusion I would give one word of caution. Don't overdo the smoking, for it *is* possible to injure the bees and brood by an excess of smoke. However, there is more danger of too little than too much. Listen to the "roar" a few times and you will soon learn how much is needed.

Providence, R. I.

SOME OBSERVATIONS AND SUGGESTIONS ON THE SMOKE-IN METHOD

BY C. D. CHENEY

Upon the advent of any new method there are always some who try it with great success, and others who fail to make it work, with enough praise from the former and more than enough condemnation from the latter. The "smoke-in" method of queen introduction is a case in point.

Fortunately there are many open-minded and careful observers who, if given time, will ascertain possibilities and limitations so as to establish the conditions for successful general use, or determine the fallacy in the method.

While A. C. Miller, from his own intimate knowledge of conditions, can work the method with uniform success, others who undertake to use it can hardly be expected to meet with the same success, owing to their lack of that knowledge.

As time passes and experiences accumulate and are reported, some comprehensive instructions should be evolved on just how to manage the smoke-in operation to enable beekeepers at large to practice the method, even tho they do not know the "whyfore."

It is not necessary to repeat here any

thing in regard to why a queen is accepted in one case and not in another. It is generally agreed that when a new queen is once quietly among her new family there is little to fear for her safety. If the bees and the new queen can be brought to the same state of mind (sounds queer, but it is the best way we can express it), or distress, or what-not, there is no ground for a fight. When conditions return to normal, all thought of previous differences are forgotten and things are accepted as they then exist.

Every one knows that bees retreat before a puff of smoke; therefore when smoke is puffed into the hive entrance preparatory to running the queen in, the bees leave the bottom-board and the bottom-bars of the frames in a general route to get away from the smoke. The consequence is that, when the queen runs in, there is nobody at home, and she is alone to fight it out with the first guard she may meet. Such a condition is about as unfavorable to her acceptance as well could be, as all methods have for their prime purpose to get the queen into close relationship with a large part of the colony without causing suspicion or a quarrel.

It occurs to me that Mr. Miller's uniform

Bees working on prickly-ash, a scrub-like bush about 12 feet high. Photographed by D. M. Bryant, Ethelfelts, Va. [The original photograph showed upward of 20 bees working on this single branch.—Ed.]

Bees on milkweed. Photographed by D. M. Bryant, Ethelfelts, Virginia.

success is due, whether he knows it or not, almost wholly to using the right amount of smoke in the first place, and then awaiting the psychological moment to run the queen in when the bees have naturally surged back to the bottom-board in their desperate effort to make an escape. He is, no doubt, able to sense the moment when the queen will find everybody home and none looking for an intruder. May I suggest that the hive be lifted an inch or two, and then bumped down hard enough to bring a goodly bunch of bees down on the bottom-board a few seconds only before the queen is run in? The philosophy of this suggestion is that the queen becomes intimately mixed with the bees while *all* are in the *state of greatest demoralization*; and by the time things begin to be natural again she has reached the combs (still among her new family), and is at home. By bumping the hive, and so bringing a mass of demoralized bees down to the bottom-board, that "psychological moment" can be made to order, and utilized, as it would seem, without fail.

If this should prove to be the deciding factor between success and failure it will

thus be possible to eliminate much of the present uncertainty in the general use of the "smoke-in," and so make it available for everybody.

So many reports of failure with the "smoke-in" queen-introducing method contain, in substance, the statement, "I removed the old queen in the morning, and waited until evening to give the colony a chance to quiet down, and then smoked-in the new queen." One may feel justified if some importance be attached to those particular times of removal and introduction as affecting the result.

The morning removal and the evening introduction appear to be favorite practice, and during the past season I proceeded that way with three queens and lost the three. This set me thinking.

It seems perfectly logical to "give the colony time to quiet down;" but from observation and experience I conclude that in such circumstances the colony doesn't quiet down, and the result seems to bear out this conclusion. I desire to call attention to

these observations, and to suggest for study and experiment that bees really "quiet down" only at night (taking no account at this time of cold and wet days), which should suggest that the logical time for removing the old queen would be toward evening. Some time toward noon the next day, when the old bees are away on business, would be the best time for introducing the new queen. This plan would probably not influence results with any cage methods, but it "looks good" in relation to any run-in method.

The "smoke-in" appears to me as the simplest introduction method yet proposed; but it needs to be better understood, so that it will be practicable in the hands of any one, whether he knows or does not know why he is to do this or that. I have been giving considerable thought to this matter, and I am giving my observations and conclusions to set others to thinking, and in the coming season to experimenting, I hope, in order that some helpful knowledge may be developed.

HANDY DEVICE FOR MELTING BEESWAX

BY J. H. TODD

I have just finished fixing sheets of foundation with melted wax, using a little device I have made for this purpose, and it works perfectly. I never could get on at all with the Vandusen tube fixer; but my device is a pleasure to work with, and can be made by any one who can use a soldering-iron.

The first thing required is a wide shallow tea-kettle. Mine is 2½ inches deep and 8 inches in diameter. With a file, cut the han-

dle off so that it projects only a little way over the lid of the kettle. This is done because the steam condenses on the under side of the handle and drips into the wax.

It also gives more room for putting the wax-container in and out of the kettle. Now for a description of the wax-container. Get a small round cocoa or similar tin, about 4 inches deep and 2½ inches in diameter, or slightly smaller than the lid-hole of the kettle. Now there are two things to solder on—a spout and a handle. In the spout cut a piece of tin 1½ inches long and ⅜ inch wide. Now in a vise or with a pair of pliers bend this lengthwise to a V shape or angle of 60°; then at one end cut up the bottom of the V for a distance of ¼ inch and bend the cut ends as in A.

Now take the tin and bend the top like the spout of a cream-jug, as in B, and here solder on the spout, pointing slightly up so that its delivery end is ½ inch above the level of the top of the tin.

Now for the handle. Get a piece of galvanized spring steel wire and a piece of ¼-inch round iron (a bolt or something of that kind); put the round iron in a vise, and neatly and tightly coil the wire around it till the length of the coil is about 2 inches. Leave 1½ inches of straight wire at both the ends of the coil, and slip the coil from the bolt or round iron. Stretch it out a little so that light will show between the coils of wire. With a hammer flatten out

dle off so that it projects only a little way over the lid of the kettle. This is done because the steam condenses on the under side of the handle and drips into the wax.

the ends of the wire. Now get the tin; and, opposite to the spout, solder on to it one of the flattened ends so that the spiral spring will stick out at right angles to the side of the tin, and so that the under side of the spring is level with the top of the tin. Take the other flattened end, bend the spring upward, and solder this other flat end on to the tin close to the first one; but fix it with its end only $\frac{1}{2}$ inch down the side of the tin. This makes a good handle which will not get hot.

The working is, of course, plain. Keep the kettle boiling slowly on an oil-stove, with the tin standing in it. The tin, of

course, contains the wax, and also a piece of flat lead to weight it down. The little spout enables one to pour the wax just where it is wanted; and if the kettle keeps boiling, it is just the right heat, and with a little practice you can run the wax exactly right. After a time the spout fills up with cooling wax. It is then time to put it back into the kettle for a moment or two. A touch of the wax at the end of the spout sends it back into the tin. By the way, don't have too large a tin or it will prevent the steam that rises from the kettle from keeping the spout hot.

Renwick, New Zealand.

THE WATERS PATENT HIVE

BY W. WATERS

The season of 1914, 1915, in New Zealand was the worst we had had for many years, not only in point of honey production but on account of the large number of queens which failed to return after mating. In the ordinary hive, where the old queen was destroyed and the young queens failed to return, the work of these hives was practically lost for the season. A new hive which I have invented makes possible the presence of two queens in the same hive for a time, so that if a queen fails to return a new one

can be reared and no time of production lost in requeening.

The reader will notice from the illustrations that the hive is a double one, altho it may be made as a single hive. By inside measurements it is 46 inches long by $10\frac{1}{2}$ inches deep, and is divided by a single central division-board, surrounded by galvanized gutters two inches wide by $\frac{5}{16}$ inch deep. The sides of the gutter are turned over and made double, and rest on the central division. The hive on each side

Double hive, permitting two queens, if desired, as used by W. Waters, Papatitoti, Auckland, N. Z.

The interior of the double hive.

holds 11 frames up to the center of the side gutter. The side gutters are $1\frac{1}{2}$ inches wide by $\frac{5}{16}$ inch deep, and fit into keepers. They can be lifted out at will.

There are two movable division-boards of $\frac{3}{8}$ -inch stuff, one on each side. This makes it possible to increase or decrease the number of frames to the colony. There is room for 15 frames on each side.

Those guards at the entrances are of galvanized-iron, and ant-proof. They fit in behind a galvanized fencing wire turned in at the end, driven into the front board, and stapled at intervals. They are intended only for winter use.

The bottom-board consists of two railings, 3 feet by 2, each 4 feet long, which carry the flooring nailed flush with the rails back and front.

One great advantage of this hive is that it requires no lifting or shifting about the apiary, for all the work can be done without other appliances. I can say, after working the hive for two seasons, it makes beekeeping an actual pleasure. There is no necessity for extra bodies, covers, and bottom-boards. Where the hive is placed, there it remains.

We will suppose that a beekeeper has 50 of these hives holding 100 colonies, and he wants to requeen them all in the spring and

at the same time prevent swarming. He is sure to have ten colonies in his apiary with queens good enough to breed from. Go to these ten colonies, and in each case lift out the side gutter and pull out the movable division. Now take five frames with the queen and place them at the outer end, and back them up with a division-board and replace the gutter. As this hive takes eleven frames to the colony you will now have six frames with no queen left in the main compartment. Back them up with a rough division-board, and they will at once build queen-cells anywhere from ten to twenty in each colony. When those cells are from eight to ten or twelve days old, go to all your other colonies and do the same as with the ten, and at the same time give a cell to each queenless six frames. The queen will hatch out, mate, and be laying in due time. In the mean time the old queen has been laying uninterruptedly. When the young queen is laying, remove the old one and pull out the division. Slide the old queen's frames back to the others and replace the gutter and division-board.

This is a simple method of requeening an apiary, preventing swarming, as the young queen will not swarm the same season, and you can allow her another frame, making twelve if she wants them.

The hive is provided with two exits at the back, which enables you to hatch and mate two queens on those six frames if you wish to have spare queens. In that case you would separate three frames from the other three by a division of perforated zinc, giving the center comb of each three a cell.

This hive may be made at very little more expense than that of the ordinary hive. It is, moreover, far and away cheaper than the

ordinary hive in this respect. It requires no nucleus for queen-rearing and mating, and you are saved all the work therein. There is no handling and introducing of queens. You require no double plant of bottom-boards, bodies, and covers for shook swarming. All the work of the apiary can be done with this hive without any other plant whatever, and very much better, and at half the cost of labor.

Papatvitoi, Auckland, New Zealand.

STORES NECESSARY TO WINTER BEES OUTDOORS

Bees in Pound Packages from the South vs. Wintering in the North

BY J. L. BYER

On page 969 the editor, replying to a question of Grace Allen, stated that they figured on 20 lbs. of sealed stores, including combs, as sufficient for northern wintering, and that 25 or 30 would be better for the North. In my department for Jan. 1 I say that for here in Ontario the most of us would want double that amount, and that we would not have any trouble in getting it used by the time our main flow started in June. I further stated that Mr. Sibbald makes his ten-frame L. hives weigh 70 lbs. without the cover, and that many others insist on nearly as much.

Now turn to page 2, Jan. 1, and see what the editor claims I say: "Mr. Byer says he himself would require from 40 to 50 pounds of stores, and Mr. Sibbald uses 70 pounds." I have just been to one of the extracting-houses and weighed up some empty combs and hives, and the results are interesting to me, especially when compared with the "20 pounds, combs and all," proposition for outdoor wintering. Ten L. combs were selected from a pile of extracting-comb, these combs having some pollen in, but no more than would be in the average combs going into winter quarters with bees on them. I was rather surprised to see that the ten combs weighed 12 lbs. If old brood-combs weigh like that in Ohio, then 8 lbs. of actual stores, either honey or sealed-over syrup, I presume, will carry the bees thru the winter. My statement was that I would want double the amount specified, so that would make 40 minus 12 pounds for combs, pollen, etc., leaving a balance of 28 lbs. actual stores. How many outdoor winterers in the north will say that is too much? Please hold up your hands. Mr. Sibbald makes his hives to weigh 70 lbs. How does that work out in actual amount of stores? I weighed a ten-frame hive this morning, and found that it tipped the scales at 16

lbs. This hive has cleats all around top so it may be a bit heavier than the ordinary run. Sixteen plus 12 lbs. for combs, etc., makes a total of 28 lbs. Seventy pounds, hive and all, minus 28 lbs., means 42 pounds of stores—pretty generous allowance, I will admit, but still quite a long way from 70 lbs. As a matter of fact, I want more than 28 lbs. of stores in my hives; and at a rough guess I would say that all our colonies this fall would run, on an average, 35 lbs. No, this is not all used in *wintering*—indeed, not half of it is consumed during the cold winter months; but after brood-rearing starts nicely during the months of March and April the stores are rapidly turned into bees. Then, again, we often get a lot of bad weather during first two weeks in May, and, needless to say, a large amount of stores is needed then.

As to cost of wintering our bees, the estimate of the editor is high enough, to say the least. Let us figure that item a bit. He estimates a cost of from five to eight dollars per hive, figuring on that fictitious amount of stores, and reckoning said stores at 10 cts. a pound. In the first place, our bees do not winter on stores worth 10 cts. a pound—not by any means. Running for extracted honey, at the close of the white-honey flow we have little honey in a L. brood-nest. Any honey put in the brood-nest goes there during the latter part of the buckwheat flow; but more particularly if we happen to have a flow in September from asters or goldenrod, which does not often occur. This honey is not worth more than 6 cts. in the brood-nests, and would bring little more than that if extracted. The bulk of stores is sugar syrup, and that will stand us just about that figure too by the time it is fed. On my estimate of 35 pounds to that of Mr. Sibbald with 42 lbs., the result would be that it costs us for wintering between \$2.00

and \$2.50 per colony—quite a difference again, between those figures and the starters given in this editorial.

As to brimstoning bees in the fall, surely an unheard-of proposition here in the North, and the only mention I have ever seen in this line was on the part of a good friend in the South, who sells bees by the pound. The shipping of bees in combless packages has a future, but no pound package can ever compete in the matter of producing surplus, with well-wintered full colonies. No, sir, "it can't be did." Whether bees will consume more or less stores here in Ontario than they will in Ohio—frankly, I don't know. As pointed out, what Dr. Phillips says proves conclusively, *theoretically*, that our bees should consume more; but as a matter of fact I am not convinced that all his claims in that line work out in practice. I know that during winter we have some thaws, causing the bees to get stirred up more or less, and yet not warm enough for them to fly; that if these thaws are at all frequent, our bees consume more stores than they do during seasons of steady cold weather.

The question of insulation is a difficult problem to settle satisfactorily; and while I believe in lots of it for our climate, I was somewhat jarred in this line when visiting friend House to see that while his bees were well protected on sides, rear, and tops, yet he had absolutely no packing in the fronts. Dr. Phillips says that the insulation of a hive is just as complete as its weakest place, so on that basis of reckoning the bees in House's apiary have no insulation except the inch board that comprises the front of the hive. It is not necessary to say as to how House's bees winter, and I do not attempt to make any explanation, but will leave that for Dr. Phillips to do.

As to the matter of snow over hives, I should think that in localities where they have many thaws snow would never be all over hives very long at a time. When snow is over hives very long we find that there will be large spaces melted around entrances, and there is no danger of water congealing there. Just at present I only wish we had snow over our hives here in York Co., as we have none at this date, Jan. 12, and we are apt to have severe weather during the next four weeks. However, I would not advise any one to take any chance on my advice not to worry over the snow problem, as we have had but three winters when our bees have been covered over so long at a time. Altho they have wintered so well so far, another season might tell a different tale. I expect and

hope that the north bees are covered over at present, and we are doing no worrying. Another thing, do not forget that I emphasized the matter of having a quilt over frames instead of a board, and that we want lots of absorbents over the quilts and an air-space between packing and tops of winter cases.

In conclusion, while there is a chance that my advice might not be the best for some localities regarding the matter of allowing snow to drift over the hives, if there is anything I am sure of it is this: that 20 pounds of sealed stores, combs and all, are entirely inadequate for wintering bees outdoors in our locality; and I again say, without any hesitation, that we want double that allowance to carry on beekeeping successfully here in Ontario.

Markham, Ont.

[The whole discussion hinges on a careless reading and an unfortunate misprint. On page 969 the little word "not" was omitted in the sentence replying to Mrs. Grace Allen. It should, therefore, have read as follows: "We should figure on 20 lbs. of sealed stores, not including combs." On the face of it, it might look as if it were an ingenious way to crawl out of a hole. Be that as it may, that this must have been the meaning is clearly shown by repeated statements to the same effect in these columns, and particularly in the A B C and X Y Z of Bee Culture, late editions. On this question we state that "the opinion of the beekeeping world is somewhat divided;" but we recommend "from 20 to 25 lbs. per colony of sealed stores." This statement has stood unchallenged in our A B C and X Y Z for the last three or four editions. In earlier editions we find the following: "See that every colony has from 20 to 25 lbs. of sealed stores." In the light of Dr. Phillips' experiments and the practice of beekeepers in the North where it is much colder than here, perhaps we should make the figures in the next edition read "from 20 to 30 lbs. according to locality."

The same lack of time, or carelessness, that permitted the little word "not" to be left out of the quotation above mentioned also caused the misreading of the statement as to the amount of stores that Mr. Sibbald found necessary for good wintering outdoors. We have no excuse to offer, except that at the time we had "too many irons in the fire."

But when the corrections are all made, we still consider that 42 lbs. is a large allowance, and 28 lbs. ample. Some of the time the beekeepers of Ontario will be compelled to use ten-cent honey. On that basis

it costs anywhere from \$2.80 to \$4.20 to winter a colony of bees. If they use a six-cent honey the figures will stand respectively \$1.68 and \$2.52. On the ten-cent basis the question may still be asked by some whether or not, if we take into consideration winter losses and the present price of sugar syrup, and the price of honey, some beekeepers could not afford to import bees in three-pound lots from the South. Understand, we do not argue this.

According to one Southern advertiser 3 lbs. of bees in 50-lb. lots would cost \$3.50. The express would add from 75 cts. to \$1.00 more.

On the 28-lb. basis per colony the wintering on a basis of 6 cts. would beat the pound shipments. On the 42-lb. estimate the difference with a ten-cent would not be great.

While buckwheat honey may not be worth more than 6 cts. per lb., a great majority of the beekeepers of Canada are not where they can get buckwheat. An aster honey is often dear at any price. Is it not true that most beekeepers use a good table honey? Sugar syrup is cheaper, but you argue that it does not go as far, pound for pound.

Wintered-over bees, you must admit, pound for pound, are not as fresh, vigorous, and strong, as young bees direct from the South. If you can shake more than three pounds on the average from your colonies in early spring, you are going some.

While you admit that Dr. Phillips' observations go to prove that bees in a cold below 57 would consume more stores, you are "not convinced that all his claims in that line work out in practice." Why not? Have you not observed that, the colder the winter or the colder the surrounding atmosphere, the more stores the bees will consume? Time and time again we have noticed in our own locality during a prolonged severe cold spell that our bees consume at least 50 per cent more stores than they do during a milder winter. It is the prolonged severely cold winter that causes dysentery, as a result of overeating to keep warm. Of course, if the winter is *too* mild the bees will use more stores because of brood-rearing. Hence it does not follow that you "should require even less stores than in Ohio."

With regard to Mr. House's practice, you failed to state that his yard is located in a deep gully, and protected by a high bluff. One would almost raise the question whether his bees needed any packing at all. Mr. House's practice hardly proves that plenty of packing is not needed.

We are glad to see that you admit, on the matter of hives buried in snow, that "there is a chance that my advice might not be best for some localities." There is, indeed, a big chance if reports mean anything. Some beekeepers, unless the statement were challenged, would get into trouble, we fear.—[Ed.]

EUROPEAN FOUL BROOD AND MY KIND FRIENDS

BY R. F. HOLTERMANN

Job had friends who sought to advise him in his distress; but we know that they only added to his discomfort. So it appears to me to be with those doctors who so kindly volunteer information for my consolation. There is "Doctor" H. Harley Selwyn, who, on page 930, Nov. 15, states, "It does sound odd to me to hear of one who has been so long in the business meeting only now with this disease."

When I was a boy, and also since that time, I have been a good deal between country and city; and therefore, with divided experiences, I probably never knew very much of either. One thing, however, afforded me great amusement. When the city boy came to the country the country youth considered him as green as grass. When the country youth came to town he was, in the estimation of the town youth, a "hayseed." Each thought his experience was the

hallmark of wisdom. There are many beekeepers who have not had European foul brood among their bees; and I do not feel the richer for having had such experience.

Then comes Dr. J. E. Crane, on page 985, Dec. 1. He is a veteran. He attempts to encourage by stating "The shiftless beekeeper may well regard this disease as a serious matter if not an actual calamity."

There is nothing in Mr. Selwyn's article that affords me the slightest consolation. On page 413 J. L. Byer states, "We dread European foul brood more than ever, and, contrary to what Dr. Miller's sentiments seem to be, we have more or less contempt for American foul brood." I may flatter myself when I say that I think I am as well posted on the nature of the disease as is Mr. Selwyn. Some of the largest New York State conventions for several years have been attended by me to get the experience

first hand from beekeepers there, and I have again and again heard in public and in private the information the four New York State bee-inspectors had upon this disease, and this information still makes me dread the disease among our bees.

Mr. Selwyn's own article condemns his argument. He says, "Notwithstanding the fact that Italians can rise up in the midst of European foul brood and overcome it, I believe that they must suffer first (some worse than others) before becoming immune to other ravages." Taking this to be a correct statement, should it be no cause for anxiety? Is this period of suffering of no practical interest? As I said once before, I doubt if a strain of bees is immune in one locality and not in another. I doubt if there are any scientific data for such a claim.

Now as to Mr. Crane: I have put into winter quarters 748 colonies of bees. There has been plenty of work each season without looking after European foul brood; in fact, it has practically always been a case of doing what has been considered the most

important, and leaving that which was the least important undone. With what I would consider a pretty extensive business, the addition of this disease to look for and stamp out will add very much to my care, to say nothing of the loss thru dead larvæ which would otherwise develop into a working force. We have not only to get rid of the disease, but we have to look for it in every colony. I shall consider that, for the safety of our own bees, as well as a duty to other beekeepers in the vicinity. The bees, as far as possible, should be prevented from coming in contact with diseased larvæ.

To save any one from further trouble, let me say that, after closely questioning quite a number who have had the disease (European foul brood) among their bees, after reading pretty well all that has been written about the disease in American bee literature, and after a season's experience with the disease, the kind of man whom I wish to advise me is the one who has stamped out the disease after it has spread among his bees, not one who admits he has never got rid of it.

Brantford, Canada.

IS THE BLACK BEE THE STRONGER?

BY WILLIAM BEUCUS

If we introduce a few Italian queens in an apiary and secure a general sprinkling of yellow thruout the yard, and if, then, we leave the queens and drones to cross as they please, we shall find that the yellow color of the workers gradually disappears. Observation of this phenomenon has caused many beekeepers to assert that the black bee is stronger, more predominant, and, therefore, the better bee. Now, it appears to me that this is not necessarily so, and that a satisfactory explanation of the reversion from yellow to black can be given.

If I remember rightly, it was Darwin who called attention to the fact that, if a number of varieties of fancy pigeons, such as fantail, pouter, etc., of various shapes and colors, be crossed, and the process then continued with the offspring, the shapes and colors will become less extreme, and in time the contrasts will disappear, leaving as a product of this crossing of breeds the original wild rock pigeon with its distinctive shape and markings from which, by a gradual process of selection, all varieties have been bred.

Now the explanation is as follows: In every species there is a constant tendency to variation—that is, there are small indi-

vidual differences. But these small variations are not all in one direction. They are in numerous directions; hence, in crossing, the individual peculiarities cancel each other and leave in the offspring the size, color, markings, etc., common to the species as a whole. Thus the species remains a constant. But man watches for variations in one direction, and by crossing with each other individuals showing the same divergence he intensifies, strengthens, and makes permanent that divergence. Now, if two or more divergences are made from the same original stock, as in the case of the pigeon, there still remains in the several varieties an obscured tendency to assume the characteristics of the original stock. The crossing of the varieties with each other thus mutually cancels the tendencies to assume their various forms, colors, etc., and strengthens the tendency to assume the form, color, etc., of the stock from which they originated because this tendency is common to all variations.

It seems to me this explains the tendency of the Italian bee to lose its distinctive color and revert to the black. The black is the older race from which the yellow has varied. The fact that Italian queens and drones are

by no means all tinged with yellow is pretty strong evidence that the black is the original stock and the yellow a derivative. But if the individual differences in the members of a species cancel each other, how could the distinctive yellow color have become so pronounced? It is impossible to give a positive answer to this question.

It is possible and probable that yellow was intensified in some locality thru a process of natural selection, the bees showing this characteristic having a better chance under changed conditions to survive. In our northern country the black bee would have the better chance because of the rapid absorption of heat during exposure to the sun. If you will watch carefully on a cool day, when there are clouds, you will find that whenever the sun is obscured the flight of bees from the fields to the hives decreases; but with the reappearance of the sun the flight at once increases. Throw a handful of dead bees on the snow in March, and you will see that they sink an inch or more below the surface. It is because heat is absorbed which melts the snow in contact with the bee. The lighter the color the less the heat absorbed. If these bees flew from the hive the darker ones would be warmed up quicker and have a better chance to return. In a warm country such as Italy, possibly the absorption of heat is not beneficial but injurious, or perhaps yellow made

possible the more easy escape from enemies. That the yellow bee reverts to the black is a common belief, and is indeed true; but this does not prove that the black is the stronger. It would be possible to breed yellow bees for extreme strength, hardihood, and yet these same bees with unusual strength in crossing would revert to the black. Yellow color in Italian bees is the conspicuous mark by which they are distinguished from the German bee. Beekeepers have associated this color with certain desirable qualities such as quietness on combs, resistance to moths, and energy in cleaning the hive and keeping it clean. Naturally they have assumed that an intensification of color was necessarily paralleled by an intensification of various desirable qualities. Hence the breeding for color which may or may not accompany hardihood, energy, excellence in honey-gathering, longevity, etc. This explains the disappointment of those who find that the extremely yellow bees show no better results in honey crops than the blacks. And when, at last, it is undeniable that some of these fancy yellow bees are not keeping pace with the blacks to which they are reverting it is assumed that the black is the stronger. The real truth is that the black is the original stock and the yellow the derivative, and that, as far as strength is concerned, either may be stronger than the other.

Cadott, Wis.

A SINGLE-COLONY WINTER CASE

BY WILLIAM G. RUSTGEN

Here is a sketch of a single-colony winter case. The bottom-board has two inch-strips (not shown in the diagram) for the hive

which is made of $\frac{7}{8}$ -inch boards cleated together.

In the fall, when the bees are to be packed, each colony is lifted off its bottom-board and placed on the bottom-board of the case. Then the case is set over the hive, and the space between is filled with packing material, and the telescope cover is put on top of all.

The bottom-board cleats on which the hive rests are 26 inches long. The hive covers 26 inches, and a four-inch board covers part of the rest, and the other two inches project beyond the end of the case. This has a piece $16\frac{1}{4} \times 2$ cut out for the end of the bottom-board to go thru.

A two-story hive can be accommodated by putting on another-story winter case. By this method a two-inch space is left under the frames, and the entrance, of course, must be contracted.

Dyer, Ind.

to rest on. The case is 25 x 30 x 14, and rests on the edge of the bottom-board,

QUEEN-EXCLUDERS

BY W. C. MOLLETT

I have noticed several comments on the use of queen-excluders by different contributors as to whether they prevent the bees from storing as much honey in the supers as they otherwise would. As to this, I think it may depend upon the kind of honey produced, whether comb or extracted. In producing comb honey in bulk or in extracting-frames I think their use is absolutely necessary if the combs are expected to be kept free from young bees—at least that is the case here. I produce only bulk comb honey, as it brings just as good a price as any, and, of course, the bees will store more honey in the shallow frames than they will in sections.

It took only a short time for me to find out that the use of excluders produces very much better results than depending upon the chance that the queen would not go up into the supers to deposit eggs. One spring I had put in full sheets of surplus foundation, and was expecting a fine lot of basswood honey, when, on examining them just before the flow of honey from basswood was due, I found that nearly all the frames contained eggs and larvæ in all stages of development. Of course this spoiled my chances for that season, and also showed that it was unwise to depend upon the caprices of the queens as to where they might deposit their eggs. In some seasons queens do not go up into the supers, but this is only the exception, not the rule. In producing section honey I do not think there would be very much danger of the queen going above to lay, as the supers are divid-

ed into so many different parts by the sections, separators, etc.

As to whether bees will store as much above an excluder as they would without it, I have never been able to see any difference during the main honey-flow; but I rather think that they will store more in the supers during the fall flow. However, as in most localities they do not secure much more than enough to carry them thru the winter from the late flow, this is not very important. I never have any trouble in getting bees to work in the supers during the main honey-flow, when I give them sheets of foundation, which I always expect to do, as I am convinced that the use of full sheets of foundation is a good proposition.

I notice that the price of zinc has been raised on account of the war. As the new wood and wire honey-boards are so much superior to perforated zinc I am not worrying very much. In my opinion the zinc excluder, entrance-guards, etc., are so much outclassed by the wood-and-wire ones that they will soon go out of use anyway. I have used the wood-and-wire excluders ever since they have been on the market, and am so much pleased with them that I would not use perforated zinc if I could get it free of charge.

The latest improvement in excluders, the ones with seven wires to each space, are still better than the ones that had only three wires to the space. I think that the new ones will, without any doubt, replace the zinc ones almost entirely in a few years.

Stonecoal, Va.

CORRUGATED-IRON BEE-SHEDS IN ARIZONA

BY J. M. HERMAN

To show that all sheds in Arizona are not built of brush and barbed wire, I am sending a picture of my sheds which are built of corrugated iron. The posts are 4x4x9 ft., made of redwood timber. These are set in the ground so that they are 7 feet high on the north side and 6 ft. 8 inches on the south side. They are located 12 feet apart each way. The stringers are of 2 x 4 pine lumber, enough to make the combined length of the shed 108 feet. The cross-rests for the stringers are 2 x 4 x 12 feet; and the braces, 1 x 4 x 6 ft., are nailed to the posts and these cross-supports.

The corrugated iron is bent down over the stringers 16 inches on the south or

lower side, and 9 inches on the north or upper side. The pieces are nailed to the sides of the stringers as well as to the top, so that they are not likely to be blown off. The ends of the shed as shown in the picture are made of the same material. There is an aisle for a wheelbarrow between the rows of hives in the middle of the shed.

I have seven of these sheds in all, holding 800 colonies, two at the home apiary, two at the south apiary three miles south of Chandler, and three at the west apiary a mile west of Chandler. These latter are 132 feet long. The whole expense was about \$700, but I know that my bees are much safer from loss by fire.

One of J. M. Hermann's corrugated-iron bee-sheds at Arizona. Mr. Herman has seven of these in all, which hold 800 colonies.

I once had almost a thousand colonies in one apiary in a mesquite location for sixteen months, and they did well, but 300 colonies is enough in an alfalfa location.

A MOVING SCREEN.

The screen that I hold in my hand in the picture is for moving bees. The frame is made of eight pieces of wood, covered with screen, the dimensions being such that there is about 1/16 of an inch play when slipped down over the top of a hive. I drive finishing-nails thru the front and back of the frame into the hive, allowing the nailheads

to stick out about 1/4 inch so that they can be pulled easily when I wish to remove the screen after moving.

I close the entrance with two strips of wood. The lower piece is two inches wide, and as long as the entrance, so that it will just slide into it. To the upper side of this a piece one inch square is nailed firmly. One nail thru this into the front of the hive keeps the entrance closed most securely, and yet the whole thing can be quickly removed.

Chandler, Ariz.

A "NEW" STARVATION METHOD OF QUEEN INTRODUCTION

BY J. ANDERSON

In GLEANINGS for Nov. 1, page 896, Mr. A. T. Rodman gives under the above heading a description of his method of introducing queens. This plan, however, is not new on this side of the Atlantic. It is thus described in the 1904 edition of "Simmins' Modern Bee Farm." "The three things of importance to be observed are as follows: (1) Keep the queen quite alone for not less than thirty minutes; (2) she is to be without food meanwhile; (3) and to be allowed to run down from the top of the frames after darkness has set in, by lamplight." Simmins proceeds to suggest a match-box as a suitable temporary receptacle for the queen, but continues: "My own practice is to carry the queens in the vest pockets, in small tubular cages made of fine perforated zinc or tin, one end permanently closed, while the other is pressed into a piece of

foundation after the queen is in. When ready remove the foundation and let her run into the hive."

Cheshire made exhaustive tests of the Simmins method, and gives his testimony in Vol. II.—Practical (published in 1887): "I tried many dozens of experiments, and found that by Mr. Simmins' method it was quite easy, not only to introduce but to get one queen to lay in half a dozen distinct hives in a single week."

There are very many beekeepers "in this locality" who use the Simmins fasting method with uniform success. It is not new, but it is, nevertheless, very interesting to find that there has been rediscovered in all its details a method described by Simmins more than thirty years ago.

Aberdeen, Scotland.

THE WINTER CASE ADAPTED TO SOUTHERN UTAH

BY M. L. SKOUGARD

Our bees went into winter quarters in fine shape. I never saw as fine a fall as we are having this year. My bees flew until Dec. 10, with the exception of a few days. I found them gathering pollen as late as Dec. 8. I pack my bees for winter. I use a winter case with four inches of wheat chaff between two inches on the bottom and a six-inch super on top, full of chaff, with a cloth over the chaff, the super lid, then the cover. I tack burlap on the bottom of the super to keep the chaff off the frames; then I put a piece of narrow blanket between the hive and super to keep out air.

As nearly as I can learn, I am the only beekeeper in southern Utah that packs bees

for winter. Beekeepers here say they do not need any protection. But in the spring is the time to tell. Last spring I gathered a nice surplus of dandelion honey. It is as pretty and yellow today as the flower itself. Mine were thru with swarming, and my bees were on the job when the other bees were just building up nicely. When some of the beekeepers learned that I was extracting so early in the season they said it was because I kept Italians, and had queens that I gave three dollars apiece for. I know that my queens have a great deal to do with it, and I know that the packing helps wonderfully.

Parowan, Utah.

THE MISSOURI APICULTURAL SOCIETY

BY AUSTIN D. WOLFE

For twelve years those in Missouri interested in the promotion of beekeeping met under the name of the Missouri Beekeepers' Association. At the twelfth annual meeting, held at St. Joseph, Dec. 7, 8, 1914, it was decided to incorporate and to attempt something of larger significance.

Having incorporated with Columbia, the seat of Missouri University, as the principal place of business, it became necessary to consider the ways and means of building up a constituency and of enlisting popular interest. In spite of considerations looking toward a meeting in December (notably the invitation to take position in the "circuit" formed by Mr. Pellett and Dr. Phillips) it appeared necessary to hold the first meeting of the incorporated organization during Farmers' Week at Columbia, January 4-6, 1916.

The result justified the decision of the executive committee. Two large rooms in the Horticultural Building were allotted to the society. One of these was used as an assembly room, with display of literature and honey. The other was a general laboratory, with no less than six different models of hives and an almost equal number of supers, all occupying one long table. On another table were the implements of the craft, many if not most of them being home-made and of practical value, which casts no discredit on a manufactured article, but merely says that the former variety will answer just as well. Then there was an extractor, a home-made uncapping-can, knives, hive-tools, nailing-frame, wire-imbedder, etc.

This being the first meeting since the granting of a charter, a constitution and bylaws were adopted. Then the program contemplated a discussion of beekeeping from the start for the benefit of the novices. Treasurer J. F. Diemer, of Liberty, unable to be present, sent a short spicy paper on "How I Began." E. B. Gladish, of Higginsville, also unable to appear, sent his brother, Mr. Charles Gladish; and the presentation of Mr. Gladish's subject, "What Hive shall I Use?" led to a discussion which soon brought out the fact that beemen generally are discarding the eight-frame for the ten-frame hive, with the Hoffman-Langstroth frame.

The society is most fortunate in coming at once into close relations with the Department of Horticulture of the State University. Dr. Leonard Haseman, associate professor of entomology, aided by an admirable working model of a bee, delivered a plain and very interesting lecture on the anatomy of the bee. It was the kind of lecture that would entertain and instruct a gathering of farmers or of scientists—just the thing for a rural school.

But all the time there was a stream of visitors who asked to be "shown." On the last day the program was entirely abandoned, and Mr. Tyler, Professor Haseman, and Mr. Darby had their hands full as they took class after class—a few individuals in each group—past the tables, explaining the nature and purpose of the hive, how and why it is constructed, answering questions on the manipulation and care of bees, elucidating the uses of the extractor and of the

different implements to be seen on the tables, and doing a general promotion work. Young men were there who wished to make their farm incomes greater. Students from the university were there, attracted by what they had learned in their courses in entomology; women and girls were there who liked honey and were willing to help produce it. Some teachers and county superintendents were there, who manifested a ready sympathy in the thought that boys and girls might take blue ribbons at school fairs for honey just as well as for corn, poultry, or puddings. The society gained a new outlook upon its opportunities, and the prospect is highly encouraging.

Officers were elected as follows:

President, E. E. Tyler, Columbia, Mo.; vice-president, Emil F. Nebel, High Hill,

Mo.; secretary, Austin D. Wolfe, Parkville, Mo.; treasurer, J. F. Diemer, Liberty, Mo.

The tone of the convention was in a marked degree optimistic, and the prospect before the society is better defined than ever before. Without entering into details it may be said that the society plans to enlist the co-operation of the extension department and the home economics department of the university, and to inaugurate a campaign to popularize the production, consumption, and sale of honey on the farms of Missouri. A convention for next year is already projected in which it is hoped that an interest far greater in kind and in extent than anything in the past will be manifested and maintained.

Parkville, Mo.

A CABINET FOR HOFFMAN FRAMES

BY M. B. WHITE

Several years ago I visited a friend who gave me my start in the honey industry. While at his home I noticed a chest in his honey-house similar to the one here illustrated. I immediately proceeded to make one like it, which has about one-fourth the capacity of the one I now present. It was not very long until it was too small, so I have just completed the new one.

Following are specifications:

18 pieces 1 in. by 4 in. by 8 ft., used for top, bottom, and back; 12 pieces 1 in. by 4 in. by 6 ft., two sides; 12 pieces, 1 in. by 1 in. by 6 ft., doors; 1 piece 1 in. by 4 in. by 14 ft., braces; 1 piece 1 in. by 4 in. by 8 ft., braces.

The work took me about a day and a half, working irregularly without anything to go by except a rough drawing I made and the actual frames. I had no tools but a saw, hammer, square, and plane.

Waco, Texas.

HOW TO BIND GLEANINGS

BY M. H. TEISBERG

GLEANINGS contains so many valuable suggestions that it is well worth while to save the back numbers for future reference. I think all will agree that the most satisfactory way to keep them is to have them bound in book form. My way of binding is so satisfactory, and so easily and cheaply done, that I should like to pass it on. Almost every beekeeper has all the necessary implements and materials except the stitching-frame, which I will describe.

An ordinary carpenter's bench-vice can be used as a press. Proceed as follows:

Arrange the twenty-four numbers that constitute one volume of GLEANINGS in order, and remove the advertising pages from all except the first and last numbers. Leave three or four advertising pages on each of the latter to serve as fly leaves. If all the advertising pages were left on, the completed book would be too bulky.

AA, uprights; B, baseboard; CCCC, cords; D, top-bar; EEEE, nails or tacks.

This done, true up the top and back edges of the volume and put it in your bench-vice between two smooth boards and screw up tight. The back side of the volume should be up, and should project about a quarter of an inch outside of the boards. Take a saw and make four cuts across the back of the volume so as to divide the back into five more or less equal parts. Guide-marks may be made first with a pencil if you like. Make the cuts one-sixteenth to one-eighth of an inch deep. Before sawing remove any of the wire stitches that are in the way by twisting them out with the point of a knife.

The next step is to sew your book together, and for this purpose you will need a stitching-frame. Almost any one can make a frame good enough in a few minutes like this:

Take a piece of plank or board six inches wide, or wider, and a foot or a foot and a half long, and to one side of it nail a frame six or eight inches high and as long as the plank. This frame is simply two uprights with a straight stick nailed across the top. Stretch stout cords between the top of the frame and the side of the plank, spacing them to correspond with the notches you sawed in the back of the volume.

You are now ready to stitch your book together. First tie your thread to the second cord from the top; then take the last number of the year and place your right hand between the middle leaves. Insert the needle in the second notch from the top, and draw the thread thru. Then put it thru the third notch on that side of the third cord which is furthest away from you. Reinsert it in the same notch, but on the side of the cord which is nearest to you. Put it out and in at the fourth notch in the same manner, then go back to the third, second, and first notches, and finally out where you started. If you have drawn the thread up snugly the cords will be drawn into the notches. Proceed in like manner with the remaining numbers, being careful to have them in proper order. Remove the book from the frame by cutting the cords, leaving the ends about one and a half inches long.

Now screw the book up tight in the bench-vice as before, and hammer the back down smooth. It should have a rounded shape. Paste a strip of muslin on the back, letting the sides overlap about an inch. This strip, together with the cords, forms the hinge on which the book opens. Let it dry in the vise all night.

The cover is made of pasteboard covered with any kind of cloth you please. A careful examination of any cloth-bound book will give a good idea of how it should be made. Paste it together. Fasten the cover to the book by pasting the outside fly leaves, the ends of the cords, and the overlapping edges of the back strip to it. Leave it in the press to dry or the covers will curl. Flour paste is good for this work. To spread it smoothly use a kitchen-knife.

Books bound in this way open flat without danger of breaking. They are much stronger than ordinary books, and I am sure that mine will last a lifetime.

As to the time it takes, the work is such a pleasure that one will be almost sorry

when it is finished. The stitching of a volume of GLEANINGS takes about an hour. Making the cover will take about another; so that, with making the sawcuts in the back, stringing the cords on the frame, pasting, etc., the time needed will probably not be far from three hours. Of course this does not include the time needed for the paste

to dry; but you can be doing other things in the mean time, so it is hardly fair to count that. If you are a stickler for smooth edges you can take the book to a printing-shop and have it trimmed. This, if done at all, should be done just after taking from the stitching-frame.

Ashby, Minn.

DIFFERENCE BETWEEN PIPING AND QUAHKING

BY J. D. ELLIS

I have been greatly interested in the discussion between you and Dr. Miller in regard to "quahking of queens." A few years ago I was walking home from the postoffice with a queen in my pocket. Suddenly near a swampy wood I heard what I supposed was a duck quacking. It began in loud slow tone, and ended in quick low tone. I and my companion with me said, "Wild ducks," and hunted for them. None were found, and we proceeded. Further on we heard the same sound again, and at once we said "wild ducks." But this was in high open field, and we were puzzled. Neither of us had ever heard that the queen or any bee ever made a sound. After close listening we discovered that the sound came from my pocket. We took out the cage, listened, and were astounded. We told it around the country, but none would believe us. You may call it "piping" if you wish, but we certainly thought it was ducks. In boyhood days I have often seen a partridge "drumming." Standing on a log it flaps its wings without moving, first slow and loud, but getting more rapid and faint. I have wondered if the queen does that.

Montreal, Quebec.

[The following letter from the editor to Dr. Miller will explain:]

Dr. C. C. Miller:—I enclose a letter from Rev. J. D. Ellis, Montreal, Quebec, in regard to the quahking of queens. This is the first instance I have heard of where the quahking was made outside of the queen-cell. He describes it so minutely and so accurately that I am inclined to think the queen made this sound inside the cage. Did you ever hear or know anything of this kind? I have always been under the impression that the piping that you refer to was a very different sound from the quahking. The quahking is more like the quacking of ducks and the piping like zeep-zeep-zeep—that is to say, sounds like a very minute, infinitesimal (if I may so express it) squeal. The piping that I have referred to, as queens answering each other back and forth in our office from separate queen-cages, was the sound of the infinitesimal trumpet—a very minute sound like some of the upper notes of a violin. The quahking, as I understand it, would sound like the coarser notes, the coarsest that the ordinary

small violin can give; in fact, I believe that a good violinist could produce either sound that the queen gives. I think there may be some misunderstanding between some of our subscribers and yourself and myself as to the actual difference between quahking and piping. If you have any circumlocution of language that will describe either I hope you will do so for the benefit of Mr. Ellis or any one else.

E. R. ROOR.

[To this Dr. Miller replies:]

Note that Mr. J. D. Ellis says he had never heard that the queen makes *any* sound; so as this was the first time he ever heard a sound from a queen he would not discriminate closely between piping and quahking. He calls the noise "quacking," but he *describes* piping, for he says it began in a slow tone and ended in a quick tone. The beginning of quahking has always seemed to me as if the queen were hurried, although I think the tones are of equal length. Certainly I don't believe any one would think that quahking begins in a slow tone, while piping does.

I feel quite confident it was piping Mr. Ellis heard, and that there is yet no proof that a queen ever quahks outside a cell, although the difference is not all—I think not mainly—made by being in or out of a cell.

If you will wait till next summer, and then listen patiently some evening to quahking and piping, I think you will say that quahking is distinctly different from piping, and that the difference is one that cannot be made by confinement in a cell.

After reading again your letter I will say that you are right about the difference in the two sounds, except when you speak of piping as being a "minute sound." That would convey the impression that it is a very faint sound. It is sharp, shrill, piercing, but not at all minute, for I've heard it distinctly several feet away from the hive. I think you are right that a violin could well imitate both sounds. When a queen begins quahking in reply to the piping of another queen, the quahking, as I remember it, *seems* louder than the piping, but I doubt if it really is, for, as already said, I've heard piping at quite a distance from the hive, and I don't remember to have heard at the same distance the quahking reply. Your word "squeal" is not a bad one to describe piping.

C. C. MILLER.

[Has any one of our readers ever heard a queen "quahk" outside of a queen-cell? Piping never is the same as the sound of wild ducks in the distance. We still incline to the opinion that Mr. Ellis actually heard "quahking."—Ed.]

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

The fellow who says he don't pay much attention to his bees, but figures to keep a hive or two for a little table honey, seldom gets more than he figures on.

Report of Michigan's Fiftieth Meeting

With an attendance of almost two hundred, the Michigan Beekeepers' Association held its fiftieth annual convention at Grand Rapids, December 15, 16. It does not fall to the lot of every beekeepers' association to enjoy a fiftieth anniversary, and the consensus of opinion of those present was that Michigan held a worthy celebration, and one that has left pleasant memories.

The meeting was marked by several interesting and novel features. One of these was the banquet supper, so kindly provided by the G. B. Lewis Co., Watertown, Wis., and by the A. G. Woodman Co., Grand Rapids, Mich. Another feature was the giving of medals.

In place of the usual half-dozen entries there were over forty different exhibits; and in the comb-honey and light-extracted-honey classes competition was very keen. The medals are cell-shaped, one inch and a half in diameter, and bear on one side the portrait of L. L. Langstroth, suggested by Dr. Phillips.

The medals were provided as follows: The manufacturers of bee-supplies, The G. B. Lewis Co., The A. I. Root Co., C. P. Dadant & Sons, R. & E. C. Porter, The Marshfield Mfg. Co., The Kretchmer Mfg. Co., and the Gus Dittmer Co., gave the gold medal. This medal is ten-karat solid gold, and known as the manufacturer's medal, value \$50.00.

The Michigan jobbers in bee supplies: The A. G. Woodman Co., M. H. Hunt & Son, E. D. Soper, and The Beekeepers' Review per E. D. Townsend, provided the silver medal. This medal is known as the jobber's medal, value \$20.00.

The bronze medal is provided by the association, and is known as the association medal.

The medals were much appreciated, and declared appropriate and beautiful in design, and created much interest during the meeting. Many of the beemen present decided that the winners would have to put up the finest of exhibits next year or the medals would change hands.

While there were over forty entries at this convention we are preparing for many more exhibits at the next meeting, in Lansing. The object in providing the medals will, no doubt, be attained. That is an exhibit worthy the name and the State of Michigan, and one that the public will come to see.

For our fifty-first meeting we hope to combine more features that will make this side of the convention a big drawing card to the general public.

Among our many visitors were some prominent beemen from other parts, including: Dr. E. F. Phillips, Prof. Jager, John C. Bull, George Williams, R. F. Holtermann, J. Danzenbaker, Dr. Kohn, and others.

The interest in the meetings was well sustained thruout, and the attendance at the closing session was equal to that of the earlier sessions.

President Running in his address alluded to the value of the summer apiary demonstrations, and touched upon the possibility of some of the Smith Lever funds being used for apiary demonstration work.

The program was full of valuable and instructive papers, which contained some excellent suggestions and ideas as follows:

E. D. Townsend, "Running Outyards for Extracted Honey."

Morley Pettit, "Notes from the Year's Work."

C. P. Dadant, "Size of the Brood-chamber."

Prof. J. H. Haughey, "Phases of Queen-breeding."

Prof. Jager, "Beekeeping in Minnesota."

A. H. Guernsey, "Transferring Bees."

R. F. Holtermann, "Question-box."

Dr. E. F. Phillips, "Some Lessons of the Last Half-century."

O. H. L. Wernicke, "Beekeeping as a Prison Industry, and its Reformative Influence."

Ira D. Bartlett, "Business Principles and System a Big Asset in the Success of the Apiarist."

Dr. E. F. Phillips, "Outdoor Wintering."

Morley Pettit, "The Bee Business in Canada as seen by a trip through Different Provinces."

The winners of the challenge medals were: Mr. and Mrs. Floyd Markham, Ypsilanti, manufacturers' gold medal; E. E. Coveyou, Petoskey, jobbers' silver medal; David Running, Filion, association bronze medal. Medals have to be won three times before they become the property of the exhibitor.

Lansing was chosen as the place for the next meeting. The A. I. Root Co. and M. H. Hunt & Son announced that they would be hosts to the beekeepers at that time, when they would serve a banquet supper. Those present at the banquet at Grand Rapids will remember what a pleasant time was spent, and visions of another good time at the Lansing meeting are already rising and will no doubt materialize at that time.

F. Eric Millen, Sec.

East Lansing, Mich.

Eastern Massachusetts Meeting

The January meeting of the Eastern Massachusetts Society of Beekeepers was held in Boston on January 8. There were 36 members present, and four visitors from Rhode Island.

Mr. Allen Latham, of Norwichtown, Ct., was the first speaker on the list. His subject was "Building up Nuclei into Full Colonies." Mr. Frank C. Pellett, of Atlantic, Iowa, was given a royal reception when he was announced as the second speaker, and talked to the society on Latham's subject, after which questions were put to both these men, and a very profitable discussion ensued.

Boston.

Benjamin P. Sands.

Death of Delos Wood

The attached clipping was taken from the Los Angeles "Times" of January 7: . . .

BEE EXPERT DIES.

SANTA BARBARA, Jan. 6.—Delos Wood, pioneer apiarist of this county and Ventura, died here today of heart failure superinduced by a severe cold. Wood is acknowledged as a bee expert of the state. For thirty-two years he had been in the business.

Mr. Delos Wood was highly respected by the best of the bee fraternity thruout California; has been very active as a member of the different beekeepers' organizations; was a writer of no mean talent on bee topics; one of the main stays of the California State Beekeepers' Association, and a regular correspondent of the "Western Honey Bee." He was an honorary member of the State Association, and president of the Ventura County Beekeepers' Club.

All beekeepers knowing Mr. Wood will feel the loss of this grand old man who retained his good nature and bright laughing ways almost to the last day of his life.

Los Angeles, Cal.

Geo. L. Emerson.

Michigan Beekeeper Passes

Mr. William E. Forbes, of Plainwell, Mich., died January 2, 1916, at the age of 75. At one time Mr. Forbes had as many as 200 colonies, and was one of the most careful and methodical beekeepers in his state. He has kept bees for over forty years, and was an expert in bee management. He disposed of most of his bees last year to a fellow beekeeper. Mr. Forbes was one of the oldest members of the State Association, and attended a great many of its meetings. The beekeeping fraternity has lost a good craftsman and a true friend.

A Beekeeper.

In a Cold Country

This district is well on toward Hudson's Bay, and is pretty cold now and then. Today, Jan. 5, it is about 30 below zero—the coldest day this winter so far.

I find Italian bees do well here in a normal season. We have a good deal of small timber in this part of the country, and the bluffs in which this timber is contained have an abundance of wild flowers, together with wild strawberries and raspberries. Last summer a three-frame nucleus built up to ten frames full, and yielded me 60 full sections besides. Moreover, I had to rob the brood-chamber of some honey during early August, in order to give them room. Altogether I got about 80 lbs. from this colony.

In 1904-'5 I bought three nuclei for New Liskeard, in Temiskaming. These nuclei filled seven hives that season, and gave me about 100 lbs. of comb honey besides. The climate and conditions there are about the same as here, so you see it is hard to place a limit to the producing area of our friend the bee.

Melfort, Sask., Jan. 5.

Geo. Weaver.

The Loss by Weight when Feeding

I do not think that Mrs. Allen will find out just what she wants to by your own and Dr. Miller's answer in the January 1st number. If a colony is short 10 lbs. of honey she wishes to know how much she will have to feed to make up 10 lbs. of sealed stores. Dr. Miller's answer of 5/7 of a pound of sugar for every pound of stores short would mean 10 lbs. of syrup in the feeder.

This thing was discussed in Gleanings some time ago, and the most of the beekeepers agreed that there is a loss between feeder and sealed stores—that to make a pound of sealed stores a pound of sugar should be fed, no matter how much water is added.

Grosvenordale, Ct.

OUR HOMES

Editor

Thou shalt not kill.—EXODUS 20:13.

Thou shalt not commit adultery.—EXODUS 20:14.

There is none other name under heaven, given among men, whereby we must be saved.—ACTS 4:12.

A few years ago a book came out entitled, I think, "The Traffic in Girls," and it made quite a sensation, especially among certain lines of people. Later on came another book, perhaps from the same author, entitled, "The Traffic in Little Girls." Since then our nation has been stirred up by the war against the "white-slave" traffic, and some of us began to think it was pretty well done away with; but every little while our daily papers in the great cities have given occasional glimpses to the effect that things are not *always* as they look on the outside.

Dear friends, it is my sad duty to show you in this Home paper that something worse than the traffic in *little* girls is still going on in some of our great cities—something *worse*, if possible, than the great war across the seas, and, I might almost say, worse than the liquor business, were it not that it is a part and an outcome of this same hellish combination. I mean that there is a traffic going on in poor innocent and helpless motherless and fatherless *babies*—babes from a day old to a week old, and that these poor helpless and homeless infants are being *murdered*, not only by the hundreds but by the *thousands*. How devoutly I wish some one could tell me it is not true, and that I have been misinformed! It is a rather long story that leads up to it, but is something the whole wide world should know about. The gradual steps that have led up to it should be a warning to those who are about to take the first steps that look so harmless, *out* of the "straight and narrow path."

Some good friend mailed me a supplement to the Baltimore *Star*, dated Dec. 20. The large heading reads:

Startling Facts in Report of Governor's Vice Commission; Social Fabric of Baltimore City Seriously Undermined; Leaders of Professional, Church, and Social Circles Involved in Exposure; Traffic in Girls and Babies is Astounding; Open Vice Conditions Pale before Orgies of the So-called Best People.

A group of leading physicians, social workers, and business men of Maryland, named about three years ago by Gov. Phillips Lee Goldsborough to study and report on vice conditions in Baltimore city and the state at large, have just affixed their signatures and forwarded to the Chief Executive of Maryland one of the most remarkable documents ever compiled in the history of the country.

Below I have clipped brief extracts, taken here and there, which might indicate

that it would be nothing strange if the Almighty should (if there is no let up) send down fire and brimstone on Baltimore as he did on Sodom and Gomorrah.

The tremendous social sore is of such great scope that members of the commission consider publication of the general conditions of the same importance to the community as would be the vital necessity of the surgeon's knife to the individual in an extreme appendicitis case.

VAST PUBLIC MENACE.

Starting out from the report with a horrible leer into the face of the community are the facts that a heavy percentage of the local population is suffering in some form from the most horrible and loathsome disease known to the medical world, and that most inadequate facilities are provided by the hospitals for the treatment of this public menace.

Men and women of all races and colors are in the grip of this monster, and even children are by no means free from its grasp.

Thru the efforts of Dr. Walker, these horrible facts so aroused the sympathies of John D. Rockefeller, Jr., that the latter has contributed \$6500 for each of the next three years to maintain a clinic at the John Hopkins Hospital to handle this disease.

A separate examination of the professionally fast women showed that 96.61 per cent indicated the presence of this terrible disease or one only slightly less loathsome.

"We found that," continues the report, "according to our rough estimate, 24 per cent of the girls in these houses are feeble-minded; that is, have not intelligence enough really to realize what they are doing. It is nothing short of monstrous for such persons to be found in such a life; they are absolutely nonresistant, and are an easy prey to conscienceless madams and victims of the degraded appetites which many men possess.

"There are inadequate facilities for the detention and segregation of feeble-minded boys and girls above 16 years of age. The practical significance of their being at large is that when free they are allowed to propagate their kind. We have numerous examples of feeble-minded girls who have had two or three children, and some who have had four or five. Their offspring are nearly always of the same type. It is of economical value to the state to put a stop to such propagation, to say nothing of the humane aspect of the case."

"It is this woman's business to acquire and to exhibit the youngest and most innocent girls that can be procured," says the report. "The greater their delicacy or charm or beauty the greater profit she can count upon their yielding her. Once they are captured and under her sinister subjection, she sees that they are on hand and accessible whether they are sick or well, in season and out of season.

The above is only part of the preliminary to the "Traffic in Babies." Omitting several columns of details, we come to the following:

"There are two well-known institutions in Baltimore which will receive infants immediately after their birth and keep them permanently. The parents, by paying to either of these institutions from \$100 to \$125, are relieved of all responsibility, and relinquish all right and claim to the child. The

mortality in these institutions varies from 75 to 95 per cent. The mortality of infants nursed by their mothers is less than 10 per cent.

CALL IT MURDER.

"We do not attempt in this study to settle the many complex problems relating to the illegitimate; but we believe that the facts show that society's method in many instances is one of repression and virtual murder. This is a harsh word, we grant, and would fain substitute a gentler term; but after all is said and done, that which we have reported is virtual murder, and slow and cowardly at that. It would be far more humane to kill these babies by striking them on the heads with a hammer than to place them in institutions where four-fifths of them succumb within a few weeks of malnutrition and infectious diseases. It is a few weeks of suffering, a few weeks of going down to death by a process that is slower than the hammer, but in most instances just as sure. Hedged in by our system of shams and our fabric of lies, we refuse to call it killing them; we dignify it by the softer name, the smoother term, of putting them into institutions where they will be cared for. But nearly all of them die, and many of us know that they die, and, moreover, may think that it is better that they *should* die.

"All of this is done in the effort to preserve a family's good name; to prevent a girl's reputation from being smirched, to save the man in the case from facing the consequences of his act. All together, it is a well-organized hushing-up by a system of subterfuges and repression in order that the certain individuals shall not have to face openly what they have done."

And now comes the sad final summing-up:

"A calculation was made concerning the infants under one month of age that had been placed in the institution by the city for 1900 to 1914 and had not been removed, except by death, under a period of six months; among all these children there was not a single survivor—a mortality of 100 per cent."

Under another section, devoted to general conditions, the report states:

"The dead infants are buried in a large hole, which serves to accommodate from 75 to 100. From time to time, as they die, their bodies are placed in the hole and covered with a few shovelfuls of earth. When the hole is filled with bodies another hole is dug alongside of it, and the bodies of infants that have been buried for several years are taken out and their bones thrown away to make room for new burials. In a small plot of ground it is estimated that about 5000 infants have been buried.

I read the above to Mrs. Root just before retiring; and in thinking it over I decided that all the police in the world, and all the legislation, and, in fact, nothing would avail Baltimore but a visitation of the Holy Spirit; and then our last text came to mind—"None other name under heaven." When the wicked men and women who are responsible for the untimely death of these innocent babies shall be *converted* and go down on their knees before an angry God, then will help come to Baltimore and other cities like her. Finally I knelt down and prayed the good Lord to move Billy Sunday to go to Baltimore. At that time I had no knowledge he had any such plan in mind; but next mail brought the welcome

news that the great city was already "up in arms," preparing the way for his coming. Below is the heading of an editorial from the Baltimore *Sun*:

15,000 kneel in prayer; 1250 meetings held to pave way for Billy Sunday; all classes represented; devotions last for half an hour, and blessing is asked on evangelist and work.

Some of you may say, "Why, brother Root, *your* prayer was not answered in the above, for the matter was planned long before you prayed." To which I answer, from Isaiah 65:24, "Before they call I will answer; and while they are yet speaking, I will hear."

Let us look at the matter a little. Men and women break God's holy command against adultery; and to conceal the crime they commit murder or pay money to some one *else* to do the murdering. It is not grown-up men who can protect themselves, but helpless *babies—their own offspring*, because they are respectable people (or claim to be), and dare not own their own children. We read about and sing about "the heathen in their blindness bow down to wood and stone;" but are there any *worse* heathen in the whole wide world than in "Glorious America," "the land of the free and the home of the brave"? May God give Billy Sunday grace to realize the size of the task he has undertaken.

"CHIGGERS" AND REDBUGS.

As to "chiggers," I am sometimes attacked by them, but not often, and never, I think, when in my work clothes. This I ascribe to the fact that, when dressed for work, I always use the spring-steel trousers-guards commonly worn by bicyclists. The guards are well worth wearing, too, to keep out dust, tickle-grass, weed stubble, and other rubbish when one is working in the farm or garden, tramping the roads, or exploring the woods and fields.

Carthage, Mo.

BENJAMIN C. AUTEN.

I think very likely the trousers-guards, or, in the absence of them, tying a string around the ankles, would largely keep off these troublesome insects. I would suggest, however, that at the same time you put kerosene around the tops of your shoes, as I have frequently had the redbugs get around on to my feet below the ankles. Perhaps I have failed to mention that there is seldom any trouble from these insects if you keep away from the wild grass and other vegetation in the woods. Where the land is under cultivation there is seldom any trouble of this kind. Keeping down grass and weeds around the home will very much aid in keeping the premises clear of such pests.

HIGH-PRESSURE GARDENING

SOME GLIMPSES OF OUR FLORIDA HOME AND GARDEN.

When we came here the first week in November I made haste to plant some potatoes. The only good sprouted seed to be found on the market was \$2.25 per bushel. Cut No. 1 shows them 40 days after planting. It is now (Dec. 31) about 50 days, and some of the hills are 2 feet high, covering the ground. There are a few potatoes already nearly the size of small hens' eggs—no bugs, no blight, not even a flea-beetle, to make the leaves full of small holes; in fact, I do not think I ever saw *perfect* potato foliage until I came to Florida. In the background you see one of the mulberry trees I have so often spoken of; also a banana, slightly touched by the frost—the one or two that we have had, but none so far to hurt anything except sweet potatoes.*

* At the left of the house in the background is the great rubber tree. Three years ago last June it was just coming out of the ground; now it is 20 feet high and 50 feet wide in its spread of branches. Mrs. Root says I shall have to move the house or the tree.

FIG. 1.—Red Bliss Triumph potatoes planted Nov. 11. Photographed 40 days later.

Cut No. 2 shows another bed of potatoes about 30 days after planting. Thru the center of the bed is a row of loquat plums, set out only a year ago, but all containing more or less bloom. On the left is a clump of the roselle bushes I have written about. The foliage has dropped off, but the "fruit" is still good. We are having it every day with cut-up oranges. Just behind them is an orange-tree full of fruit.

Cut No. 4 is my favorite Royal grapefruit, still bending with its load of fruit in spite of the fact that one or more are taken every day for my "fruit supper" with a couple of apples brought from Ohio.

FIG. 2.—Bliss Triumph potatoes 30 days after planting.

FIG. 3.—Buckwheat sowed in November. Photographed after only 30 days.

Cut No. 3 is explained by the two letters below. I found the bees on the blossoms the first time on Christmas.

Mr. A. I. Root.—I am a beekeeper in a small way. I have 40 stands for comb honey. I take GLEANINGS, and like it much. I read very carefully your experiments in Florida. I am trying to propagate buckwheat that will stand sun and wind, and not blast. I have seed from the third selection, and think it quite an improvement. I should like to send you some seed for you to plant in Florida; and if it produces a good crop, I should want you to send the seed to me for next year's planting, and would send you some more seed ground here. In that way I could get two selections in one year.
Nelson, Pa. FRED H. SELPH.

Later.—I sent you the buckwheat yesterday by mail. I would drill it about three inches apart, and use some fertilizer. I find that 3-8-10 fertilizer is about the thing for buckwheat. The buckwheat I sent is all from one stalk, 1113 kernels.
FRED H. SELPH.

SWEET CLOVER IN CALIFORNIA; SOMETHING ABOUT THE WAY IN WHICH IT IS BRINGING UP BARREN SOIL.

I am sending you herewith an article clipped from the Redlands *Daily Facts* under date of Sept. 28, that seems to me to contain so many valuable things about sweet clover that it should have as wide a circulation as possible. There seems to be no limit to the possibilities of this plant in building up and rejuvenating old soil. Indeed, it is surely becoming known as a factor in the welfare of future generations.

Redlands, Cal., Oct. 20. P. C. CHADWICK.

A DESPISED WEED PROVES PRECIOUS BOON TO FARMERS.

The story of how this unappreciated native "weed" has been found to increase the yield of subsequent crops, following its incorporation into the soil, to a greater extent than any other legume ever tested in California, is told by W. M. Mertz, superintendent of cultivations of the Citrus Experiment Station of the University of California at Riverside, in a circular on "*Mellilotus Indica* as a Green-manure Crop in Southern California," just published by the University of California, and obtainable free by writing to the College of Agriculture at the University.

Here is related the story of how for many years past the University of California has been testing a wide variety of "cover crops" at Riverside and elsewhere. Various clovers, vetches, and other leg-

umes, as well as rye, barley, etc., have been grown as a winter cover crop, and then plowed under in the spring, in order, by green manuring, to introduce nitrogen into the soil, aid the activity of useful soil bacteria, and improve the texture, humus content, and general condition of the soil. Then potatoes, corn, sugar-beets, and other crops have been grown on the test plots to find out how much the fertility of the soil has been improved by this treatment.

The resulting increase in fertility has been most gratifying. Land on which common vetch had been plowed under gave an increased yield of 18.7 per cent; burr clover, 30.4 per cent; and Canadian peas, 43.4 per cent.

But when sweet clover was grown and plowed under, the yield of the test crops following showed an actual average increase of 64.8 per cent.

This is nearly half as great again an increase of yield as it has been possible to obtain by plowing under cover crops of rye or barley, and applying also 1902 pounds of nitrate of soda or 1188 pounds of dried blood per acre.

FIG. 4.—Our Royal grapefruit tree close to the dining-room door. "Short-cut from producer to consumer."

Another remarkable merit of this new cover crop, sweet clover, is that it is extremely effective in preventing "plow-sole," or irrigation hardpan, an ailment to which a large proportion of irrigated orchard soils in California are liable. Frequent cultivations of dry pulverized soils, together with frequent irrigation, tend to wash down the fine clay particles and deposit them in a dense, hard layer of varying thickness just under the cultivated area, and thus soils become impervious to water. Sweet clover, however, though an annual plant, in six months sends its roots deep down, often as much as eight feet. This great root system is extremely useful to the orchardist, keeping the deep layers of the soil in good physical condition and opened up for irrigation.

The increased production of a crop up to 64 per cent is certainly wonderful if there is not some mistake in the figures. It illustrates again how much there is to be discovered all round about us if we go to work with faith and enthusiasm to develop God's gifts.

SWEET CLOVER.

From Cowley County, Kansas, comes an authentic report of a man who pastured 35 head of cattle weighing 500 pounds apiece; 6 sows and 33 suckling pigs on nine acres of sweet clover from April 10 to May 6. The sweet clover had been seeded in the spring of 1914, and was, therefore, but one year old. On May 26, after the stock had been removed for twenty days, the sweet clover was growing rapidly, and had reached the height of eight inches. From Harvey County, Kansas, comes an equally authentic report of a man who, up until May 22, had been pasturing his milk cows on sweet clover that was but one year old. So well had these cows been doing on the sweet clover that the owner was delighted with the results and the quantity of

milk received, and quite likely those cows are still in that same field. On that particular farm there was plenty of alfalfa; but owing to losses caused from bloating, the owner was afraid to risk valuable cows in an alfalfa field.

We should like very much to hear from others who have made this same observation, and should like to have any other interesting facts for or against sweet clover which will be of value to the man who is thinking about seeding this crop.

It seems absolutely certain that sweet clover will find a place on many grain-belt farms, which cannot be filled by either red clover or alfalfa. It is, therefore, important that we get as many facts from one another as possible.—*Farmer and Stockman.*

SWEET CLOVER—35 ACRES.

I am very much interested in the new sweet clover. Will you kindly send me a few seeds when the crop is harvested? The farmers are just beginning to see the value of this wonderful plant in this part of the state, and one friend of mine has put in thirty-five acres this year after trying three acres last year with which he was so well pleased that he planted the larger field.

Princeton, Ill., July 21. G. S. RICHARDSON.

THE AVOCADO PEAR IN JAMAICA.

I am sending you under separate cover a seed of the avocado pear. You mentioned the alligator pear in GLEANINGS in the early part of the year. I thought you would like a seed. This seed is not of the alligator kind, but they grow here. The avocado pear grows here without cultivation of any kind. When there is a good crop a lot of the fruit is fed to pigs when ripe. At present we can get two fair-sized ones for one cent and a half. The alligator pear is called so because of its shape.

HERBERT HOLLI.

Brown's Town, Jamaica.

TEMPERANCE

GOD'S KINGDOM COMING.

I have been for some time past making clippings from our exchange periodicals in regard to the "temperance wave," and now there are so many that I thought at the time *must* have a place that they would pretty nearly fill a single issue, and even if we did so, there would be two troubles: First, before they would get to Medina and get in print they would be out of date. Secondly, many of you would find you had read the same thing, or a later version of it, already.

On the last day of 1915 we found in our Bradentown daily the following:

DRY TERRITORY TAKES IN SEVEN MORE STATES; OVER 3000 SALOONS AND MANY BREWERIES, DISTILLERIES, AND WHOLESALE HOUSES WILL CLOSE.

WASHINGTON, Dec. 31.—Seven states become dry at midnight tonight. Over three thousand saloons and a large number of breweries, distilleries, and wholesale liquor-houses will be closed.

The states are South Carolina, Iowa, Colorado, Oregon, Washington, Idaho, and Arkansas.

The Idaho laws are said to be the most drastic in the country. It makes the possession of any kind of liquor a crime.

From the *Plain Dealer* of Jan. 1 I clip as below:

SEWER GOES ON DRUNK.

CHARLESTON, W. Va., Dec. 31.—Twenty-five thousand pints of whisky, brandy, and rum confiscated by the State Prohibition Department, were emptied into a sewer here yesterday. The process required three hours' work by four men who worked in relays to prevent being overcome by the fumes.

And now comes one of my "happy surprises."

The *Cleveland Plain Dealer* has heretofore favored license rather than prohibition; and it has also carried "booze" advertisements, at least to some extent. In the daily for Jan. 4 I could hardly believe my eyes when I read the following:

HOME MAP-MAKING.

While belligerency is making over the map of Europe, prohibition is making over that of the United States. The first day of the new year deserves a high place in the annals of the dries.

Seven states were added to prohibition territory with the dawning of Saturday, bringing the total number to nineteen wherein the manufacture and sale of intoxicants has been outlawed. From one

ocean to the other and from the Gulf to Maine the dry territory stretches, with only a break here and there, where a wet or local-option state intervenes.

The closing of so much territory to the liquor business on New Year's day marked the culmination of an exceptionally successful year for the drys. In-to state after state they carried their fight on the saloon, meeting their opponents in legislatures or before the people, and usually worsting them. In Ohio they met defeat when the dry amendment to the constitution was rejected in November, but that was one of the few reverses they met during the year.

And the fight of the drys will continue unabated during 1916.

Six states are to vote on complete prohibition before the year ends; and a seventh, Florida, may put the issue to the test. In addition to these contests for statewide prohibition the drys will continue to press their enemies' strongholds upon the issue of local option. Four states remain which have so far refused to enact laws establishing local option. In Pennsylvania, the greatest of the four, not even the campaign pledge of a popular governor and the governor's later strenuous efforts to make the pledge good, were sufficient to secure the enactment of such a law.

It is not impossible that, by the end of the new year, half the states of the Union will have completely outlawed the traffic in intoxicants. Even the possibility is significant of the trend of popular thought on the problem of the saloon.

After reading the above, it occurred to me I had not, for some time, noticed any "booze" advertisements in the *Plain Dealer*, and I have just searched over several issues, and *don't find one*. For years past I have been pained because not one of our Cleveland dailies seemed to have the courage to follow other great cities and announce "No more whisky advertisements." May God be praised if it is really true that our leading daily has decided to take the lead.

WHAT "BOOZE" MAY DO

The superintendent of our Sunday-school recently told us about a young man of his acquaintance who gave great promise, not only of being a great scholar but of being one who would likely be a blessing to his age and nation. A member of our Bible class told us further that he became an expert civil engineer, and was employed by the government to survey for miles along the Atlantic coast, and, if I am correct, he did a large and important work along the coast of Florida. Well, this man, highly connected, of such education and ability, got to drinking, lost his position, and, in spite of all his great circle of friends and relatives could do, went down and down.

Recently here in Bradentown, out on the dock, we had a bad fire. A hotel built near the boat-landing, on piles driven into the water, was burned. You might think that, with water below and on every side, it would be an easy matter for the fire company. Not so. It was only by wading in

the water that the firemen could work. Now read the clipping below from our Bradentown daily about this same expert civil engineer.

The body was burned beyond the possibility of certain recognition aside from peculiarities of the teeth, which were recognized.

J. P. Petrousa, proprietor of the hotel, stated today that Gray was a roomer at the hotel, that he occupied the room with an employe, who awakened him just before the employe took the plunge to safety in the waters of Manatee River.

It was reported his helper not only "awakened him," but that he got him *out of bed*, and he must have *gone back again* into the burning building. This is nothing so very strange. Do you recall what I said about the boy who persisted on lying across the track before the coming train? I will tell you something more about that. In taking him toward home we came to a cattle-guard. I cautioned him, and tried to help him get across safely. He struck me a brutal blow, then tried to *run* across, slipped down between the sharp-edged timbers, and when I got him out the blood was trickling down into both his shoes.*

Away back in that good old book we are told "It biteth like a serpent and stingeth like an adder," and, again, "Yea, thou shalt be as he that lieth down in the midst of the sea, or as he that lieth on the top of a mast."

MICHIGAN PAPER TELLS WHAT RESULTS FROM GETTING RID OF SALOONS.

BENTON HARBOR, Mich., Dec. 1.—An editorial recently appearing in the *News-Palladium*, of this city, presents at once an emphatic statement of the results of getting rid of the local saloon, and an honest man's argument for the extension of those benefits to the whole state. The paper says:

"Our experience here in Berrien County should convince every thoughtful and intelligent person that the abolishment of the sale of liquor by law is the best possible thing that can happen. Right here in Benton Harbor we have noted the effect in the way of a more orderly city, more happy homes, brighter-faced children, and many more cheerful women; and not only this, but there are scores who, previous to this important change, were scantily clad and poorly fed, who now enjoy the necessities and many of the luxuries of life.

"If a single drunkard were saved, and one family made happy, then the great reform would be worth all that it has cost us. But when there are scores of them, and when our streets are practically cleared of drunkards, the number of prisoners in our county jail reduced, and the expense of carrying on criminal litigation in this county cut down to a minimum, it would seem that all fair-minded people would be convinced of the desirability of the blessed state of affairs that we now enjoy; and it would also seem that all unselfish people residing within the borders of this county would be willing to work with zeal and energy to bring about statewide prohibition in order that every one within the borders of Michigan may be as blessed as we are ourselves."

* After this, when I supposed he had gone home, I found him *once more*, lying across the railroad track.

Engine Power costs less - NOW

By using 1916 Model

WITTE ENGINES

Gasoline, Kerosene

Gas, Distillate.

Buy Direct; Cash or Easy Terms

Stationary engines, 2, 3, 4, 6, 8, 12, 16 and 22 H.P., less than \$17.50 per horse-power. 6 H.P., only \$97.75, F. O. B. Factory. Portable engines and Saw-Rig outfits proportionally low. Proven highest quality for 23 years. Before you arrange to try any engine, at any price, read my free book, "How to Judge Engines." "Next Door to Everything"

Reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business, distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

The but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

February cash orders are subject to a special discount of 2 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to prepare carefully the bees for winter, and anticipate all possible requirements.

This Washer Must Pay for Itself

A MAN tried to sell me a horse once. He said it was a fine horse and had nothing the matter with it. I wanted a fine horse. But I didn't know anything about horses much. And I didn't know the man very well either.

So I told him I wanted to try the horse for a month. He said, "All right, but pay me first, and I'll give you back your money if the horse isn't all right."

Well, I didn't like that. I was afraid the horse wasn't "all right," and that I might have to whistle for my money if I once parted with it. So I didn't buy horse, and about the man badly. Now this set me thinking.

You see I make Washing Machines—the "100 Gravity" Washer.

And I said to myself, lots of people may think about my washing-machine as I thought about the horse and about the man who owned it.

But I'll never know, because they wouldn't write and tell me. You see, I sell my Washing Machines by mail. I have sold over half a million that way.

So, thought I, it is only fair enough to let people try my Washing Machines for a month, before they pay for them, just as I wanted to try the horse.

Now, I know what our "1900 Gravity" Washer will do. I know it will wash the clothes, without wearing or tearing them, in less than half the time they can be washed by hand or by any other machine.

I know it will wash a tubful of very dirty clothes in Six Minutes. I know no other machine ever invented can do that, without wearing out the clothes.

Our "1909 Gravity" Washer does the work so easy that a child can run it almost as well as a strong woman, and it doesn't wear the clothes, fray the edges, nor break buttons the way all other machines do.

It just drives soapy water clear thru the fibers of the clothes as a force pump might.

So, said I to myself, I will do with my "1900 Gravity" Washer what I wanted the man to do with the horse. Only I won't wait for people to ask me: I'll offer first, and I'll make good the offer every time.

Let me send you a "1900 Gravity" Washer on a month's free trial. I'll pay the freight out of my own pocket, and if you don't want the machine after you've used it a month, I'll take it back, and pay the freight too. Surely that is fair enough, isn't it?

Doesn't it prove that the "1900 Gravity" Washer must be all that I say it is?

And you can pay me out of what it saves for you. It will save its whole cost in a few months in wear and tear on the clothes alone. And then it will save 50 cents to 75 cents a week over that in wash-woman's wages. If you keep the machine after the month's trial, I'll let you pay for it out of what it saves you. If it saves you 60 cents a week, send me 50 cents a week till paid for. I'll take that cheerfully, and I'll wait for my money until the machine itself earns the balance.

Drop me a line today, and let me send you a book about the "1900 Gravity" Washer that washes clothes in six minutes.

Address me this way—H. L. Barker, 1622 Court St., Binghamton, N. Y. If you live in Canada, address 1900 Washer Co., 357 Yonge St., Toronto, Ontario.

SITUATIONS WANTED

WANTED.—A situation as assistant queen-breeder or for both comb and extracted honey; am expert at both; will go either north or south.
S. B. BARDEN, General Delivery, Philadelphia, Pa.

Married man, age 37, wants position as apiarist; has handled bees since childhood. Understands either comb or extracted production, and queen-rearing in full colony.
J. C. ADAMS, 20th and Rose, Detroit, Mich.

BEEKEEPERS' DIRECTORY

Well-bred bees and queens. Hives and supplies.
J. H. M. COOK, 70 Cortlandt St., New York.

Nutmeg Italian queens, leather color, \$1.00; 12 for \$10.00 return mail.
A. W. YATES, 3 Chapman St., Hartford, Ct.

QUIRIN's superior northern-bred Italian bees and queens are hardy, and will please you. More than twenty years a breeder. Orders booked now. Free circular.
H. G. QUIRIN, Bellevue, Ohio

QUEENS.—Improved three-banded Italian bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00 each; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.
H. C. CLEMONS, Boyd, Ky.

You can have your beeswax made into *best quality* foundation; also the wax from old combs or slungum. We get it all out. On shares or very cheap for cash. New factory. Old liberal terms. Cheapest and handiest transportation for all Northern beekeepers. You always get your own wax back.
J. J. ANGUS 454 Fulton St., Grand Haven, Mich.

Convention Notices

A meeting of the New Jersey Beekeepers' Association will be held in the Entomology Building, Bleeker Place, New Brunswick, N. J., on Feb. 10, 11, 1916. Mrs. Geo. Demuth, of the Bureau of Entomology, Washington, will address the meeting. Others will discuss various phases of the business. Don't fail to hear the man who wrote Farmers' Bulletin No. 503.
New Egypt, N. J. E. G. CARR, Sec.

THE NATIONAL BEEKEEPERS' ASSOCIATION CONVENTION, HOTEL SHERMAN, RANDOLPH AND CLARK STS., CHICAGO, ILL., FEB. 22, 23, 24, 1916.

PROGRAM

MORNING SESSION, 9 O'CLOCK, FEB. 22.

Delegates to the National Beekeepers' Association convention will present their credentials to the secretary at the Hotel Sherman before 9 A. M., Feb. 22. Opening of convention,

by Dr. Burton N. Gates, President
Appointment of committees
Reports of officers and committees
Discussion, "The Work of the National Association"
Paper, State Organization,

by Benjamin P. Sands, Boston, Mass.
AFTERNOON SESSION, 1:45.

Address, Extending the Use of Honey in Cooking,
by E. H. Bruner, Chicago
Address, Teaching the Value of Honey in Our Public Schools,
by Geo. W. Williams, Redkey, Ind.
Paper, Advertising and Selling Ripe Honey,
by R. M. Spencer, Ventura, Cal.

Paper, Use and Misuse of Prime Swarms,
by Grant Anderson, San Benito, Texas
EVENING SESSION, 7:30.

Address, Possibilities and Limitations of Inspection,
by Frank C. Pellett, Atlantic, Ia.
Address, Beekeeping in Canada (illustrated),
by Prof. Morley Pettit, Guelph, Ontario
MORNING SESSION, 10:00, FEB. 23.

Address, Out-apiaries,
by C. P. Dadant, Hamilton, Ill.
Address, Insuring Honest Queen Values,
by Kenneth Hawkins, Plainfield, Ill.
Paper, Importance of Bees in Pollinating Economic Plants,
by L. H. Pammel, Ames, Ia.

AFTERNOON SESSION, 1:45

Address, Establishing a Trade Name,
by E. R. Root, Medina, Ohio
Address, The Comb-honey Market,
by R. A. Burnett, Chicago
Address, Shipping Honey, by F. G. Snook, Akron, O.
The Depressed Honey Markets,
by J. E. Pleasants, Orange, Cal.

Paper, The Qualities of Western Honey,
by J. H. Stoneman, Blackfoot, Ida.
NATIONAL BEEKEEPERS' ASSOCIATION BANQUET,
7:00 P. M.

Evening session immediately following the banquet.
Address, Beekeeping Improvement thru Agricultural School Work,
by Prof. Francis Jager, St. Paul, Minn.
Paper, Varying Characteristics of European Foul Brood,
by Grover Matthews, Filer, Ida.

MORNING SESSION, 10:00 A. M., FEBRUARY 24.

Paper, The National Honey Day and Its Possibilities,
by Floyd E. Smith, Dallas, Oregon
Discussion and demonstration,
Shipping Honey by Parcel Post,
led by E. D. Townsend, Northstar, Mich.
AFTERNOON SESSION, 1:45.

General discussion
Election of officers and directors
Adjournment

It will be seen that the last day's program is not very full. This program will be extended when the plans not completed at this writing are finished.

WESLEY FOSTER, Sec.

TRADE NOTES

EARLY CASH ORDERS.

The discount for early cash orders is two per cent for the month of February. This is worth saving. If you know what your needs are, send in your orders. There are two added reasons for being forehanded this season. In many cases there is an increasing delay in delivery of shipments because many railroad lines have more business than they are able to handle promptly. In some instances, especially in the East, conditions are so bad that there is an embargo on all shipments of freight except perishable goods. Then, too, the effect of the great war on the prices of many things is raising prices of materials to such an extent that we shall be compelled to increase selling prices on numerous articles into which these materials enter when our

present stocks are used up and we have to buy further supplies. For all three reasons, therefore, you will be wise in placing your orders early for such goods as you need.

HOTBED SASH.

The time is here for starting early-vegetable plants in a cold frame. If you are not provided with sash, remember we can supply them as usual, made of cypress, 3 feet 4 inches by 6 feet, 1 3/8 inches thick, for 4 rows of 8-inch glass, shipped KD, \$1.00 each; \$4.75 for 5, or \$9.00 for 10; 8 x 10 glass for same at \$2.80 per box of 90 lights. Three boxes will fit up 10 sash.

ALSIKE-CLOVER SEED.

We have secured a fair lot of alsike-clover seed which we offer, while it lasts, at \$22.00 per bag of 2 bushels; \$11.50 per bushel; \$6.00 per half-bushel; \$3.25 per peck; 25 cts. per pound, bags included, not prepaid. Alsike seed is so fine that four to six pounds to the acre is sufficient for a good stand. The market is quite firm on medium and mammoth clover seed, and it is worth, as a rule, 50 cts. to \$1.00 per bushel more than the price here named for alsike. We do not carry it in stock, but can get it for those who cannot conveniently obtain it near home.

SWEET-CLOVER SEED.

Having now secured a good stock of choice western hulled white-sweet-clover seed, we are prepared to offer much lower prices than have ruled for some time past. There has been a larger crop of seed harvested, and we believe there is also an increased demand. The scarifying process, insuring very high germination of the seed, makes ten pounds per acre sufficient where twenty to twenty-five has been recommended. This fact makes the same quantity of seed reach twice as far; or, to put it another way, to seed the same number of acres, only half the amount of seed is required. This fact, together with the increased production of seed, has prevented this year the usual advance in price. Some producers who have been holding their seed for the high prices which have prevailed the past two seasons are, we fear, going to be disappointed.

The hulled seed, which we offer for shipment from Medina, is scarified. The unhulled is not, because the hulls must first be removed before the hard shell of the seed kernel can be scratched. It does not pay to use unhulled seed, even at half the price of hulled and scarified seed, because, as a rule, the per cent of germination in unhulled seed is usually quite low. Too often a poorer stand will be secured with two or three times the number of pounds per acre of unhulled seed than of hulled and scarified seed. Nevertheless, we can still furnish the unhulled seed to those who want it.

Until further notice we quote the following prices:

	In lots of	1	10	25	100
	lb.	lbs.	lbs.	lbs.	lbs.
Hulled white sweet clover,					
<i>Melilotus alba</i> ,	24c	22c	21c	20c	
Hulled yellow sweet clover,					
<i>Melilotus officinalis</i>	20c	18c	17c	16c	
Hulled yellow annual,					
<i>Melilotus Indica</i>	8c	6c	5c	4c	

Unhulled white or yellow at 6 cts. per pound less than the hulled for the same quantity. Those who can use large quantities should write us. We may be able to supply the hulled and scarified seed from western Iowa or Kansas in good-sized lots at attractive prices.

I am Anxious to Serve You

L. W. Crovatt, ^{Box} 134 Savannah, Ga.

Root's Goods Exclusively

Warehouse, River and Abercorn Streets
1916 Catalog sent on request

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Geo. L. Emerson, Manager, 948 East Second St.

Where the Weed foundation-machines are making perfect non-sag foundation. Send us your wax to be made into foundation. We buy wax too.

Root Redwood Hives.—A sample hive body with cover and bottom KD, \$1.00. Quantity prices on application. We cut hive parts to order.

New machinery for manufacturing hives and frames has been added. Extractors are now shipped "knocked-down" from the factory at Medina.

The A. I. Root Co., San Francisco, Cal.

245 Mission Street

We have moved. Office and warehouse in the same building.
Write for catalog and send us your list of wants.

"Hats Off to the New Management"

writes a Mission, Texas, customer

The old reliable line of Root's Beekeepers' Supplies with our new system of business management assures Texas beekeepers of service such as they have never before experienced.

Mr. B. I. Solomon, who is now in charge, has been with The A. I. Root Company for some years and knows their method of doing business.

We intend to carry a large and complete stock of supplies, and we also have our Weed foundation machines in shape to care for all orders promptly.

Give us an opportunity to convince you of our service.

Planet Jr. Hand Cultivators

The garden tools for big results

They are saving time, lightening labor, and producing better crops for over two million farmers and gardeners. Planet Jr tools last a life-time. Fully guaranteed. **72-page Catalog, Free!**

Describes over 70 tools including 12 entirely new ones, and improvements to our Seeders, Wheel-Hoes, Horse-Hoes, Harrows, and Corn, Potato, Orchard, and Beet Riding-Cultivators. **Write for it today!**

S L Allen & Co Box 1106S Philadelphia

No. 4 Planet Jr Combined Hill and Drill Seeder, Wheel-Hoe, Cultivator and Plow pays for itself in a single season in the family garden as well as in larger acreage. Sows all garden seeds (in drills or hills), plows, opens furrows and covers them, hoes and cultivates easily and thoroughly all through the season.

No. 11 Planet Jr Combined Double and Single Wheel-Hoe, Cultivator, Plow and Rake. Straddles crops till 20 inches high, then works between. The plows open furrows and cover them. The cultivator teeth work deep or shallow. The hoes are wonderful weed-killers. The rakes do fine cultivation and gather up trash. Unbreakable steel frame. Strong high steel wheels and specially hardened steels—new this year. The greatest hand-cultivating tool in the world.

No. 11
We make 32 styles of seed-drills and wheel-hoes—various prices.

NEW KEROSENE LIGHT

Beats Electric or Gasoline

MEN WITH RIGS OR AUTOS MAKE \$300 A MONTH

10 DAYS FREE
Send No Money

We don't ask you to pay a cent until you have used this wonderful modern light in your own home ten days—we even pay transportation charges. You may return it at our expense if not perfectly satisfied after putting it like every possible test 10 nights. You can't lose a cent. We want to prove to you that it makes an ordinary oil lamp look like a candle; beats electric, gasoline or acetylene. Lights and is put out like old oil lamp. Tests by Government and 33 leading Universities show it **BURNS 50 Hours On ONE GALLON** common kerosene (coal oil), and gives more than twice as much light as the best round wick open flame lamps. No odor, smoke or noise; simple, clean, no pressure, won't explode. Several million people already enjoying this powerful, white steady light, nearest to sunlight. It's **GUARANTEED**.

Aladdin
MANTLE LAMP

No Money Needed
We Furnish Capital

Without any sales experience, yes even without capital, you can make a big success by placing the Aladdin on trial. If you haven't capital we will help you with our liberal credit plan. **Every home wants and needs this wonderful light**, that from half the usual amount of oil produces the brightest, mellowest light obtainable. To sell the Aladdin is a simple matter of getting the light into people's hands. After a trial nobody wants to go back to old feeble lighting methods. Hundreds of men are making \$100 to \$300 a month. Here are two letters just like thousands we receive:

"Out of eight calls I sold six. Then ordered in four dozen lots and sold five lamps a day. My patrons all say they are fine after using them a year."—H. B. Stewart, S. Dak.
"Between Jan. 2 and Feb. 20, I sold about 275 lamps. I never saw anything that would sell equal to it."—Charlie Conrad, Ohio.

Get One FREE We want one user in each locality to whom we can refer customers. Be the first and get our special introductory offer under which you get your own lamp **FREE** for showing it to a few neighbors and sending in their orders. Write quick for beautifully illustrated **FREE Book** and get full particulars. Address nearest office

Sample Sent Prepaid—10 Days FREE to responsible men. Tell us what territory you prefer, whether you have a rig or auto so you can work in country, how long you have lived in the community, etc., so we can give you full information, agency terms, credit plan and sample lamp for free trial.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hands. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

17 CENTS A DAY! Remember this brand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY--Write 'for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

The Oliver Typewriter Co., Cleveland, Ohio

946 Prospect Avenue

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

A black and white photograph of a field. In the foreground, there are several beehives (skeps) stacked on the ground. The background is filled with trees in full bloom, likely cherry or apple trees, with many small white flowers. The overall scene is a rural landscape during spring.

THE IDEAL BEE-VEIL

Oftentimes when out in the yard working with the bees one stoops over to pick out a frame, and, as usual, bees keep buzzing around his head, watching for a chance to sting. The cloth veil which is often used sticks to the face when one bends over, and gives the bees an opportunity to sting. The IDEAL BEE-VEIL is constructed of cloth of wire, there being a cord at the top of the veil used to pull the cloth around the crown of the hat. The lower part also has a cord which fastens around the waist. The wire on the IDEAL veil does not strike the face, and prevents the bees from stinging. It can be readily seen that a veil of this kind has the cloth veil far outdistanced for comfort and utility. Sparks from the smoker do not burn holes in the IDEALS as in the netting veil.

The veil is manufactured by us, and is recognized by the best and largest beekeepers as the most practical veil on the market.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL., FEBRUARY 6, 1915.

COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and capping white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color, and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy*.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1*.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 10 unsealed cells, exclusive of the outside row.

4. *No. 2*.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

CINCINNATI.—Very little honey is selling at present. We quote No. 1 comb at \$3.75 to \$4.00; No. 2 at \$3.50 to \$3.75; white clover extracted in cans, 7 and 9; amber in barrels, 1/2 to 7, according to quality and quantity. For choice bright yellow beeswax we are paying 28 cts. per lb. delivered. Cincinnati, Feb. 3. THE FRED W. MUTH CO.

ZANESVILLE.—The market shows no material change as regards demand or prices. In small lots the better grades of white comb bring around \$4.00 per case, jobbers receiving customary discount from prices to the retail trade. White extracted we quote at 9 to 11 cts., according to quantity. Producers receive for beeswax 28 cts. cash, 30 in exchange for merchandise.

Zanesville, Feb. 8.

E. W. PEIRCE.

DENVER.—Local demand for comb honey is light, with ample supply. We are selling in a jobbing way as follows: Fancy white, per case of 24 sections, \$3.15; No. 1 per case, \$2.93; No. 2 per case, \$2.70; white extracted, 8 1/2 to 8 3/4; light amber, 8 to 8 3/4; amber, 7 to 8. We pay 25 cts. per lb. in cash and 27 in trade for clean yellow beeswax delivered here. THE COLORADO HONEY-PRODUCERS' ASSOCIATION. Denver, Feb. 4. F. RAUCHFUSS, MGR.

ST. LOUIS.—The demand for both comb and extracted honey of late has been very mild, and we believe stocks here are quite ample to supply the demand. We are still quoting white comb honey, 24 sections to the case, at \$3.25 to \$3.50. Amber, \$2.50 to \$3.00; extracted honey in 60-lb. cans from 5 to 6, according to quality. Beeswax is firm at 28 1/2 for pure, impure and inferior less.

R. HARTMANN PRODUCE CO.

St. Louis, Feb. 7.

INDIANAPOLIS.—There is quite a demand for honey at present, but more especially extracted. Comb honey has been moving rather slowly of late. We are not buying any comb or extracted, but we are being offered honey by producers, and they seem very anxious to dispose of it. We are selling No. 1 or choice white comb honey at \$3.75 to \$4.00 per case; No. 2 white comb at \$3.50. Best quality of extracted is bringing 9 1/2 to 11 cts. We are paying 28 cts. cash or 30 in trade for good average wax delivered here.

We conduct a Bee and Queen Rearing Business in Florida during the winter, and at Canton, Ohio, during the summer. We now have a carload of selected Italian Bees in Florida for the purpose of supplying you with Bees and Queens for EARLY SPRING DELIVERY. WE GUARANTEE PURE MATING AND SATISFACTION IN EVERY RESPECT, OR MONEY REFUNDED. We are breeding from Queens that gave a surplus of 300 pounds per colony in a 24-day honey-flow. Will it not pay you to have this strain of bees in your yard? Prices as follows:

ISLAND-BRED ITALIAN QUEENS.

Shipments begin March 1.

	1	6	12

THE J. E. MARCHANT BEE AND HONEY COMPANY, CANTON, OHIO

QUEENS OF QUALITY

The editor of *The Beekeepers' Review* and his sons have 1100 colonies of bees worked for extracted honey. With all those bees working with equal advantage, all having the same care and attention, they have an opportunity unexcelled to ascertain without a reasonable doubt colonies desirable as breeders from a honey-producers' standpoint. Likely, never in the history of beekeeping was there a better opportunity to test out the honey-getting strain of bees than this. Think of it, 1100 colonies with equal show, and a dozen of those colonies storing 250 to 275 pounds of surplus honey this last poor season (with us), while the average of the entire 1100 being not more than 40 pounds per colony. We have sent two of our best breeding queens (their colonies producing 275 pounds surplus each, during the season of 1915) to John M. Davis, and two to Ben C. Davis, both of Spring Hill, Tenn., and they will breed queens for the *Review* during the season of 1916 from those four superior honey-gathering breeding queens. Those young queens will be mated with their thoroughbred drones. Our stock is of the three-banded strain of Italians; also that of John M. Davis; while Ben C. Davis breeds that disease-resisting strain of goldens that is becoming so popular.

By this time you are likely thinking that your strain of bees may be improved some by the addition of this superior strain of *Review* queens, and how you can secure one or more of those superior honey-gathering queens as a breeder. We will tell you. They will be sold to none except *Review* subscribers. If you are a paid-in-advance subscriber to the *Review* for 1916, we will mail you one of the daughters of those famous queens in June for a dollar. If not a subscriber to the *Review* for 1916, send \$1.75 for a year's subscription to the *Review*, and one of those famous queens. These queens are well worth two dollars each compared to the price usually charged for ordinary queens, but we are not trying to make money out of this proposition, only we are anxious to have every subscriber to GLEANINGS a subscriber to the *Review*, and we are taking this way to accomplish the object. A few of the very first orders for queens that we receive can be mailed in May, but the majority will not be mailed until June. Orders filled in rotation. Have your order booked early and avoid disappointment. Address with remittance

THE BEEKEEPERS' REVIEW, Northstar, Michigan.

ITALIAN QUEENS THREE-BANDED

Ready April 1. Of an exceptionally vigorous and long-lived strain of bees. They are gentle, prolific, and the best of honey-gatherers. Untested, \$1.00; 3, \$2.75; 6, \$5.00; 12, \$9.00. Tested, \$1.25; 6, \$6.50; 12, \$12.50. Send for my free circular and price list, and see the natural conditions under which my queens are raised. Will book orders now.

Honey market reports continued from page 2.

NEW YORK.—There is a very light demand for comb honey and light extracted. Buckwheat extracted has a fairly good demand at 6 to 7. Shipments from foreign countries are light, and the market is pretty well cleaned up on these grades. West Indian is selling for 50 to 55 cts.
New York, Feb. 9.

CHICAGO.—Little can be said in the way of reporting sales of hone during the past two weeks, for the reason that sales have not been made in any volume. January is always a dull month, and has been unusually so, as far as this market is concerned; consequently prices are nominal, concessions being made to induce business. The best grades of white comb honey are bringing 15 to 16; the under grades from 1 to 3 cts. less. Extracted white ranges from 7 to 9, according to kind and quality, and amber grades from 5 to 7. Beeswax brings 30.
Chicago, Feb. 4. R. A. BURNETT & Co.

Convention Notices

The annual convention of the Pennsylvania State Beekeepers' Association will be held in the Chamber of Commerce, Lancaster, Pa., March 3, 4, 1916. An interesting program is in preparation. Every beekeeper, whether member of the association or not, is urged to be present. A good meeting is looked for.
H. C. KLINGER, Sec.
Liverpool, Pa., Feb. 1.

SPECIAL NOTICES

We have just finished printing 54,000 seed catalogs for our old-time friend Mr. A. T. Cook, of Hyde Park, N. Y., who expects to do a larger business this year than ever. You will remember Mr. Cook as an old advertiser of temperance cards as well as seeds. He has a good supply of both on hand, and is now ready to take prompt care of all his customers. Now is the time to begin thinking about that garden, and we are sure it will be a pleasure for you to look over Mr. Cook's catalog.

VALUABLE FREE BOOKS.

Every farmer who owns an engine or expects to buy one ought to know about engines—how to judge them, how to apply simple tests, how to figure exactly what an engine is worth. This interesting and valuable information is given in the free illustrated book, which will be sent without any obligations to any reader. Simply send name today to E. H. WITTE, 193 S. Oakland Ave., Kansas City, Mo.

EXPERIENCE VERSUS THEORIES.

The best products manufactured today are those which are built on experience. Now, we will take as an example Farm Fence, because this is an article that almost all farmers buy each year. A fence built on Shop Theories is one thing, but a fence built on experience to meet the farmer's requirements, one that has successfully stood the test for years and years, is quite another matter. Kitzelman Brothers, of Muncie, Ind., whose ad. appears in this issue, are making a fence that is built on experience. It contains many practical ideas of farmers themselves, as they have been selling their fence direct to the farmer for 33 years. They have learned from experience what a farmer's fence ought to be to give satisfaction from a farmer's standpoint. You should write for their free catalog at once if you are interested in securing a good grade of fencing at money-saving prices.

All poultry enthusiasts will be interested in the catalog recently issued by the Model Incubator Co., of Buffalo, N. Y., and New York city, bearing the title "First Aid to Poultry-keepers." Not only the beginner but the experienced well-versed breeder will find the catalog of the greatest help in all the many and varied problems of poultry-raising. Being compiled by authorities it is a book which should be in the hands of every one now in the business and every one who intends to enter the business. It is attractively gotten up, well illustrated, and substantial enough to be used as a

We have counted 450 berries, blossoms and buds on a single plant. A postal will bring the plants, also enough seed of the new CEREAL FETERITA to plant a rod square of ground. Also a pkt. of perennial ORIENTAL POPPY seed. Send 10 cts for mailing expense or not, as you please. Write today and get acquainted with **THE GARDNER NURSERY COMPANY** Box 749, Osage, Iowa.

handy book of reference. You can do no better than send a postal request for the catalog if you are interested in the subject.

We call particular attention to the advertisement of Mr. Herman A. Clark, of Saratoga, Cal., who is advertising dried prunes. The editor visited his ranch last winter and was delighted to see the kind of fruit he is putting out. Mr. Clark is an old Medina County boy, well known to all the members of The A. I. Root Company, and we can vouch for his responsibility. Any one who gives him a trial order will be almost sure to give him a repeat order as his goods are first-class in every respect.

PRACTICAL BOOKS FOR THE GARDENER AND THE FARMER.

The above is the title of a four-page leaflet we have just finished printing. This contains a list of standard practical books which answer questions that occur every day. They tell what to do. They are written for the specific use of the gardener and farmer, amateur or professional, furnishing the latest and most authoritative information on every phase of agricultural or horticultural work, on a large or small scale. An edition of 5000 of these leaflets is just off the press. Send for one so you can decide which books will be of the most benefit to you.
THE A. I. ROOT COMPANY, Medina, Ohio.

NOW IS THE TIME

Dept. T, CLEMENS BEE SUPPLY CO.,
128 Grand Ave., Kansas City, Mo.

Equipment purchased during the quiet winter months may be made ready for busy spring and summer months. The early-order discount pays you interest on your money.

“Root Quality” equipment means BEST QUALITY equipment. The Root bee supplies are up to the minute. The most complete line of bee supplies made.

We sell Root's Goods in Michigan. Order from Root catalog, or we will quote on request. February, cash discount, 2 per cent. Beeswax wanted.

M. H. Hunt & Son, 510 N. Cedar St., Lansing, Mich.

When You Think of Bee Supplies, Think of Indianapolis

We Sell Root's Bee Supplies
---the Goods that Satisfies....

Indications just now are very favorable for a good season next year. A good season means an excessive demand for Root's goods at Root's prices. By ordering now you will receive your goods promptly, also save the cash discount for early orders, which is two per cent in February, and you can put them together in your spare time.

If you are interested, and it is your intention to order your supplies before goods are really needed, just try placing a trial order here. We are quite sure you will continue with us year after year. Some, of course, never buy supplies till after they are needed. But the men who are most successful are preparing right now for next season.

We allow you 30 cents a pound in trade for good average beeswax delivered here.

Finest extracted honey in five-gallon cans ready for immediate shipment. Write for quotations.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

"Next Door to Everything"

Reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business, distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

February cash orders are subject to a special discount of 2 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to prepare carefully the bees for winter, and anticipate all possible requirements.

This Washer Must Pay for Itself

A MAN tried to sell me a horse once. He said it was a fine horse and had nothing the matter with it. I wanted a fine horse. But I didn't know anything about horses much. And I didn't know the man very well either.

So I told him I wanted to try the horse for a month. He said, "All right, but pay me first, and I'll give you back your money if the horse isn't all right."

Well, I didn't like that. I was afraid the horse wasn't "all right," and that I might have to whistle for my money if I once parted with it. So I didn't buy the horse, altho I wanted it badly. Now this set me thinking.

You see I make Washing Machines—the "1900 Gravity" Washer.

And I said to myself, lots of people may think about my Washing Machine as I thought about the horse, and about the man who owned it.

But I'll never know, because they wouldn't write and tell me. You see, I sell my Washing Machines by mail. I have sold over half a million that way.

So, thought I, it is only fair enough to let people try my Washing Machines for a month, before they pay for them, just as I wanted to try the horse.

Now, I know what our "1900 Gravity" Washer will do. I know it will wash the clothes, without wearing or tearing them, in less than half the time they can be washed by hand or by any other machine.

I know it will wash a tubful of very dirty clothes in Six Minutes. I know no other machine ever invented can do that, without wearing out the clothes.

Our "1900 Gravity" Washer does the work so easy that a child can run it almost as well as a strong woman, and it doesn't wear the clothes, fray the edges, nor break buttons the way all other machines do.

It just drives soapy water clear thru the filters of the clothes like a force pump might.

So, said I to myself, I will do with my "1900 Gravity" Washer what I wanted the man to do with the horse. Only I won't wait for people to ask me. I'll offer first, and I'll make good the offer every time.

Let me send you a "1900 Gravity" Washer on a month's free trial. I'll pay the freight out of my own pocket, and if you don't want the machine after you've used it a month, I'll take it back, and pay the freight too. Surely that is fair enough, isn't it?

Doesn't it prove that the "1900 Gravity" Washer must be all that I say it is?

And you can pay me out of what it saves for you. It will save its whole cost in a few months in wear and tear on the clothes alone. And then it will save 50 cents to 75 cents a week over that in wash-woman's wages. If you keep the machine after the month's trial, I'll let you pay for it out of what it saves you. If it saves you 60 cents a week, send me 50 cents a week till paid for. I'll take that cheerfully, and I'll wait for my money until the machine itself earns the balance.

Drop me a line today, and let me send you a book about the "1900 Gravity" Washer that washes clothes in six minutes.

Address me this way—H. L. Barker, 1623 Court St., Binghamton, N. Y. If you live in Canada, address 1900 Washer Co., 357 Yonge St., Toronto, Ontario.

1916--Advance Lewis Bee-supply News--1916

THE NEW LEWIS CATALOG this season, like BARNUM'S CIRCUS, is better, bigger, and grander than ever.

As a progressive beekeeper, you read the bee-journals, all the bee-books you can get, and attend the conventions, BUT—

IF you do not get the LEWIS CATALOG FOR 1916 you are neglecting a liberal bee education. In no other form can you get so much good, meaty knowledge about bee fixtures, apparatus, tools, and whatnot as you can right in the LEWIS CATALOG—and the pity of it is, the man who does not avail himself of this opportunity passes up that which he may have for the asking—for it is free.

Send Right Now for a New Lewis Catalog

Here are Only a Few of the Distinctive Features Contained in It.

Our NEW METAL-BOUND DIVISION-BOARD in the full-depth size is to be found illustrated, described, and listed.

A very good tool in the shape of a KNIFE FOR SCRAPING AND CLEANING FILLED SECTIONS is illustrated, described, and listed.

A WOVEN WOOD-AND-WIRE CHEST, which is a low cost article with many uses, is illustrated, and described.

One page is given over to the RAUCHFUSS FOUNDATION CUTTING-BOX, a practical little outfit for the beekeeper.

Two other articles, a SECTION-HOLDER NAILING-FORM and FRAME WEDGE DRIVER are offered.

Two whole pages of INSTRUCTIONS TO BEEKEEPERS BY C. P. DADANT will be found interesting to the old beekeepers as well as the new.

One page devoted to the PROSPECTIVE BEEKEEPER is very interesting, and many new thoughts are presented.

SWEET - CLOVER SEED

Quick Germination

Get our "Scarified" Sweet-clover Seed, which will germinate from 85 to 95 per cent the first year, and thus insure you a good stand right from the start. By sowing our seed you will save money, as it takes only about half as much scarified to sow an acre as ordinary hulled seed.

Prices	1 lb.	10 lb.	30 lb.	100 lb.	60 lb. a bu.	5 bu. a bu.	10 bu. a bu.	Lbs. per acre
Unhulled White, re-cleaned	\$0.25	\$2.00	\$5.10	\$16.00				
Hulled White, re-cleaned and scarified .	0.30	2.75	6.75	22.50	\$13.50	\$4.80	\$4.50	25 to 30
Hulled Yellow, re-cleaned and scarified	0.20	1.80	5.10	17.00	10.20	9.50	9.00	8 to 12
<i>(Melilotus Officinalis)</i>								

When seed is wanted by parcel post, be sure to include postage. Bags will be included in the weight in parcel-post shipments.

Please Note—All of our seed is thoroly cleaned. The scarifying process usually breaks some of the seeds, and we remove all broken seeds. This is an important saving to you. Samples on application.

Dadant & Sons, Hamilton, Illinois

YELLOW SWEET CLOVER.—Many people fail to recognize the value of the biennial yellow sweet clover as a honey-plant. The fact that it blooms two weeks earlier than the white variety makes it especially valuable to the beekeeper. Be sure, however, to get the biennial variety as quoted above.

EDITORIAL

A Short Course in Apiculture in Indiana

OUR Indiana readers, at least, will be glad to know that there will be given a short course in bee culture at the Winona College of Agriculture, Winona Lake, Ind., during the week of March 20. We hope to present the program of the work later on.

Varying the Size of the Entrance During Winter

IN the case of outdoor-wintered colonies be sure that the entrance to the passage-ways is not clogged with dead bees. When the bees are confined at the home yard the entrances may be contracted during severely cold weather, or during a time when there is a high wind, to advantage; but it should be enlarged when the weather moderates. In-making the contraction, do not disturb the bees.

The Curse of Goldens

ONE would almost think that we had inspired Mr. Arthur C. Miller and Mr. S. H. Burton to write their articles on goldens in this issue. Quite the contrary. As a matter of fact, we believe Mr. Miller, at least, is a little hard on them, for not all goldens that we have had any experience with were as bad as those he describes. The California Beekeepers' Association, Mr. Chadwick reports, also knocks them.

The average beeman should understand that when he buys queens or colonies of the extra-yellow strain he buys some good and some bad.

A Correction; Those 4100 Cases of Honey

IN William Lossing's letter, page 2, editorial department, we inadvertently in the copy made him say he produced 4100 cases of honey, when it is evident that he meant to say that he had only *shipped* that number. If he had produced this amount of

honey he surely would be some beekeeper. Many are writing him, desiring to know if there are other locations like that, notwithstanding the territory he says is already overcrowded. It surely would be good bee country if there were many beekeepers producing 4100 cases of honey.

Our apologies are due to Mr. Lossing and to the beekeepers in the valley, several of whom we know personally, having visited them some years ago.

Lectures and Demonstrations in Connecticut

THE trustees of the Connecticut Agricultural College have engaged A. W. Yates, of Hartford, to give a course of lectures on beekeeping, accompanied by demonstrations. The lectures will be given on Saturdays during April and May, and will be open to students and others who may be interested in this subject. The topics of the lectures are as follows:

1. Establishing an apiary. Natural history, hives and location, adaptability of the person.
2. Comb and wax. The mystery and origin of wax, its relation to honey, commercial value.
3. Spring management. The early necessity of a force of young bees to care for the queen, spring dwindling, stimulative feeding.
4. Diseases of bees. Causes, how to detect, treat, and prevent.
5. Increase and queen-rearing. The importance of good queens, easy methods of rearing and making increase.
6. Wintering. Providing the colonies with sufficient stores in a compact brood-nest, packing, ventilation, and feeding.

The Nuisance of the Follower-board or the Division-board in the Modern Hive

REFERRING to what Mr. J. E. Crane has to say on page 141 in commenting on the statement of E. F. Atwater on the flimsiness of the average division-board in the modern hive, we may offer this suggestion:

Leave it out entirely. We have been doing it for the last two years, and use it only when there is less than a full complement of frames in the hives. In our opinion a clumsy thick follower-board in a ten-frame hive with nine frames will not help matters much. What we need is extra room without a follower-board.

That room is not needed with the ordinary unspaced frames that can be squeezed closer together to remove the one desired. But with the self-spacer there is or should be, at least, extra room in the hive. By removing that naughty division-board, and keeping it out where you have a full complement of frames, with either eight or ten frame hives the extra room will be provided.

First Annual Report of the Minnesota Inspector of Apiaries

MR. CHARLES E. BLAKER, the State Inspector for Minnesota, has just put out his first annual report. It is unfortunate, as Mr. Blaker says, that up to 1915 there is no available record of inspection work in the state, which handicaps the work somewhat.

So far the work has been chiefly with American foul brood, as the European type of the disease has not made much of a start. It was reported in 1914, and then discovered in several other points in 1915. On account of the danger existing when this disease becomes prevalent, a full description is given of it, methods of treatment, etc., along with descriptions and methods of treatment of American foul brood and of sacbrood.

Out of 452 apiaries visited, disease was found in 57; 7114 colonies were examined, and 269 found diseased.

Beekeepers of Minnesota may obtain a copy of this report on application to Chas. E. Blaker, Inspector, 4420 Grimes Ave., Minneapolis.

Bees and Smelter Smoke, again

IN our issue for Dec. 15, page 915, we stated that the beekeepers of Ontario, Canada, were about to bring suit against a silver-smelting company for alleged damages to their interests in the sum of \$30,000. We have heard nothing further from this, altho the case was to come up in the courts in November. Whether it has been settled we are unable to say. At all events, we learn from a clipping from the *Illustrated Buffalo Express* of December 19 that means have been discovered for eliminating almost entirely the injurious effects of smelter smoke on either plants or animals. As the

Buffalo paper is published near the scene of the trouble referred to, it is possible some compromise has been effected, or that the damage claimed is merely nominal.

It appears that the new means of filtering the smoke prevents the incrustation of certain chemicals on vegetation which, when eaten by animals, caused more or less trouble. No mention is made of bees in the clipping referred to.

If any of our subscribers in Canada or the United States know the outcome of the Ontario case we shall be glad to have them write us.

The Importance of Scattering Colonies of Bees in Fruit Orchards

IN this issue, page 145, Mr. J. E. Crane brings out a point that is worth the careful attention of every fruit-grower and beekeeper; namely, that bees in orchards do better work in pollinating the blossoms if the hives are *scattered* thruout the orchard. That has been our policy where we put out bees in this way. If the season is a little unfavorable the trees nearest the bees will show more fruit than those further removed.

Mr. Crane mentions that a prominent fruit-grower stated before the Vermont Horticultural Society that he scatters the bees all thru the orchard, "with the result that in seasons when during fruit-bloom it is cold and cloudy the three or four trees close to a hive of bees were much more fruitful than those further away." Mr. Crane draws the conclusion that "as we are apt to have a great deal of such weather in northern New England this season of the year," this is a "very important consideration."

Beekeepers will get calls for bees to be located in fruit-orchards more and more; and what is an advantage the fruit-grower is also to the advantage of the beekeeper—more pollen more brood, and more returns when the honey-flow comes on in June and July.

Bee Inspection in Idaho

THE sum of \$3000 was appropriated by the Legislature for bee inspection in Idaho during 1915 and 1916, which is more than double the amount ever expended before for the same period. This has made it possible for the inspection to cover much neglected territory.

State Horticultural Inspector Graham, in his annual report for 1915, says that 3648 colonies were found diseased, or were kept in box hives in violation of the law, out of

30,511 colonies inspected. There were 2639 colonies treated, and 1009 were destroyed.

Mr. Graham estimates that 1,780,000 pounds of honey was produced in the state during the year, valued at about \$175,000. Probably two-thirds of the honey was shipped out of the state.

We have taken these figures from a brief review of the report in *The Idaho Statesman* for January 26.

Bran Cookies

We wish to call especial attention to one of the honey recipes in *Farmers' Bulletin* No. 653, "Honey and Its Uses in the Home," of which mention has already been made in these columns. The recipe entitled "honey bran cookies" No. 2 we have found to be exceptionally fine. Not only are these cookies of delicious flavor, but containing, as they do, the ingredients of bran and honey, they are very fine for building up bone and tissue, and also have a mildly laxative effect. We have found that the addition of one or two eggs to the recipe improves the cookies somewhat. Here it is:

Three cups bran, $\frac{1}{2}$ cup sugar, $\frac{1}{4}$ to $\frac{1}{2}$ teaspoonful soda, $\frac{1}{4}$ teaspoonful cinnamon $\frac{1}{2}$ teaspoonful ginger, $\frac{1}{2}$ cup honey, $\frac{1}{2}$ cup milk, $\frac{1}{2}$ cup butter, 2 eggs if desired. If the bran is coarse add a little flour. Mix the ingredients thoroly, and drop from spoon on to a buttered pan and bake about 15 minutes.

L. C. Root, Son-in-law of Moses Quinby, still Young at 75

MR. LYMAN C. ROOT celebrated his 75th anniversary at his home recently. Besides the numerous friends who came to call on him, many letters of congratulation came from far and wide.

Mr. Root will be better known to the readers of *GLEANINGS* when we say that he is a son-in-law of the late Moses Quinby, the author of "Mysteries of Beekeeping Explained," and also of the only reliable cure for American foul brood. After Mr. Quinby's death Mr. Root revised the work. This was in 1884. So complete and thoro was the revision that the publishers said that he "might in justice have claimed to be its author; but with rare modesty, and in a spirit of reverence to one who had devoted his life to the advancement and popularizing of bee culture, he preferred to retain the title of Quinby's 'New Beekeeping.'"

Our readers will remember that Mr. Root, in our Quinby number of last year, had an article on page 267, April 1st issue, telling something about Quinby's old home and

relating some reminiscences of his father-in-law who in the olden days, without movable-frame hives, made money from his bees, and who one year produced so much box honey that he broke down the honey market of New York. But this was away back in the early '50's.

The career of Mr. Root, the son-in-law, has been no less remarkable. In the early days he was a well-known contributor to *The American Agriculturist* and *The Country Gentleman*. While he has not done very much with bees since his removal from New York to Connecticut, he has been an active factor in civic life in the state of his adoption. He has held varied positions of honor and trust, having been recently elected member of the State Board of Trade of Connecticut, and for a number of years he was treasurer of the Stamford Board of Trade and a delegate to the State Board. He is treasurer of the Civic Federation, and an active member of the Universalist Church and of its men's forum. In politics he is a Prohibitionist; but, nevertheless, while milk inspector he served under a Democratic mayor and a Republican council.

Those who had the pleasure of hearing the address he delivered at the Jenkintown field meet, where there were nearly a thousand beekeepers present, will remember Mr. Root not only as a man of ability but one of exceedingly pleasant face that bespeaks the character of the man. Like our Mr. A. I. Root, to whom he is not related, he carries us back to the olden days when beekeeping in America, and practically in the whole world, developed from the old box hive to the modern movable combs, section honey-boxes, comb foundation, and the extractor. Both the Roots are within one year of being the same age, and in all these years they have been good friends.

The Colorado Spraying Situation, again

ONE of the prominent apple-growing districts is western Colorado. As would naturally be expected, beekeeping interests are also well represented there. Altho honey-producers ought to be on the best of terms with the fruit-growers, their interests being so closely intertwined, unfortunately peace does not always prevail. Spraying seems to be the cause of the disturbance.

Of course, there is always present, more or less, a dispute on the pros and cons of spraying while the blossoms are on the trees. This were enough to call out a quarrel had it not been that a new situation developed along with an advance in methods of orchard practice. At one time clean

cultivation of the ground under the trees was the rule; but a short time ago the orchard men began planting sweet and red clover for soil-renewal purposes.

Here the trouble began afresh. The poisonous spray dripping from the trees, and sprinkling the clovers beneath, it was claimed, was poisoning their colonies in great numbers. The red-clover cover crops would come into bloom when there was a dearth of honey from any other source. The arsenate of lead, when sprayed on the trees after the petals on the trees had fallen, would drip on to the clover-blossoms where the bees were working. From a personal canvass of the situation we were convinced the bees were killed by the spray. A complicated discussion ensued, part of this thru the columns of GLEANINGS IN BEE CULTURE, and part of it in correspondence. In the following summaries of their argument the chief parties to the discussion hit the high spots of the question.

J. G. Brown, a Colorado beekeeper, called the attention of the beekeeping public to the situation last August in an article in GLEANINGS, in which he stated that bees had been poisoned by the spray falling on red clover. Beekeepers were moving their colonies to more favorable locations.

Dr. E. F. Phillips surmised that the losses were due to European foul brood. To his statement J. A. Green replied that he had lost too many colonies to be convinced that the damage came from anything else than spray poisoning. He wrote an article in GLEANINGS on this situation several years ago.

It was the opinion of B. W. Douglas, formerly State Entomologist of Indiana, that the beekeepers in Colorado were needlessly excited. The dripping from the trees, he contended, could not poison the clover blossoms underneath when so much greater pressure is needed to force the poison into the blossoms. In the second place, only an inexperienced grower would use so much material that it would slop over on the ground.

C. P. Gillette, State Entomologist of Colorado, wrote that he knew positively that much damage had been caused by spraying during fruit bloom, but he lacked conclusive evidence that bees had been poisoned in working on the clovers. Thoro spraying, he averred, always resulted in a large amount of drip.

Neither spraying the blossoms nor spraying while the clover is in bloom is sane horticultural practice, according to Dr. H. A. Surface, of Pennsylvania. No fruit-grower, he said, should leave a cover crop

until it blooms. He agreed with Douglas that it is poor practice to use so much spray.

Dr. A. J. Cook, Horticultural Commissioner of California, was well satisfied that the sprays falling on the cover crops of red clover would and did kill bees. The whole difficulty could be eliminated, he said, by using the annual sweet clover for a cover crop that would come into bloom at a time when the trees would not be sprayed.

Our sympathies naturally go out to the beekeepers. We are convinced that bees are killed by the thousands in Colorado by the sprays that fall upon the red-clover cover crops. The fact that the colonies immediately build up as soon as they are removed from the vicinity of the orchards, and die outright when left there, is significant. See what Wesley Foster says in his department in this issue.

Shipping Bees by Express in Combless Packages versus Shipping them by Freight with Combs, Hives, and Equipment

FOR some time back we have been coming to the conclusion that sending bees by freight in car lots—hives, combs, and all—is a very expensive way of moving bees. In the first place, it is a little difficult to make a carload of bees come up to the minimum weight on which freight must be based. Those who have had experience in shipping bees know that all colonies must be light, and it is not easy to crowd in enough light colonies to make up the minimum weight.

In our several shipments from north to south, and *vice versa*, we have found that the strong colonies would not go thru nearly as well as the weaker ones. To put it in another way, a colony of moderate weight will have more bees and brood alive and in good condition on arrival at destination than a strong one. Two and a half to three pounds of bees, with double screen top and bottom, to a single brood-chamber, will ship better than four or five pounds. Of course, if one uses two-story hives he can ship more bees; but the ratio of difference will be about the same.

It has been our experience that it costs about \$1.00 per colony for freight on bees from Florida to Medina. When we add the cost of cartage at both ends of the line, the cost of crating, which amounts to \$40 or \$50, and cost of a man's transportation both ways, the cost per colony runs \$1.50 per colony. To prepare a hive of bees, screened top and bottom—hives, combs, and all—it is worth, we will say, \$4.50 includ-

ing a queen. The cost of getting that colony of bees to the North will run somewhere about \$1.50. If we add the risk that one takes, delays en route, and double time of a man on the basis of 40 cts. an hour, and his railroad transportation, the entire cost per colony runs up to nearly \$2.00. This will make the total cost about \$6.50 per colony placed in the yard.

Let us now look at the other proposition of sending bees without combs by express. If we could send bees and brood without combs or hives we could figure out the proposition a little more exactly. As this is impossible the only thing we can do is to figure the brood in the form of bees. We usually reckon that about 3 lbs. of bees, with necessary crating, will aggregate 7 lbs. On this basis 30 lbs. of bees will run about 70 lbs.

Our traffic manager, after corresponding with different railroad and express companies, has prepared a table of prices in shipping combless bees from three or four different points in the South to various points in the East. The following is the table:

Live Bees from				
Fitzpatrick, Ala., to				
	2 lbs.	5 lbs.	7 lbs.	10 lbs.
Cleveland	.45	.57	.66	.77
New York	.47	.60	.71	.84
Chicago	.45	.56	.63	.74
Medina, O.	.45	.57	.66	.77
From				
Kansas City, Mo., to				
Cleveland	.45	.56	.63	.75
New York	.47	.63	.72	.86
Chicago	.44	.51	.57	.65
Medina, O.	.45	.56	.63	.75
From				
Jacksonville, Fla., to				
Cleveland	.48	.63	.74	.89
New York	.47	.60	.71	.84
Chicago	.47	.67	.71	.86
Medina, O.	.48	.63	.74	.89
From				
Apalachicola, Fla., to				
Cleveland	.48	.63	.74	.89
New York	.48	.65	.77	.93
Chicago	.47	.60	.69	.83
Medina, O.	.48	.63	.74	.89

For example, a 3-lb. package from Fitzpatrick, Ala., which would be equivalent to 7 lbs., would run about 66 cts. to Cleveland; 71 cts. to New York; 63 cts. to Chicago; 66 cts. to Medina, and so on the prices run from 60 to 75 cts. from all the different points.

But some will argue that three pounds of bees from the South is not equal to an ordinary colony in the spring in the North. Well, suppose we make it 4 lbs. Even then the express per colony will be less than \$1.00.

Compare this figure with the freight. \$1.50 to \$2.00 per colony, and you will see that the combless package of bees by express is considerably cheaper, providing, of

course, that the shipper *guarantees* arrival in good order. There are three or four breeders in the United States who are willing to do this.

But there is still another way of looking at it. Two thousand pounds minimum of bees, combs, hives, and all by freight from Apalachicola, Fla., to Medina, Ohio, would run up to \$349.20. Two hundred and eighty-five 7-lb. packages (each containing 3 lbs. of bees) by express, aggregating 2000 lbs. would run up to \$253. To the freight shipment we must add 50 to 100 per cent more. To express shipments we add nothing. It will be seen that the figures stand largely in favor of sending by express. But this is not all. Bees sent by express will not take over two or three days from the South to the North, while by freight it will take from a week to ten days to get them thru, with a corresponding damage to brood and bees. Still again, when bees are sent by freight, unless extraordinary care is taken to water them at intervals, the unsealed brood is destroyed and sometimes sealed brood is scorched by the bees becoming too hot.

There is one more point to be considered, and it is important. When one wants to move 300 colonies he cannot very well shake off all the bees and let the brood die; and, moreover, he cannot send the bees by express unless he has a full complement of combs and hives at the other end of the route. But the average beekeeper in the North who has lost heavily by wintering can easily recuperate his losses by getting his bees by express.

Last, but not least. When full hives, combs, and brood are shipped, there is also danger of transmitting bee disease. There is very little likelihood of such danger by express.

A California Man Succeeds in Sending Bees by the Pound in Large and Small Lots; Invert-sugar Queen-cage Candy Not an Unqualified Success in Shipments

In reference to shipping bees in pound packages, which appeared in our columns recently, Mr. J. E. Wing, of San Jose, Cal., one of the most extensive queen-breeders in the country, and who has done a large business in shipping bees successfully without combs, writes:

I have been reading the editorial on page 744, Sept. 15, and Mr. W. D. Achord's article on page 1031, Dec. 15th issue, on the pound-package business with interest, as I do quite a bit in that line myself. Out of

about 1500 pounds shipped in 1915 my loss was not one per cent, and some of the shipments were not easy ones. I sent a small shipment to New Jersey for an experiment, and they arrived with only a few bees dead. Other large lots went to Colorado, Idaho, Nevada, Oregon, Washington, Utah, Oklahoma, and all parts of California. One place in this state I consider quite a hard shipment in the middle of summer, and that is Imperial Valley. For such conditions where the weather is extremely hot I do not agree with Mr. Achord that water is not necessary. I use the Root one and two pound cage exclusively; and as the cages are very substantially made I make arrangements when sending a large order to have the empty cages returned. In this way I am able to save the buyer a little money, and also myself, and I find the cages are good for a number of trips.

I received many inquiries from British Columbia the past season for bees by the pound from people who are very anxious to buy bees that way. I shipped there during 1914 with never a single loss; but they now have a quarantine law which bars the shipping of bees in any form from the United States. Their beekeepers there are up in arms against the law, and it seems to me if they could be made to understand that disease could not be sent in with the pound packages, perhaps they would modify the law to allow bees to be shipped in without combs.

In one of your letters last summer you mentioned writing to Dr. Phillips in regard to something better for queen candy. I have had no success at all in sending queens to Australia when using candy made with invert sugar, but with short shipments it seems to be all right.

San Jose, Cal., Jan. 9.

J. E. Wing.

There are two or three points in this letter which are of more than ordinary interest. The first is that he as well as Mr. Achord has been shipping bees in pound packages successfully, and with a loss of only one per cent. What Mr. Achord, Mr. Wing, and others have done, others can do.

We show elsewhere that bees without combs can be shipped by express in pound packages for less money than colonies of shipping weight of equivalent capacity can be sent by *freight in car lots*. When we say "equivalent capacity" we figure three pounds of bees as more than equal to three pounds of bees in a colony with a little *sealed* brood. It is not practicable to ship stronger colonies than three pounds by freight, hive, combs, and all, and of course all the *unsealed* brood dies *en route* unless one is unusually successful, as we have been a time or two, by giving the bees water before they ate up their larval food.

Three pounds of fresh bees, placed on

good combs in a good hive, by May 1 will make a fair colony to start in the business. Such a colony ought to be better than 3 lbs. of bees that have suffered the rigors of winter, and possibly may die in a few days. While it is true that wintered-over bees would have brood in various stages to replace those dying, much of that brood is chilled by unfavorable weather. We have had some bad spring dwindling after May 1, and considerable after April 15. Three pounds of fresh bees by May 1 will be able to stand more extremes of weather than wintered-over bees. But suppose the 3 lbs. of bees are not the equivalent of three or four pounds wintered over. It costs anywhere from 60 cts. to \$3.00 in stores, depending on the amount and kind of stores used to bring a colony thru winter.

Understand, we are not at this point advocating that a beekeeper in the North should brimstone his bees in the fall to save the stores; but here is a condition that is not uncommon: Many wintered-over colonies that have a mere handful of bees and a queen, if given fresh bees from the South, will be in shape to gather honey by June 15 when white clover comes on in most localities. Frequently there are oceans of clover, but not the bees to gather the nectar because of a severe winter just preceding.

Mr. Wing brings out another point; namely, that invert sugar as a food for pound packages and for queen-cages does not take the place of honey. Our experience during the past year proves that he is probably right. We had more losses in transmitting our pound packages and our queens in mailing-cages during 1915 when we used invert sugar exclusively than when we used a food made of powdered sugar and *unboiled* honey. A *boiled* honey appears to be inferior to a candy made of invert sugar syrup. It would seem then that in order to make successful shipments of bees and queens long distances we shall have to secure a honey of the finest table quality from a yard where there had been no foul brood for two or three years back.

Our own and Mr. Wing's experience, contrary to that of Mr. Achord's, shows that water during very hot weather helps materially to get combless bees thru in good order.

Mr. Achord has demonstrated beyond question that the old cages for bees in half-pound, one-pound, and two-pound sizes were a little too small. We have already made arrangements to enlarge ours, and shall probably continue to use water during hot weather. It can do no harm, and may be of great assistance.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

It is predicted in European bee journals that the great war will give quite an impetus to beekeeping. Well, I'd rather see the business languish in this country than to have it flourish with that kind of impulse.

It warms one's heart to see a crusade started in the great city of Chicago to save the boys. It costs much less to stop a boy taking the first step in crime and make a good man of him than it does to wait till he is a man and then convict him of murder.

A. I. ROOT asks, p. 81, whether any of the veterans can tell who it was, years ago, that told about a wire-cloth paddle instead of a wooden paddle to knock down an angry bee. Wasn't G. M. Doolittle the guilty party?

A. I. ROOT, p. 83, tells of his "surprise" Christmas present in the way of a bunch of fluffy chicks. I too had a surprise that you'd never guess. In lieu of any other Christmas present, a very dear friend gave me his word that he'd give up entirely the use of tobacco. And I didn't give him a smoker, either.

REPLYING to your question, Mr. Editor, p. 5, I don't know the relative strength of honey and sugar—tried to get a ruling from Washington, but failed. But I've had the idea that a pound of sugar will sweeten more than a pound of honey. I think a syrup of 2½ sugar to 1 water is *about* equal to honey (altho in some respects greatly inferior).

H. SPUEHLER, in *Schweiz. Bztg.*, 24, ventures the guess that foul brood abounds in this country because so much sugar is fed, and that giving an Italian queen help because Italians do not feed sugar. But I doubt whether sugar is fed here as much as in Europe, judging by the pages and pages in German journals occupied with denatured sugar. Then as to Italians, the queens given are not from Italy, but reared in this country, and so are in just as much danger from sugar-feeding as others.

BEER consumed in this country in 1915 amounted to 18.24 gallons per capita. That's the least in 10 years, and 2.3 gallons less than in 1914. It means an average of 2/5 of a pint for every man, woman, and child for every day in the year. But some of us didn't drink our share. The per capita of spirits was 1.25 gallons, the least in 16 years, and .18 of a gallon less than in

1914. Let us hope that the pendulum will continue to swing in the same direction in 1916.

LATELY I saw the statement that there was no need to have a queen a year old before deciding whether she would be good to breed from, for we could tell before she is three months old what kind of layer she will be. That shows that prolificacy was counted the only thing needed—a view held by many. Such people should read Doolittle, p. 10. I don't see how I can estimate a queen's value until she is more than a year old.

THE United Honey-producers' Association, under the leadership of Geo. W. Williams, is quoted on page 46 as saying that some of the old fossils will "open their eyes when they wake up some of these mornings and see the United Honey-producers doing the things that they have been dreaming and talk, talk, talking about for a quarter of a century." Don't be too hard on the "old fossils," George. Some of them did a good bit more than talk—and, by the way, you're doing some talking yourself—they put up quite a lot of good money. Like enough, they would commend to you the word of Ahab to Benhadad, "Let not him that girdeth on his armor boast himself as he that putteth it off." If you will be our Moses, we'll rejoice; but please don't shy stones at any honest effort of the past, even if it didn't have the same success you will have.

"WE consider a good windbreak next to packing," says ye editor, p. 56. I wonder, now—I just wonder—whether that might not be made a little stronger. After studying over it quite a bit, I feel inclined to say that a sufficient windbreak is more important than packing. Set a hive without any packing in a dead calm, with a zero temperature, and another with the best of packing, in the same temperature but with the wind blowing a gale, and I believe the unpacked hive would have the best of it. To be sure, you're not likely to have a windbreak that will make a dead calm, but it's working toward it; and a windbreak of even a few scattered trees makes more difference in the force of the wind than it generally gets credit for. [We felt just as you did; but on thinking it over we thought that, if we came out as strong as you express yourself, the public might think that we were too radical; but if we can have your company, we shall subscribe to all you say.—ED.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

I wonder if any of the readers of GLEANINGS have had any success in securing honey from the hairy vetch. It is a good forage-plant, and said to be an excellent honey-plant as well.

* * *

"Tickling the Palate of a Nation" is a mighty big job as it seems to me, page 34, Jan. 1. But tickling it with honey is certainly better than with the thousand and one artificial compounds now on the market.

* * *

I believe the complaints which E. C. Bird makes of the net-weight law, page 948, Nov. 15, are quite just. It has cost us a great many dollars to grade and stamp our honey this year, without any sufficient advantage to any one to make it pay, so far as I can see.

* * *

Dr. Miller asks, page 5, Jan. 1, why ten days is not just as well to cage a queen to cure a hive of European foul brood as two or three weeks. May be in cases where disease has just started; but I would not advise so short a time where the disease has gotten a good start.

* * *

Grace Allen is thrilled by the marvelous mechanism of the stomach of a bee. There are more wonders all about us than we dream of in our wildest moments. We can never exhaust them; and so the great loving Father would reveal himself to us thru the things he has made.

* * *

Mr. F. R. Bethun informs us, page 994, Dec. 1, that there is in Australia a great demand for honey for army contracts. Slowly but surely honey is being more and more appreciated; and before many years it will come to hold the place in dietetics that belongs to it.

* * *

That "Serious Situation in Florida" seems to me serious indeed, page 1009, Dec. 15. The Florida fruit-growers had about all the trouble before they could well stand up under. It was the last straw that broke the camel's back.

* * *

It was with pleasure that I read P. C. Chadwick's experience with the mud wasps

(page 925, Nov. 15). These wasps here-about seem to lay an egg on the base of the cell before filling with spiders. They prefer those same crab-spiders for their young here as in Kansas. But several years ago the supply of this kind failed; but the wasps were equal to the occasion, and filled their cells with other kinds, little and big, and their larvæ did not suffer.

* * *

That editorial, "The Economy of Honey as a Food," is just splendid, page 1010, Dec. 15. If we had more such illustrations I believe it would add immensely to the popularity of honey. The facts are that honey at present prices is about one of the cheapest energy-producing foods we have, with the exception, perhaps, of potatoes and the grains, and sugar and molasses.

* * *

I fear that the Oklahoma foul-brood law may prove something of a boomerang (page 940, Nov. 15)—it's something to do for an inspector to examine every yard of bees in a state, or for every beekeeper who sells honey, bees, or queens to go before a notary public and swear he has no disease among his bees.

* * *

Mr. Lewis L. Winship, page 1022, Dec. 15, relieves his disgust of home-made hives. But a factory-made hive in the hands of an ignoramus of a beekeeper is a sorry affair, not much better. We used to hear a good deal about making hives "fool-proof;" but I came to the conclusion some time ago that fools were poor material out of which to make beekeepers.

* * *

The index to the 43d volume of GLEANINGS is one of the best we have ever had. It doubles and trebles the value of back numbers, and gives us an amount of information on almost every subject connected with beekeeping that is surprising. When we compare this volume of over 1000 pages with those in the seventies we can readily see how fast we are moving forward.

* * *

"Do Bees Perish during Winter when Their Hives are Completely Covered with Snow for Long Periods of Time?" editorial page 3, Jan. 1. Our experience has been that bees winter at their best out of doors

under such conditions. The facts are, snow is one of the best non-conductors of heat or cold. The hive is wholly protected from the wind, and temperature is quite even. Snow is soon melted around the sides of the hive; and if a colony is fairly strong it comes thru all right.

* * *

That article taken from the *Weekly News Letter*, page 1045, Dec. 15, on sweet clover, is of great value to all interested in the growth of this plant. I am surprised how rapidly the interest in this plant is increasing. I remember well when I first sowed alsike-clover seed, probably the first sown in Vermont, forty-nine years ago this coming spring, and I hoped it might help us out when there was little white clover; and now for the last five years it has saved us from ruin. I believe the sowing of sweet clover in meadow and pasture will prove another help in the right direction.

* * *

J. H. Lovell tells us, page 1040, Dec. 15, that hawkweed was introduced into this country from Europe some fifteen or twenty years ago. May be he is right; but if so, there must have been an earlier introduction, for it has been growing in this vicinity for more than forty years. But that does not make it respectable. It is a bad weed. It not only sends out a host of tiny winged seeds to cover new territory at a distance, but sends out creeping roots to make new plants near by. I know of no way to get rid of it in rough pasture land but to lime and sow to sweet clover, a good growth of which will smother it and furnish a lot of good feed at the same time. (Oh, yes! I remember now—*salt is said to kill it.*)

* * *

There seems to be quite a mix-up of ideas between Dr. Miller and the editor on Grace Allen's question in regard to the amount of sugar syrup to take the place of a given amount of honey for winter stores, Jan. 1. Dr. Miller says, page 3, that $5/7$ of a pound of sugar in syrup will equal a pound of honey. I believe, doctor, you are mistaken. If we add $2/7$ of a pound of water to $5/7$ of a pound of sugar we shall have a syrup that is a little over $28/100$ water, while honey is only $17/100$ water; besides, the bees will consume more or less in storing the syrup in their combs and getting rid of the surplus water. I have found by experiment (weighing) that a colony will not weigh any more two weeks after being fed than the amount of sugar fed them. If fed

thin syrup they will weigh less. Whether a pound of sugar syrup of the same density as honey will go further is another question.

* * *

The death of Henri Fabre seems like the loss of a personal friend. He was one of the most fascinating writers of my acquaintance. Every beekeeper surely ought to read of his painstaking experiments. The history of his early life is as interesting as any story well can be. In one of his books he tells how he began making observations as a child. He had discovered the sun in the heavens, and he wanted to know how he could tell this fact, so he shut his eyes and opened his mouth; then he opened his eyes and shut his mouth, and knew for a certainty that he was able to recognize the sun thru his eyes. "How foolish!" we say; but it was thru just such painstaking, careful observations in later life that he gave us a mass of information about insect life that will enrich the world for all time.

* * *

On page 928, Nov. 15, E. F. Atwater gives his opinion of eight and ten frame hives and following boards. I wish every manufacturer of hives would read what he says, and take it to heart, particularly in regard to eight-frame hives and division-boards. Let me quote: "As the eight-frame hive has room for eight frames and a thin division (not over $2/3$ thick) *it is seriously faulty. That flimsy worthless follower is one of the worst nuisances ever put into a hive.*" (Italics my own.) He says further: "If propolis is at all plentiful the division-board is often broken when being removed, and sooner or later is left out entirely, and the self-spacing feature of the frames destroyed entirely."

Now, that just hits the whole subject squarely on the head. I just wish those who send out such hives had to open them as the inspector has to in the presence of the owner. I never ask who makes their hives; for if I knew I fear I should never think of them just the same again. In the hands of a large majority of beekeepers they are not a movable-comb hive at all, and they no more think of taking the frames out of their hives than they think of taking their heads off when they go to bed. Perhaps I have said enough; but the suggestion of Mr. Atwater is a good one, that, instead of eight frames and a flimsy following-board, better make all ten frame and use but nine frames and a substantial following-board that can be taken out without tearing it to pieces.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The fact that the honey crop was very short in the northern part of the state and shorter than usual in Imperial Valley may have a tendency to explain why our honey market is now well cleaned up.

It was pretty well agreed by inspectors at the "state meet" that the symptoms of all kinds of brood diseases converge until it is a very difficult matter, in many instances, to tell just what the disease may be.

Every beekeeper should send to the United States Department of Agriculture for a bulletin known as Separate 637. It gives some valuable hints on organization, and incidentally tells some very pointed things of the rural producer.

Prospects at this date, Jan. 20, may be said to be exceedingly bright for a honey crop. The late rains have soaked the soil to a considerable depth. Honey-plants are in a thriving condition. We must remember, however, that a dry spring would yet reduce our chances for a honey-flow greatly.

The "Golden" came in for a few more knocks at the State Association meeting, and also received some praise. The prevailing opinion is that golden Italians are not a mixture of races that have been blended to produce color alone, but Italians bred to produce color as well as quality.

The heaviest floods for fifty years, if we are to believe the local press, have just passed (Jan. 20), and the damage has been very heavy by washouts and washaways. A Los Angeles paper is authority for the statement that a thousand colonies of bees were washed down one canyon. This is, perhaps, overestimated; but that there were many colonies washed away by high waters there is no doubt. The government record in some localities reached the proportion of 15 inches in three days. The loss of life will figure close to a score.

At the time the World's Fair exhibit was in the hands of Mr. M. H. Mendleson, he estimated that \$20,000 would be needed to make a creditable exhibit. This was frowned upon by the association as visionary, and they lost no time in queering the

work of the exhibit committee. Now comes Prof. Lynch, who had charge of the small exhibit displayed, most of which was made possible by his own means, who says that Mr. Mendleson's estimate was under rather than over estimated. Prof. Lynch also says that Mr. Mendleson was the man of all men in the beekeeping fraternity to place an exhibit in an artistic manner.

At an early hour on the morning of Dec. 30 I was awakened by a snapping and crashing noise, and was trying to decide just what was causing this unusual disturbance, as it did not cease. I had called to my wife to learn if possible what the disturbance was all about. At that moment the telephone rang long and loud. I immediately suggested fire. My wife bounded for the phone, and I to the outer door. Snow! Well, of all the surprises this was the limit. The immense wide-spreading pepper-trees on the street in front of my home were breaking down under the weight of snow. Such a beautiful and rare sight is not often witnessed in this semi-tropical clime. The whole valley was covered with the "beautiful," while to the south the hills where my bee-ranch is located lay under a full foot of snow. It continued to fall thru the day and night at intervals, and, tho melting some all of the time, it reached a depth of five inches in this city. There was imminent danger of the most destructive frost for years on the following night. The sky was clear and all indications at eight o'clock at night were that there would be a rapid decline in temperature, augmented by the carpet of snow. But nature came to our relief, a new storm moved in from the ocean, and all was saved, for the temperature the following morning had run up to 35. I have some beautiful snow pictures which I might submit to the editors for the use of GLEANINGS, but I am timid on these matters. At the time of the great freeze in 1913 I submitted an "ice picture" to GLEANINGS, with an article describing its destruction. I was liberally criticised by California people for even daring to tell the truth. So it is easy to see why I am timid on this matter—not because it was not all so, but because the Californian is looking for tourists and investors; and any words that might keep a dollar from the state are looked upon as criminal utterances, truth or no truth.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

TAKING OFF HONEY IN MIDWINTER.

Yesterday, Jan. 21, our men went to two of our outyards to take off a load of honey. Who would think of doing such a thing in the very midst of winter? Yet we do precisely such a thing, a practice followed for several years, tried out pretty thoroly now, and without finding any ill effects as a consequence. A year ago there was not a month during which we did not take off surplus honey. The same is true of last year's crop, a good deal of which is still on the hives, while some is in storage. Orders are being filled every week, quite large ones sometimes, and we must have a supply of honey to fill them with.

While we found it a good plan to keep our supers of comb honey, just as they come from the hives, in a warm basement specially heated for the purpose, it requires a good deal of extra effort and expense in double handling and fuel. We also found that, with our comparatively mild winters, it does not do any harm, apparently, to the colonies to keep these supers for us until we need them. Of course, every effort is made earlier in the season to prevent too many supers remaining on any one colony. One or two is the usual number that we believe the colony can keep moderately warm from its cluster below, while more than this might result in the honey in the upper ones granulating sooner or later in the winter months.

When the honey supers are removed from the top of the hive on the moderately warm days in our southern winters there seems to result no actual harm to the colony. The bees usually fly on such days—in fact, are often out hustling pollen, and sometimes even nectar from the scattering sources then at hand, and the disturbance is not serious. Indeed, the writer has, upon two occasions, been along to take off some of the uppermost supers during quite cool weather when the inmates were clustered in the brood-chamber below, and seemed not to be disturbed in the least except from the jarring of the hive.

BETTER FOUL-BROOD INSPECTION.

Professor Pattoek, State Entomologist, College Station, Texas, in charge of the Texas foul-brood-inspection work, has recently made an extensive trip thru southwest Texas, looking into the foul-brood situation at various points. Prof. Pattoek is very enthusiastic about this work for the

beekeepers' interest, and is seeking their earnest support. This should certainly be forthcoming from every beekeeper in Texas.

The question that has arisen among a number of beekeepers that I have come in touch with lately is whether we are really operating under an efficient plan of inspection and eradication work, or whether some better plan might be adopted that would give better results. On account of the great area covered by the state it was found quite difficult indeed to carry out the plan of a single state inspector as in many other states. While this was tried out in the beginning it was soon found advantageous to have a number of deputy inspectors, at least in the greater infected districts. Then the county-inspector system of carrying on the work was adopted, and is the plan under which the work is done at the present time. The county inspectors are recommended by the state entomologist for appointment by the local or county beekeepers' association. The organization of each county where the disease may prevail, and the prompt selection of an inspector, is therefore encouraged. Even counties adjoining those where infestation exists should organize and have a local inspector to guard against any outbreak.

The doubt existing in the minds of a number of well-posted beekeepers is that of a probability of inefficient men finding their way into these positions on account of a certain "pull" or influence they may have in their home county.

Again, it has been asserted that a queen-breeder, supply-dealer, or even an extensive honey-producer, thus using his influence and getting the position as foul-brood inspector, might find it to his interest, on account of the fear that the publicity of the presence of the disease in his locality might hurt his business, to suppress the fact that it does prevail, to the detriment not only of the beekeepers in that county but the industry at large.

In other instances it has been exceedingly difficult to obtain good men for the place because those well qualified could not serve, and the work finally fell upon persons entirely unfit for the position. While there are excellent county inspectors, there have also been some very poor ones; and the question is, "How can we overcome these objections?" From those who are capable of giving proper advice on this subject I should be glad to have suggestions.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

ARE DROUTHS INCREASING?

"I note that you and Dr. Miller have been in the bee and honey business for nearly half a century, so I am led to ask, "What of the future?" It has been very dry here for the past five years, and the secretion of nectar has been so poor that the average for those five years has not been one-fourth what it was during the five years preceding, when we had opportune rains and fair skies intermixed. Do you believe the earth is drying up?"

Profit in any productive industry centers quite largely on the cost of production; and if the crop is cut down by excessive drouth to one-fourth of the average, then the outlook would be dubious provided any great extent of the country were to suffer in that way. From my experience I have found that good honey crops come in connection with abundant rainfalls, interspersed with clear skies and high temperature, and that nectar depends on vigorous plant growth, and successful plant life on abundant moisture and heat.

Prior to 1903 we had six years with scanty precipitation, which gave poor honey yields during all of those years, as well as a scanty growth of crops, and the theme of conversation among the farmers about here was that we had cut off our forests, and ditched our land to such an extent that, whenever it rained, instead of the forests and swamps holding the water, the water entered the drains, ran off in the streams to the lakes, and from the lakes to the ocean. Thus we had killed the goose which laid the golden egg. I must confess that such theorizing sounded so good that nearly every one here in central New York believed it, even when the papers told of floods in other parts of the United States.

Up to June 12 of that year there was not an inch of rainfall in these parts. For days the sun rose and set, looking like a ball of fire, even in mid-day, on account of the haze or smoke in the atmosphere. On June 6 I had occasion to go from Syracuse to Buffalo, and saw fires, set from sparks from the railroad trains, running right out in the standing grass in the meadows, the farmers fighting these fires, trying to save the little grass that had grown. When I saw these fires burning down the alsike and white clover's stunted growth, I had anything but an optimistic view of beekeeping for the future.

But at 1:30 A. M., June 12, 1903, I was awakened by a clap of thunder, and soon the water was pouring in torrents on the roof above me. It rained from then on till noon, when the rainfall measured $3\frac{1}{2}$ inches. To make the story short, the rest of the season was more than usually wet; and as the rain came in time for both basswood and the sowing of buckwheat, we got a very fair crop of honey, even after losing everything from clover.

The next four seasons were wetter than usual in these parts, and so all talk about scant rainfall from cutting off the timber and draining the land ceased.

That the drouth, not only in the time of bloom, but perhaps months previous, has played havoc with our honey-yield is, in all probability, true; but there is water enough still, if it had an equal distribution. The cutting-away of the forests and the construction of drains may have something to do with this unequal distribution, but I doubt if any one knows just why drouth comes to a certain locality one season and not the next. Irrigation would be a remedy, but is too expensive to consider for raising honey alone. During the past summer I found that a drouth for a year or two is not always so detrimental to a good honey-yield as I had formerly supposed. Farmers about here seeded their ground as usual with alsike clover during the springs of 1912, '13, '14. During the springs of these years, in this immediate vicinity there was a drouth just at the time this seed should have sprung up, and there was great wondering why there was little or no alsike clover to grow and bloom during the summers of 1913, '14, and hence very little was sown during 1915. We beekeepers about here knew little what was in store for us until about June 15, 1915. At that time fields began to be pink with alsike bloom, and from June 20 to July 15, hundreds and hundreds of acres were just one sheet of pink alsike, so they could be seen in all directions for miles around. This, with a fair yield from basswood, gave us the largest yield of white honey known in this section since 1877. Nature is wonderful in her ways, and capable of holding seed dormant for years; and when a favorable time comes, she starts all these seeds into life. As to the question, "Do you believe the earth is drying up?" I will leave that to Dr. Miller, as he has lived and kept bees many years longer than I.

GENERAL CORRESPONDENCE

SUNDRY APHORISMS

BY J. E. CRANE

On page 992, Dec. 1, Arthur C. Miller gives us some "Sundry Aphorisms." First he tells us not to have any weak colonies, which is very good advice, particularly in autumn. However, in mid-summer it is often a very decided advantage to divide our colonies so some of them will be weak. He next tells us that bees winter well with him on aster honey, but may die on sugar-syrup stores, and gives as the reason, "Worn-out bees. Handling a lot of sugar syrup, or a lot of thin nectar late in the season (late means when clusters are contracting) puts too much labor on the bees, and ages them, and that late, particularly with old queens." Then he calls on Mr. Crane to sit up and "take notice," which I hereby do. Now, I have fed tons and tons of sugar syrup during the past thirty or forty years, and this is the first intimation that it "ages" bees seriously to feed them any winter stores they may lack "when clusters are contracting." I fail to see why it should age bees seriously to carry down five, ten, or twenty pounds of sugar syrup into their combs, which is usually completed in twenty-four hours. "Particularly with old queens;" why should it wear out bees with an old queen sooner than bees with a young queen? Our genial friend informs us that the remedy is to put in young queens about Aug. 20. Why, bless you, my good friend, the rearing of brood is nearly over by Aug. 20 in this "locality," and the young bees reared after that time would be few in number. But I suppose Mr. Miller wanted to draw me out and tell why I had so many weak colonies a year ago. I will tell; but it was not by feeding sugar syrup after the clusters were contracting, by a long way. It was this way: 1914 was a very poor season, and July 25 found my home yard with little surplus or increase, and even the hives nearly bare of honey, but a good supply of bees. I had several hundred dry combs that I wanted protected from wax-worms. I also wanted some increase. So I disregarded the old advice to keep all colonies strong, and made some 75 new colonies by dividing about the first of August, giving my new colonies young queens, and then fed both old and new colonies daily a thin sugar syrup to promote breeding, expecting to build all up

to good strength before cool weather, when they could be given their winter supply; but August proved quite too cool for such work, and I found what I did not know before, that bees will not build up on sugar syrup as well as on honey. However, it proved a financial success, altho I had to go into winter with more weak colonies than I like.

SHALL THE HIVES BE PUT IN THE ORCHARD?

Another aphorism. If you must keep bees among the fruit-growers, do not put your hives in the orchards, but only near them—say "horse-distance off." Now, I confess I don't just know what a "horse distance" is. Is it the distance you can see a horse distinctly, or hear him whinner? or is it the distance it is safe to hitch a horse from a hive of bees? The dictionary throws little light on the subject, so I conclude it is a pretty considerable way off, more or less. But even with this definition I can not quite agree with my friend, and this is why:

While attending the annual meeting of the Vermont Horticultural Society recently I learned of an extensive fruit-grower who, without any regard to the advice of our friend to set bees a "horse distance" away, has actually had the presumption to take hives of bees right into his orchard, scattering them around here and there, one in a place, with the result that in seasons when, during fruit-bloom, it was cold and cloudy, the three or four trees close to a hive of bees were much more fruitful than those further away—a very important consideration, especially as we are apt to have a great deal of such weather in northern New England at this season of the year.

And, again, he says, "If fruit-growers practice spraying while trees or cover crops are in bloom they should know what will happen. No bees will be kept near them, and all the wild bees will be killed off." Not quite so fast, my friend. While we know that spraying at times does kill bees, it also appears to be a fact that at other times it does not. Would it not be well to look into the subject carefully before we condemn *all* spraying of fruit-trees when in bloom?

Middlebury, Vt.

A CONTRACT BETWEEN FRUIT-GROWER AND BEEKEEPER

BY GEORGE H. WEST

Here is my form of contract for placing and keeping bees in an apple-orchard for pollination purposes. I think it may interest many of your readers.

This agreement, made in duplicate, and entered into this 21st day of July, A.D. 1913, by and between George H. West and Wm. H. Bartleson, both of El Paso County, Colorado, *witnesseth*,

That said West is the owner of the SE quarter of the NW quarter of Sec. 32, town 21 south, range 58 west, being 40 acres of land in Crowley County, Colorado, planted mainly to apple orchard, now in bearing, but some 10 acres being in alfalfa, and is desirous of having his fruit-blossoms properly pollinated each year; and that said Bartleson owns some 90 hives of honeybees, and desires to secure a location for them where they may have proper range for pollen and honey:

Now this agreement is hereby entered into by and between the said parties for their mutual benefit *to wit*: Said West agrees to lease to said Bartleson for the term of ten (10) years, unless sooner terminated, as

hereafter stated, a tract of land about 78 feet by 142 feet, located on said 40 acres, and near the southeast corner thereof, for the annual rental of one dollar (\$1.00) per year, where said Bartleson agrees to locate and keep his bees, with the privilege of erecting such buildings as he may require for his uses in said business, with the right to remove his said bees, buildings, and improvement from said tract at the termination of this lease. The number of hives of bees on said tract shall not be restricted, except there must not be at any time less than eighty (80) hives of bees during the blooming period each season. And said Bartleson agrees to the above terms, and is to move all said hives of bees to this specified tract, and is to keep them there during his lease, and to pay said rental annually.

It is further mutually agreed between the parties hereto, that if said West should sell this land, or if said Bartleson should sell all his bees, such action will terminate this lease; otherwise it may be renewed, upon the same terms, upon its expiration.

GEORGE H. WEST,
WM. H. BARTLESON.

PUZZLES; THE CURSE OF GOLDENS

BY ARTHUR C. MILLER

Bees are contrary little cusses, with apologies to Mr. Crane. They persistently prove that what we *know* we know about them isn't so.

On August 8, to a nucleus from which I had a few moments before removed the queen and all brood, I gave a frame of brood of all ages from the egg to six days sealed. That was at 11 A. M. At 4 P. M. on August 10 there were two *sealed* queen-cells on that comb. There were no queen-cells or cups on the comb when it was given. On opening those cells the grubs were found spinning their cocoons, and had them perhaps one-eighth done. Do or do not bees select grubs too old to make good queens?

Perhaps Dr. Miller can tell. To make more clear the foregoing case I will explain that the brood came from a thrifty colony with a fine young queen which had been laying less than a month, and it was given to the nucleus with the bees adhering to it. Why such proceedings on my part? Well, the queen and brood was given to a colony I was making up. And the bees were left on the brood given to the nucleus because it was easier than shaking them off, and also

I was willing to strengthen the nucleus a little, as I was to give it a cell in a few days.

Case 2. Comb of bees and brood with two unsealed queen-cells was given to a nucleus which had a virgin four days old. The queen-cells were completed, four others well under way, and the virgin very much alive, when the matter was discovered three days after the combination had been made. Failure to notice the record was the cause of the combination. What is the explanation?

Case 3. A fair colony with a fine thrifty queen four weeks in it. First two combs, at back, honey; second two, beautiful worker combs almost full of sealed drone brood, a few cells with larvæ, and some with a single egg each. Next comb about half worker and half drone brood all in worker comb. (Just there a veteran inspector said, "Drone-laying queen.") Next comb, a perfect sheet of worker brood with workers emerging. Then he changed his mind. Rest of combs, beautiful worker brood; jolly nice mess that would be for a novice to bump into and try to have explained,

wouldn't it? The new queen had been laying for a week or ten days before the laying workers started in, and they kept to the back part of the hive. (Combs are parallel to entrance.)

Some one will want to know how I treated such a case. I didn't. I just left it to the bees. As the drones hatched, the workers threw them out and the queen occupied the comb. The laying workers die or quit laying after a time, a few are still there, but the colony is booming along; so, why worry?

What is the cause of such a combination? I'll tell you in two words—"Golden Italians." The Golden bees are a curse to the industry. They are no more Italians than an Ethiopian is a Caucasian. The claim that they were developed from Italians by selection is a grievous error. I have seen them from many breeders, and had a great many strains of them myself; but I have never seen one that did not bear the birthmark of the Eastern races—not only the birthmark, but the accursed treacherous temper of the Eastern bees.

Prejudiced, am I? I used to think very well of the Cyprian bee, but I changed my mind. So completely am I weaned from any love for "Golden" bees that not only will I not have them myself, but I am trying to get rid of any trace of "yellow" blood in every yard I inspect. But true pure "leather" Italians are extinct, so far as I can find, so I am taking the best I can get, and am trying to breed out the yellow trace.

Have you noticed the increasing number of reports of cross bees and of the trouble beekeepers are having with outsiders? The trouble has been growing ever since the introduction of the Eastern bees and the cult of the "beautiful yellow queens."

Case 4 will illustrate their bad temper, and a phase of it beyond my ability to explain. An apiary of about 30 colonies of "Golden Italians," wonderfully gentle, good workers and prolific, a desirable strain from a friend of long experience, and se-

lected from a couple of hundred colonies. Six colonies were sold, two each to men who came and picked what they wanted, and the two gentlest colonies were sold to a woman. All were beginners. The original yard was six miles from the nearest lot of the sold bees, and each was about six to eight miles from each other. All queens were clipped. That was in 1909. In 1910 the bees of every single colony of that stock in each of the four yards were uglier than yellow hornets, not at one time, but all the time from spring to fall. The same was true in 1911, even tho some of the queens had been superseded. In 1912 most of the colonies had been requeened with new stock; but wherever any trace of the old blood remained, uncontrollable temper was met with. One of the colonies owned by the woman retained its ugliness thru 1913 and 1914. In August, 1914, I went into that stock and there was the original clipped queen—six years old. It seemed a shame to kill a queen of such long-lived stock and so vigorous, for the combs were full of brood; but the bees were always looking for trouble; and when they couldn't find it they made it. For three years that colony was not touched by me, and I always dreaded it, and always got an awful stinging. And, by the way, some of that queen's bees lived until May of this year.

Will some one explain why gentle stock and gentle bees of individual queens went bad and stayed bad? If it was a case of supersedure and new matings, the answer would be simple; but it was the bees of the original queens all gentle one year, all ugly forever after.

Does some one say bad handling? Well, I handled the original yard and helped on the others, and I am no spring chicken in the bee business.

Bees are contrary—ah! Mr. Crane objects to my saying "little cusses" (a "cuss" equals a "customer"), so I will use an old New England phrase and say that they are "contrary little critters."

Providence, R. I.

FROM FOUR TO ONE HUNDRED COLONIES

BY CURD WALKER

Seventeen years ago, about one year before I ever saw GLEANINGS, I bought my first bees. They were in a box hive nearly three feet long, and split open on one side. It contained a good colony of black bees, however, and later on that same spring I bought three more colonies, one in a round

gum and two in home-made patent traps in very bad condition. That year I got two swarms, but the moths killed one of them before winter.

The next year I began to get acquainted with Mr. C. H. W. Weber, of Cincinnati, who sent me my first queen-bee of the Ital-

Apiary and queen-rearing yard of Curd Walker, Jellico, Tenn.

ian stock. I lost this one, but soon got another and succeeded with it, then I got started with an outfit of five hives from Mr. J. M. Jenkins, of Wetumpka, Ala., which I got for about \$6.00 for the five eight-frame hives. They never gave me satisfaction. I made a few hives that were worse still, so I tried the Danzenbaker, a few at first, and liked them well for the production of honey, either comb or extracted, as I could use the body and one super for the queen to occupy. But for the last few years I have bought nothing but the ten-frame Langstroth, as it is the Ideal hive for my work in handling frames. I have now 100

colonies of fine Italian bees in up-to-date hives with 200 queen nuclei. I did over \$1100 worth of business in 1914, with a clear profit of over \$700.

We have seven girls and two boys in our family. We are all big honey-eaters, and we have not had to have a doctor in fifteen years. We often eat nearly 60 lbs. of honey in a month when we don't have molasses. We can give the best record of health of any family in this part of the country. I used to think I had bad lung trouble, but when I began to follow Terry it disappeared soon.

Jellico, Tenn.

PROOF THAT BEES FLY LONG DISTANCES IN CALIFORNIA

BY P. C. CHADWICK

I have scarcely recovered from my surprise after reading the editorial on page 965, Dec. 1, endorsing the article of Mr. F. M. Baldwin on the distance bees will fly in quest of stores. It is utterly impossible for me to conceive the idea that a perfectly healthy bee would not go five miles for honey if necessary, and even up to ten, on special occasions. If Mr. Baldwin's bees will not go one mile for nectar I am convinced there must be something wrong with his strain of bees. If it were really true that a bee would not go more than a mile and a half for nectar, the bee business in California would be much less profitable than at present, and in many instances could not be maintained on a paying basis. There are so many instances to my personal knowledge where from three to five miles are covered, the idea of only one and a half miles of flight being common seems utterly absurd. I have never thought for a moment that a bee is led by the sight of flora, and cannot yet believe that such is the case.

The editor has knowledge of the location of my Tremont yard, and its distance from the orange-groves, for he has stood on the edge of the canyon and looked far away to the foot-hills where it is located. The distance to the nearest orange-trees is three miles, and it is necessary for the bees to penetrate the groves to some extent to get at the nectar quickly, yet this apiary gathers annually just as much honey from the orange as do those nearly two miles closer.

A few years ago we had a very dry season, wild flora being at a low ebb, and very little chance for a bee to secure a load of nectar from any near source out in the foot-hill region. The apiary of Mr. E. D. Bullock was at that time located down in the "bad lands" district, between San Ti-

mateo and the Moreno Valley, and was a good seven miles from the orange district, yet his bees went to the orange-groves for honey.

This season at Tustin, Cal., an apiary of Mr. Geo. J. Brown was a distance of five miles from the nearest sage, and that only a fringe, it being seven miles to any sage of consequence, yet some colonies in this yard stored as much as sixty pounds of sage honey. There is absolutely no chance for any mistake in this conclusion—first, for the reason that the honey secured was undoubtedly from the sage; and, second, the fact that there was nothing at that time from which bees could secure honey out in the level valley, which is devoted to the culture of walnuts, oranges, lemons, and beans, none of which were in bloom at that time. In the case of the flight from the apiary of Mr. Bullock there was positively no chance for the bees to see the flora until several miles from their hives.

Some years ago my uncle, J. K. Williamson, had an apiary in Appleby Canyon, which is located several miles from the bluecurl fields near the city of Beaumont; yet morning after morning have I watched his bees line out for the bluecurl fields to the northeast, which is the direction of these fields from their location. This source was figured on as a great asset for the stimulating of breeding late in the fall, and while not a heavy producing source shows that even a light flow will take the bee miles to his work. To those who know Appleby at the point of the location of this apiary it will be plainly apparent that the flora could not be observed before they had traveled a distance of more than a mile, and had made an elevation of several hundred feet up out of this canyon.

The beekeeper of the East does not have the chance to observe the long distances of flight which we have here in the West, and I can look back now upon the misgivings I had years ago about where my bees were securing nectar in quantities, and point to the very source from which they were gathering, altho at that time I did not think it possible for a bee to fly the distance.

Mr. Baldwin sets some very convincing observations before us, all of which seem irrefutable; yet if such is the case with him I would surely try another strain of bees, for I cannot believe the average bee would not go two or three miles almost as quickly as one.

As to the theory of the flight of bees depending on the distance they can see the flora, I have no faith in the idea, but believe the scent of nectar has far more to do with locating of profitable fields than the sight. As a matter of fact, a bee when not loaded can fly several miles at a speed that would make an automobile exceed the speed limit if following her, and to take a little trip across country to search for nectar would hardly be classed as a laborious task. It is a well-known fact that, when one bee finds a source from which a load can be secured quickly, it is soon made known to others of the hive. The line of flight is followed by other colonies as the excitement is increased, until the entire apiary is in a wild rush for the source from which the goods are being secured. I should not be at all surprised if the crossing of the flight of other bees nearer the source has not often led to the directing of the forces of a distant apiary to the new fields. The fact that the distance a bee will fly is generally underestimated is proof that the source

This illustration shows an elm-tree which stands very near Washington's tomb at Mount Vernon. On one of the main limbs of the tree will be noticed a peculiar growth which contained a colony of bees last spring.

IRVING W. DAVIS, New Haven, Ct.

from which honey is gathered is indeed far too often misjudged.

Redlands, Cal.

[In an editorial Dec. 1, p. 965, and elsewhere in our columns for several years back, we have stated that bees as a rule in mountainous or hilly country, especially if the apiary is located on high ground overlooking a big valley, will fly much further than in territory where the ground is level, and more or less thickly wooded. This alone would explain the difference between Mr. Chadwick's observations and those of Mr. Baldwin. But it occurs to us that there are other factors to be considered. When there is absolutely no nectar which the bees can gather less than three and five miles away, it is not an uncommon thing for them to fly that far. But they do not always do

so. There are dozens and dozens of recorded instances of where bees in one yard will be on the verge of starvation when there is good bee-pasturage $1\frac{1}{2}$ miles away.

In Mr. Alexander's location at Delanson, N. Y., the bees flew five miles at times, and, on account of this, it was possible for their owner to maintain 700 colonies all in one location. Buckwheat and goldenrod, which were abundant some falls, would furnish nectar the fore part of the day, and later the bees would clean up the territory within a mile, and then apparently they would keep going further and further in making a clean-up as they went until they would reach out as far as five miles. It would be perfectly natural for them to keep going further and further as long as they could find nectar. We had a very marked case of this at our Hudson apiary two years ago.

There is still another factor to be considered. If bees can gather a liberal supply of honey within $\frac{3}{4}$ of a mile from the home

yard, and that supply keeps up, they will not go further than that. In fact, we know of instances where they would go no further than a thousand feet because there were not bees enough to clean up the range in that distance.

The conditions in and about Mr. Chadwick's home are favorable for long-distance flight, and the same is true at Delanson, N. Y., and other hilly and mountainous parts of the country, and the bees kept on further and further to get a fresh supply. A favorable breeze would carry the aroma of those orange groves right over those bees, and, of course, they would keep on till they found its source.

Whether bees have long-distance vision, probably cannot be definitely proven. Possibly they are governed more by scent, which in the bee is highly developed. If that is the case, favoring winds would have something to do with the length of the flight.—ED.]

HIGHER PRICES AND A BETTER DEMAND FOR HONEY

A Scheme to Raise Money for Advertising

BY WALTER S. POWDER

I seldom contribute to the columns of GLEANINGS, and yet I never pick up a copy without a desire to respond to some of the communications, and occasionally I cannot refrain longer and send in an article. I know that I lack talent and ability; but I can sweep, carry out ashes, and can even cook a steak to perfection. I live in the Hoosier State, where the very atmosphere has brought forth noted writers—right at the home of James Whiteomb Riley—but "Our Jim" is now down in Florida while I am here in the blizzards, and I think that has something to do with my delinquencies. My little contributions have never been snubbed or ignored by the editors; and when I send in an article I look forward to its appearance thinking that I am going to stir up a hornet's nest, and that the contributors higher up will all take off their hats and boost my article! Alas! no one pays any attention to my articles except a very few who write me direct; but none of them have asked me to step out and fight, and I guess I still have something for which to be thankful. I am content to find my name in the annual index.

Well, I have an idea that I believe will interest every beekeeper. Much has been said about boosting honey as to both the price and the demand, and I believe I have

a solution. Two or three things have stimulated my idea lately, one being how citric-fruit growers have created a demand for their goods by advertising, and the pineapple industry is following the same course. Evidently it is a success, otherwise their advertising would not continue. Did you ever watch a garbage-wagon going thru an alley? I did, and what do you think I saw? An awful lot of empty karo-cans, evidently sold by advertising; and just suppose those cans had been empty honey-cans! Would not we be a-flying? It takes money to advertise, and no feasible solution has ever been offered, but I know of one. I would have the National issue stamps, beautifully lithographed in two or more colors, gummed and perforated, and the same size of our postage stamps, or, perhaps, more like our Red Cross stamps. They could be offered by the National and associations, and publishers and supply-dealers would gladly act as agents. They would be used on the backs of letters, and thousands of beekeepers would be glad to use them, even tho they were not members of any association nor even reading a bee publication. They could be sold at any fixed price, say one dollar per hundred, or may be fifty cents per hundred. The money thus brought in could be used by a committee in judi-

David Running's home yard at Filion, Mich., from which over 10,000 lbs. of honey was harvested last season.

cious advertising. The stamps should be beautifully engraved, and the first thing one thinks of is a clover-head with a bee. Some other flowers would engrave nicer than a clover-head, and the flower need not necessarily be a honey-producer. I would suggest a calla lily, or lily-of-the-valley, and I would have a very little reading-matter—say, for instance, “Eat Honey” at the top of the stamp, and the initials of the National at the bottom. The stamp fad is a fad

everywhere now, especially if the stamp is artistic, and I found a lot of pleasure in using a lot of Red Cross seals, and find that other people are inclined the same way. I have explicit faith in this if tried out, and it would not cost a great deal to try it. We shall not know till we try, like the man who could not distinguish his mushrooms from toadstools. “Eat them; if you live they were mushrooms; but if you die they were toadstools,” said he.

Indianapolis, Ind.

NO SWARMS EXCEPT FROM OCCASIONAL SUPERSEDURE COLONIES

BY DAVID RUNNING

Our home apiary, as shown in the illustrations, gave us last season a surplus of 9972 lbs. besides what we ate and gave away, which would make the total surplus considerably more than 10,000 lbs. We try to see that all colonies are headed with good queens in July or early August. All colonies are fed up for winter between Sept. 20 and Oct. 1, and we make sure that each colony has an abundance of stores to last until fruit-bloom the spring following. I consider this important in this northern locality.

Our bees are all wintered in the cellar, and are put in about Nov. 20, depending somewhat on weather conditions at that time. Our winter loss is usually less than one per cent. We take them out the latter part of March or early April—this, too, depending somewhat on the weather.

We take the hives out at night and close

all entrances down to about $\frac{3}{8}$ by 3 inches so the bees will fly slowly when the weather warms up. We do not open any hives till fruit-bloom, as we have made sure the fall previous that all colonies have plenty of stores to last until that time, and we do not want covers loosened to allow the heat to escape. During fruit-bloom all queens are clipped, and such other manipulations as are deemed necessary are attended to, such as equalizing stores, etc.

We use the eight-frame hive entirely; and as soon as more room is needed an extra body of drawn combs is given on top without queen-excluder. About a week or ten days later the queen is shaken down into the lower story, a queen-excluder put on, a super of drawn combs is added, and what was formerly the upper story is placed on top again, making the colony three stories high. At this time our clover flow

is usually on. A week later all queen-cells are cut from the upper story; the bees from the brood-nest are now shaken on either foundation or drawn combs (if on foundation one comb is placed in the center to catch pollen and eggs), queen-excluder replaced, and, if needed, another super of empty combs added: upper stories are replaced on top, and what was the brood-nest (eight combs of brood just shaken) is placed on top of the entire hive, making the colony four or five stories high.

If more supers are needed later, they are added just above the queen-excluder, but no further attention is paid to the brood-nest unless they have been marked for requeening. Our surplus is entirely from clover; and as we have a stock of about 12,000

The brood-chamber is finally placed above the supers—a part of the plan to prevent swarming.

drawn combs we do not do any extracting until the flow is over, when all honey is taken off with bee-escapes and extracted. We work six yards, and do not have any swarms excepting occasional supersedure colonies.

The one picture showing people standing among bees is a view of this same apiary taken at a field meeting before all the crowd had arrived. Notice the school in the background; also notice the dandelions in bloom in the yard, and feeders on some colonies. Altho there was an abundance of dandelion bloom last spring, the weather was so cold the bees could not work it.

Filion, Mich.

Mr. Running's apiary, taken just as the crowd was gathering for a field meeting.

FOURTEEN DOLLARS' WORTH OF SUGAR EVERY THREE DAYS, AND RAIN BETWEEN SPELLS

BY S. H. BURTON

The season of 1915 in Southern Indiana was the worst known for several years. I have been keeping bees for seven years; and while this is not long compared to others, still I have never seen a season that was so full of promises and disappointments as the one just past. Bees came out of their winter quarters in fine shape for

the season of 1914, having been a banner honey year with us, so that the hives were full of stores to carry them thru. (These stores were principally aster; but I have never observed any bad effects from bees wintering on aster honey.)

With the opening of spring the bees bred up rapidly; and after fruit-bloom it looked

as if every hive in the yard was full of bees to overflowing, and we were going to have a case of wholesale swarming. Then it began to rain. The bees loafed, and consumed what little stores they had left, and began a hand-to-mouth existence. In two weeks brood-rearing had stopped altogether, and they were in a starving condition. By May 1 it was apparent that we would have to feed to pull the colonies thru till yellow poplar bloomed about June 1.

With the blooming of poplar the bees worked with a vim; but it seemed as if they gathered very little honey, as the continuous rains washed the nectar out or thinned it up so that it was of very little value. After poplar bloomed we then expected the bees to hold their own from white clover, which was just beginning to show on lawns and meadows. The excessive rains brought the blossoms out with a rush, and the beekeeper again smiled with the anticipation of a white-honey harvest. But tho the bees worked vigorously on the blossoms I guess they did so from force of habit, or to keep from getting the blues, as no honey could be found in the hives.

By July 1 the colonies began to dwindle rapidly; and in place of spring dwindling we had a genuine case of *summer dwindling*. Ever hear of that before? July 4 was spent at the various outyards examining colonies and deciding what was best to do under the circumstances. The cornfields were full of heartsease and bluevine, our mainstay last year at this time, and we thought conditions would surely get better soon. We made several trips to the bottom cornfields to see if we could discover any bees working on the blossoms, but failed to find a single bee, and came to the conclusion that all colonies, even the wild bees in the woods, were in as bad shape as ours. We waited a week longer, and then took a look. The bees were too weak to fly, and were clustered outside of the hives in great bunches, as if preparing to swarm. We brushed them off by the handful. They barely had strength enough to crawl. We rushed to town, and throwing a couple of 100-lb. bags of sugar in the back seat of the auto we stopped at the home yard long enough to load up what feeders were in stock, grabbed a huge granite pitcher, a

A progressive orchardist makes sure of perfect pollination. In case the weather is cold during the blossoming period it pays, and pays big, to have the colonies distributed about the orchard, especially if it is a large one. The cover picture shows a corner of this same orchard.

couple of large milk-buckets, and we were on the road to "rescue the perishing." It was apparent that the feeders would not work, or the bees, rather, as they were too weak to crawl to the feeders. What was to be done with these starving creatures in the middle of the summer, with the temperature around 60 F. to save them? We poured the syrup on the empty combs, and shook the bees on to them. This scheme worked fine, and the bees began to take up the syrup rapidly. We filled every comb in every hive, closed up the hives, and went on our way, rejoicing that we had saved our pets from starvation.

Three days later we again examined the hives, and not a drop of syrup was to be seen. This looked expensive. Could we afford it? Fourteen dollars' worth of sugar every three days, and rain between spells! We figured that every cloud has a silver lining; and if we could save the bees they surely would repay us next year. As the San Jose scale is said to be a blessing in disguise to fruit-growers, so this bee-famine is probably a blessing to the up-to-date bee-keeper in that it eliminates the box hive and cleans up a lot of foul brood and weak colonies that were a menace to the beekeeping fraternity.

Fall came, and with it an early frost which ruined the prospect for a flow from goldenrod and aster. Feed we would, and feed we must, even if it cost us \$5.00 per colony. This would be cheap for good strong colonies next spring. We began a systematic gathering-in to the home yard of every colony scattered throughout our numerous outyards for the convenience of preparing them for winter. Weak colonies were given special attention; and if large enough to fill a quart measure they were

not united; but every comb was filled with extracted honey or good thick sugar syrup; and they were packed away snugly for winter. I do not believe it pays to unite weak colonies in the fall, as it is but a short time till the colony united is no larger or stronger than it was before you added the other colony to it.

The law of the survival of the fittest was amply exemplified during the past season. A few colonies seemed determined to live and sting, and gather *some* stores in spite of adversity. Occasionally in our examinations we would find a colony with its accustomed vigor and a slight amount of stores, and even some brood when things seemed to be going backward rapidly in most of the hives. Most assuredly these colonies were marked, and in the future we shall breed from them in preference to the colonies that were too weak to take the feed offered it. We have also learned that the goldens are absolutely worthless in a season like the past; and we pinched the head of every golden in our yards when we were feeding and preparing for winter. We have learned that a cross between the Italian and gray Caucasian makes a hustler worth trying to. We divided a colony of Caucasians early in June, putting in some brood from the parent hive with a few combs of Italian for a start. This hive was placed in an all-Italian yard where the virgin would be sure to cross with an Italian drone. This hybrid queen bred up very rapidly, and at the close this colony had more stores and bees than any other colony in the yard.

We have a storehouse full of empty sections, plenty of foundation, supers, and empty hives, eating southern extracted honey, and have abundant hopes for the future.

Washington, Ind.

COMBS OF HONEY IN A PACKED SUPER

BY L. S. EDISON

In the illustration on next page a novel and effectual scheme for wintering is pictured. It is adapted to double-walled or single-walled hives where a telescope cover is used. A regular super for five-inch-high sections is best.

The inner boxes or trays are made of thin boards from orange-boxes with $\frac{3}{8}$ -inch ends, and filled with ground cork. They fit flush with the top of the super. Between

them will be seen two section-holders and two shallow frames. They contain unfinished sections and combs of honey which insure the colony plenty of stores and room for the first light flow from flowers and fruit bloom. In the eight-frame super the space admits only one section-holder and two frames.

Over this is placed a super cover with screen tacked on the escape space, and then

half a dozen thicknesses of burlap as wide as the super, and long enough to reach well over the ends. This makes a cheap and very warm as well as ventilated winter case.

It takes care of the unsalable honey, and gives the bees No. 1 stores. Their natural home in the rotten, lined, hollow tree could serve them no better.

Des Moines, Ia.

SOME NEW EXPERIENCES IN BEEKEEPING

BY GARDNER B. WILLIS

Two years ago I had a colony that had two queens in October. I saw both at the same time, and all was quiet and peaceful in the hive. I left the bees alone for them to choose the queen they wished to keep.

MOTH LARVÆ.

Last summer, in a nucleus I observed some young bees still in the cells, and alive after their heads had come thru. The next day they were still there. I took a tooth-

pick and removed one, when, to my surprise, a small white worm came from its abdomen. About eighteen were like this, either a small white worm about half an inch long in the abdomen, or in the bottom of the cell. I removed all the bees in the cells that were like this, and have seen nothing like it since.*

DRONES IN WINTER.

I have a hive in my back yard that has at least 75 drones in it. One warm day early in December I observed drones going and coming from this hive. My first thought was that the hive was queenless. I unpacked it and looked it all thru, but there was the queen with one wing that I clipped last summer. I know the colony is all right, altho it has all these drones.

The only way I can account for this, and yet I don't see how it can mean anything, is that I took these frames and bees from a fourteen-frame hive used for queen-rearing, and this was done before the frost came. There has been no excluder or separator in the hive since the change was made. But there were the drones and the queen, and a good strong colony of bees with plenty of stores.

SMOKE METHOD OF INTRODUCING.

Much has been written about introducing queens. The smoke method has been hit often and hard; but from my experience it has seldom if ever failed. I starve the queen for half an hour, and then introduce by the method advocated by Arthur C. Miller.

One day last summer I found a black queen in one of my queen-rearing hives in the backyard. The bees had balled her; and when I came to the rescue, there she was, a black queen. Where she came from I did not know. On the other side of the division zinc was the queen that belonged to the hive.

Another experience I must mention. I introduced a queen; and, looking at the nucleus two days later from which she was taken, there she was, where she was before, and laying. The hive to which she had

Unfinished sections for extra winter stores in a packed super.

* We have seen the same thing. Probably not the wax worm, but the larvæ of some fly.—ED.

A branch of a Northern Spy apple-tree covered with mosquito-bar during the blossoming period to keep the bees away. There were 876 blossoms on this one branch. The rest of the tree bore a normal crop. There were just five apples on this branch, and three of these dropped before becoming ripe. The bees are necessary for pollination of the blossoms.

been introduced was opened soon after, and no queen could be found. It is reasonable to suppose that she came out, or was dragged out, and found her way back to her nucleus.

There is a man out in the country who has several box hives of blacks. He sells prime swarms to me for 50 cents apiece.

I furnish hives and frames. He hives them. He is well satisfied, and so am I. The blacks are requeened with Italians. He says there is more money selling prime swarms than raising honey. He says the box hives are good enough for him, and less trouble.

Providence, R. I.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sightings Among the Bees

BY H. H. ROOT

The experiment of covering a branch of a fruit-tree with mosquito-bar while it is in blossom in order to show the loss in fruit by keeping bees and other insects away during the blossoming period is not new. Experiment stations and individuals have before proved the value of the bees in this way. A couple of years ago a similar experiment (?) was tried with rather astounding results. One of the suburban magazines under "Practical Hints" gravely published an illustrated article from a contributor who said that he had found that draping his young fruit-trees with mosquito-bar during blossoming-time kept the bugs from *biting the blossoms* and otherwise destroying them! This writer was evidently so blinded by the anticipated vision of the al-

mighty dollar or two that he would receive for his contribution that he did not notice that what he wrote was fiction rather than fact. We wrote the publishers a letter of explanation, and they published our letter in full without comment, no doubt being too full for utterance. The picture which they had printed was very much like the one shown herewith except that the tree was smaller, and all of it was tied up with the mosquito-bar.

Last spring, simply for our own satisfaction, we covered one of the branches of a Northern Spy apple-tree with a bee-tent, tying strings closely around the branch so as to make a sort of bag, enclosing the whole branch. This was just before the blossoms had fully opened. Just before tying on the

mosquito-bar we counted the blossoms on the limb and found that there were just 876.

The branch was left covered until all of the blossoms had fallen. All the other branches on the tree, as might be expected in case of a Northern Spy tree, bore a good crop. When we removed the mosquito-bar we counted the apples on this one branch, but it did not take as long as it did to count the blossoms, for there were just five. Later on, three of these fell off before they became ripe. From the 876 blossoms, therefore, we secured but two good apples.

The wind plays a part in distributing the pollen and fertilizing the blossoms, and no doubt the circulation of air within the bag was not quite as brisk as that outside, and yet grains of pollen are almost microscopic in size; and if the wind had a very important part in the pollenization of blossoms it surely seems more than five of these should have set fruit, for the open-mesh mosquito-bar would not amount to much of an obstruction to the passage of the pollen, espe-

cially since the tree in question was on the southwest corner of the orchard, and the covered branch on the south side of the tree.

It seems to us that no one should question the value of bees and other insects in pollenizing fruit-blossoms. Since there are usually ten or more bees to one other kind of insect, may we not claim that the bees are largely responsible for the distribution of the pollen?

If there are enough bees in the locality, each orchard need not necessarily have bees; and yet, if the weather happens to be cold during the blossoming period, the bees will not go as far from their hive as usual, and consequently the pollenization is not complete by any means. The largest fruit-growers are well aware of this, as evidenced by the determined effort on their part to get the bees. No beekeeper need pay rent for a location if there are progressive orchardists in his vicinity who know the value of the bees.

WINTERING OVER EMPTY COMBS

BY T. RAYMENT

This practice is not at all uncommon in Australia, where some of the largest honey-producers consider that the proper place for combs at all times of the year is on the hives. Of course, one is constrained to admit that the rigorous winters of the northern states of America are not encountered in the great sunny commonwealth, tho the climatic changes experienced in Australia are probably just as detrimental to life—that of insects in particular. The thin-blooded creatures of the tropics painfully endure a degree of cold that would be quite unnoticed by the inhabitants of the colder zones.

In those seasons when a severe winter threatens, it is no great stunt to forecast such a contingency in North Gippsland, Victoria. It is better to remove all surplus honeycombs from the hive. This procedure is not primarily to reduce the size of the hive, but to obviate any subsequent food trouble due to the honey absorbing excessive moisture from the atmosphere. Generally, however, it is quite safe to place a body of *empty* combs under a well-stored brood-nest.

The writer has in mind a certain autumn when the wax-moths were exceptionally troublesome; and to minimize labor two supers of dry combs were placed under each brood-nest, without any apparent det-

eriment to the welfare of the bees. To illustrate the conditions that exist in hives so treated, let us take, for analogy, an ordinary living-room. As the temperature outside drops down with the advance of evening, if we successively rise to higher levels

Super larger than the brood-chamber, and with combs crosswise of those below.

inside the room we should be able to maintain an equable warmth without much difficulty, since the warmest portion of the room is next to the ceiling.

Empty combs under the brood-nest may be left for winter in sunny Australia with perfect impunity. That the same scheme will be uniformly successful in the United States with a greater diversity of weather is debatable. In a recent issue of the *American Bee Journal* I dealt with the eight-frame hive and empty combs from a standpoint not altogether dissociated from the above subject. In the same issue Samuel Cox states, "It is almost impossible to do successful beekeeping with eight-frame hives." Gosh! Samuel, you're an intrepid man to father such a sweeping statement. Your humble servant harvested an average of 360 pounds of extracted honey per eight-frame hive in 1912 in an apiary of 150 colonies. Now I want to ask you, Mr. Editor, how much, over and above that amount, would ten-frames have yielded? But perhaps you had better look up the *American*

Bee Journal to absorb my ideas of what constitutes an eight-frame hive. No, Mr. Cox, a man who can make a success of apiculture with ten frames can repeat the trick with eight, twelve, or fourteen, divisible or reversible, Long Idea, or any other pattern.

However, I appear to have got on to a side line. What I wanted to do was to direct attention to the method of amalgamating, if it is permissible so to describe it—two sizes of bodies into one whole. Mr. E. Garrett, one of the pioneer apiarists of Australia, and a neighbor of mine, uses a super considerably larger than the brood-chamber. In the drawing I have endeavored to illustrate his method of adaptation, which may be used with any odd-sized bodies. It will be noticed that the scheme permits the combs of the super to cross those of the brood-nest at right angles, which is quite a desideratum. The "overhang" of the super is closed underneath by two slats, 3 x 20 x 1/2 inch.

Briagalong, Victoria, Australia.

BEE CULTURE IN LOUISIANA; SOME OF THE HONEY SOURCES

BY J. F. ARCHDEKIN

The honey-flow in this section is divided into three distinct periods. These overlap or merge into each other, so that there is no spring in the flow after it begins in the stop. The bees always have some flowers available to work on. In the following I will mention only the main honey sources, and make no mention of many others.

The spring crop is secured from willow, tupelo, and white clover. Willow is a good yielder, and the bees gather a considerable amount of nectar from it. Where I came from (Missouri) willow yielded only pollen so far as I could see, and I was, therefore, surprised at the amount of honey stored from it here. Tupelo opens a day or two after willow, and a little later white clover comes on. Tupelo is the main source, however, as it is more abundant than the other two. The honey is classed as tupelo, and is white in color, heavy in body, and of fine flavor. It is hard to find words to describe the intensity of this flow. It comes in a veritable flood, and the bees work with might and main. They start out at the first streak of dawn and remain afield until long after sunset. The flow is of short duration, and they seem to realize that the time in which to fill their hives is limited.

The summer flow begins at the close of the tupelo, and continues in a long slow flow all summer. This is gathered from numerous flowers, only a few of which I can name. It is sufficient to say that practically all the honey-plants common to the central states are found here in addition to a world of others. There is a profusion of bloom all thru the season. Cotton is the main field crop, but I have never seen a bee on a cotton-blossom. It is very strange, too, as I understand it is a good source in most sections. This summer honey is red in color, and of very poor quality. The flavor is rank, with a distinctly sour twang. Strange to say, this honey fermented in the comb both before and after it was sealed. As it was stored very slowly I don't understand what caused it to sour, especially in view of the fact that the weather was dry all summer.

Goldenrod, horsemint, and boneset are the mainstays of the fall flow, which is in full swing by September 10. Asters and smartweed are also abundant. This flow is as heavy as the spring flow, and a good crop is secured besides putting the colonies in shape for winter. It lasts about a month. This fall honey is a light amber, of good

body and excellent flavor. It is a most excellent table honey. After the close of the fall flow the bees continue to gather pollen all winter on days when it is warm enough to fly.

Bordlonville, La.

THE ADVANCEMENT OF APICULTURE IN GREECE.

BY H. H. ROOT

John G. Poppageorge, of Athens, Greece, who is going to introduce American methods of beekeeping into his own country.

During the course of a year many visitors find their way to the Home of the Honeybees, some of them from countries far distant. During this last season we had visitors from at least four different foreign countries. One of these, Mr. Herbert J. Rumsey, of Dundass, New South Wales, Australia, contributed the beautiful picture shown on our cover of the Nov. 15th issue as mentioned editorially.

Another visitor, also a very interesting one, was Mr. John G. Poppageorge, from Athens, Greece. Mr. Poppageorge has spent some time in the United States, is thoroly familiar with American ways and speaks English most fluently. On his trip to this country last summer he was twice arrested and held on suspicion of being a spy, but was finally able to prove his innocence by the papers he had in his possession. On reaching this country he spent some time visiting some of the larger honey-producers and he expects ultimately to go back to his own country and to interest his government in promoting an apicultural department.

On the day that Mr. Poppageorge reached Medina it so happened that quite a large number of summer-school students from Wooster, Ohio, came up to study bees for a few hours. Our friend from Greece was an interested onlooker. The illustration below shows the group in our apiary with Mr. Poppageorge helping to demonstrate bees to those less familiar with them and their habits.

Summer-school students from Wooster University having a field meeting of their own at the "Home of the Honeybees."

EUROPEAN AND AMERICAN FOUL BROOD

Their Differences, History, and Methods of Treatment

BY OREL L. HERSHISER

Continued from page 57, Jan. 15.

Some of the conditions under which European foul brood will abate or disappear of itself are now known to be, 1, a vigorous, prolific queen; 2, a strong colony of resistant bees; 3, a good and prolonged honey-flow like that from white clover or buckwheat. In a good honey-flow the larvæ are fed on nectar and pollen fresh from the flowers, and uncontaminated with infection, and a constantly and rapidly increasing number of them will reach maturity in health.

When these conditions obtain, European foul brood may be treated as follows with even much less loss of time of our queens than by any of the methods described in the preceding articles.

Given a colony of normal strength, mildly diseased. Remove from the hive all brood-combs except the one having the most sealed brood and the fewest diseased larvæ. Place this comb next to one of the side walls of the hive. Brush the bees into the hive, being sure the queen is there also. Next to the comb of brood place a frame of foundation; and if it is an exceptionally strong colony, use two of them, and fill up the remaining room in the hive with drawn comb, either old or new. In fact, all the hive may be filled with foundation except the single frame of brood, except that it is often more economical to use the combs we already have.

The object is to discourage the queen from laying for a day or two while the foundation next to the frame of brood is being drawn out. There are but few cells in the comb of brood, where the queen will naturally commence to lay, where in to deposit eggs. This colony has been made abnormally strong compared with the amount of unsealed brood. It can easily clean out the few diseased larvæ, and all new larvæ being fed with uncontaminated nectar and pollen will be able to keep the diseased larvæ cleaned out from this time on, and a cure will usually result. If the queen skips over and lays in the drawn comb before the foundation is drawn out, a cure will also usually result. This circumstance indicates an unusually strong colony that is the better able to resist the disease.

In this treatment the queen is retarded—in not stopped—in laying for only a day or two, and the loss in the production of bees for the honey-flow that may follow is re-

duced to the minimum. Also there will be no "swarming out" as so often occurs where the shaking or brushing treatment is employed unless troublesome pains are taken to prevent it. We have cured the colony by simply aiding the bees in doing that which they could almost accomplish without aid.

If the colony is badly diseased, but strong, remove all combs and substitute one of mostly sealed brood containing little or no disease and complete the treatment as above described. In a strong colony, not badly diseased, this treatment may be varied by placing the bees and queen on clean combs, or part combs and part foundation, in the lower story and the brood above, and separated from the queen by an excluder.

To produce the maximum crop of honey we need to keep the queen depositing eggs as rapidly as possible in anticipation of the harvest. The great value of this method of treatment, therefore, clearly appears.

WHAT TO DO WITH THE DISEASED BROOD.

Some have stacked it up over another diseased colony for the healthy brood to mature, keeping the queen confined to her brood-chamber by an excluder. This, the writer considers, is bad practice, for the reason that, after the healthy brood has matured above the excluder, there usually would still remain the diseased brood in the chamber below to treat, thus carrying the disease along. In exceptional cases this colony, during a good honey-flow, if of resistant stock, might cure itself because of its having been made abnormally strong. A better way, however, is to take a nucleus consisting of the queen and two or three frames of brood and bees from a strong healthy colony, and this because such a colony is probably highly resistant. Shake the bees from the remaining frames of brood into their own hive and divide this brood among the healthy colonies. Here we have a goodly queenless colony to which may be given the diseased brood, and which may be stacked up four or five stories high if we are careful to leave sufficient bees on each comb to care for it. Make as many such hospital colonies, if we may so call them, as may be necessary to use up all the diseased brood that may be found in the apiary. On the ninth day after so collecting the brood, go thru these colonies and de-

stroy all queen-cells, and at the same time give a ripe queen-cell, or introduce a virgin queen from the best available Italian breeding stock, keeping her confined to the lower story by an excluder. This will usually result in a fine colony, free from disease, no loss of combs, and, if favored with a good honey-flow, a good crop of clean honey.

It is apparent that this method disposes of all the infection to be found in the apiary at the first treatment, which is very important, and it is also economical of time. It also gives us the best use of all our bees, and these strong hospital colonies will store honey in a manner not excelled by the best of the other colonies.

THE VALUE OF RESISTANT STOCK.

It is a well-established fact that certain vigorous strains of Italian bees are the most resistant to European foul brood, and yield more readily to treatment of the disease than other strains. And it is not too much to say that good resistant Italian stock contributes more to successful treatment than any other single factor. The first step, therefore, that should be taken for its prevention or treatment is to requeen with a resistant strain of Italian bees, if they are not already of that race. It is seldom that the native black bees or their hybrids will successfully resist the disease or attain a permanent cure. With resistant Italian bees the problem is comparatively easy.

When inspecting and treating the first of my apiaries to be attacked by European foul brood I noticed that three or four unusually strong and otherwise excellent colonies of Italian stock never showed any

trace of the disease. The queen of the best of these was used as a breeder; and every hive in the apiary, except these three or four, was requeened with queens reared from this breeder. The next season all the queens of the previous season's breeding were removed, and requeening was done with queens reared from the same breeder. A part of the apiary was requeened in the same manner the third season, and would have all been so requeened had not the breeder been suddenly superseded. The object of this line breeding was to fix the resistant qualities so that in future breeding there would be a fairly good prospect of their being transmitted and a strain of Italian bees established that could be depended upon to put up a good resistance to the disease.

Subsequent results proved the wisdom of breeding with European-foul-brood resistance as the object sought. Resistance is not obtained at the expense of other desirable qualities, as it apparently goes hand in hand with vigor, good wintering, and good honey-gathering characteristics. This particular breeder was doing service for the third year when she was superseded, and possibly for a year or two before I had occasion to select her, which adds the further quality of vitality to the stock selected.

Kenmore, N. Y.

[This is the third of a series of four articles by Mr. Hershiser on the history and treatment of foul brood. In the fourth and last article, which will appear in the March 15th issue, he will complete and summarize his discussion of methods of treatment.—
ED.]

"Backlot Buzzer" apiary, owned by Dr. C. Elton Blanchard, Youngstown, Ohio. Six of the colonies were made from two-pound packages of bees. Each was put on empty combs and foundation, with a queen about May 1. The doctor considers his hobby a paying one, as a good crop of comb honey was secured.

A COLLAPSIBLE SINGLE-COLONY WINTER CASE

BY J. H. FISBECK

The illustration shows a plan of a winter case which is collapsible, quickly applied, can be made so as to fit different-sized hives, and, when applied, one can examine frames of bees by only removing the cushion. The case may be removed without taking it apart, is very neat, and absolutely water-proof. While the plans specify $\frac{3}{8}$ -inch lumber and 2 x 2½-inch space for side packing, which is sufficient here, these measurements can be changed to suit climate.

The special features that characterize the case are, the rapidity in which it can be put on and removed from the hive, and the

and clean method of removing the side packing in the spring, especially for one having bees on a nice lawn. It is this also that makes a nice fit to a hive on uneven ground, and the possibility of applying it to an odd-sized hive, *i. e.*, driving a long thin finishing-nail with one light tap thru the holes in the case into the hive. Have the nails long enough so as to be able to adjust the case to fit the slats after the nails are driven in. Next place these removable slats on the nails, which should be level. Pour in shavings till they reach the top of the hive. Shavings above the hive should be in the form of a cushion to

small amount of room it takes to store away in summer. The case only needs to be unfolded to be in readiness for the hive; but it is advisable to use hinges with loose pins, especially the last pair put on, as it is much easier to work when making it. The oilcloth at the corners keeps the packing dry, and prevents the hinges from rusting. The inside of the case is free from cleats, etc., making it a simple matter to pour in shavings and also to remove them from below.

Another valuable feature is the simple

permit examination of the bees in the spring. One can have the top of the cushion open if he desires to empty them of shavings in the spring. To remove shavings from the sides of the hive, jerk out the nails and bottom slat, and shavings will fall on a cloth on the ground.

I tack tar paper over the boards on the outside, between the legs or cleats, with tins and tacks. The cover is made of $\frac{3}{8}$ -inch boards cleated around the edge and covered with a sheet of rubberoid.

St. Louis, Mo.

CAPPING AND COMB-MELTERS UP TO DATE

BY H. BARTLETT-MILLER

For large yards capping-melters have undoubtedly come to stay. Up to now the ultimate design has been undecided, obviously, because too many are designing by experience alone instead of experience and theory. True, experience has shown us a few of the essentials regarding the labor side of their construction; but the effective side, both as to the capacity of the machines and the effect upon the honey, are matters which, tho fully recognized as not fully satisfactory, are (or were) largely unsettled.

The designing, making, testing, and the discarding of honey-melters of various and successive designs, has, for nine years past, been a hobby with me. Root's double-walled can melter, with the screens, was too readily blocked up, and the honey on the flat bottom was too long detained in contact with the heat. No successful capping-melter can have any flat surface. Lots of others have this grave fault.

The next obstacle is a multiplication of small tubes. This was the objection laid by the editor of GLEANINGS against Mr. Beuhne's melter, viz., that continued expansion and contraction would cause the tubes to leak at their joints. Let me add that I want a melter that the ordinary beekeeper can make with his own soldering-iron; and altho he may manage a few big tubes he cannot and will not fuss around with small tubes, such as Severin's $1\frac{1}{4}$ -inch square tubes are; and if the bee-supply firms should turn them out they would be very expensive, and also unnecessary. Melters with a wide flat bottom are also out of the race for perfection, as the iron surface buckles; and while the wax and honey flow to the gutter all right, they flow in a few defined streams according to the amount of buckling of the metal, and the rest of such buckled surface is wasting heat only to annoy the operator. The one I illustrated a few years ago also was faulty, because it had to be cleaned out at the bottom of the gutters about every four hours. I want a melter that will go on like the sands of time if need be.

The greatest fault I have to find with the most promising of the melters so far illustrated is the lack of melting surface for the amount of fuel used. Another serious fault is that all of them have places at which the flow of honey to the exit is delayed for a longer or shorter space of time. The ideal melter must allow the wax and honey without the slumgum to flow uninterruptedly

and swiftly away from the heat which melted it; and furthermore—and this is important—the whole weight of the wax and honey should be used to press the contents of the melter on to as large a surface as is possible to be made available; therefore no inside-heated surface should be upright.

And now let us see. We will take Severin's melter described on page 724, 1911. This has been much lauded, both in New Zealand and in the United States. Mr. Severin has sent out a description of another melter since then which he thinks (I don't) is a great improvement on his 1911 melter. That melter had eleven tubes $1\frac{1}{4}$ inches square and $16\frac{1}{2}$ inches long. Thus the actual melting surface was $2\frac{1}{2} \times 11 \times 16\frac{1}{2}$ inches, or a total of 454 square inches—far too little surface for the capacity of a melter $18\frac{1}{4}$ inches long and $16\frac{1}{2}$ wide and 8 deep. Then it had the fatal fault that all the wax and honey which passed the tubes fell on a flat surface; and everybody who has used a melter knows that the oxidizing of slumgum in contact with heat, such as the slumgum which stuck to the under surface below the tubes must have met with, is the cause of the darkening of the honey. Such a melter ought to have been scraped continually down beneath the tubes—an impossible job when extracting. Then the fact that the slumgum is not quickly removed from both wax and honey is in itself a damning fact in any melter.

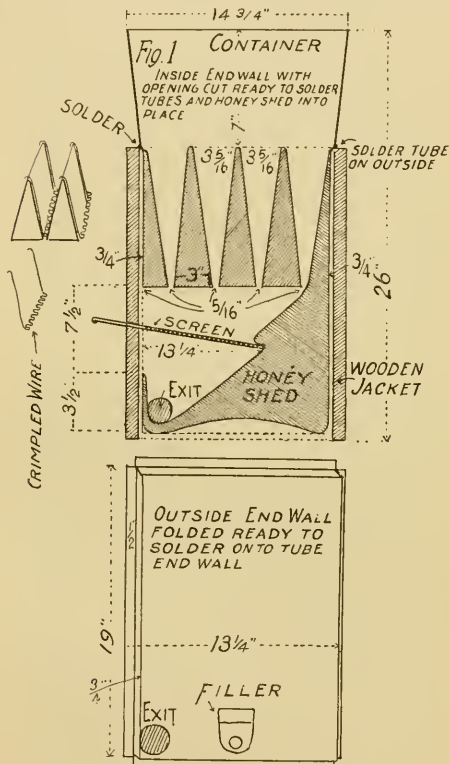

Now criticising (as I hope all will criticise mine) Mr. Severin's new melter described on p. 15, 1915, the fact of its having those 221 (whewation!) tubes in it, puts it out of court at once; for the man who requires an inexpensive affair, and having only half-inch tubes precludes its being a great success in melting constantly old brood-combs. True, melters were originally made for cappings; but when we want to get honey out of old combs that for various reasons have to be disposed of, you can just bet that the capping-melter will have to do the job. Anyway, it ought to be built to do both. Again, all the slumgum of Severin's new melter falls thru the tubes on to a flat surface. To be practical it should all fall upon a screen, to be withdrawn on occasion, and dumped into the wax-boiler, and the honey and wax should run right down a sloping surface to a gutter.

My melter was designed to melt up, if necessary, every surplus comb in an apiary of 200 colonies, such combs being sometimes

filled with a dense honey which the four-frame hand-power machine will not extract at any speed. The amount of slumgum can be imagined, and also the needed capacity of the melter to do an effective day's work. I tested the previous melter whose details were, to all intents, the same as the one about to be described, in the presence of the government apiaries inspector, Mr. S. V. Westbrooke. We placed five quarts of hot water, not boiling, in the melter; lighted and pumped up one No. 5 Prince's kerosene-stove to work the melter. Then we cut out of their frames 20 Langstroth combs filled solid with partly candied honey, wires and all. This was in mid-winter, when the honey was all but frozen. In the space of twenty minutes from lighting the stove the melter was empty. The inspector had held intermittently a thermometer so that the stream from the melter fell on the bulb, and in no case did the temperature go over 146 degrees until the last few ounces were running away from the melter and the water boiling at a terrific rate, which accounted for the heat rising to 165 degrees. This was for a few seconds only, before we put the stove out, the trial having been a complete vindication of the perfection of the melter to handle solid combs, let alone cappings. That melter differed from the one about to be described only in having a central tube that, sloping each way, necessitated a gutter at the end to connect them. This cross-gutter used, upon occasions of a great rush of material, to block up, as it was not water-jacketed, and the present melter also permits of the screen for holding the slumgum, the previous one sending everything into the separator.

Before I describe the melter I want to impress upon beekeepers a few facts about latent heat. I find not a few melters whose many tubes are filled with water which has no possibility of coming in contact with the heating surface of the lamp. This is a great error. Steam contains 962 times the latent heat that boiling water does. That is to say, that, given a certain amount of boiling water applied to a surface, it would melt only one 963d part as much honey or wax as that same amount of water connected with steam would melt; so that all heating surfaces in a melter should be surface-heated with live steam, and not merely boiling water. Furthermore, the deeper the tube the cooler the lower portion of that tube as compared with the top. Now, if we employ a tube of small size the boiling steam melts the honey first which is at the top of the tube. This honey flows down

the small diameter on to the (usually) flat but somewhat cooler surface below the tubes, and there meets no other cooler wax to which to give any surplus heat over its own melting-point, which, it is more than likely, it absorbed from the tube—i. e., supposing the tube, of course, to be filled with live steam and not merely just of boiling water. Therefore the deeper our tube the less damage from honey being too long heated; and the more efficacious our melter from honey which can hardly avoid becoming super-heated at the top of the tubes giving off its surplus heat to that almost

Cross-section and plan view of Bartlett-Miller's capping-melter.

but not quite melted wax lying nearer the bottom of the tube. This is a scientific principle which, once only a theory with me, I have proved to be fact by methods which it is out of place at this juncture to explain. Suffice to explain that, the deeper our tubes, the more effective, and the less dangerous our melter will be up to a certain point; for we must not have our tubes too deep for practical work or we should never get enough honey into the melter to cover them.

I wanted a melter that the ordinary practical bee-man could, if necessary, make

at home. I also wanted one that the bee-supply firms would sell at a figure more reasonable than, say, Mr. Beubne's machine sells at; lastly, one which had not the bug-bear of a large number of small tubes to run up cost and trouble.

THE NEW MELTER.*

My melter is 24 inches long (could be any length). Fig. 1 is a cross-section view of the end of the melter. The inside end of the melter should be cut out with the snips ready for the ends of the tubes to be soldered in. Let the ends project inside, say $\frac{1}{4}$ inch, and use the "trough" so formed to run your solder down. After you have the ends of tubes soldered into both of the inside walls, one at each end, the outside wall, which makes the water-jacket, is simply flanged around in a piece of scantling with a mallet, and the whole job is ready for the water-filling funnel piece to be soldered on over a hole cut at the lower part of one end. Keep this filled fairly low, so that you can see the water in it and use it as a gauge to see when refilling is needed.

After studying this melter you will observe that the spaces at the bottoms of tubes are available for the full width of the $\frac{5}{16}$ -inch when old combs are being melted, but that the crinkled wire is used when clean honey and wax are going thru. The recess in the "honey-shed" is to allow the wire-cloth screen to fit in, which prevents any slumgum passing; it should the wire edge of the screen get slightly bent from abuse when shaking slumgum into the wax-boiler. The operator may use two screens alternately, or scrape the one down as occasion demands.

All the weight of wax and honey is used to press on the wedge-shaped surfaces. That there may be no outside walls to throw away heat compared with the surface of the tubes, the two end walls and the two sides are wood-jacketed so that all the heat is kept in the melter. The tubes have an aggregate heating surface, apart from the honey-shed, of 1584 square inches, or 11 square feet—a surface not nearly attained as actual wax-contact surface by any other

melter ever designed. It will be found advisable to solder the exit-tube into the inside wall so as to allow that part of the honey-shed soldered into the same opening to go over, not under, the exit-tube, for, if soldered under the tube, it dams back any small amount of slumgum which may slip down while changing screens.

The screen and clips to support it need no describing. Any one can bend fence wire to shape, and cover with wire cloth; but keep the screen midway between the top edge of the gutter and the bottom of the front tube. This gives a clearance of three good inches, both above and below.

Either sheet copper (tinned) or heavy galvanized iron will answer, altho the iron pits inside badly after two seasons. Do not forget to use the melter with the exit end of the gutter two inches lower than the other end, and place the filling formed at the top end. Then if you always see water in the funnel at the top end you can rest assured that your melter is not running dry. You will find you will not be troubled much with refilling, as the steam has plenty to do at melting, and very seldom gets a chance to evaporate.

Everything runs completely away. The slumgum is held back by the screen, and everything is on a fairly steep slope, and all wax and honey are off the melter less than 30 seconds after melting. I have run honey thru this melter twice after recandy-ing, and cannot see that it darkened one particle. Of course, when old combs are going thru, one must expect a darkening as a result of hot honey absorbing stain from cocoons, pollen, and general comb dirt; but with fairly new comb no discoloration results; the honey runs away too rapidly. As to cappings, three people will not keep it going if the stove is kept going properly (unless they are regular comb-butchers). The novelties I claim in this melter are, rapidity of honey clearance from melter; increase of melting surface; separation of slumgum, thus preventing discoloration; and impossibility of overheating the contents at any point.

Kibi Kibi, New Zealand.

* Perhaps the readers will get a better idea of this melter if we explain briefly that Mr. Miller uses three large wedge-shaped tubes, of the dimensions given in the cross-section drawing, which, with the corresponding sloping sides of the melter, make four spaces thru which the cappings and honey pass, which gradually decrease in width until the final opening is only $\frac{5}{16}$ of an inch into the straining-compartment beneath. All the tubes being heated by steam, an unusual amount of melting surface is thus provided. Above the tubes is a hopper-shaped compartment into which the cappings and honey fall from the knife. The narrow spaces between the tubes are filled in with kinked wire when desired, to prevent unmelted wax from falling thru.—Ed.

Amount of Stores Needed

I have noticed the editor's reply to Mrs. Allen, page 969. In this locality we need ten combs about full. The hives, bees, combs, honey, and all should weigh at least 65 or 75 pounds, November 1. If a colony with this amount of stores has a good queen it will be in splendid condition next spring.

Havana, Ala.

J. S. Patton.

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Talk about hard luck, a prominent bee-man out in Indiana prided himself on the way his hives were arranged in nice neat rows out in his back yard. Somebody thought they were tombstones and filed a complaint against him for keeping a dog cemetery inside the city limits.

Wiring Frames and Transferring Colonies

My plan of wiring combs may not be new, but I have never seen it mentioned by any one. I use a common soft-iron wire about No. 14 or 16. In fact, I use common wire used for baling hay. I cut a piece exactly as long as the frame is wide, so as not to extend out. The wire is nearly the size of the hole in the frame made for it. I then run the wire thru the second hole from the top, and fasten it to the wax by pouring a little melted wax along the upper edge of the wire. This fastens it securely. It might be better to use two wires—one thru each of the two center holes in the frame. I put up some with two wires, and some with only one. I cannot see but one wire answers every purpose. The bees will draw out the combs right over the wire, and I have yet to see a comb the least sagged. You can certainly get perfect combs drawn by this method. A wax tube or wire-imbedder might be better, for fastening the wire to the combs; but as I did not have one I simply ran a little wax along the top edge with a spoon. You can do it very fast.

Here is my method of transferring bees from box hives: I lay the box hive down on the side. From the top end I measure down 20 inches and saw thru the board. I then pry this piece of plank off, set my hive-body over this hole after putting in three or four frames of drawn combs containing some brood, fill out with foundation, put on the cover, and the job is completed. The bees will go immediately up to cover the brood, and soon the queen will be up, when you can put your excluder under. When I have the old box open I remove as much of the old wax as possible, so as not to interfere with the brood. You can nail a piece over the bottom of the old hive, just leaving an entrance for the bees. The piece taken from the old hive can be used for this purpose. Should the hive body be a little wider than the box you can easily nail a strip along the side to make it the desired width.

Newbern, N. C.

F. A. Ganes.

[The principal objection to the use of one or two heavy wires instead of a greater number of fine wires is that the combs are not as well protected against breakage, either in the extractor or when they are being handled.—Ed.]

The New York Contest

We are getting many inquiries, asking for particulars about our proposed postal-card scheme having for its object the booming of honey as an article of food. Some want to know what ideas we want incorporated, others what size the sketches should be; others ask whether we want them in colors or in black; whether photos of apiaries would do, etc. To all these inquiries we can only say, "This is for you to work out." It is more the idea than the perfect execution of the idea we are after.

A very good thing has been suggested to us—a label to be pasted upon the top of every honey section as it stands in the shipping-case, the label nearly or entirely to cover the wood, with reading as follows:

This section of honey (14 oz.) equals in food value	
24 oz. beefsteak.....	(30c)
30 oz. of codfish.....	(40c)
20 eggs	(50c)
11.2 oz. cream cheese....	(16c)
2 quarts of milk.....	(16c)

[The comparative figures on label were taken from *American Bee Journal*, Dec. 1915.]

One of our committee says: This is the best thing which has been offered, altho not exactly in line with the postal-card scheme. But we may recommend it, also in connection with a photo of the articles named, all upon a postal card.

H. L. Case, F. Greiner, W. F. Marks,
Committee.

Wild Bees and Their Honey

I am sending a few of the bees variously called Mexican bees, Spanish bees, and wild bees. The comb is of paper instead of wax. Their honey is said to be very sweet, and is deposited in the comb in layers round and round the circumference of the nest. The nest is built in the branches of some tree or shrub. I do not believe that the honey is any better than that of the domestic bee, but depends altogether upon the character of the nectar obtained, just the same as that gathered by any other bee. The report of its excellence comes from the testimony of some boys who robbed out a nest; and the extravagance of their statement is probably the outgrowth of an intense love of honey gratified in an unusual and unexpected manner.

These little fellows stung me up some when I caught them to put them in the cage, but especially when I cut off a scrap of their nest to send you. The nest looks like a hornet-nest, egg-shaped, about 12 inches long by 10 inches thru.

La Feria, Texas. George M. Plumb.

[The bees sent by our correspondent are considerably smaller than ordinary honeybees and are more brilliantly colored. The head and thorax look very much like those of ordinary bees except that they are smaller. The abdomen is quite different. The upper part is not segmented, but bald and jet black. The lower part is segmented, the segments being a brilliant light yellow, approaching somewhat the color of yellow-jackets. The abdomen ends in a sharp point. We have seen similar bees occasionally, and they are found quite frequently in Florida. Sometimes there are strains or varieties very similar in shape and size, but having a greenish luster.

The nest, as mentioned by our correspondent, is fibrous; and, with the exception that the cells are smaller, it looks very much like a hornet-nest, the material being evidently made in the same way, and looking like paper pulp.—Ed.]

Probably Pure Honey

We are mailing you under separate cover part of a tumbler of honey. This represents some of the contents of some tumbler honey picked up on the market which is put up by a Chicago concern at a very low figure; and while the color is good it does not taste just right. We would thank you to advise us just what you think of this honey.

Penn, Miss. The Penn Co.

[We should not be suspicious of this honey, because it seems to have sufficient flavor to justify the belief that it is pure. If it is adulterated at all it is adulterated with invert sugar, and the price of invert sugar at the present time is such that it would be practically impossible to put that in and make any money, providing the hon-

ey was sold at a low price. It is our opinion that this is a sample of pure honey; but you will remember that good honey of good flavor is selling at a very low price, and it would be possible to make up a blend of several of these cheap honeys and still keep them all pure.—Ed.]

Four Untested Queens, but Purely Mated

After reading Mr. Webb's experience with untested Italian queens, page 74, Jan. 15, and the editor's request for others' experience, I take the liberty to send mine, tho in only a small way. Last summer I sent for five untested Italian queens from four different breeders and succeeded in introducing four, one from each breeder, and all four proved to be truly mated.

Tuxedo Park, N. Y. E. Wilson.

Death of Jacob Creighton

Jacob Creighton, of New Haven, Hamilton County, Ohio, a beekeeper of fifty years' experience, died December 11, 1915, of pneumonia. He was a veteran of the Civil war, and in his 71st year at the time of his death. He leaves four daughters to mourn his death. He owned an apiary of 103 colonies, and was very successful as a beekeeper, and exhibited bees and honey of his own production several years at the county fair at Carthage, Ohio.

Hartwell, Ohio. C. A. Brooks.

Making Hives

By Grace Allen

Oh, it's tap-tap-tap—
Hear the hammer striking,
Shaping up a thing today for years and years
to come,
Making of some piney boards,
Nails and honest effort,
A home for bees to live in and to labor in
and hum.

So it's rap-rap-rap—
See the nails drive under,
Patient nails to cling and hold while bees
throb out and die,
While days with tender dawns
And pomp of purple evenings
Close their scrolls forever as the years go
rolling by.

So it's rap-tap-tap—
He and I together,
Making hives with patient nails and vision-
ing and thought.
Nations are at war;
Yet not alone in battle,
But here in work and wonder too, His pur-
poses are wrought.

A. I. Root

OUR HOMES

Editor

Search me, O God, and know my heart; try me and know my thoughts; and see if there be any wicked way in me, and lead me in the way everlasting.—PSALM 139:23.

Nearly sixty years ago an old gentleman gave me some advice that has been of benefit to me all my life. He was a money-lender. I went to him with my father to borrow \$500, in order that I might go into business as partner with the man I was working for. My father was to sign the note with me. When told *why* I wanted the money Mr. Beekman said something as follows:

"My young friend, I have money to let, and it is my business. Your father for security will be all right; but I want my money to do good, and not harm. I should like to give you a little advice; but judging from past experiences with young men, I fear it will do no good."

I urged him to go on.

"Well, you have doubtless heard hard stories about me. Perhaps you have heard me called hard names."

I assented, because it was true.

"Well, this is because, if I loan money at a reasonable rate, I must have it back according to agreement. I should go bankrupt myself if I did not insist on this. If I understand, you have already a good job at fair pay."

I assented again.

"Well, even though I have money lying idle, and want to have it earning something, I would advise you at your age to stick to work and *earn the money* instead of borrowing. By the time you have earned \$500, or something like it, you will know better how to take care of it, and perhaps be able to start in business alone."

He then turned to my father and remarked that "Boys in their teens seldom listen to any such advice."

Right here I surprised both my father and Mr. Beekman by saying:

"Mr. Beekman, I not only thank you from the bottom of my heart, but I am going to take your advice;" and as father and I drove home he said I had lifted quite a load from his mind by the course I had taken. In a year or a little more the man I was going in with ran away, leaving debts right and left unpaid.

During the past season, on account of the large amount of money we have been handling we have borrowed more money than usual. The bankers loaning us the money said:

"We are glad to help great enterprises by giving them such accommodations as their statement entitles them to; but we must be *sure* there is no blundering carelessness or crookedness in reporting conditions. Have your business audited by some *outside disinterested* firm, and we shall be glad to accommodate you in every way in our power."

This was so strikingly like what our good old friend Mr. Bleekman had said to me years ago that it brought the whole thing to my mind.

This "auditing" business was a new thing to me, and I asked a great many questions. Of course national banks are audited every so often by a government inspector, and in the same way there are firms in our great cities that make a business, when required, of going all through any factory or great business concern so they may certify to the great world at large that the institution is not a hollow shell or "make believe" that may "bust up" almost any day. This institution might do a lot of good by informing the *proprietors* of things they didn't know about. We have lately been told in regard to the *Eastland disaster* that the paid inspector had not looked the old boat over for the last *three years*.

Right over in Summit Co., adjoining Medina Co., they recently found a man who had been receiving a salary *for years* for caring for canal locks, after the locks of the old unused canal had *rotted away!* When called to account, he replied that, as nobody objected, he thought it all right to draw his salary.

Does it not begin to look as if some outside "auditing institution" were needed all over our land? And finally, dear friends, is there not *greater* need that the Holy Spirit should look into your hearts and mine to see if there be any crookedness or cheat, and admonish us?

While pondering on this matter it occurred to me I had seen something in God's precious word that "hit the nail" exactly "on the head," and after considerable hunting I found it.

Dear reader, are you ready to make *with me* this prayer of David *your* prayer?

"Search me, O God, and know my heart; try me and know my thoughts; and see if there be any wicked way in me, and lead me in the way everlasting."

POULTRY DEPARTMENT

THE 17 CHICKS AND THEIR MOTHER.

I told you they were "safely housed" (?) near our bedroom window, etc.; but before I tell you what happened I want to give you a picture of them, and tell you how to make a very safe and efficient home for a hen and chickens, without very much labor and expense. First, get a nice smooth grocery box, rather long and wide, and shallow. The one pictured above was 34 inches long, 20 wide, and 8 deep. I removed the cover carefully, and nailed one end against the end-board inside of the box, so as to make a sort of letter A. Then the back side was boarded up with shingles placed up and down, and inch-mesh netting tacked over the front side, as you see in the picture. To cover the edges of the wire netting I nailed strips of planed lath over the front as you see. Well, I used this last winter without any floor but the ground under it, and no harm came to the chicks. I don't like any kind of wooden floor, neither does the mother or chicks. If right on the ground, the whole thing can be moved over to fresh grass, the hen can scratch and dust herself, etc. But, listen! before the chicks were a week old a skunk or opossum dug under a back corner and pawed out two chicks. The hen then moved over to the opposite corner, where he dug under again and got two more. If you, my friend, have

The hen that stole her nest out in the woods and brought home 17 chicks

"been there," you know something how I felt about my "Christmas present."

I moved her and the 13 remaining chicks to one of the houses where netting is let down into the ground about a foot all round; but in two days the same "varmit," being *hungry again* for a "chicken dinner," dug down and managed to get thru at one

corner and took *three more*, leaving only eleven. I said to Mrs. Root and Wesley:

"This sort of business *is going to be stopped—on our chicken-ranch, any way.*"

I made a square frame of wood, 48 x 20 inches, for the coop to rest on; but instead of covering this with a flat piece of netting I made a sort of basket about like the lower part of a corn-popper. Then we dug out a place for it, putting the dirt back into the basket, and now "mother biddy" can scratch and roll and dust herself on her dirt floor just as if there were *no* wire netting under her. Well, we have our house for sitting

hens; but the same varmint (or one like him) dug under, as I have explained, and left only the egg-shells where a hen was almost ready to hatch; and altho this room is 6 feet by 8, we have just "floored" it entire with netting about a foot below the ground. I feel some better now, but I am not *quite* over being "mad" about the loss of my chicks yet. So

The three rows of potatoes shown on p. 129, Feb. 1, just three weeks later. on Christmas day.

I bought 10 cents' worth of strychnine, and am going to try *that*, and this reminds me that I forgot to tell you that, during the "fracas," I caught him (or them) in two different traps, but he in some way pulled out of both.

A BED OF POTATOES PLANTED NOV. 18, 1915.

The picture will show you, if you examine closely, the way in which we make our raised beds with deep wide paths between. This bed contained a heavy stand of feterita, as I have explained, that was ruined by blight; and before planting the potatoes it was all spaded under, and is now rolled so the potatoes have just what they like—a mass of decaying humus in which to grow and expand. In the background you have a better view of the great 3½-year-old rubber tree, 25 feet high, and 50 feet spread. The coop that held the 17 chicks is at the foot of the tree among the pineapples.

HOW TO MAKE HENS LAY.

I am reading the poultry department in GLEANINGS as well as every other. I have at present 20 Plymouth Rock hens. I feed them regularly, giving them from one to two quarts of wheat twice a day in the straw, or some place where they have to scratch for it, and I pound some green bones and broken chinaware on a flat rock once or twice a week. I wish that some time you could be here and hear the music they make. As soon as they hear the hammer strike they come from every direction and pick the food off the rock. I have not hands enough to keep their bills off from the rock. My hens pay me well for that extra care, and a few eggs all winter until January, when they start to do better every day. I have sold since Jan. 1 21 dozen and 7 eggs. The highest price has been 30 cts. for the first 3 dozen; then the price dropped to 20 cts. on March 6. I sold 5 dozen for 15 cts. per dozen, making a sum of \$3.50. Now, March 23, eggs sell at 13 cts., and it is said the price will drop to 10 cts.; but as we are six miles from the nearest store we keep them for our own use, and take the good sizes for setting, because it does not pay to drive a horse to town or take them on horseback as I did March 6, riding to town eight to nine miles.

All my neighbors a mile around me are wondering, and ask me what I feed my poultry. I told them the full truth about it. We have now, since this winter, one of our neighbors so close by us that the chickens would get mixed up were it not for the difference in race. I have Plymouth Rocks, while she has Rhode Island Reds. The first days her chickens came over here searching for food (and found some too) I waited until they had roosted, and then took them over to her. My! how light they were! I thought I had only a handful of feathers in my arm. She got her first eggs the second week in March; one every second day.

One neighbor fed 120 chickens all winter without getting one egg in return; but now, as they started to lay, he sold most or half of them because wheat is high and he ran short. Would it not have been better to sell that number last fall and feed the rest a little better? He also has the idea that if he sows the feed in the straw they can't find it, and sows it on a plain clear ground.

I knew a lady in Colorado who used to say, "If my hens would lay better I would feed them more." What do you think about that mistake? I am sure

if the hens could speak they would have said the same, but the other way, thus: "If you would feed us more we could lay more eggs." I once was packing in about 24 dozen eggs for market when she came in the house. She was astonished, and remarked that she had never seen an egg for a long time.

We raised eight children—four boys and four girls. The oldest one is eighteen, and we never consulted a physician or had one in the house except when our little son at the age of four broke his leg above the knee. Then, of course, we were compelled to call for the surgeon, about nine miles off, and the bill was \$20. The boy is now eight years old, and his limb is just as good and strong as the other one, and not a bit shorter. The man did his work well, and came only that one time. He told us what we had to do, and we got along all right.

In regard to the high cost of living, we agree with you. We use only graham for bread, and I put only two or three cups of white flour in it. We take two to three sacks of wheat to a neighbor, run it twice through the chopper or feed-grinder, and the coarse parts, or bran, which remains in the flour-sieve we use for breakfast cereals—cook it well and eat it with milk. We also use wheat for coffee, so we reduce the cost of living to a great extent.

MRS. MARGARETE GREEN.

Weiser, Idaho, March 28.

ELECTRIC-DRIVEN VEHICLES AND STORAGE BATTERIES.

I have several times on these pages mentioned my electric automobile, and told what a convenience it is, especially for an old man. But I did not think, until lately, to contrast the expense of running an electric compared with a gasoline vehicle. Last fall, however, I was offered an electric in very good repair, at a low price. While the batteries in mine are sufficient for a trip of only thirty or forty miles, this new one was good for sixty or seventy. Before taking the machine, however, I made inquiries in regard to storage batteries, and was somewhat discouraged on learning that the expense of renewing batteries, without saying anything about the cost of the current, is away beyond gasoline. As an illustration: Ernest has a gasoline machine that will carry five passengers at a little over half a cent a mile when gasoline was down as low as 13 cts. a gallon,* and a gallon on fair roads has run him 24 miles. Well, a storage battery with 28 cells will, I am told, give probably 6000 miles, and likely give good service for two years. But when the battery needs to be renewed, at the present cost of metals it would be about \$180. This would be 3 cts. a mile for the upkeep of the battery, against half a cent a mile for gasoline.

While at the Ohio State Fair I saw a neat little outfit for lighting rural homes by means of an electric current, at a price of only about \$100. When I inquired about

* It is now 22c and going higher.

renewing the battery he said they guaranteed them for two years; and renewing the batteries costs \$20, or \$10 a year. Now, we have seen that the cost of running a battery for an automobile is about six times as much as for gasoline. From this I gather that the cost of running electric lights in the home is something like six times as much as if the current were taken direct from a gasoline-engine. In that case, however, you could have light only while the engine is running. Therefore it behooves one who has such a rig to get his light from his storage battery just as little as possible.

We hope there may be some improvement made in storage batteries so as to reduce the cost. Electric automobiles, on account of the above, will probably be mostly used by those who have plenty of money—at least the expensive ones that will go from 75 to 100 miles with a single charge of battery. The *convenience* of electricity, especially for short trips up town and around home or between one's home and his place of business, will always make them in demand. When I am tired of hoeing in the garden, it is a very great privilege to get into my little electric car and rest while I run over to the factory or run around town and visit people. Where I am well acquainted, the grocer will bring me whatever I wish without my getting out on my feet at all. It is also, on account of its simplicity, well

adapted for women to manage and to run around with. Where one has a plant that furnishes a current, as we have, the expense of charging a battery is not much. Where, however, you are obliged to pay the town or electric lighting company for charging your batteries, this involves considerable cost in addition to the expense of renewing the batteries when they are used up. The present high price of lead is just now making storage batteries still more expensive.

Later.—I clip the following from the *Cleveland Plain Dealer*. It comes from West Orange, N. J., and is dated Sept. 20:

GOOD BY, HORSE; EDISON SAYS STORAGE BATTERY FOR DELIVERY WAGONS FINISHES DOBBIN.

"It is the beginning of the end of the horse. Horses in the near future will be used only as ornaments. Their commercial value will be nothing."

Thomas A. Edison laughed today at his plant here as he surveyed another of his accomplishments—a storage battery for delivery wagons.

Before half a hundred experts he explained the mechanism. They stood awe-stricken as the light horseless delivery wagon rolled around the yard.

I have been for some time watching and hoping that Edison or somebody else would invent a storage battery that would not cost so much for the upkeep; and the clipping above may be an indication of what is coming. But, as I have outlined, the objection to electricity in place of a horse has been, and is at present, the expense of renewing the battery when it is used up.

TEMPERANCE

ANOTHER VICTORY IN THE LINE OF WHISKY ADVERTISING.

We clip the article below from the *New York Evening Journal*.

No whisky advertisements in any of the Hearst publications hereafter.

Public Health, Public Morals, and Public Righteousness Demand a Campaign against the Drink and Drug Evils.

I note in a recent issue of *The American* an advertisement of a whisky masquerading as a medicine.

I wish all our papers to reject all whisky advertising of whatever kind, and all advertising of any ardent liquors, and all advertising of any medicinal preparations containing alcohol or opiates in habit-forming quantities.

Furthermore, I do not think that passive opposition to such great evils as the drink habit and the drug habit is sufficient for forces as powerful and as vital in the community as our newspapers.

I think our papers have more active duties and more positive responsibilities. I think they should campaign for a system of sumptuary laws.

1.—To prohibit the sale of injurious and habit-forming drugs except by the state and upon the prescriptions of regular physicians.

2.—To prevent the sale of alcoholic beverages except where the proportion of alcohol is fixed at

some definite and known innocuous proportion.

3.—To make the taking or administering or prescribing of alcohol or opiates in habit-forming quantities a criminal offense, from the penalties of which regular physicians shall in no way be exempt.

The campaign against the drink evil and the drug evil is a matter of public health, of public morals, and of public righteousness which it is the duty of our papers actively and aggressively to promote.

WILLIAM RANDOLPH HEARST.

WHO ARE THE VOTERS, AND WHO DO THE VOTING ON THE WET AND DRY QUESTION?

Before discussing the above I want to quote a little from the *American Issue* of Jan. 21:

Mr. R. W. Walters, a structural-iron worker of Toledo, was sent to East Youngstown at the time of the riot, by the *Toledo Blade*, to report what he saw. Mr. Walters says:

"More than one man was seen with a torch in one hand and a tin cup of whisky in the other." Mill property was not attacked, but the mob looted and burned the homes in the community. Mr. Walters further says, "The rioters were so drunk that two gangs of strikers met on a hill and fought each other."

REAL CAUSE OF THE TROUBLE.

The *Coshocton Tribune* calls attention to the fact

that employers and employees were not far apart in their negotiations, and their differences were not of a nature to provoke the outbreak; therefore there must be another reason, and then the *Tribune* gives the reason:

"The entire affair was only another monument to the ability of the open saloon to convert an irregular gathering into a whisky-crazed riot. *Had there been no saloons in Youngstown there had been no riot.* Had the men who composed that mob been deprived of booze the state of Ohio had been spared another whisky-inspired disgrace, and the city of Youngstown the humiliation of appealing for state troops to maintain order within her corporate limits."

YOUNGSTOWN WET AND DRY.

The saloons in Youngstown opened last Friday afternoon after being closed for five days because of the riot. The first 12 hours following the opening two men were sent to the hospital with battered heads, one man was held up and robbed while intoxicated, and 32 others were arrested on charges of intoxication, disturbance, and disorderly charges growing out of drunkenness.

This is the 12-hour record as shown by the police blotter. During the five days the saloons were closed only ten persons were arrested for intoxication, and these secured liquor from nearby towns.

Now, then, friends, is it not true that the class of people described in the above are the ones who voted Youngstown wet? and will not these people do it again? Was it not the same class down in Cincinnati, that kept the whole state of Ohio wet, contrary to the wishes and intention of the God-fearing and law-abiding people of our state? A while ago there was talk of letting only those vote who could read and write; but it didn't pass, and I am glad it did not. Well, just now the best and most highly educated women (and *mothers*) of our land cannot vote; but the confirmed drunken inebriate votes, and, so far as I know, so does the most desperate criminal who happens to be out of jail. Is it not getting to be about time to draw a line somewhere?

IS WHISKY A MEDICINE FOR GRIP OR ANYTHING ELSE?

We clip the following from the Bradentown *Evening Journal*:

A WARNING.

Whisky-dealers, ever eager to increase their business and their profits, have taken advantage of the prevalence of grip in the East, and thru newspaper advertising have sought to increase sales by representation that their goods are a panacea for the ills of life, including grip.

The Commissioner of the Health Department of New York has issued a warning against the use of whisky by persons suffering from the grip. This action by the Health Department authorities was the result of recent advertisements claiming whisky to be a sure cure and preventive of the grip.

"There is nothing more injurious to the patient suffering from grip than whisky," said Dr. Charles Balduon, director of the Bureau of Public Education of the Board of Health. "This Department wants to refute the ridiculous claims sets forth by whisky concerns in some of the Sunday papers."

"Whisky-drinking should be condemned in general; but for victims of colds or bronchial troubles, whisky acts as a poison. Such claims attributed to

whisky are misleading to the public, and do great harm."

WANTED, BRIGHT BOYS.

If the following, clipped from the *Gospel Trumpet*, could be put into the hands of every father who has one or more boys it doesn't seem *possible* we should have so many who would vote "wet."

Wanted, some bright boys full of life and cheer, to stand at my counters as drinkers of beer; to fill up the ranks, without further delay, of the army of drunkards fast passing away. Sixty thousand a year will only supply the loss to our trade from drunkards that die. Send those who can toil, or have wealth to bestow, for profits are small on old drinkers, you know. Let them come from the shop, the school, or the home, we'll welcome them all who ever may come. Let mothers surrender their sons to our cause, and fathers keep voting for good license laws. For if you will vote to keep running the mill you must furnish the grist or the wheels will stand still.

"GRAY AND TATTERED, AND KNEE-SHAKY."

Dear Mr. Root:—I am inclosing a clipping that I am sure will please you to read. I hope the good work may go on until a saloon cannot be found on this green earth. But why not commence at the root of the evil, the breweries and distilleries?

Indianapolis, Ind., Jan. 15. J. F. KIGHT.

Below is the clipping:

POOR OLD JOHN.

Last year alone, 15,000 saloons were put out of business, and more than 100 breweries and distilleries were closed, it is believed, forever.

Say what you will, John Barleycorn is having a hard time, and we wouldn't give 30 cents for his future. He is despised in the best circles, and the friends of his youth know him no longer. He is old and gray and tattered, and his knees are shaky. He totters. He is a pariah. He is a criminal; and when he eventually gasps his final breath and the sheet is pulled over his head there will be more rejoicing than mourning.—*Macon News*.

RENTING PROPERTY TO SALOON MEN.

There is a conscientious awakening in the hearts of individuals who have been renting property to saloon men. They are realizing that to accept such rents is to become a partner in the whisky business.

As an example, at the Sailors' Snug Harbor, which is located on Staten Island, are operated on its property fully 100 saloons. This institution is a home for sailors; and many years ago, when it was first organized, a farm was presented it. The city grew, and now the farm is simply a part of the city, covering ten squares. The income from rentals is great, and especially from the saloons. The trustees of this institution recently decided against the saloon, and as fast as the leases expire none will ever be renewed.

This will add one among the largest dry sections to the city of New York, and is a fine example of the waking up of conscientious men to the fact that there is a good way and a bad way to make money.—*Southern Fruit Grower*.

THE "KIDNEY CURE" SWINDLE.

We clip the following from the *Rural New-Yorker*:

The United States Government is after the manufacturers of so-called "kidney cures," and it has been able to show up several of them as frauds. Many of these so-called "cures" contain from 40

to 50 per cent of alcohol, probably in the form of brandy. The Department states that alcohol is a medical irritant, dangerous in many cases of kidney disease. There seems to be no doubt that these so-called remedies are merely substitutes for rum. They are practically worthless as remedies, and actually harmful, not only because of the amount of alcohol they contain in its effect upon the system, but because they establish the taste for liquor. A case is reported to us where a man died after several years of ill health, and it was found that he had swallowed three barrels of one of these remedies, and paid for it at the rate of nearly one dollar a bottle. There is no wonder he died, and the wonder is that his heirs had anything left after he passed away.

If the above winds up some of the malt whisky ads we can all rejoice.

CIGARETTES BARRED FROM THREE GREAT PERIODICALS.

The following letter, written to one of the employees of The A. I. Root Co., I am sure will cause rejoicing by all well-informed good people:

Mr. DeForest M. Olds, Scoutmaster,

Dear Sir:—With the exception of a few advertisements heretofore accepted, and which we are under obligations to print, no cigarette advertisements will hereafter appear in any of our publications.

Not only will we exclude cigarette advertisements, but after January 1, 1916, except in one advertisement previously contracted for, all reference to cigarette uses will be excluded from tobacco advertisements in our publication.

In spite of the fact that this policy will result in a reduction of several hundred thousand dollars in our annual advertising receipts, we believe we have taken the right course in this matter.

For the reason that several men connected with your organization have made inquiries about our advertising policy, we believe that you too may be interested in this announcement.

Very truly yours,

THE CURTIS PUBLISHING COMPANY.

The Ladies' Home Journal

The Country Gentleman

M. E. Douglas,
Manager Sales Division.

Philadelphia, Pa., Dec. 30.

CIGARETTES—SHALL THEY CONTINUE TO BE FURNISHED FREE TO "CREATE AN APPETITE?"

I believe it is true generally, or at least I hope it is true, that the boy who is looking for a job stands no chance at all if his prospective employer discovers he uses cigarettes. Nobody wants him. I believe our oldest grandchild, Leland I. Root, has never before furnished anything for GLEANINGS; but while attending school at Lebanon, O., he forwarded the following clipping from the *Commercial Tribune*:

GIRL OR CIGARETTES? CAN'T CHOOSE BOTH IN TOWN IN KANSAS.

LEWIS, Kan., May 8.—"Fingers that handle cigarettes shall never hold ours." "It's nix on nicotine," so far as cigarettes and the girls of Lewis, Edwards County, Kansas, are concerned.

The Lewis Anti-cigarette Club now numbers in its membership virtually every girl in the Lewis High School, as well as many of the young women of the town outside of schools. On the membership roster are all of the leaders in the social younger set.

The avowed purpose of the club is to drive the cigarettes from Lewis. It was getting a foothold. High-school boys and young men of the town generally were taking to the habit.

Lectures from the pulpit, pleadings of parents, sober advice by physicians, failed to check the cigarette fad. So the girls of the town took it up. At a meeting held recently at the home of Miss Lottie Crabtree the Anti-cigarette Club was formed. It started with but six girls as charter members.

Before the week was over, virtually every girl in the high school was enrolled. The next Sunday the membership roster was swelled at the Sunday-schools. Now there are but few girls under 20 years of age who are not members.

The girls take a solemn pledge to shunt cigarette smokers, and keep it.

At first the boys regarded the club as a joke. But it wasn't so funny when revival meetings started in the town Sunday night, and after church every blessed girl deliberately cut the escorts lined up at the doors and struck out for home alone.

SOMETHING FROM A MISSIONARY ABOUT THE BEES OF SOUTH AFRICA, ETC.; ALSO SOMETHING ABOUT THE MONKEY THAT WAS STUNG TO DEATH BY BEES.

Dear Mr. Root:—For some months we have been receiving GLEANINGS, and are very much interested in many of the articles. We often wonder to whom we are indebted for the paper. I believe that if you were here you would not be in the bee business very long. However, in Abyssinia, some 250 miles from here, there must be great quantities of honey produced, for every year there are tons of beeswax brought down the Sabat. The bees of this part have stings and tempers too. Sometimes a swarm will occupy a place about our premises in which it is not welcome. I remember that once a swarm of bees found a box to their liking; and so, after some months, one of our missionaries thought that there might be some honey, so he rigged himself up with mosquito-netting and lifted the lid. That was as far as he got. Some flew so hard against the netting that it was driven against his face, and he got stung. He took refuge in the house; and during the rest of the day, when any one showed himself at a window the bees came dashing against it. Chickens were stung to death; a monkey died from the effects of the stings it received. Another time the box was opened and a little honey removed. The honey here is made from the blossoms of the acacia and other trees, and is quite strong. It is very dark in color.

The people here live on dura, a sorghum; but it does not produce from suckers after the first head is removed.

C. B. GURAME.

American Mission, Doleih Hill, Sabat River, Egyptian Sudan, Sept. 11, 1915.

Why, my good friend, almost ever since the time GLEANINGS was started we have been sending it free of charge to foreign missionaries like yourself. All we ask is to let us know at the end of the year that they read it and are glad to have it keep coming. We shall be pleased also to have you tell us about the bees in different parts of the world where they may be located.

Patented
Cog Gear
Head

Protect Your Trees, Shrubbery, and Garden by Using a MYERS Hand or Power Sprayer

Spraying is not a fad, but a common-sense business proposition. For the small sum you invest in equipment and the time you devote to your orchards, you receive in return a large crop of perfect fruit that commands the "top-notch price" in the market.

MYERS SPRAY PUMPS always produce the desired results by giving that thorough distribution of the spraying material that is so essential. They are made with the Patented Cog Gear Head and operate one-third easier than pumps or less improved design. If you spray with a Myers Spray Pump, and use good materials, you will be pleased with the results of your work.

Write for catalog showing Bucket and Barrel Sprayers, Power Sprayers, and all kinds of Spraying Accessories.

Dangerous Indigestion

Indigestion, Constipation, and the more serious ills to which they lead are so common and cause so much needless pain and suffering that Dr. John Harvey Kellogg has written a book telling how to prevent and remedy such disorders. The greatest living authority on diet and digestion here gives you the results of his forty years' experience as Superintendent of the Battle Creek Sanitarium where he has studied and treated thousands of cases of indigestion and resulting ills. "Colon Hygiene" is a book of facts—not theories. Do you want to renew your energy and stamina, stop suffering from headaches and backaches, have clear eyes, a smooth, ruddy skin, feel the exhilaration of real good health tingling through your body? If so, send this coupon now for a free examination of this splendid book. Learn how easy it is to live life anew—to acquire the dominant personality that comes from good health—to become suffused with the joy of living. All this, and more, you may get from Dr. Kellogg's book of 400 pages, which the coupon will bring to you. This free examination offer is limited, so send the coupon NOW before it is withdrawn.

Send No Money—Just the Coupon

Bee book free

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

BLANKE MFG. & SUPPLY CO., Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST. LOUIS, MO.

More Profit

THROUGH better, more intelligent, more economical use of good tools will come the profit that is so hard to find each year on many crops. Plant right so you will get full benefit. Work faster with better tools so you can cultivate and spray often. Study whether there isn't some tool that will do your work better.

IRON AGE

Potato machinery, spraying machinery, garden tools, etc., are built to give you just what you need to do things right. Almost any combination you can think of in each line. Eighty years of factory and farm experience behind their manufacture.

Ask your dealer to show them, but write us for separate booklets fully describing lines in which you are interested. Let us make good our claims.

“Hats Off to the New Management”

writes a Mission, Texas, customer

The old reliable line of Root's Beekeepers' Supplies with our new system of business management assures Texas beekeepers of service such as they have never before experienced.

Mr. B. I. Solomon, who is now in charge, has been with The A. I. Root Company for some years and knows their method of doing business.

We intend to carry a large and complete stock of supplies, and we also have our Weed foundation machines in shape to care for all orders promptly.

Give us an opportunity to convince you of our service.

ARTHUR J. COLLINS BOX 42 MOORESTOWN, N. J.

Planet Jr. Tools Farm and Garden

cut down work and boost your crops

Old-time farming no longer pays—these scientific tools do the work of 3 to 6 men, give bigger yield, and save their cost in a single season. Invented and made by a practical farmer and manufacturer, with half a century's experience. Planet Jrs are strong and lasting. Every tool fully guaranteed.

72-page Catalog (184 illustrations) free!

Describes over 70 tools, including 12 entirely new ones and improvements to our Seeders, Wheel-Hoes, Horse Hoes, Harrows, Orchard- and Beet-Cultivators. Write postal for it!

S L Allen & Co Box 1106S Philadelphia

No. 25 Planet Jr Combined Hill and Drill Seeder, Double and Single Wheel-Hoe Cultivator and Plow is a splendid combination for the family garden, onion grower, or large gardener. It is a perfect seeder, and combined double and single wheel-hoe. Unbreakable steel frame. Capacity — 2 acres a day.

Planet Jr 12-tooth Harrow, Cultivator and Pulverizer is stronger, steadier in action, and cultivates more thoroughly than any other harrow made. Non-clogging steel wheel. Invaluable to the market-gardener, trucker, tobacco, or small-fruit grower.

No. 25

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hand. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

17 CENTS A DAY! Remember this brand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY--Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

The Oliver Typewriter Co., Cleveland, Ohio

946 Prospect Avenue

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

Gleanings in Bee Culture

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hand. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

17 CENTS A DAY! Remember this brand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

The New "F" Super and Its Advantages

The "F" Super is one of the new improvements which we have added to our line. It consists of a super holding 4 x 5 x 1 3/4 plain sections, and can be furnished in either eight or ten frame size. The eight-frame super holds 28 sections and the 10-frame 32 sections. This super is unlike many of the supers on the market, as it takes standard equipment and offers the beekeeper who at any time might care to change over to extracted honey an exceptionally good item.

It can be used for extracted honey by purchasing 5 3/8-in. frames which will fit the inside of the super, or it can be used for comb honey. This saves the beekeeper from purchasing a whole new outfit should he ever care to change over to extracted honey, and at the same time gives him an A1 comb-honey outfit for the same price as a comb-honey super can be purchased.

Any row of sections can be taken out and replaced with a shallow frame without making any other changes or adjustments. Some of our customers who have been substituting in the shallow 5 3/8-inch extracting-frames on each side or in the middle are inclined to believe the bees enter the super much quicker.

Prices of the "F" super will be gladly furnished upon application.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12 1/2 oz. net or 13 1/2 gross. The top of each section in this grade must be stamped, "Net weight not less than 12 1/2 oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells, all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

- Honey packed in second-hand cases.
- Honey in badly stained or mildewed sections.
- Honey showing signs of granulation.
- Leaking, injured, or patched-up sections.
- Sections containing honey-dew.
- Sections with more than 50 uncapped cells, or a less number of empty cells.
- Sections weighing less than the minimum weight.
- All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color, and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.
Honey contaminated by honey-dew.
Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES
Adopted at Cincinnati, Feb. 1913

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-AM), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

KANSAS CITY.—The supply of comb honey is not large, and the demand is light. The supply of extracted is large and the demand very light. The market is really overstocked. We quote No. 1 white comb, 24 sections per case, \$3.00; No. 2 ditto, \$2.75; No. 1 amber ditto, \$2.75 to \$3.00; No. 2 ditto, \$2.50 to \$2.75; No. 1 white extracted, per lb., 7½ to 8; amber ditto, 6 to 7; No. 1 beeswax, 28; No. 2, 25. C. C. CLEMONS PRODUCE CO.
Kansas City, Feb. 16.

BUFFALO.—Business in honey in this market is small. The retail trade is fully as good as usual at this time of the year. A great many of the retailers send to the country for their supply, thinking they can buy cheaper from the producer. The demand here is about equal to the supply in good white comb, lower grades pretty slow; extracted slow sale, unless offered at very low price. Choice to fancy white comb brings 15 to 16; No. 2 and 3, 10 to 12; extracted white, 7 to 9; dark, 6 to 7. Beeswax, 28 to 30.
Buffalo, Feb. 19. W. C. TOWNSEND.

NEW YORK.—The market on comb honey is practically at a standstill at present, and of late the demand has been next to nothing, there being some little demand, however, for No. 1 and fancy white, but there is no demand for off grades whatever. Our stock is not heavy, but it is more than sufficient to fill the present demand. We have letters coming in right along from producers asking what we can get for comb honey, and we write them that, as the season is practically over, we would not feel justified in stocking up. As to extracted, the market is in pretty good shape, with a fair demand. There seems to be plenty of supply of all kinds, with the possible exception of California water-white sage; but we would not encourage shipments without first writing us. We quote nominal: California, 6½ to 8, according to quality; clover and basswood, 7½ to 8; off grades, amber and light amber, 6½ to 7; buckwheat, 6 to 6½; West Indian, 55 to 65 per gallon, according to quality. Beeswax is in fair demand from 29 to 30.
New York, Feb. 17. HILDRETH & SEGELKEN.

THE J. E. MARCHANT BEE AND HONEY COMPANY, CANTON, OHIO

"A Square Deal"

Markham Ont., Oct. 1, 1915.

Mr. H. D. Murry, Mathis, Texas.

DEAR MR. MURRY:—As I have used quite a number of your queens during the last three seasons, I thought you might be interested to know how they have turned out. They have given universal satisfaction, and in only three or four cases in this time have any queens shown to be defective. In each case such queens were promptly replaced. While the queens have given satisfaction, that is only one factor that pleases me in my dealings with you, as during all the time I have had business connections with you promptness in answering letters, and other features that go to make the ordinary routine of business a pleasure have always been in evidence. While I feel that I can confidently recommend your queens as being satisfactory in every way I certainly can also assure prospective customers that they can be sure of a "square deal" every time they do business with you. J. L. BYER.

Starting twenty years ago with queens from H. L. Roby, of Worthington, W. Va., and later securing a fine breeder from J. P. Moore, Morgan, Ky., then by constantly, carefully selecting by breeders from the colonies giving the best yields of honey and showing the most desirable traits otherwise, I have built up a strain of bees unexcelled for beauty, gentleness, and honey-producing qualities. Please write me your needs for this season in the way of queens, nuclei, and bees by the pound, and I shall be pleased to give you prompt and satisfactory service. Three-banded Italians. No disease. Tested queens in March; untested queens after April 1. Prices before May 1: Tested queens, \$1.25 each; \$1.00 per dozen; untested queens, \$1.00 each; \$1.00 per dozen.

H. D. Murry, Mathis, Texas

If Your Bees Have Foul Brood

Get my queens. Three-band and Golden Italians.

One Untested Queen, \$1.00, six, \$5.00. One Tested Queen, \$1.50; six, \$8.00. One-frame Nuclei, \$2.00; 2-frame, \$3.00. Add price of queen wanted.
1/2 lb. bees, \$1.50; 1 lb., \$2.50.

W. J. LITTLEFIELD, LITTLE ROCK, ARK.
414 West 7th Street

Three-band Italian Queens

My queens are bred from imported mothers. They are the best for honey-gathering and gentleness. I fill orders as promptly as possible. GUARANTEE that all queens will reach you in good condition, to be purely mated, and will give perfect satisfaction.

PRICES --- April 1 to July 1

Untested	one, \$0.75; six, \$4.25; doz., \$8.00
Select Untested90 5.00 9.00
Tested	1.25 7.00 13.00
Select tested	2.00 11.00 20.00

L. L. Forehand, Fort Deposit, Ala.

Do You Need a Queen for that Queenless Colony?

We can furnish tested Italian queens by return mail, \$1.00 each. These queens are not cull nor inferior in any way because they are cheap. They were reared last September and October, and wintered in four-frame nuclei expressly for our early spring trade in tested queens. We expect to have untested queens ready to mail about April 10; \$1.00 for single queen; \$9.00 per dozen. We began rearing queens for sale in 1886. Our strain of three-band Italians is well known to leading beekeepers. We have never had a case of foul brood in our apiary, and we guarantee every queen sent out by us. We solicit your orders.

J. W. K. Shaw & Co., Loreauville, Louisiana

ITALIAN QUEENS THREE-BANDED

Ready April 1. Of an exceptionally vigorous and long-lived strain of bees. They are gentle, prolific, and the best of honey-gatherers. Untested, \$1.00; 3, \$2.75; 6, \$5.00; 12, \$9.00. Tested, \$1.25; 6, \$6.50; 12, \$12.50. Send for my free circular and price list, and see the natural conditions under which my queens are raised. Will book orders now.

Honey reports continued from page 2.

INDIANAPOLIS.—The demand for honey the past week has been unusually good, more especially comb. We are selling No. 1 or choice white comb at \$3.75 to \$4.00 per case; No. 2 white comb at \$3.50. Extracted of best quality is bringing 9½ to 11. We are paying 23 cts. cash or 30 in trade for good average wax delivered here.
Indianapolis, Feb. 18. WALTER S. POWDER.

CHICAGO.—During the past few days there has been more movement in honey than for some weeks past, which, of course, is usual at this time of the year; prices, however, are weak. Best grades of white comb honey are selling at about 15 cts. per lb., with the amber and off colors at from 1 to 3 cts. per lb. less; extracted white, 7 to 8, according to the kind and quality. Amber grades range at from 6 to 7. Beeswax is steady at 30.
Chicago, Feb. 16. R. A. BURNETT & Co.

DENVER.—Local demand for comb honey is light, with ample supply. We are selling in a jobbing way as follows: Fancy white, per case of 24 sections, \$3.15; No. 1 per case, \$2.93; No. 2 per case, \$2.70; white extracted, 8½ to 8¾; light amber, 8 to 8¼; amber, 7 to 8. We pay 25 cts. per lb. in cash and 27 in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, Feb. 19. F. Rauchfuss, Mgr.

ST. LOUIS.—The demand for both comb and extracted honey in this market is still very light, and stocks quite large for this time of the year. We are still quoting light amber comb honey, in 24-section cases, at \$3.25 to \$3.50. Amber from \$2.50 to \$3.00; extracted honey in 60-lb. cans, from 5 to 8½; Southern amber extracted in barrels, 5 to 5½, according to quality. Beeswax is firm at 28½ for pure; impure and inferior, less.
St. Louis, Feb. 18. R. HARTMANN PRODUCE CO.

ALBANY AND SCHENECTADY.—Lower prices have stimulated the demand for honey, and it looks now as tho the market will be well cleaned up, and no stock to carry over. In fact, there is a scarcity already of buckwheat, both in comb and extracted; this will help out on clover. We quote fancy white at 13 to 15; medium grades, 10 to 12; buckwheat, 12 to 13; extracted, light, 7 to 8; amber, 6 to 7; buckwheat, 6½ to 7.
Albany and Schenectady, Feb. 18. CHAS. MACCULLOCH.

ZANESVILLE.—There is little change to report since last quotations. For the season the demand is about normal and price about stationary. Better grades of white comb go to the retail grocery trade at \$4.00 a case with some concession on quantity orders. Best white extracted, 9 to 11, according to quantity. Twenty-eight cents cash, 30 in trade, is paid producers for beeswax, selling prices being largely arbitrary, and varying with quantity.
Zanesville, Feb. 18. E. W. PEIRCE.

Woodman's Section-fixer Gold Medal

for the finest comb honey at the recent Michigan fiftieth anniversary convention was won by Floyd Markham, of Ypsilanti, Michigan. He says:

"We have several kinds of machines for folding sections and putting in the starters, but since we got one of your Section Fixers, about two years ago, no other machines for the purpose are used in our shop. It pays to use bottom starters, and your Section Fixer is the only machine that I know of that will do the job at any rate of speed and do it right."

DO YOU KNOW that with this machine you always handle large pieces of foundation, which makes the putting in of bottom starters easy! Special circulars will tell you all about it. Price \$2.75 with lamp and one form block, shipping weight 5 pounds, postage extra.

BEE SUPPLIES Send your name for new 1916 catalog out in January.
Dept. T, CLEMONS BEE SUPPLY CO.,
128 Grand Ave., Kansas City, Mo.

Equipment purchased during the quiet winter months may be made ready for busy spring and summer months. The early-order discount pays you interest on your money.

“Root Quality” equipment means BEST QUALITY equipment. The Root bee supplies are up to the minute. The most complete line of bee supplies made.

We sell Root's Goods in Michigan. Order from Root catalog, or we will quote on request. March cash discount, 1 per cent. Beeswax wanted.

M. H. Hunt & Son, 510 N. Cedar St., Lansing, Mich.

“If Goods are Wanted Quick Send to Indianapolis”

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

Dangerous Indigestion

Indigestion, Constipation, and the more serious ills to which they lead are so common and cause so much needless pain and suffering that Dr. John Harvey Kellogg has written a book telling how to prevent and remedy such disorders. The greatest living authority on diet and digestion here gives you the results of his forty years' experience as Superintendent of the Battle Creek Sanitarium where he has studied and treated thousands of cases of indigestion and resulting ills. "Colon Hygiene" is a book of facts —not theories. Do you want to renew your energy and stamina, stop suffering from headaches and backaches, have clear eyes, a smooth, ruddy skin, feel the exhilaration of real good health tingling through your body? If so, send this coupon now for a free examination of this splendid book. Learn how easy it is to live life anew—to acquire the dominant personality that comes from good health—to become suffused with the joy of living. All this, and more, you may get from Dr. Kellogg's book of 400 pages, which the coupon will bring to you. This free examination offer is limited, so send the coupon NOW before it is withdrawn.

Send No Money—Just the Coupon

GOOD HEALTH PUBLISHING CO.

1002 Main St., Battle Creek, Mich.

Send me, all charges prepaid, "Colon Hygiene." After examination, if I remit only \$2 or return the book, I will remit the balance. (Write your name and address in the margin.)

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

BLANKE MFG. & SUPPLY CO., Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST. LOUIS, MO.

The Double-walled Massie Bee-hive

Surest Protection for Bees---Increased Supply of Honey---the Best Hive for any Climate

The Massie Hive for Comb or Extracted Honey

Furnished in the clearest of lumber, in either Cypress, White Pine, or red-wood; all brood and extracting frames are made from White Pine.

The Dovetailed Hive for Comb Honey

THE VENTILATED BOTTOM admits fresh air into the hive, lessening the chance for swarming, and gives renewed energy to the bees. It is also equipped with a feeder without extra cost. Fifty years in the bee-supply business has shown us that the MASSIE is THE VERY BEST HIVE, and testimonials to this effect are received daily from those who are using this hive.

Why not give us a trial order? Satisfaction fully guaranteed. Early Cash Order Discounts..

We are also extensive manufacturers of DOVE-TAILED HIVES and all other apiarian supplies. If you are in the market for supplies be sure to get our prices before buying elsewhere. We will mail our large illustrated catalog and SPECIAL price list to any one upon request.

KRETCHMER MFG. CO., 1000 3d St., Council Bluffs, Ia.

The Whole Country Praises The New Lewis 1916 Beeware Catalog

FROM CALIFORNIA: "Much pleased with your 1916 catalog. Other catalogs are all right for the man who knows the goods and knows just what he wants. Your cuts, description, and arrangements are so good they will give delight to the amateur or the one who wants to know in detail of new things."

FROM MARYLAND: "We are in receipt of your 1916 catalog and wish to compliment you on same."

FROM TEXAS: "Have heard quite a good many expressions from beekeepers who have received a copy of the 1916 Lewis Catalog, commenting on the beauty of this catalog and upon its improvement over any catalog they have ever seen."

FROM WISCONSIN: "Received your 1916 catalog. It is a dandy."

FROM NEW YORK STATE: "Congratulate you on its neat appearance. Each season it is a little better than the preceding one."

Send Right Now for a New Lewis Catalog

Here are Only a Few of the Distinctive Features Contained in It:

Our NEW METAL-BOUND DIVISION-BOARD in the full-depth size is to be found illustrated, described, and listed.

A very good tool in the shape of a KNIFE FOR SCRAPING AND CLEANING FILLED SECTIONS is illustrated, described, and listed.

A WOVEN WOOD-AND-WIRE CHEST, which is a low-cost article with many uses, is illustrated and described.

One page is given over to the RAUCHFUSS FOUNDATION CUTTING-BOX, a practical little outfit for the beekeeper.

Two other articles, a SECTION-HOLDER NAILING-FORM and FRAME WEDGE-DRIVER are offered.

Two whole pages of INSTRUCTIONS TO BEEKEEPERS, by C. P. Dadant, will be found interesting to the old beekeepers as well as the new.

One page devoted to the PROSPECTIVE BEEKEEPER is very interesting, and many new thoughts are presented.

EDITORIAL

WHO can send in a good photograph of an exhibit of bulk comb honey, in glass, if possible for publication in our July 1st issue? A subscriber requests information about the exhibiting of bulk comb honey.

Our Cover Picture

THE illustration on our cover for this issue shows David Running's concrete honey-house, work-shop, and cellar. The entrance to the latter is in a side hill, as shown—a most convenient arrangement. Mr. Running's description of the building, with two other illustrations and plans, appears on another page.

This Honey-house Number

IF the reader of these pages ever expects to go into beekeeping extensively enough to need a building aside from some woodshed or room in his private house, he will do well to lay this number aside and keep it for future reference. It contains nearly every feature useful in a honey-house, bee-house, or house-apiary; and at the same time it shows the arrangement of the hives in the yard with reference to the building. Wherever possible, it is advisable to put the apiary on a slight grade, and the building on the edge of a side hill. In this way the loads of honey, as Mr. Chadwick points out, will run down grade into the building. If the honey-extractor is on the side of the building that stands up on stilts, the honey can be run by gravity into a receiving-tank below. If this is elevated above the height of the wagon-box plus the height of a 60-lb. square can, one can draw his honey into the can and put it on the wagon without any lifting.

During the winter months beekeepers will do well to make their plans, if possible, to

get the building erected before the active bee season begins.

Of course, where ground is on a level, as it is in most cases, one will be compelled to use a honey-pump.

Prospects for the Next Season's Honey Crop from Clover and Basswood Good

MR. FRANK MCNAY, formerly of Mauston, Wis., but of late years of Pasadena, Cal., remarked to us last winter when we were visiting at his place that he thought he could explain why basswood and clover would yield some years and not others. Said he, "If the ground freezes wet there will be honey; but if it freezes dry there will be no honey." This winter it froze wet, and it has been staying wet in practically all the clover and basswood regions of the northern states. If Mr. McNay's rule holds true, 1916 will be a bumper year for the clovers and basswood, provided, of course, no drouth sets in in the early part of May and June. It is to be hoped that the coming summer will not be exactly the reverse of the last one.

The Advantages of House-apiaries

WE would call attention particularly to Mr. E. C. Barber's article in this issue describing his beehouse and workshop. The house-apiary side of it shows some very excellent features—features that could be adopted to advantage in a house-apiary containing many more colonies than are provided for in this.

The scheme of furnishing light and ventilation by means of swinging sash is as good as anything we have seen. When one works inside of a building the bees will sometimes fly off the combs and drop down on the floor. By tilting the sash the bees usually fly to the window and escape. The

plan of painting the entrances different colors, while not new, is good.

At the close of the article Mr. Barber gives some reasons for preferring the indoor plan of keeping bees. Every one of them is good. Except for the expense of a building of this kind we do not know but we would rather keep bees this way than by the usual plan outdoors.

.....

The Pendulum Always Swings Back

SOME years ago an analysis of the honey market revealed the fact that comb-honey prices were firmer than those of extracted. So many large producers had changed over from comb to extracted, that comb honey at certain seasons of the year was a scarce article. Noting this, GLEANINGS urged the production of more comb honey, believing that the general market would be better balanced thereby.

It now appears that the pendulum may be swinging back again toward the other extreme. At least, there seems to be quite a large amount of comb honey in many of the principal markets which is moving but slowly and at a rather low price proportionately. Comb honey, while not a perishable product, is more likely to deteriorate if kept too long. We believe the 1916 market would be better balanced if a somewhat greater proportion of extracted honey were produced.

.....

A Memorial to Joseph E. Wing, the Apostle of Alfalfa and Sweet Clover

THE following, from the *Rural New-Yorker*, will explain:

Here is something for those who knew and loved Joseph E. Wing, of Ohio. Since his death a fund has been raised by popular subscription for a memorial to this great agricultural teacher. The money is to be used to provide lectures on agriculture at one or more of the agricultural colleges each year. It is to be known as the Joseph E. Wing Memorial Fund Lecture. Men of national reputation will attend each year and discuss the things which Joe Wing stood for. It is better to have many persons each contribute small sums to such a fund, and we have no doubt some of our readers will want to help. If so, they can write direct to H. C. Price, Newark, Ohio—the chairman.

GLEANINGS most heartily joins in this, and hopes its subscribers, especially those in the West, who have profited by Mr. Wing's work in the extension of alfalfa,

thereby creating new bee territory, will contribute to this fund.

As stated by the *Rural*, it is better to have many persons each contribute a small sum than to have a large amount from a few sources. If there ever was a man in this country who helped give untold wealth to the western prairies and desert lands, Mr. Wing was that man. He did much thru his advocacy of alfalfa and sweet clover to develop the honey industry, too, in an indirect way, in that thousands of carloads of alfalfa and sweet-clover honey are now produced in localities that furnished no honey before. He was also an advocate of sweet clover; and a month or so before he died he suggested that we get after a certain experiment station that was advising the farmers to kill sweet clover everywhere, saying that it was a noxious weed; and we did go after them by telling them they must have been asleep along with Rip Van Winkle, and that it was now time for them to wake up.

.....

Under Such Circumstances Don't Kick the Barrel

FROM the *Atlanta Constitution* we learn that bees are likely to figure in a trial before the supreme court of Georgia.

It seems that "an Atlanta negro, Roscoe Richards, was standing last summer over a barrel full of watermelon rinds. The barrel was also full of bees feeding on the rinds, a fact which Roscoe didn't know. As he bent his head down into the barrel to see if there weren't something worth picking up, another negro kicked the barrel. The bees arose angrily and alighted all over Roscoe's ebony head and face.

"Roscoe turned over in the air; but when he alighted he came down like a cat on his feet, and his razor was already out and open. He is said to have attacked the other negro, and literally cut him to pieces. Richards employed lawyers; and when the case came to trial recently, he pleaded not guilty, and interposed the simple plea of 'self-defense.'"

.....

The Work that has been done by the Bureau of Entomology in the Line of Apicultural Inspection Work

IT has been our pleasure to note an editorial in the *Entomological News*, referring to work done by the Bureau of Entomology, Washington, D. C., under Dr. E. F. Phillips, and particularly to the work done by one of his assistants, Dr. James A.

Nelson. We are pleased to present a portion of what the *Entomological News* has to say.

The Embryology of the Honey Bee. By James Allen Nelson, Ph.D., Expert Bee Culture Investigations, Bureau of Entomology, U. S. Department of Agriculture. Princeton University Press, Princeton, October, 1915, 12mo. Pp. vi, 282; 95 text figs., 6 plates; \$2.00 net. The broad and comprehensive way in which the bee-culture investigations of the Bureau of Entomology have been considered and treated since Dr. Everett Franklin Phillips was placed in charge of them in 1907 is strikingly illustrated by the publications which have emanated from the investigators concerned. Snodgrass has given us the results of a careful and original re-examination of the anatomy of the honeybee; Casteel has corrected our notions of the manipulation of the wax scales and the behavior of the bee in pollen collecting; McIndoo has informed us on the olfactory sense and on the scent-producing organ; Phillips, C. A. Browne, B. N. Gates, G. F. White, and G. S. Demuth, singly or in conjunction, have dealt with various practical phases of apiculture and especially with bee diseases, while Phillips has summed up these and other researches and experiences in a recent volume in *The Rural Science Series*. Now comes the still more esoteric volume on the embryology of the honeybee. The keynote to all this work is in the first sentence of the preface contributed by Phillips to Nelson's book before us: "The good beekeeper is he who is interested not only in those things which have to do directly with the production of honey, but to whom everything pertaining to honeybees has a deep interest." The conception that "everything pertaining to honeybees" should include an extensive and intimate knowledge of structure, physiology, behavior, and embryology exhibits a breadth of view which it is a pleasure to emphasize in a journal devoted rather to pure than to applied entomology.

Butschli (1870), Kowalevski (1871), Grasi (1884), Blochmann (1889), Petrunkevitch (1901, 1903), Dickel (1903), and Nachtsheim (1913) have described various phases of the development of the egg of the honeybee; but Nelson's work is more extensive and thorough-going than any of these, altho it is devoted to the embryonic history of the workers and queens only, not of the drones.

The Massachusetts Convention and the Spraying Situation

WE wish to call especial attention to the program of the annual beekeepers' convention at the Massachusetts Agricultural College, March 14, 15, 16. A complete program of this convention is given under Convention Notices on another page of this

issue. One of the chief subjects for discussion, and one which should interest every beekeeper and fruit-grower, is the subject which will be discussed in the Beekeepers' Round Table on "Spraying Practices versus Beekeeping." The Round Table discussion on this subject is an effort to bring out various aspects of a problem confronting the beekeepers of the country as a whole. First, Dr. Burton N. Gates will present "The Beekeepers' Standpoint." Second, such evidence as has been obtained by the chemist, which bears upon the possibility of bees being killed by arsenical sprays, will be presented by Dr. E. B. Holland, chemist. Third, the horticulturist who is obliged to spray in order to control insect pests will present his side of the question, stating, doubtless, how his practices may be adapted so as not to conflict with the beekeepers' interests. He will also, possibly, explain the relationship of his spraying methods to the insects which are being combated. W. W. Chenoweth will present this phase of the situation. Fourth, the forest entomologist will explain his policy in similarly combating insects, and suggest any method which may be carried out in an effort to obviate a conflict with beekeeping interests. A. F. Burgess will consider this phase. Fifth, Fred Southard will present the side of the municipal forester, and will endeavor to determine how the different varieties of shade-trees in towns and cities may be sprayed for insect control without working harm to the beekeeping interests. Sixth, a final discussion will take place in which it is hoped that prominent beekeeping authorities will take a leading part.

It is hoped that the material which is prepared for this occasion will be reported and presented in form for publication, in order to be available for beekeepers and spray men the country over.

The Opening-up of More Bee Country by the Purchase of Territory by the United States in Northwestern Mexico

OUR readers have already been informed of the wonderful bee country known as the Imperial Valley in southern California. This country, formerly a desert, has, by irrigation, been opened up so that now it is one of the most productive of any region in the United States. It is said to have land equal to that in the Nile Valley in Egypt. But it appears that there are thousands of acres beyond the boundary line that are just as good, and which Uncle Sam is desirous of purchasing, and which Mex-

ico, in her present impoverished condition, is equally anxious to sell.

For some reason which no one is able to explain satisfactorily, except thru the agency of bad diplomacy and crooked politics, the southern boundary line of the United States takes a sharp dip upward, thereby missing some of the best soil on the continent. Had the original boundary been carried down along the line of parallel 32, the area of the Imperial Valley would have been much larger than it is. It would make available thousands and thousands of acres of land that would open up good bee locations, and which would be as good as any territory now in the United States.

Two bills are now before Congress providing for the purchase of Lower California, that large peninsula that extends southward for 800 or 900 miles, and also for the purchase of that strip which bars us from the Gulf of California.

In view of the fact that this opens up some beautiful bee country our subscribers, especially those in the West, are urged to write to their Senators and Representatives in Congress, urging them to support and vote for these two bills. According to a writer in the *Independent*, Mr. Edwin E. Slosson, "It is an exceptionally favorable time to secure these much-needed accessions to our territory now when the presidency of Mexico is held by a man who owes his position to American support, and when the Powers whose ambition such action would thwart are occupied elsewhere. . . . The money we would pay for it would be very welcome to Mexico, now impoverished by five years of anarchy."

There certainly can be no objection to the acquisition of additional territory to the United States by honorable purchase, whatever we may think of the present policy of the warring nations in Europe in the line of land-grabbing simply because they are big and powerful.

This crooked boundary line which, early in the '50's, took a sharp dip northward, goes back to some crooked history on the part of some of Uncle Sam's diplomats in the early days. During those times Daniel Webster did some things that will not go down very greatly to his credit. According to Edwin E. Slosson, already referred to, the children who are now studying United States history will come to regard Daniel Webster as the New Yorkers now regard Benedict Arnold.

It is going to cost millions and millions to undo the work of Webster and some of his colleagues.

There are additional reasons why we

should have the Gulf of California and Lower California, because it is apparent that Japan and Germany have been looking with covetous eyes on this part of the world. Mexico is too weak to protest against either of them establishing coaling-stations there; and if Uncle Sam acquires the territory it will end all possible chance of international complications over the Monroe doctrine, because it is to be presumed that neither of the nations mentioned will attempt to put foot on our territory when once acquired.

Imports of Honey; Why the Price of Domestic Honey of Lower Grade is Down and Markets Slow

THE general belief that the low prices received for southern extracted honeys of low grade have been caused by increased imports of low-grade extracted from Latin America is confirmed in Bulletin No. 325 published by the Department of Agriculture.

During the fiscal year ending June 30, 1915, the United States imported three times as much honey from foreign countries as had been imported in any previous year. The total foreign imports for the five fiscal years ending June 30, 1910 to 1914, were 104, 113, 115, 116, and 75 thousands of gallons, as compared with the 303,965 gallons imported in the fiscal year ending in 1915. The value of the imports for last year totaled \$124,843.

This change has been due to the war in Europe which closed to commerce certain of the countries which had been heavy buyers of Latin American honey. The beekeepers left without a market shipped the product to the United States.

The bulletin sums up the statistics in the following conclusions:

"Compared with the total production of the United States as reported by the census, the heavy imports for the present fiscal year, which from all sources probably total over 600,000 gallons, are therefore about 12 per cent, though probably less, if compared with the actual production. Compared with the portion of the home crop actually marketed, however, the percentage would be much larger, and its absolute bulk compared to the quantity of low-grade extracted honey produced here for market is so great that it has seriously interfered with the marketing of the latter, and, combined with the financial depression in the South, where the lower grades are largely produced and consumed, has forced the prices of such

grades to extremely low figures. The heavy inward movement of foreign honey shows no present signs of abatement and must be accepted as a probable factor for some time to come."

Before hasty proposals to raise the tariff on foreign honey are broached, it should be remembered that Porto Rico and Hawaii, insular possessions of the United States, together exported to this country during the fiscal year of 1915 more than the total imports from foreign countries combined. Consequently any tariff legislation directed against foreign honey could not affect the larger part of the imports. The imports from the island possessions have arisen so high during the last two years that, even if practically all foreign honey were shut out, it would be impossible to reduce the total imports to what they were in 1912 or 1913.

The new bulletin will be found of interest to beekeepers generally, and may be obtained from the Superintendent of Documents, Washington, D. C., at five cents a copy.

The Lament of Job, Again; What is the Matter with the Alexander Treatment for the Cure of European Foul Brood?

The following letter, received from Mr. Pressler, of Pennsylvania, will explain:

Mr. Editor:—In your editorial, page 89, entitled "Lament of Job," you wish to know if there is any one who has been able to stamp out absolutely European foul brood. Then you say, "How about it, Dr. Miller?" I believe that precludes all but the old Nestor of bee lore. What is the matter with hundreds of men like Dr. Alexander, scientific in more than one of the many branches? If Dr. Holtermann wants to know if "any one" ever succeeded, let him come right here to Williamsport. I can take him 14 miles east of here, where the first beekeepers' association was organized in this state for the purpose of checking the spread of this disease. This culminated subsequently in the formation of the state organization here in our court-house, with the writer as presiding officer. At that time every yard was infected in this county, including thousands of colonies, and now I am satisfied not a cell abounds. All were cured absolutely, and without the loss of a single dollar other than labor, and at first a few dollars for experimenting on formaldehyde gas.

Ellis E. Pressler.

Williamsport, Pa., Feb. 8.

No, Dr. Miller is not the only one who is invited to tell how we can cure European foul brood absolutely, without leaving a trace of the disease behind. If we are cor-

rectly informed, some who have tried the Alexander plan have found that the disease came back again. Others report that it worked successfully. This treatment as Mr. Alexander gave it out a few years ago, and that proved to be such a great success with him and many of his followers, was as follows:

Go to every diseased colony you have, and build it up either by giving frames of maturing brood or uniting two or more until you have them fairly strong. After this go over every one and remove the queen; then in nine days go over them again, and be sure to destroy every maturing queen-cell, or virgin if any have hatched. Then go to your breeding queen and take enough of her newly hatched larvæ to rear enough queen-cells from which to supply each one of your diseased queenless colonies with a ripe queen-cell or virgin just hatched. These are to be introduced to your diseased colonies on the twentieth day after you have removed their old queen, and not one hour sooner, for on this very point your whole success depends; for your young queen must not commence to lay until three or four days after the last of the old brood is hatched, or 27 days from the time you remove the old queen. If you are very careful about this matter of time between the last of the old brood hatching and the young queen commencing to lay, you will find the bees will clean out their breeding-combs for this young queen, so that she will fill them with as fine healthy brood as a hive ever contained. This I have seen in several hundred hives, and have never seen a cell of the disease in a hive after being treated as above described.

It is not necessary to remove any of the combs or honey from the diseased colony; neither is it necessary to disinfect any thing about the hive. Simply remove the old queen, and be sure the young queen does not commence to lay until three or four days after the old brood is all hatched. This treatment with young Italian queens is a perfect cure for black brood.

In addition to the foregoing letter we have received a large number of other communications—so many, in fact, that we are not able to give space to many of them; and what we do publish will have to be condensed. We may say, in the mean time, that one of our correspondents in Canada believes that European foul brood is one of the worst scourges that ever visited this country. He says he has had extended experience with it, and thinks the only way to get rid of it is to burn every colony—hives, bees, combs, and all. If it gets a start in the apiary he would burn the whole yard. He would favor legislation to compel every beekeeper to exterminate colonies affected with this scourge.

Another correspondent believes that, in addition to requeening, the McEvoy treatment with two shakings should be used, and the hives disinfected.

Quite a large number, including Mr. Pressler, believe that the Alexander treatment is quite effective.

We are surprised at the amount of testimony that seems to favor Dr. Miller's views as expressed in one of his *Stray Straws* in this issue—namely, that it is not necessary to destroy the combs. In the midst of the mass of this conflicting testimony the reader will have to exercise his judgment in the matter so far as the law and the inspectors will permit.

In the mean time the reader is referred to one of Dr. Miller's paragraphs on this subject in this issue that is characteristic of the man. Verily, the sage of Marengo will never grow old. If there was ever a man who is able to carry a smile into printed matter it is he.

A Safety-first Safety-valve

Two beekeepers have had trouble with their steam uncapping-knives, in that the opening in the end of the knife became clogged and the steam pressure in the boiler increased enough to burst the boiler. It is next to impossible to have any such trouble with the ordinary amount of fire used under one of these little boilers unless the opening at the point of the knife for the escape of the steam becomes clogged up. In ordinary use this opening will be kept clear; but if the knife is used to push away the cappings or slungum in the capping-melter, especially when the knife itself is cold before steam is up, some of the melted wax, or fibrous material from the cocoons, may clog the opening in the point of the knife so that the steam cannot circulate. Consequently, unless the rubber hose blows off the tube, either at the knife or at the boiler, something will surely "happen." Of course, a wooden paddle is the proper implement to use to poke away the accumulation of cappings, altho when the knife is hot and steam is issuing from the point, there is very little danger that it will get clogged up; but to be on the safe side we believe that a safety valve should be applied. If a common tea-kettle is used for a boiler—and, by the way, this makes one of the very best boilers imaginable—there is not much danger of a serious explosion, for the cap will be forced out before the steam pressure reaches a really dangerous point. As has been explained before in these columns, if a tea-

kettle is used the cap should be fitted in tightly enough to hold the steam, by means of several layers of cheese-cloth.

A large cork, at least an inch in diameter, if not pushed in too tightly, works after a fashion; but for a ten-pound pail, a gallon honey-can, or copper can made for the purpose, we recommend the following arrangement for a safety valve.

Steam honey-knife boiler, showing construction of safety valve. A, clip which holds super-spring to adjusting-screw. B, super spring. C, tin cap covering 1-inch brass tube. D, rubber packing within tin cap.

The tube for the hose should be soldered at one side of the can or boiler, as indicated in the accompanying sketch. About an inch and a half from the opening where the boiler is filled, solder an ordinary brass binding-screw from the carbon of an old dry battery. Hunt up a round tin "salve-box," the cover of which is just large enough to fit over the opening in the boiler, and cut a round piece of rubber packing that will just fit inside. If none of this is at hand, heavy cardboard will answer nearly as well. See C and D in the drawing.

Out of heavy tin make a little clip, A, and punch a hole in one end so it will just slip over the screw before mentioned. When the super spring is in position, as shown, put on the tin clip, A, and turn down the brass nut until there is some tension on the spring—just enough to keep it in position. When you use the knife, if steam leaks out under the cap turn the screw down a little more.

With this arrangement, in case anything should go wrong with the knife, the steam, when the pressure increases somewhat, will leak out under the cap. Furthermore, this sort of arrangement is far easier to open up for the purpose of adding more water. There is no hot slippery cap to unscrew, for the super spring can be pushed back away from the tin cap. It is not even necessary to change the adjustment of the screw.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

WILLIAM BEUCUS, you say, p. 117, "The black is the older race." Where do you get that? All authorities I've ever read say the other way.

"We still incline to the opinion that Mr. Ellis actually heard "quahking," page 124. Then that's the first quahking outside of a cell, and the first with tones of unequal length.

TIMBERLINE RIGGS, something seems wrong with your foundation, p. 102. You say, "In order for the disease to get a start, our bees must in some manner become weakened in vitality." "In this locality" the disease gets a start in colonies with strong vitality. And I'm a bit skeptical about its being crowded out of a weak colony—or a strong one either.

ARTHUR C. MILLER, after reading your article, p. 107, I don't wonder I didn't succeed with the smoke-d-stress method. I followed the instruction to give so many puffs, and I know they couldn't have filled with smoke the deep space below and all the supers above. You say, "When colonies are at work in supers, for gracious sake let them alone." Now you quit that. About the only time I wait to introduce a queen is when a colony is queenless, and that's mostly when supers are on. And then you don't want me to butt in. Huh!

FIVE pounds of sugar and two pounds of water make a syrup of the consistency of honey, and so I counted that 5 pounds of sugar might take the place of 7 pounds of honey. But there may well be a loss in the feeding, and it may also be that honey is the better food, so a pound of sugar may be none too much to replace a pound of honey. But, say! don't print this Straw in the copy you send J. L. Byer. I don't want that Kanuck to be chucking over my back-down.

M. JOHNSTONE'S plan for proving a plurality of laying workers in a colony, p. 78, is bright. Years ago it was proven in Europe in a different way. From a colony of laying workers many of the bees were taken and dissected, and a large proportion of them were found to contain eggs. I wish Mr. Johnstone had explained what he meant by saying "you will never forget the appearance of those discovered in the act." I suspect, however, that I know, for the only one I ever caught in the act had a striking appearance with its wings crowd-

ed up about its head in a very uncomfortable manner.

NO TROUBLE to make labels stay on tin if you have the right paste, p. 93, but not a word as to what the right kind is. Now, isn't that exasperatingly aggravating? If you know, why don't you tell? [As for the right kind of paste, it is not proper to advertise in the reading-columns. The fact is, however, you can buy a paste at almost any drugstore or stationery-house that sells paste that will fix labels to tin. There is a special paste for the purpose, however, and the same is advertised in another column.—Ed.]

AN Ohioan with nine colonies and a few neighboring colonies asks how he can rear queens from his one Italian colony and be reasonably sure of pure mating. A bit difficult. It's just as bad to have neighboring bees two blocks away as to have them in your own yard. You can encourage drones in your Italian colony and suppress drones in the others and then take your chances. Possibly you can have drones suppressed in neighboring colonies. But it isn't best to have drones and queens from the same colony.

THE new spelling in GLEANINGS is in the line of economy, and I rather like the looks of it, except "thru," which gives me a jolt every time. But if I'd always been used to "thru," spelling it "through" would give me a still worse jolt. I remember when honor, labor, etc., in place of honour, labour, etc., and aretic in place of aretick seemed just as strange as the present changes. Our spelling is by no means a fixt thing, and I wouldn't be stopt from making other improvements that should be accomplisht.

R. F. HOLTERMANN, I don't know whether I'm Eliphaz, Bildad, or Zophar; but while you're sitting among the ashes busy with your potsherd I may as well join the others, if only to "darken counsel by words without wisdom." You fear European foul brood cannot be stamped out. Well, you never entirely stamped out the weeds in your garden; yet I venture to say you've done good gardening. And you can raise good crops of honey while fighting European foul brood. When I first met it I looked forward to it with horror. As I look back upon it there's nothing very bad except the foolish loss of a lot of good combs that you can avoid. Cheer up, brother; things are not so worse as they might be.

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

I am glad to note Mr. Crane's success with kerosene to keep off robbers. We have used carbolic acid, but should prefer kerosene.

That cabinet for Hoffman frames, page 122, Feb. 1, is a delight to look at, and probably more than that to possess. When we were feeding last fall, we realized that we needed some convenient contrivance for holding the frames that were removed from the supers for feeding. This looks admirably suited to the purpose, at least for a small apiary. In large yards, if much feeding were done in supers the surplus frames of comb must require careful handling. There are other times, too, when the bees are not occupying all the frames, and combs are awkwardly fragile things to stack up carelessly. Mr. Doolittle's overhead plan would take care of a generous surplus.

Don't we have good-looking covers? I cannot resist saying how I appreciate them and enjoy them. The Florida view on the cover of January 1 is exceedingly interesting, with the white hives under the drapery of picturesque Spanish moss, and then the little lake beyond. If ever I get to Florida again I shall certainly go looking up some apiaries, just as, if ever I get across the water, I shall go hunting out some of those rare and wondrous honeys described so fascinatingly on page 995. Dec. 1, and shall never be quite content till I have tasted the honey of Narbonne and that of Bourbon.

I feel like raising my voice in profound gratitude when I read any protest against division-boards. They are the one thing I despise, and the effort to pull them out is dangerous to my disposition. "I don't see a bit of sense in them—not a bit," I have declared over and over again to Mr. Allen, yet I might never have dared speak right out in meeting, as I supposed everybody else must be devoted to them and utterly dependent upon them. But now I am pleased to add my word. Somebody had persuaded us, when I once threatened never to use one again, that they were necessary to the building of straight combs, so for a while we slavishly used them when there was a lot of foundation to be drawn; but when the live or super once got filled with combs, out with a swish came my pet aversion. They are all right and convenient when you're making a nucleus or contracting a colony, but in a full hive—no, thank you.

Aren't all those articles about this new bee disease creepy? Whether we like the thought or not, war does not seem to be confined to the human race alone. Nature stages a perpetual war. Germs, insects,

plants, and animals are at war against one another. See what the bees alone have to fight. Even with the help of man's intelligence it is a hard battle against moths and spiders, ants, and birds, even robber bees, and, worst of all, against the diseases, germ or otherwise, that sometimes wipe them out by the thousands and hundred thousands.

MARCH

This mad young March! with the sting
of his laughter
Flung back like a dare as he roars
thru the days,
While troops of wild winds, reeling
recklessly after,
Dance round with delight at his riotous ways!

Who cares what rough unrest he brings?
He's doing things! He's doing things!

He lashes the trees till their sap is
atingle,
He teases the grasses and bullies the
birds,
He rowdies around with the shutter and
shingle,
And shouts without rhythm unmusical words!

Who cares what savage song he sings?
He's waking things! He's waking things!

The hives by the fence as with gossip
are humming—

"We know him, the rogue!" Aye,
they know him, those bees!
And swift thru his winds they are going
and coming
To plunge in the pollen of feathery
trees.

They chide no mood whose courage
flings

The bonds from waking hearts of things.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

During January bees did not get much chance to fly, and the temperature ranged around zero for a longer time than is common here in Colorado. Bees, however, seem to be wintering well, as none but weak colonies have died so far. The quality of winter stores seems to be good on the whole, despite the late nectar secured from the sweet-clover bloom. There is abundant snow in the hills, and the ground is in good condition. Alfalfa and sweet clover are up to normal if not above. Comb honey will be all gone before the new crop comes on, and there will be very little extracted left when new honey is extracted.

BEEEMEN AS HONEY-TRADE BUILDERS.

Colorado beekeepers are certainly not far behind others in the pushing of honey sales. The extracted-honey crop of Colorado was very poor, and, to hold their customers, I know of half a dozen beekeepers who have purchased in the aggregate twelve cars of California, Nevada, and Arizona honey to supply the trade they have built up. Probably more than fifteen cars of extracted honey produced west of Colorado will be distributed by Colorado beekeepers and Colorado associations. The price paid ranges from five to six and a half cents delivered in Colorado, and is sold at seven and a half to nine cents in a wholesale way.

EXPERIMENT-STATION BULLETINS.

The Colorado Experiment Station has just published Bulletin No. 211, "Colorado Plants Injurious to Livestock," by George H. Glower and W. W. Robbins. This is a most valuable paper to the livestock industry, and is well worth reading by beekeepers who wish to learn the relation of plants and flowers injurious to animals, that are of economic value to the honey industry.

Probably ninety-nine per cent of the losses to livestock come from larkspur poisoning; but the white larkspur growing on the plains east of the mountains has never caused any losses to livestock, so far as known. The larkspur growing in the foothills causes most of the trouble. Both furnish nectar for bees.

The wild cherry, of so much value to the beekeeper who lives near the foothills, is very dangerous to cattle if they eat the wilted leaves.

The lupines, milkweed, and the famous locoweed, are some of the other honey-plants that are the bane of the cattleman. The beekeeper who knows the various poi-

sonous plants will be better informed, and of more practical value to his neighbor, if he has a thoro knowledge of the poisonous plants of his district. He should know that larkspur comes on in June, lupines and loco at about the same time, and that larkspur poisons generally in June and July, while lupines do most of their damage late in the season, when cattle and sheep eat the pods.

THE BEEKEEPER'S SHOP.

One of my first recollections as a boy is the establishment my uncle Oliver Foster had for carrying on his beekeeping operations. He had four separate buildings surrounding his home apiary. On the east side was the warehouse for bee-supplies, which he handled in ear lots. Under this building was the bee-cellar. Next to this building, on the southeast of the apiary, was the wood-working shop where he manufactured some of his own inventions such as the Foster super. There he had his sawtables, engine, and lumber storage. On the west side of the apiary was the wax-house and vinegar-shed combined. This was handily near the pump, as every beekeeper readily will realize the advantage of having water close by when working wax. On the north side of the apiary was the extracting-house, comb storage, and everything was handled methodically; and there was a place for everything under cover. I do not recall ever seeing any empty hives piled outside. A house was built at each outyard so that all equipment could be kept dry.

The extracting-house necessarily had the most thought put upon its arrangement, as here was where the rush work of the season was done. The building was mouse-proof. The uncapping-can was placed at one end of a table upon which the honey was piled as brought in. Filling of the cans from the strainer-covered vats was done at one side of the extractor, and slightly below it, as honey-pumps were not used. All the work in the honey-house could move forward in a regular procession, no one getting in the way of others. As a boy I often got in the way in my desire to eat the honey-wet cappings, and I don't know of any chewing more delicious—do you? As fast as the cappings were drained comparatively free of honey they were taken to the wax and vinegar house, where they were washed, the honey water going to make vinegar, and the wax into the rendering-vat. This house also was the foundation factory where thousands of sheets of foundation were made.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

One of the most unfair resolutions ever offered and passed by any organization was passed by the State Association. An exhibit was ordered, after which a resolution was offered disclaiming any responsibility by the association for the expense entailed. In other words, the association gave full sanction for an exhibit to be placed, for which it was to have the credit and somebody else pay the expense.

While visiting a friend recently, my attention was called to a colony of bees of exceptionally high honey-gathering qualities. My friend said he could tell that queen's daughters from any others in the yard of over two hundred colonies. I asked him what particular characteristics they possessed that they were so easily recognized. He answered that it was principally by the way their bees stung. They were Syrians.

In the *American Bee Journal* for December, page 412, Mr. Byer takes issue with Dr. Phillips on the matter of over-production. To my way of thinking, Mr. Byer has the best of the argument. The fact that it is necessary to resort to all kinds of ways to dispose of a season's output is conclusive evidence of over-production. Under-consumption, to be sure, may be explained as the reason for over-production; but until consumption is increased to a point where it absorbs the production, over-production will remain a fact.

In starting an experiment station for bees on an island in San Francisco Bay, the State University has taken the lead in disease control by scientific search. Why not give the entire foul-brood work over to men who are educated, and equipped to handle the situation? When our last foul-brood bill was up for sanction by the State Association I was told that the inspectorship must be in the hands of the beekeepers. What we need as an inspector at the head of this department is an educated man, one who can give a scientific analysis of any disease which may be found.

From the *Wide World Magazine* I have clipped an article that tells something of

migratory beekeeping in the Holy Land. After reciting the unique position of Palestine geographically in that the flora of three nations meet there, it tells how two brothers followed the flora, camping first in the low altitude, after which they transported their hives on camel back to a higher elevation, thus following the consecutive blooming period of different flowers. By using modern extracting machinery they were able to secure six tons of honey from one hundred colonies in a year. But the most striking assertion in the entire article was that this yield exceeded the yields on the great honey-farms of America and Australia threefold. The assertion that this yield is three times as great as on the big honey farms of America and Australia places some doubt as to the knowledge of the writer on the entire article.

Dr. A. F. Bonney, in the *American Bee Journal* for October, page 243, says: "I made several ventures into the domain of advertising to sell honey by mail, and find one serious handicap—the breaking of containers by careless mail-clerks and others who handle the sacks. These men, or many of them, seem to have an inherent hatred for parcel-post packages that are at all heavy, and a fragile tag is little or no protection." Dr. Bonney may know the honey business; but the assertions he is making in regard to postal employes is not placing them in the proper light, and leaves me to conclude that Dr. Bonney knows very little about true conditions in the postal service. Ten years of my life have been spent in the railway and city delivery service of Uncle Sam, and I wish to say that in nine cases out of ten it is with the packing rather than the men who handle the packages. The fragile tags are respected by postal employes, but they will not cover the faults of the one doing the packing. When a fragile parcel goes into a sack a fragile tag is attached to the sack outside. These sacks are handled as carefully as is possible with the volume of other parcels that are daily going thru the mails. If honey is packed properly it will be delivered in good condition; but do not expect to send comb honey thru the mails without proper shock-absorbers, corrugated paperboard, or something of that nature. Comb honey requires more careful packing than eggs.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Mention is made in the January 1st issue that it has been rather cold in Florida. My father is "wintering" on the east coast, about 100 miles south of Jacksonville, and he writes me that during all January there were only three days when he wore a coat, and there had been no frost whatever. Incidentally he says in one letter, "This place looks like a paradise to me"—some boost for Florida, eh?

The cold weather predicted in my Notes for January 1 has failed to arrive. At this date, Feb. 5, we have had little severe weather and almost no snow. We have had abundance of rain and much mild weather all thru January, but not nearly as warm as friends in Ohio have written me about, when the thermometer went up to over 60 degrees. The highest noted here was 47 on two different days, and unfortunately both of those days were very cloudy; so after having a very mild January our bees did not have a thoro flight. No doubt in some sections of Ontario if the sun shone on those two very mild days the bees had a fine flight. Even at the north yard, where snowfall is usually heavy, there has been but little there this season.

On page 75, Jan. 15, request is made from purchasers of queens that they report percentage of pure matings in untested queens bought. We have bought a lot of queens, and only the untested brand; and while I have kept no memorandum as to actual results as to pure matings I must in all sincerity say that in the great majority of my dealings we have been thoroly satisfied. More than that, I firmly believe that some of the most honorable men in the beekeeping business are engaged in rearing queens, and our treatment in nearly all cases has been all that could be desired. Punctuality in answering business letters is a splendid feature in any business; but with the queen-breeder it is an actual necessity, and with few exceptions I have had no cause to complain in that line. Any queens that have not made good have always been replaced at once. With these few exceptions, and in some cases, knowing the generosity of the breeder, I have hesitated to report any mismatings, etc., feeling that I had no real cause to complain, and

knowing that, if I did, queens would come at once to replace any that were not what they should be. In one instance, in common with others, we were much disappointed with the methods of doing business and the poor trashy stock of a certain breeder of Carniolans, so called. Failure to answer letters, etc., is bad enough itself; but when stock is worthless in the bargain, that is a combination none too pleasing to the man who spends good money for queens.

HONEY PUBLICITY.

At the Syracuse convention held a few weeks ago, much of the time was taken up in discussing various plans of advertising honey. A writing-tablet that has been used by New York beekeepers for a number of years was on exhibition, and to the writer this appears to be a good thing. This writing-tablet, as many know, is like the ordinary tablets used for school and other work; but in addition it has a lot of printed literature on both sides of the front cover, telling of the products of the bee. One of the chief difficulties in circulating this tablet, as nearly as I could judge by the discussion, was the matter of getting stationary dealers and others to handle it. It occurred to me that perhaps some of the dealers in beekeepers' supplies could handle this in the regular way with other goods; for with but little alteration the tablet could be used in any place, and I feel sure that our New York friend would not be at all jealous. The changes I have in view are the following extracts which would have to be cut out in order to make the tablet acceptable to all parts of the country.

"Scotland and Ireland produce a superior grade of honey in the Eastern hemisphere, and New York and New England in the Western."

None of us would dispute those claims; but there are other localities producing "superior grades" too. What is there to hinder some wholesale plan being originated to get a tablet like this before the public? It is a plan of advertising that could be carried on at cost; and as these tablets are constantly before children and old people as well, would not the plan be a good paying proposition? This is a live subject, and personally I should be pleased to hear the views of others better qualified to speak on a matter of this kind than I am.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

THE HONEYBEE AND HONEY.

"Is the honeybee a native of North America?"

The honeybee is not a native of either of the Americas if I am correct. I am told a colony was landed in Boston, Mass., in the year 1670, and that they were brought there for a twofold purpose. The prime object was to secure their delicious and health-giving product which is so thoroly enjoyed by nearly every one; and, second, the great and almost universal benefits coming to all localities where they are kept, on account of their unpremeditated work in the fertilization of all blossoms in which nectar is secreted."

"Do you mean to say that the honeybee is a necessity toward the perfection of fruit from all blossoms?"

I do not wish to be understood as saying from *all blossoms*; but, according to close observation for the past 45 years, *all blossoms which secrete nectar* need the honeybee or some other winged insect for their perfect pollination. I am well aware that Darwin, the great naturalist, had nothing to say about nectar secretion in flowers when he said, "The more bees the more flowers; the more flowers the more seeds; the more seeds the more flowers; the more flowers the more bees." This shows that, even tho he may have observed closely, he did not think it as important to mention that there are more of the seed-producing plants which do not need the aid of the bees or any other insects, than there are of those which do—that it is only those which do need the aid of the bees that the bees visit, and that the reason why the bees do so visit is because they are invited thru the bountiful supply of nectar secreted by such needy flowers. This is true of fruit as well as of seeds.

Take the wheat from which our bread is made. Did you ever see a bee at work on its bloom? The reason for this is that it is self-pollinating, therefore no nectar is secreted; and no nectar, no bees. On the other hand, take buckwheat. The bees hover over it till their merry hum is music to the apiarist's ears. Why? Because nectar is secreted. Neither a rustling breeze nor a hurricane could pollinate the blossoms. Among forest trees, the basswood with its thousands of inverted or hanging-down flowers calls for the bees to turn themselves upside down to pollinate them; hence nectar is secreted. On the other

hand, the beech-tree bloom is pollinated with the slightest breeze thru its foliage.

What is applicable to the buckwheat and basswood applies to nearly all of the fruit-trees. Hence we find the apple, pear, cherry, plum, and peach, all secreting nectar when the weather is favorable. In certain places years ago, bees were banished, owing to a belief that in gathering nectar the embryo seed or fruit was deprived of something needful for its full perfection. Later it was found that a lessened or poorer crop resulted, so the bees were invited back again.

"But what about the honey part?"

We are told, and truthfully, I think, that honey is the most wholesome and easily absorbed food known to man. Owing to the peculiar conditions and environments of honey-bees during their period of winter confinement in the hive, their surplus honey, stored by them for the purpose of carrying them thru the winter period, is something entirely different from any other substance. It is already prepared by the bees before it is placed in the cells. When we eat honey we have only to assimilate its varied life-giving elements. This is the only food of which it can be truthfully said that some other animal has specially prepared it for our assimilation, thus precluding the necessity of that labor on man's part.

"That is something entirely new to me. I had looked on honey as the sweetest of all sweets, and so proclaimed when I was offering for sale my extracted product."

We were told nearly half a century ago that honey is not as sweet as cane sugar, altho the different acids it contains gives the impression to the sense of taste that it is sweeter. This accounts for the fact that for hundreds of years honey has been termed "the sweetest of all sweets;" and the question asked, "What is sweeter than honey in the honeycomb?" Here we have the pleasure of the sensation produced by sweetness without the danger of retarding the action of our digestion when honey is eaten in large quantities, as is the case with most of the candy and sugars.

Some object to eating comb honey from the fact that the wax comb is entirely indigestible. But because it is wholly indigestible the stomach makes no effort whatever to digest it. The particles chewed fine are an aid to digestion. Comb honey is the most wholesome, not only of any sweet, but of any food known to humanity.

GENERAL CORRESPONDENCE

AN UNCAPPING-ROOM ARRANGED ON THE GRAVITY PLAN

BY P. C. CHADWICK

I have long thought of giving a plan of my honey-house and extracting-outfit arrangement. This issue furnishes me the opportunity.

I am making no claim that I have an arrangement superior to all others; but I am sure I have one which is far superior to many others. So I give my plans with the idea that they may be of assistance to some, and am looking forward to the possibility of gaining something from the ideas of others.

Gravity plays a prominent part in all the work of getting the honey from the hive

such a manner that when the wheelbarrow strikes the door the weight begins to rise, and allows the door to swing open. As soon as the door is cleared the weight pulls the door shut. The honey is now on the wheelbarrow in the extracting-room ready for work. Usually three supers of eight frames each are wheeled in at a time—two in front and one behind. The frames are taken from the back super, uncapped and extracted, and returned to the wheelbarrow without removing the super. The top super is then extracted in the same manner and set back on the first super extracted, to make way to

P. C. Chadwick's apiary, showing how the ground slopes down toward the honey-house, and then falls away abruptly behind the building—an ideal arrangement, considering general convenience.

until it reaches the can. Let me first say that my yard is located so that nearly every hive is on higher ground than the honey-house, making the work of wheeling the honey a comparatively easy task. The floor of the honey-house is on a level with the ground at the entrance door, but at no other point. The ground slopes rapidly under the house, to the rear, where the fall has reached a point that will allow the honey-tank to go under the rear of the building as shown in the cut. The honey is wheeled direct on to the floor of the honey-house, the door being connected by a weight and pulley in

the last super of the load. In this manner the entire load is disposed of without lifting a single filled super. If more than one person is engaged in the extracting operations, two wheelbarrows may be used to keep a continual line of supers arriving and departing.

The interior view shown gives an idea of the arrangement of the extracting equipment. The extractor needs no explanation. No. 3 is the uncapping-box, which, as may be seen, has a V-shaped bottom, the draining-screen fitting down into the box to the beginning of the V shape as shown by the

Interior of P. C. Chadwick's extracting-room. The capping-lox, 3, has a V-shaped bottom, and is fitted with a screen as indicated by the line 4. The extractor and capping-box both drain into the strainer, 1, 2, from which the honey runs by gravity into the tank below.

dark line and Fig. 4. Board No. 5 fits across the uncapping-box at No. 6, where the notch may be seen for the further end, a like notch being on the near side. This board has in the center a cone-shaped hole, dug out with a gouge chisel to allow the end of a frame a support where it will not slip when uncapping, and also allow the frame to be reversed by simply turning it in the cone. In this way the frame may be reversed by a simple turn of the fingers of the supporting hand without even laying the knife down.

The stove may be plainly seen, No. 9 being the knife-pan with knives ready for use. The knives are in easy reach at all times, and may be exchanged quickly, and often enough to keep the caps coming off rapidly, and with little loss of time. When a frame is uncapped it is set into the extractor, and another taken from the wheelbarrow on the return to the un-

capping-box. The wheelbarrow is supposed to stand close at hand. No. 7 is a rack to hold extra frames uncapped ahead of the extractor when help is being used to turn the extractor during a rush.

No. 8 is a water-pan filled with clean water to remove any honey from the hands or knives that may chance to be encountered. This pan I consider a very essential part of the equipment to insure cleanliness.

Rear view of Chadwick's extracting-house showing the large tank, and place for filling cans under the tank.

Nos. 1 and 2 are the strainer. On the bottom of frame No. 1 is nailed a galvanized screen wire of the finest mesh obtainable in common screening stock. This sets in frame No. 2, resting on a rabbeted edge, which leaves the wire two inches above the bottom of the frame. Frame No. 2 is covered with a heavy piece of tin into which is made a spout forming a large funnel which fits into the pipe leading to the tank below down thru the floor.

The tank may be seen in another picture.

A pair of scales stands under the gate of the tank at a level which will support a sixty-pound can at the right height. The honey is drawn into the can until the beam goes up which is a sign there is a little more than sixty pounds of honey in the can. Now comes the first heavy lifting of the entire operation, as the can must be lifted into its case to be labeled 60 pounds net, and with its partner nailed up ready for the journey to the warehouse.

Redlands, Cal.

ADVANTAGES OF THE CENTRAL EXTRACTING-PLANT

A First-class Carrying-rack for an Automobile

BY W. H. CRAWFORD

By our plan honey from all the outyards is extracted at home, which reduces labor and expense to a minimum, and at the same time allows the beekeeper to be at home most of the time during the harvest. The honey-house is large, and equipped with an eight-frame power extractor, and 1½ H.P. engine, uncapping-can, two large honey-tanks, etc.

The honey is produced in full-depth eight-frame supers above queen-excluders, with seven combs spaced so as to fill all the space without using division-boards. Fifty extra supers are provided and filled with combs or full sheets of foundation before extracting begins. When the honey is ready to extract, as many supers filled with combs as will be needed to make a day's work are loaded on the auto and carried to the outyard. The hives that are ready to extract are located, and one super full of empty combs is placed near each hive so located. The combs in the empty supers are spaced, and an escape-board is put on top of each one of them. One man with a hive-tool pries loose and lifts up the super full of honey, when another man quickly places the empty super in its place and puts an escape-board on the empty super. The first man then sets the full super on top. The quilt and cover are adjusted so as to make the full super absolutely bee-proof so that robbers cannot get into it; for often they make mischief as soon as the bees desert it, if allowed to do so. Now we have a super full of empty combs between the full combs above and the brood-chamber below, so that the bees are escaped into the second story containing the empty combs, instead of into the brood-chamber. Hence not a moment of time is lost to the bees in storing honey in the super, which fact is very important.

The full supers are allowed to remain on the hives over night, giving time for the bees to desert them. Each day in going for the supers of honey, now ready to be carried to the honey-house, other empty supers of combs are carried along, and placed on other hives that are found ready to be extracted in the same manner as already described. Next the full supers now ready to be loaded are loaded on to the auto and taken to the honey-house at home. During this whole time, not a comb was taken out of a super nor a bee brushed off a comb.

The honey is extracted the same day that it is taken from the bees while it is yet warm; for if allowed to remain over a night after being taken off the hives it is twice as hard to uncap and extract.

By this method we have the same amount of empty combs and supers on hand all thru the season to be used as described above, and they certainly do yield as large profits as anything used in the production of extracted honey.

We work each yard once a week, picking out such hives as are ready to extract and passing over such as are not ready, for another week. Only one super at a time is given each colony; therefore it means the loss of quite a bit of honey to allow the full combs of ripe honey to remain on the hives after being finished.

For hauling the honey we use a platform on the automobile 5½ feet wide and 5½ feet long, made of boards 1 x 12 inches by 5½ feet long, cleated together with strips 2 x 2 inches by 5½ feet long, put together so as to make a solid floor. Three sides of it are provided with five rods ½ inch by 3 feet long to each side, both ends of them threaded and provided with nuts; also both ends of each rod are bent to a

right angle. One end of the rods passes thru holes made in the cleats on the sides of the frame and are fastened with the nuts in a way to allow the rods to turn around. Three flat bars of iron $\frac{1}{2}$ inch thick by $1\frac{1}{2}$ inches wide by $5\frac{1}{2}$ feet long with five $\frac{1}{2}$ -inch holes in each of them are provided, and the other ends of the rods are fastened in them in a way so as to let them turn in them as the other ends turn in the cleats on the edges of the frame. These rods and bars make the sides of the frame and are fastened together at the top of each corner with a latch.

The rear seat of the automobile is taken off, and a small bed $3\frac{1}{3} \times 5$ feet by 9 inches deep is made to fit on the car, reaching up flush with the top of the fenders of the rear wheels.

The frame described above fits snugly on

top of the bed and the fenders of the machine, reaching two inches over the sides of the fenders.

While loading and unloading all three sides of the frame can be let down entirely out of the way by unlatching the corners and allowing the rods to turn half around like a crank, so that the sides of the frame are swinging straight down, entirely out of the way in every respect, leaving a nice smooth floor with not a single thing in the way in loading. Then, like turning a crank half around, the sides of the frame are elevated and fastened at the top corners and not a super can get away while being hauled to or from the outyards. This frame holds twelve eight-frame supers to the tier. We have hauled twenty full supers to the load and fifty supers of empty combs to the load.

Roswell, N. M.

CONCRETE WORK - SHOP, HONEY-HOUSE, AND BEE-CELLAR

337 Colonies Wintering Indoors

BY DAVID RUNNING

My building is 16 x 40 ft., outside measure, with a bee-cellar underneath, the ceiling of which is 2 feet below the surface of the ground. The entrance to the cellar is in a side hill. The honey-house and shop are on the main floor, and the second floor is a

large storage room. The bridge shown [cover picture—ED.] drops down for loading and unloading honey or supplies. Notice the pump between the doors. We have plenty of water always at hand—a big help in keeping things clean.

David Running's 16 x 40-foot concrete building. The end view of this building and the entrance to the bee-cellar are shown on our cover.

The material in this building, including lumber and cement, cost only \$206.75.

The building is 18 ft. high to eaves from cellar floor, and 25 ft. to peak. The chimney is 29 ft. high, with 9 x 13-inch flue opening at the cellar floor. I built this building myself, so I cannot give you the cost of labor, as it was done at odd times when I was not busy at beework. The total cost of material was \$206.75, as follows:

Lumber and shingles.....	\$103.38
Cement	64.81
Nails	3.92
Gravel	4.95
Bolts	2.26
Locks and hinges.....	1.60
Hooks16
Cedar sticks for overlays.....	4.75
Sash, windows.....	9.08
Brick	7.40
Tile	4.50
Total.....	\$206.75

The walls are *six inches thick*. Concrete was made by mixing one part of cement to six parts of gravel. As many stones were put into the forms as possible without having the stones touch each other or come closer than 1/2 inch to the surface of the wall. This accounts for the small amount of cement used.

The door and window frames in the cellar were made of 2 x 6 oak plank, and hemlock was used for those above the ground.

The cellar ceiling joists were put in 6 1/2 ft. from the floor, and covered with cheap lumber, one foot of dry sawdust placed on top, then an air space of about one foot, then another set of joists covered with matched flooring. The shop ceiling is 7 1/2 ft. from the main floor with matched flooring above. The hip roof gives a large roomy upstairs for storeroom. The ceiling

over the vegetable-cellar in the front part is single floor without sawdust covering. This gives us a 9-ft. ceiling in the extracting-room above.

The temperature in the bee-cellar (when bees are in) remains between 45 and 49 degrees F. The outer vegetable-cellar stays about 6 degrees colder with the middle doors open as shown in the plan.

The bees are placed in the cellar in long tiers and piled five colonies high with 2 x 6-inch plank on edge underneath. There is just room for a small man to get around between the tiers, so all colonies can be inspected at any time except two piles (ten hives), behind the chimney. We have 312 colonies in the back or bee-cellar now, and 25 chaff hives in the front cellar (see drawing). The cellar is the best place for colonies in the regular chaff hives in this northern locality. We do not expect to lose a

single colony of bees this present winter. Before putting the hives in the cellar all entrances are enlarged to 1¼ inches by the width of the hive by inserting two wedges between the sides of the hive and the bottom-board. The cellar is always so dry that we can light a match (the eight-day kind) on the floor or walls at any time. We have wintered colonies (nuclei) in this cellar when the bees filled only the space between two combs. When putting bees in, also when taking them out, the cellar is kept full of smoke; but no smoke is used on the individual colonies. This is our twelfth winter for using this cellar; and since we learned how to prepare our bees for winter (about nine years ago) our winter loss has been less than one per cent. All covers are left sealed on in the cellar, and are *not loosened before fruit bloom in spring.*

Filion, Mich.

A COMFORTABLE WORK-TENT

BY G. FRANK PEASE

The tent shown in the illustration is my living-tent, containing four rooms and a screened-in gallery. The floors and side walls are of wood, having two windows for every room, that swing in, and screens for each. This tent is one of seven, and is as comfortable as a wooden house.

The automobile, a Studebaker, has been

driven nearly 5000 miles in eight months, with less than ten dollars for repair bill. It has carried heavy loads nearly half the distance. I have drawn about 400 colonies of bees, a carload of bee supplies, lumber, wire fence, hogs, goats, and even a horse, besides hauling all my supers and honey from yard to yard. It will hold 36 colonies

G. Frank Pease's work-tent, auto truck, and solar extractors at his Louisiana location.

at one load, and is indispensable for handling the twelve apiaries scattered in a thirty-mile circle.

I find that it is cheaper to bring all honey to the home central yard to extract than to move extractors, etc., from yard to yard, because the honey has to be hauled to market anyhow, and it is just as well to

carry back empty supers as to go empty; besides, it saves building extracting-houses at all yards.

The solar extractors shown are home-made, and melt cappings in a short time, and the wax is hot enough to run into cakes.

Michigan.

WHY I PREFER THE HOUSE-APIARY

BY E. C. BARBER

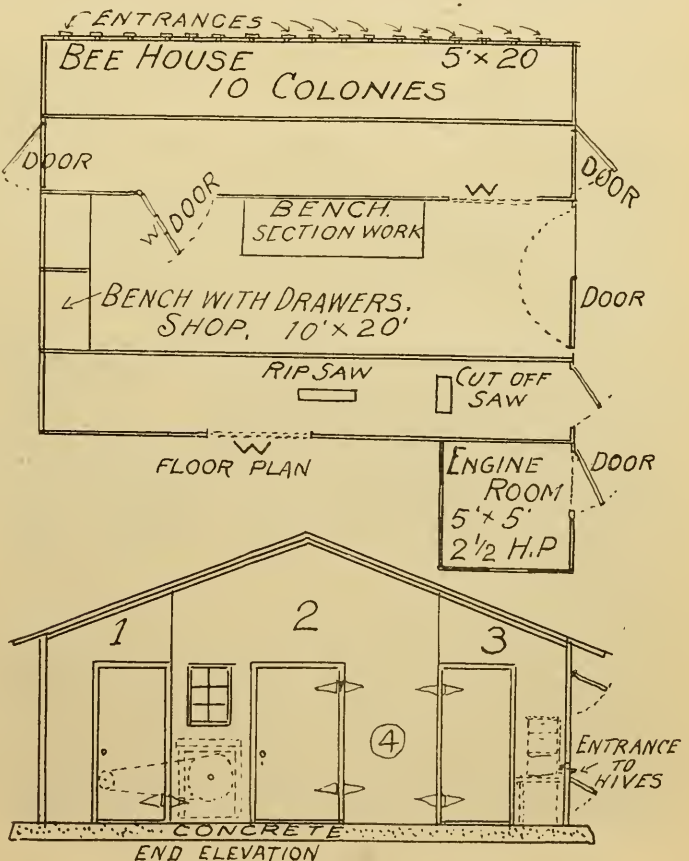

The drawings show the front and floor views of my shop, honey-house, engine-room, and house-apiary. No. 2 in the sketch shows the shop, which is 10 x 20 ft., and has a concrete floor. No. 1 shows the engine-room, 5 x 5 feet, which has a 2½-horse-power engine.

The work-bench is clearly shown. This is three feet wide, and runs the length of the shop. In this bench there is a cross-timber, half way from the floor to the top of the bench, where my shafting hangers are bolted. The belt from the gas-engine runs thru two small holes thru the side of the building into the shop. There are two circular saws, one a cutoff, and one a rip saw.

The other bench I use for section work only. There is also a bench at the end containing eight drawers, where I keep foundation, sections, etc. The shop has four windows and two doors, one of which leads from the shop into the house-apiary.

The house-apiary is an addition built on to the south side of the shop. This building is 5 ft. wide, 20 long, and 7 high at eaves, 9 ft. at the side of the shop, containing a hive-bench 20 inches high and 24 inches wide. On top of this bench there are two sheets of galvanized iron 10 ft. long and 24 inches wide, on which my hive-bottom boards

rest. I use the wide space of the bottom-board the year round. The front ends of these boards are placed tight against the side of the apiary-house. The opening thru the building is cut the full size of the entrance of the bottom-board. I place the hive on the bottom-board, which leaves two inches of the front of the bottom-board, which I cover with a piece of wood 2 inches wide and as long as the hive is wide. The hives are placed between 7 and 8 inches apart. The entrances on the outside have a two-inch frame all around them. These

Addition built on the south side of E. C. Barber's shop, 20 feet long and 5 feet wide. It is covered with two-ply paper, granite finish. Cost for material and labor, \$22.50. Ten colonies are being wintered inside this building, temperature 45 to 50 F. In hot weather the side can be opened to give plenty of ventilation. There is also a door in each end.

are painted different colors—red, white, and green, alternately.

Just under these entrances is an alighting-board 12 inches wide and the length of the building. This is set at an angle of 45 degrees with the side of the building. This alighting-board was placed after the photos were taken.

There are two long windows and three doors. These swing out at any angle desired, to admit air circulating in extremely

hot weather. They also give light when working with the bees. The bottoms of these windows are placed 24 inches above the entrances and alighting-board, which is about the same height as the hive with two supers on. These windows can be opened and closed from the inside of the house. There is also a door at each end. These can be opened for ventilation in very hot weather. A hinged door, 20 inches wide, is fastened on to the back of the hive-stand.

The door swings up back of the hive-stand, and is used for the purpose of holding planer-shavings in packing bees for the winter, giving a space of 2 inches in front of the hives, and about three inches in back, and seven inches between each two hives.

In the spring this door is unhooked and swung down so that the edge comes even with the floor, and the shavings on the galvanized iron can be removed very easily. The interiors of these buildings are painted with two coats of

Close view of Barber's house-apiary, with ventilators open.

white paint, and the exteriors are covered with two-ply granite-finish roofing-paper. The frames are 2 by 4, covered with hemlock boards planed on the inside so that they can be painted easily.

I prefer the house apiary instead of the outside yard for several reasons. First, you can work at your bees and not be among those flying in the air, especially if the windows in the house are closed. What few bees fly from any hive you are working on inside of the house, instead of trying to frighten or sting you will fly to the window to get out. Second, you do not have to carry the hives in and out of the cellar in the spring and fall, or move them to their winter quarters. Third, your bees are always protected from the snow, rain, and winds. Fourth, they are at leisure for a flight in the winter any time when it is warm enough, such as the past few days have

Bees wintering in a house apiary.

been, when the thermometer was around 70. Fifth, in this house-apiary I can see a big difference in spring brood-rearing; also protection during cold nights, when bees are working in sections during the summer.

I cannot see that my bees make mistakes in finding the entrance to their own home. I think it is due to the different colors

E. C. Barber's apiary out of doors.

Class in beekeeping at the Ontario Agricultural College, Guelph, Ontario.

with which I have painted my entrances. I can feed my bees in early spring or late fall and not have any robbing going on, because I feed inside the house with an empty super on top of the hive, with five-pound honey-cans with covers perforated. I do not have as much robbing and trouble with the bees in the house as I do with those that are in the yard apiary. The bees which are in the house seem to be much further advanced at the beginning of the honey-flow than those in the yards, especially in bees and brood.

I get more honey from bees in the house than I do from those in the yard. I think it is due to the protection of the house in cold nights. I have found at midnight that the bees outdoors which were working in

sections during the day were not building comb in the sections, due to the nights being too cold, while those in the house were as busy as any bees could be.

I intend to build another house, which will be 40 by 7 ft., with one side to the east and one to the west, with two rows of hives the whole length, one on each side. This house will hold 40 colonies. I shall not change the plans of the hive-stand, windows, and entrances, because I like this design very much.

The expense of a structure like this will not be as much in the long run as hives, winter cases, shavings, building-paper, packing-quilts, or double-walled hives, and the extra labor it takes to care for the bees in winter and spring.

Framingham, Mass.

SIXTH ANNUAL APICULTURAL SHORT COURSE IN ONTARIO

BY MORLEY PETTIT

This short course was held at the Ontario Agricultural College, Guelph, January 11 to 22, 1916.

Owing to war conditions a large attendance was not anticipated. On the opening day, however, there was an attendance of twenty-seven (later increased to thirty-five) young men and a few ladies. Practically every one of these had been previously engaged in beekeeping. They included beekeepers owning one hundred or more colonies, sons of successful beekeepers, and in one case a beekeeper's hired man. Many different parts of Ontario were represented, also Quebec and the State of Michigan. The get-together spirit was much in evidence, and the interest shown at all the lectures was very gratifying.

It is the purpose of this course to give the underlying principles of bee nature, a knowledge of which is essential to successful bee management. Fifty-nine lectures and demonstrations were given, covering the different phases of beekeeping. Typewritten copies of each lecture outline were distributed to the class so the main points could be followed closely and carried home for future reference. As far as possible the lectures were illustrated with stereoscopic views and the actual objects under discussion. Members of the class were also given laboratory practice in hive construction, and a visit was made to the apiary of a successful beekeeper in the neighborhood of the college.

One important feature of the work was

the display of apianian apparatus and implements. The educational value of this was clearly demonstrated by the keen interest shown by those present.

In conducting this course, the Provincial Apiarist, Mr. Morley Pettit, was assisted by F. W. L. Sladen, Apiculturist, Central Experimental Farm, Ottawa; F. E. Millen, B.S.A., Lecturer in Apiculture, and State Inspector of Apiaries for Michigan; F. W. Krouse, President of the Ontario Beekeepers' Association; James Armstrong, Selkirk, Vice-president of the Ontario Beekeepers' Association; also some of the apian inspectors of Ontario. Lectures on allied subjects were given by other members of the college staff. Mr. Frank C. Pellett,

State Apiarist of Iowa, paid the class a visit, and lectured on beekeeping conditions in his state.

Throughout the course there were many kind words of appreciation by members of the class, and on the last day a vote of thanks was tendered Mr. Pettit and the other instructors for the valuable information received and the systematic arrangement of the work.

It is proposed to hold a summer school for beekeepers at the Ontario Agricultural College some time in June, when bees are active and apian practice will be possible. Persons interested should write at once for particulars to Morley Pettit, Provincial Apiarist, Guelph, Ontario.

COMPLETE SPECIFICATIONS FOR A 12 BY 24-FOOT BUILDING

BY HERBERT LYON

This design is for a building 12 x 24 feet, and 8 feet from bottom of joists to top of plate. The floor joists are 2 x 6 inches and 11 feet 8 inches long, laid 16 inches from center to center. Two 2 x 6-inch by 24 feet spiked to the ends of the joists complete the floor frame. (See No. 7 in the illustration.) A 4 x 6-inch by 24-ft. girder properly supported lengthwise under the center of the frame should be used.

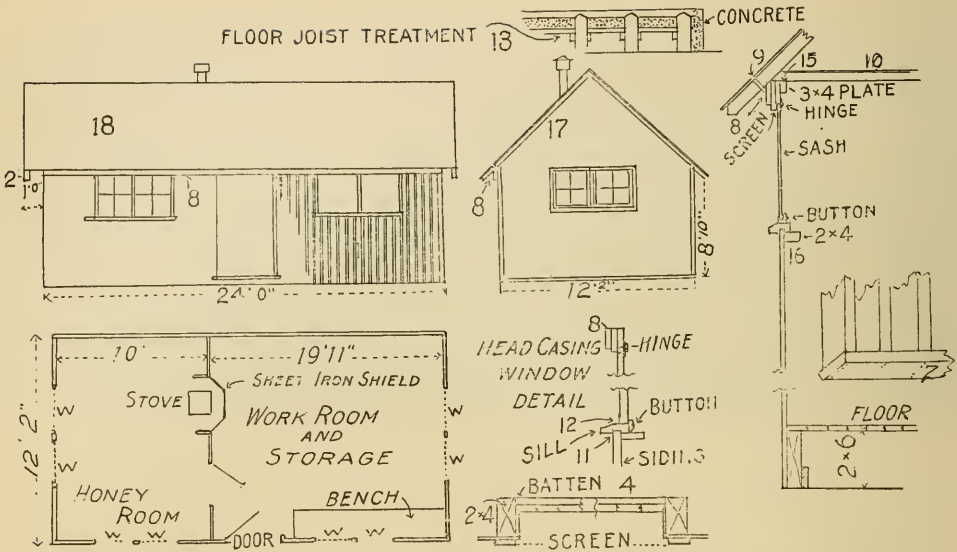

The plates are of 3 x 4-inch material halved together at the corners, and placed 8 feet from the bottom of the floor joists to the top of the plate. (See No. 15.)

Two 2 x 4-inch door studs (No. 4) extend from the top of the floor joists to the bottom of the plate (2 feet 10 inches between studs). A 2 x 4-inch level with the under side of the window sill (No. 16) extends from the outside of one door-stud around

the building and finishes against the second stud. Corner posts and braces can be used or may be dispensed with. The siding is 1 x 10 inches, 16 feet long, matched barn boards, laid vertically. The joints can be covered by $\frac{3}{8}$ x $1\frac{1}{2}$ -inch battens, painted a contrasting color and applied after the siding is painted.

The outside door and window casings are of 1 x 4-inch white pine or cypress set back from the edge to form a rebate for screens. Run a 1 x 6-inch fascia along the long sides of the building, the top edge of which is even with the top of the plate. This will form the head casing for windows and door.

The rafters are 2 x 4-inch, placed 16 inches from center to center, 8 inches to 1 foot pitch. These should be notched over the fascia and seated on the top edge of the fascia ends of siding and plate.

Sheath the roof with North Carolina pine roofers. Cut the ends an even foot beyond the siding. Cover the sheathing-boards with rubberoid roofing.

Cut window openings $\frac{1}{2}$ inch less than the size of the sash on sides and top. Allow for sill at the bottom. Note the plowing necessary to receive the siding. (No. 11.)

The windows are four light barn sash, 2 x 2 feet 8 inches, hinged at the top, and rabbeted at the bottom to receive a lip in the sill. They should be cased in the sides and top with stock the same thickness as

the sash. If the house is built over a beecellar it would be well to lay a double floor, the under one diagonal. If desired, a concrete floor can be laid, but I do not recommend it.

Build a board partition to separate the rooms. An opening can be made to admit a stove. Protect all woodwork near by with sheet asbestos. A movable sheet-iron shield can be used to shut off either room when heat is wanted in only one room. Use galvanized-iron funnel for chimney.

Mount Kisco, N. Y.

AN EXTRACTING-HOUSE ON WHEELS

BY T. E. HOLMES

One of the great problems that confront the apiarist who has his bees in outyards run for extracted honey is an economical extracting-outfit. Some erect a building at each yard, and haul the equipment from yard to yard. The more yards you have, the more expensive this plan becomes.

I have visited beekeepers, read articles on this subject, and have come to the conclusion that a portable extracting-outfit is the only feasible solution of the problem. The one that is the subject of this article is 16 ft. long, 8 ft. wide, and 6 ft. high. The framework consists of two-by-fours covered with a light canvas. The extractor is an eight-framer, run by a gasoline-engine, both being placed clear to the front end, leaving no vacant space. The extractor is in the left-hand corner, and the engine sits directly over the front axle of the wagon, where it is evenly balanced.

The extractor is placed on the floor. A pipe runs from the gate of the extractor thru the floor, and then to a tank outside. This does away with all handling of honey while the extracting is going on.

The engine is a 2½-horse-power Stover. It is larger than necessary, but it is run at a low rate of speed, and consequently the vibration is reduced to a minimum.

We use steam uncapping-knives.

In regard to an uncapping-box, we have solved the problem to my entire satisfaction. To my knowledge it is the only one in use; and if it appeals to any in the beekeeping fraternity they are perfectly welcome to use it. It is simply three or more trays made any length and width most convenient. The trays used in this outfit are made of 1 x 6-inch boards, two feet wide and three feet long. Heavy wire is nailed on the bottom and then a sheet of

tin with thin strips between the screen and tin. This is to give a clear space for the honey to run to the lower end, where a bucket is placed to receive it. The cappings can be only six inches thick in each tray. With such a thin layer, practically all the honey drains out over night. When one tray is filled, another is placed directly on top of the filled one. When not using the steam-knife, the blade is shoved into the cappings where the steam helps to warm the honey so it drains faster. I had only about ten gallons of honey left in the cappings, which yielded 200 pounds of beeswax.

Koger, Biddiek, and myself. With it we extracted twelve different yards twice.

Meridian, Idaho.

[A year or so ago some one suggested the use of capping-trays somewhat similar to those described by our correspondent. We felt at the time that the idea was sound; but to our knowledge no one else has tried it.

Is there any objection to the plan? If so, we do not see it. Such trays would be easy to make, and inexpensive. If a beekeeper found that he did not have capacity enough, he could simply make a few more trays. We hope more of our readers will try these trays, and report.—Ed.]

This outfit is owned jointly by Messrs.

AN ELEVATOR IN THE HONEY-HOUSE

BY A. N. CLARK

I have recently designed a freight elevator for a beekeeping friend who stores his empty hives, supers, combs, etc., on the second floor of his building, and has found it a laborious task to carry them up and down stairs each season.

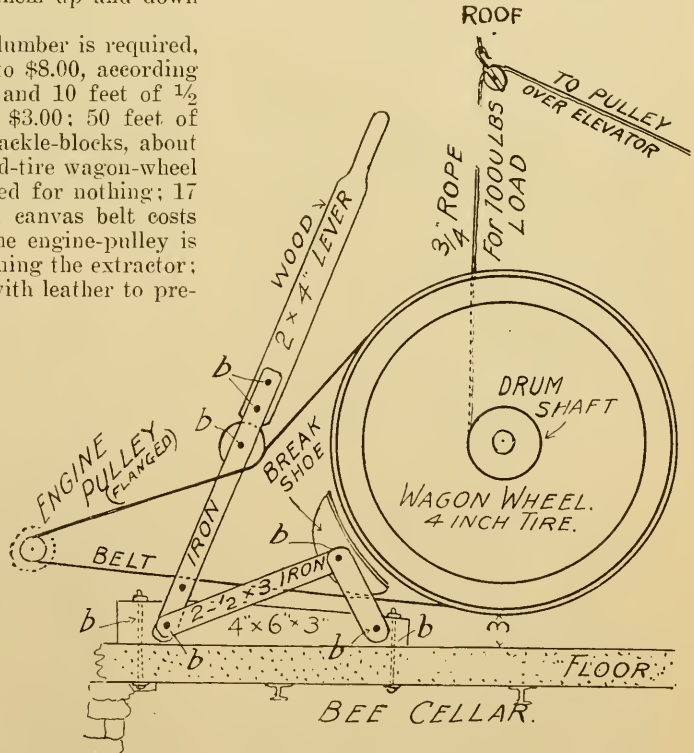

would run about 40 ft. per minute with the direct hitch.

Lansing, Mich.

[Our artist, Mr. Murray, suggests that

Less than 200 feet of lumber is required, which would cost \$2.00 to \$8.00, according to location; nails, bolts, and 10 feet of $\frac{1}{2}$ x 3-inch iron bar, about \$3.00; 50 feet of $\frac{3}{4}$ -inch rope and three tackle-blocks, about \$2.75. A discarded broad-tire wagon-wheel can sometimes be procured for nothing; 17 feet of four-ply stitched canvas belt costs about \$2.00, and the same engine-pulley is used that is used for running the extractor; but it should be lagged with leather to prevent excessive slipping, and flanged. Total cost of materials will range from \$10 to \$15.

The sketch shows the end of rope attached directly to the bail of the elevator, which answers the purpose of lifting light loads like empty hives; but if used for hoisting cases of honey and other heavy materials it is better to attach a tackle-block to the bail, and hitch the end of the rope to a rafter or beam overhead. Such a hitch requires more rope, but develops more power and moves only half as fast. Cutting down on the speed is desirable, as with a high-speed engine of, say, 500 revolutions, the elevator

the elevator could just as well be arranged to run down into the basement in case bees are wintered in the cellar; accordingly he made the drawing to show this feature.—Ed.]

THE WINDOWS OF THE HONEY-HOUSE

BY B. BLACKBOURNE

An important part of the honey-house is the window; and altho by the superficial observer it may be dismissed with scant consideration, a little thought spent upon this one item alone when planning a honey-house will be amply repaid by the convenience afforded later.

Before discussing different types of windows especially suitable for honey-houses, let us consider what are the particular requirements of such windows. These are, to admit light; to admit air without allowing bees to enter; to clear the honey-house of bees trying to get out, *without admitting those attempting to get in.*

The usual method employed is by the use of wire cloth. This is tacked outside the window, and bee-escapes are fitted at the top corners or else the wire cloth is carried six inches above the opening, and the upper border held out a quarter of an inch as suggested in Dr. Phillips' "Beekeeping." In both these methods it is necessary for the window to be open; and unless Dr. Phillips' sliding sash is used the bees are likely to collect on the window-pane, and many will not find their way to the wire cloth at all. The ordinary sash window is certain to be a nuisance, and a casement window cannot be used unless it is made to open inward, which is inconvenient, and even then bees will get back of the window and collect on the pane.

Simmins, in his "Modern Bee Farm," recommends a good window, which I have used in my bee-house for some years. The glass panes are brought down to $\frac{1}{2}$ inch from the frame at the bottom, and this is left open. On the outside perforated zinc is tacked to the frame and extended 6 inches

up the front, and $\frac{3}{8}$ inch from the glass. The bees fly against the window, fall down, pass thru the opening, crawl up the zinc, and escape. During a honey-flow bees escape well by this method; but if a sudden check comes while one is extracting, or while there is honey in the house, the bees scent it from the outside, and in a comparatively short time find their way down the zinc and into the house. Wasps frequently lead the way, as they are very much quicker than bees in finding an opening; but once the bees have found the way in they don't forget it in a hurry. Very soon the whole apiary is in an uproar; bees inside pass the stolen honey thru the zinc to those outside, and, owing to the hundreds inside buzzing up and down the windows, clusters very soon collect in the top corners. Owing to this trouble I made removable strips of wood with which to close the openings during extracting time, or while I had honey in the house. Then there was the trouble of getting the clusters of bees out in the evening. With this style of window, too, there is another danger. When handling queens in the house it is quite possible to lose the queen, owing to a momentary carelessness, and she will very likely get out before she can be caught. Then, too, the window cannot be opened for ventilation.

Details of clutch and brake for operating Clark's honey-house elevator.

chance of their doing so when the operation can be carried out so quickly. The disadvantage of this window is that it must be kept closed, as wire cloth cannot be fixed outside.

Some beekeepers, I believe, advocate openings for ventilation covered with wire cloth, quite apart from the windows, to admit light. If, then, a few bees collect inside, the window can be opened momentarily to let them out without danger from stray bees outside getting in, which bees will be busy around the ventilation openings. But this means more expense and complication in the building itself.

I have devised a window which I think fits the bill exactly, altho I have not yet had the opportunity of testing it. The

I have found (and other beekeepers have remarked on it in GLEANINGS) that it is a mistake to allow bees unavoidably carried into the bee-house, or that have entered by the door, to return at once to their hives. One such bee returning full of stolen honey to its hive when no honey flow is on will set the whole apiary in an uproar; thousands of bees will be buzzing around the windows and door, trying to get into each other's hives, so that robbing may be started. It is, therefore, a better plan to retain all such bees in the house, where they will cluster on the windows, and some expeditious method is required of turning them out in the evening.

Mr. Isaac Hopkins' suggestion for the honey-house window is a good one—viz., that the window shall be hung centrally, so that with half a turn it can be reversed. Bees usually collect and cluster in one of the top corners. One turn, and the whole lot are outside; and, even supposing any are trying to get in, there is very little

Artist Murray's suggestion of letting the elevator in A. N. Clark's honey-house run down into the bee-cellar.

windows should be made of one sheet of glass in a frame of good thickness (this to allow ample room for bees to cluster inside the frame against the pane), and hung from one side like a casement window; but instead of using hinges a flat piece of iron of the same width as the thickness of the frame is screwed on, this iron projecting an inch or two above and below the frame, and rounded. The projecting portions slide in grooves cut in a length of wood nailed above and below the opening. Fig. 1 shows the window in position. The bees collect inside. All that is necessary to turn them

out is to slide the window along to the position BC, so that the back part moves from A to B, and swing the window around on the point now at B—see No. 2. A similar frame should be made for the wire cloth for use in warm weather. Always slide the window along before swinging around, then there will be no danger of crushing bees before the window is in its new position. When ventilation is needed, slide the window along to position EA, and wire-cloth frame to position AB, and manipulate as before.

Hoo, Minster, Ramsgate, Eng.

A SIDE-HILL HONEY-HOUSE

Three and One-half Feet Difference in Floor Levels of the Two Rooms

BY E. S. MILES

Our honey-house is located on ground sloping considerably, about $3\frac{1}{2}$ ft. drop in 16 ft. The main room, which opens to the southwest, as shown in the first view, is 16 x 48 ft., with sides 9 ft. high. The addition, or ell, is 12 x 18 ft., with 12-ft. sides. The roof of the whole building is level; but the floor of the ell is 3 ft. 6 inches lower than the floor of the main room. The trees shown at the left are well back toward the other end of the building, and some of them are 100 feet or more from the far end, so that we have a place for our home apiary well away, and partially behind the building from the platform where we load and unload, as shown. There is a door also in the back for use in working with the home bees.

The third picture shows a part of the main room facing the door. The door is closed, and does not show in this picture, but is directly on the other side of the work-table, with the full-depth super upon it. This cut shows about one-half the width

of the main room. The part to the right, not shown, is piled full of supers. At extracting time the space occupied by the piles of bottom-boards, and the 10-lb. pails, is used to store the filled extracting-supers as brought in while extracting.

There is also a window in the main room, which does not show in the picture, between the extractor and the piles of bottom-boards, which, when uncovered, gives ample light for uncapping. It is covered in the picture, as it let in too much light to show some of the other articles properly. The honey-tank, which is 36 inches high, holds 4800 lbs.

A rope may be seen behind the tank in the third picture, which is attached to the wall at one end, and runs down thru a pulley attached to the platform on which the tank rests, and up and around a windlass attached to the wall, so that, when the honey gets low in the tank, it can be tilted up toward the front so as to expedite the emptying.

E. S. Miles' side-hill honey-house having two rooms, the floors of which are at different levels.

A floor can be seen at the left, about three feet above the tank, on which can be noticed some pasteboard boxes. This floor is in the ell, and makes a loft that opens into the main room, and is up about 4½ feet from the floor of the main room. It makes a convenient storeroom for the almost innumerable articles connected with a well-equipped bee business that are used only occasionally.

The end of the main room at our back, as we face the third view, is equipped with a full window in the center, and the door before mentioned; also a half-window on the side near the door. We have a table in front of the window, where the section honey, mostly from the home yard, is sorted, scraped, and graded. It is then set on covers, or escape-boards, and transferred to the floor near the tank and extractor.

At the right, and back, as we face the last picture, are steps ascending to the main floor; and across the side of the ell opposite the tank is the workbench for all carpenter work necessary. At this bench we nail the shipping-cases and case the section honey, while the extracted, when filled into the cans or pails, is usually set back on the main floor, to be cased up and loaded from the door.

From the above, it will be seen that we have a honey-house with a door handy for use with the home yard, and also two doors with platforms of suitable heights to load wagons without lifting, on the two ends furthest from the beeyard so that, in going and coming in outyard work, we have little trouble from bees. It is made with four 4 x 6 sills set on substantial posts, resting on concrete blocks, with 2x6 joists 16 inches apart, and yellow or hard pine flooring.

The sides of the building are of 2 x 4 studding, 24 inches apart, boarded with shiplap, then papered and sided with regular 6-inch house siding. The roof is made of 2 x 4 rafters, 24 inches apart, sheathing and shingles. It is bee, fly, and mouse proof. I don't remember the cost; but I think the material was about \$300, or may be a trifle more. We built it ourselves, and the bees paid us our wages as well as for all the material and all that's in it and the ground it stands on.

A building this size will handle the crop from 300 colonies without serious crowding. By using a cheap shed for empty supers it could be made to handle the crop from 300 to 500 colonies.

Dunlap, Iowa.

SOME ADVANTAGES AND DISADVANTAGES OF A HOUSE-APIARY

BY BENJAMIN C. AUTEN

To keep colonies of bees in a house-apiary, one precaution is absolutely necessary-- the passageways from the hives to the open air must be bee-tight, and carefully maintained so. This makes it necessary to nail the hives firmly to the floor, and to nail solidly any part of the passageway liable to get dislodged. Even a careful explanation of the reasons might not be convincing; but a trial of a carelessly constructed bee - passage will be.

There are some advantages in keeping bees indoors. They are less excitable to work with than out of doors, apparently not considering the opening of the hive much of an intrusion. On the other hand, they are not easy to get away from in case they do stampede. Another advantage is, they can be worked with in all kinds of weather, thus permitting the utilization of time that otherwise might be unavoidable. Another, high winds do not scatter the hives in pieces over the prairie.

There are a good many disadvantages, however, some of them perhaps trivial; but even trivial disadvantages have great weight when an operator has an overburden of

other difficulties. Entrance manipulations are largely barred, as the outside opening must be at some considerable distance from

B. C. Auten's house apiary, showing the hive entrances just under the eaves.

the hive, the hive of necessity standing back some distance from the inside of the wall to give opportunity for handling supers, etc.

All young bees falling off the frames indoors are irretrievably lost. That may be the case also in outdoor handling; but the loss is not noticed, if it occurs, as the lost bees crawl out of sight at once.

It is next to impossible to hive a swarm indoors, as the bees take up their quarters

A close view of the entrances, with the bees clustering out.

mainly on the outside of the hive. If the hive is taken out of doors to hive the swarm in it, it is then a decidedly nasty job to get the hive placed in position indoors with the bees in it, partly because a large part of them will not be in it even then.

With bees kept in a building, unless the entrances are at a considerable distance from one another, the bees will mix from hive to adjoining hive on the outside wall of the building, then all go into the stronger hive, thus draining the weaker hives.

I had my bees several years indoors, and about two years out. Now that they are

out, sometimes I wish they were back in; but when they were in I wished most of the time that they were out. One reason for wishing them inside is, I would not have to worry about marauders interfering with them, and perhaps leaving the hives torn up in winter time when the bees might perish from my being ignorant of their distress.

Carthage, Mo.

[Mr. Barber has overcome the tendency of the bees to mistake their entrances, and he also provides large windows so that those that get inside the building can find their way out. See his article, page 193.—ED.]

GARAGE AND HONEY-HOUSE COMBINED

BY HENRY HOGRAVE

I am contemplating building a honey-house in the near future according to the plan shown herewith. This, when completed, I hope will save me much time and labor.

As you will observe, I have a garage in the same building; and as my yard is di-

rectly north of it with rows of ten hives on either side of a center driveway thru the entire apiary, I can run the auto into the yard, load up, and take it to the honey-house.

The extracting-room will be located on the second floor, part of which floor will

rectly north of it with rows of ten hives on either side of a center driveway thru the entire apiary, I can run the auto into the yard, load up, and take it to the honey-house.

The dummy (platform) located next to the garage is another feature of the plan

also be used for storing supers during the winter months. The honey-tanks, bottling, and honey-storage rooms, as well as the workroom, will be on the ground floor, being convenient for loading honey to be delivered, or receiving freight, etc.

Waukesha, Wis.

A DEMOUNTABLE EXTRACTING-HOUSE SUITABLE FOR A HOT CLIMATE

BY JOSEPH GRAY

In this locality we have to consider heat as the big factor, and plan accordingly. All our hives are set north and south, with the ramada (shelter or shed made of

branches) running east and west. The extracting-house is set at the east end because the evening sun is hottest at the west end of the ramada, which is shaded to protect

the hives. For the same reason our house is screened on the north, and closed solid on the south. The doors are solid instead of being screened, and open from the solid half of the building. This protects the opening from robbers. A screen panel above the doors lets out the heat. Here in Imperial Valley we are often at work with the thermometer in the shade well over 100 Fahr.

I favor a portable house, for the reason that, with the changing of crops, a whole district may be plowed up and become of no value from the apiarist's standpoint. One of the troubles of a really portable house is the roof. I have seen many materials used; but the cheapest, simplest, and best is a wagon-cover 12 x 14 feet of strong 12-oz. standard duck, made waterproof and durable by the use of beeswax dissolved cold in gasoline. The mixture must be very thin, and applied with a brush. Oil-dressed duck rots faster, and is stiff and hard, while beeswax is pliable and resistant to wet.

I do not want bees around my workshop; therefore it is away from the extracting-house. All I ask for is a good workbench and elbow room.

The extracting-house is made up of four panels—two ends and two sides. The side-panel framework is made up of 2 x 3-inch pieces except the top rail, which is a 2 x 4, with outside top edge beveled to fit the slope of the roof. The extra inch makes a small eave on which to fasten the canvas.

The north side panel is all wire screen;

the south side all wood, put on from the inside. The building is put together with 4-inch nails, a brace, a No. 3 or 4 bit being used to drill the hole, thus preventing splitting. If the lumber used is surfaced on four sides it will make a better job than rough lumber, as the former is of better quality, and almost free from knots. The end-panels framework is 2 x 3 inches, the ridge being 3 inches above the side plate.

The corners of the building are held together with 5-16-inch lag screws 3½ inches long. I use a No. 5 bit thru the first half and No. 4 bit for the screw part. The door is made of light wood, and opens on the south side. This throws the bees back against the screen. A wood door and screen window attract fewer bees to the exit, as the scent is emitted thru the screen. The question of two doors is a matter of choice; but they are a great convenience during the afternoon. The east door can be used, as the bees are on the west side of the building at that time. Bees are always attracted to the sunny side of the house.

To close the building for winter stores or workshop, use shutters of beaver boards on a wood framework.

The uncapping-can is a double washtub, the upper one with wire bottom. A pipe from the lower tub leads to the receiver from the extractor. A sack is laid in the top tub to catch the cappings, and in this manner the cappings are easily carried, when dry, to the solar extractor.

Gray Heber, Cal.

REARING BROOD IN MID-WINTER IN THE CELLAR

BY GEO. H. REA

Speaking about raising bees by artificial feeding in the cellar, Mr. Editor, here is something that will interest you.

Friday, January 28, temperature 70, sun shining brightly, and no wind, I could not resist the temptation to set a few colonies out of the cellar and play with them awhile. Fifteen colonies were put out. I have never seen bees in better wintering condition. Not a sign of a spot did they make in their splendid flight, either on the hives or the white shirt that I wore. In the afternoon they were so thick on the ground, gathering water, that one could scarcely walk about the yard without tramping on them.

These bees were cellared December 5. Winter stores were mostly buckwheat honey with a little goldenrod and aster honey. Six, that were a little light when cellared, were given a candy cake (about one pound) to be sure that they would go thru a long

winter's confinement. The candy is nearly all consumed.

Under the stimulus of this slow feeding, these six colonies now have brood in from one to three frames, young bees emerging by the hundreds, and the queens laying eggs as in spring. None of those without candy have brood or eggs. All were equally quiet in the cellar.

Perhaps the fellows who don't believe in this abnormal brood-rearing will have a chance to say, "I told you so," next spring; but I am not worrying about it. I have had this experience before. More about that candy and another feeding experiment later on.

So far the open winter and unusually warm winter weather have not affected our cellar temperature. It holds right along at 43. After twelve years of cellar wintering, and with a number of cellars part of the

time, I am convinced that it is the best method of wintering, in this part of Pennsylvania at least. About an average of 43 degrees, and as little change as possible from that, seems to be best.

Beekeepers should look well to the bees' winter stores. The unusual amount of flying weather will cause heavy consumption of honey. Many colonies, especially in the central and eastern counties, were light in the fall, anyway.

The regulation cake of bee candy may be given, or a feed of thick sugar syrup may be given on one of these warm days. Now, I suppose some one will hold up his hands and cry out against winter feeding because it will stimulate brood-rearing—a cold spell coming, consequent losses, etc. It won't hurt if the feed is all given at one time and made with just sufficient water to melt the sugar, and no more. Bees will fly frequently from now on, anyway, but it would make no difference if they didn't fly for a month.

It is interesting to know that, notwithstanding our small appropriation for apitary inspection, 933 apiaries were visited, 9384 colonies inspected, and 258 cases of foul brood found and cared for. Of these, 61 were American foul brood and 197 European foul brood.

THE SPREAD-OUT HIVE.

McCready's Spread-out Idea hive, page 30, interests me. Most enthusiastic beginners invent a hive about the first thing they do, and generally it is about the most impracticable kind of hive too (no reflections

on McCready's, however). This Spread-out Idea is good, only I think it needs some fixing. My twentieth anniversary in beekeeping will arrive next April, and I have a notion to invent a hive by way of a celebration. If I do, it will embrace the Long-idea and the Spread-out Idea. I may call it "The Ladies' Friend, or Anti-lift" hive.

Reynoldsville, Pa.

[Some two or three winters ago Mr. J. E. Marchant and later Geo. H. Rea were conducting some experiments in making bees breed while in our cellars. Both proved that by feeding candy they could build up weak colonies in mid-winter into thoroly strong ones with young bees. A constant supply of fresh food has a tendency to start brood-rearing; and, as they proved at the time, this can be done provided one knows how.

The average beginner and perhaps the average beekeeper would do well to let the proposition alone, for breeding in the cellar is sometimes accompanied with dysentery; but when nice clear crystalline candy is used, and cellar conditions are right, there will be but little danger.

Mr. Rea, who is now back in Pennsylvania, it would seem has been trying the same experiment again, and he was likewise successful again, even in a different locality and in a different cellar.

What man has done, man can do, but it does not follow by any means that all men should try mid-winter feeding.—Ed.]

Gold medal offered by the Michigan Beekeepers' Association at the fiftieth annual convention at Grand Rapids, Dec. 15 and 16. Awarded to Mr. and Mrs. Floyd Markham, Ypsilanti. See report by F. Eric Millen, page 125, Feb. 1.

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Of all the uses for honey the one where you hand a couple of well-filled sections over the line fence to your skeptic neighbor is about the best recipe of all.

We shall have one of the best honey seasons next year, I think, I ever saw, judging by the white clover. In all my years of beekeeping I never saw a better prospect. Bees went into winter quarters in good shape. All have plenty of winter stores. Unless something unforeseen interferes, I think we shall have a record-breaker of a honey crop.

J. W. Bittenbender.

Knoxville, Ia., Dec. 2, 1915.

Honey Souring in Combs

I should like to know if honey in the comb or otherwise ever goes bad. I do not mean sour—just bad, so it would be harmful to eat it. What are the causes? Would the presence of wax-worms do it if I had found nests in some of it? I am speaking of honey taken off hives last fall, and kept in a dry place in extracting-frames, the frames in the supers covered.

Wm. C. Nelson.

Mount Vernon, N. Y., Jan. 18.

[Honey in the comb will sometimes sour, become watery at other times, so as to be too thin, and the excess of water in the honey may be the cause of the souring. Some honey is more inclined to turn to an

acid flavor than others. Of course, the honey may granulate in the combs; but this is no sign of inferiority. There is no other change that takes place in honey that we know of. The presence of wax-moths would have nothing to do with the matter. If honey is kept in a warm dry place it should ordinarily keep in nice condition; and the warmer and drier it is, the less tendency there is to granulation and turning sour.—Ed.]

A Honey-bread that is Genuine

In reply to your editorial, page 45, Jan. 15, I will say if the food commissioner were to get after me I would not have to plead guilty, as I could show him that my bread contains honey. Being entirely alone for the past dozen or more years I do my own cooking and baking, and invariably put honey in my bread, and nearly all other baking and cooking. I use at least a part honey; and if every family would do this we should need more bees to supply the demand.

Union Center, Wis.

Elias Fox.

Another Course in Apiculture

The Agricultural College at Cornell is offering this coming term of 1916 a course in practical beekeeping. The course consists of one lecture and two laboratory periods of 2½ hours each, weekly. The students are to be given practice in nailing hives, making wax, making hard and soft candies, artificial cell-cups, etc. Later on, when weather permits, each one will have opportunity to handle the bees, and will be required to mount a collection of the nectar-yielding plants of this region. I think you will be glad with me that the great State of New York is at last waking up to the importance of her beekeeping industry.

Ithaca, N. Y.

Wendell T. Card.

Is It Necessary to Mark the Net Weight on a Pitcher of Honey?

If one of my neighbors brings a pitcher for some extracted honey, is it necessary for me to tag the pitcher so much net? Can a trader have a sixty-pound can of honey in his store, and draw out of it for a customer? Can I sell a section of honey to my neighbor without stamping it?

J. B. Mason.

Mechanic Falls, Me., Jan. 27.

[Unless you do an interstate business it will not be necessary for you to mark anything. If Maine has a net-weight law of its own it would be necessary for you to mark the exact contents by weight or measure of any regular package of any commodity that you might be selling. As a pitcher is not a regular package it would not be necessary, in our opinion, for you to mark this in any manner whatsoever. In fact, it would be impractical. The law contemplates only

regular packages that are supplied to the trade or to individuals. A glass tumbler or a jar, tin can, or anything of that sort, would have to be marked with the net weight, either in quarts or gallons, or pounds or ounces. Usually a 60-lb. can is not considered a package; but to be on the safe side we would advise marking even a 60-lb. can when sent out.—Ed.]

Bees Have Trolley Ride

The sketch represents the plan of my honey-house, bee-cellar, and hive-carrier. The building is 16 x 24, 8 feet high, and the cellar is 7 feet deep. The carrier is of the barn-litter-carrier type, except that it is equipped with a small block and tackle for the purpose of lowering it to the ground while being loaded with supers for the extracting room, or with colonies for the cellar which are lowered thru a trapdoor in the floor of the honey-house. The heavy wire track will carry over 300 pounds. The track can be equipped with switches to accommodate many rows of hives. By using cement block for building, the above contrivance will cost about \$200, not including labor.

Fairfax, Ia.

C. F. Wieneke.

Honey-dew from Oak Galls

In the autumn of 1884 I was invited to inspect the apiary on the famous Rancho Chico, the estate of Gen. John Bidwell. I found over one hundred colonies in fine condition, and some had built comb and stored honey outside of the hive. Looking for the source of the extraordinary yield of honey I found that it came from galls on the white oak. Many trees were covered with the exudation, as if it had been sprayed on by the hundreds of gallons. Some trees were more abundantly supplied with the galls than others; but the infestation was practically universal.

These galls were about the size of a common pea, and so numerous on the terminal twigs that frequently there would be several in an inch length of twig. So profuse was the exudation that, solidifying as it dripped, it hung like stalactites.

This honey-flow is not like the flow caused by aphides, the producing insect being entirely different. It was found that the exudation from the gall took place while the

insect within was in the form of a grub or worm. Later the grub transformed into an imago, and finally emerged a delicate-winged insect that seemed to be a miniature honeybee. Many of the winged insects appeared in December of the same year. While the same galls and attendant exudation have been seen by me in later years in a minor degree, there has never been anything so profuse since.

Placerville, Cal.

H. G. Hulburd.

Sounds Cold from Oregon

I always thought that Oregon had a fine climate, but I think it is about as changeable as that of any other state. At present we have 10 inches of snow, and it is still snowing. Last night my bee-shed got so heavy with snow that it broke down, falling on the hives. It didn't do much damage, but I shall have a little fun fixing it up again.

My bees did very well last season, and are in very good shape at present; but I don't know what this cold snap will do to them, as I was not expecting such cold weather here in the valley. It is 10 degrees above zero today, Jan. 13.

Aurora, Ore.

C. E. Sprague.

Here is a super which I have found very serviceable, allowing the use of 4 x 5 sections without waste of space, and providing for an extracting-frame. Any 16 x 20 deep super can be used.

Ann Arbor, Mich.

E. G. Mann.

A. I. Root

OUR HOMES

Editor

Eye hath not seen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him.—I. COR. 2:9.

I have been reading the *Sunday School Times* for so many years I could hardly attempt to tell how long, and it was one of my "happy surprises" when I found glimpses on its pages that its editors had been reading these Home papers of mine at least occasionally. Well, some two or three years ago I was *again* "happily surprised" to receive a personal letter from Chas. Gallaudet Trumbull, telling me of a wonderful new spiritual experience he had just received. I at once wrote him asking permission to print the letter in these Home papers. I have never heard from him personally since, and, of course, I could not give the letter to you all. I have, however, been pleased to get glimpses of this experience in almost every issue of the *Times* since. The tract we have been sending out, "The Defeat of Injustice,"* is one of the fruits of that experience. A few weeks ago at our Bradentown prayer meeting I read the following clipping from the *Sunday School Times*:

"Daddy, did you notice tonight that I bowed my head and put my hands up to my eyes?"

The little girl of five years had cuddled into her father's arms in a corner of the library while the evening shadows were gathering, for one of the precious little times of confidences.

"I was naughty today, Daddy."

"Were you, Annie?"

"Yes, and I was asking Jesus to forgive me. Whenever I am naughty now I bow my head and just tell Jesus, and ask him to forgive me."

"And he always does it, doesn't he, Annie?"

"Yes," the little girl answered. And then in a sudden burst of confidence she poured out the problem of her child-heart. "Daddy, it's awful hard to be good, isn't it?"

That heart-cry of the little girl finds its response in every Christian's heart. No man would wish to deny the truth that is wrapped up in that confession. Yet there are two serious falsehoods implied in our "axiom," "It's awful hard to be good."

It is not only hard to be good, but it is utterly impossible for fallen man to be good. A Christian has come to an encouraging point in his experience when he is able to realize this. Not only is it true that "none is good, save one, even God," but it is also true that no one else *can* be good. This is the message of the Incarnation. God in Christ came in the flesh and "was good"—a thing that was impossible for fallen man.

Then I followed it with part of a letter from our son Huber, as below:

Dear Father:—At the Laymen's Missionary Conference in Cleveland last week I had the opportunity to hear Charles Gallaudet Trumbull, editor of the *Sunday School Times*. He made a splendid address, and I wish you could have heard him. The whole theme of his address was this: During a time

of temptation make no effort to fight against it yourself, but let Jesus Christ carry on the fight. He illustrated his point by telling a story. It seems that a little girl, after joining the church, was asked by an older person whether she felt any different since becoming a Christian. She replied that she most certainly did. When her friend asked her in what way she felt different she said, "Now when Satan knocks at the door of my heart I just tell Jesus to go to the door, and I pay no attention to it myself. When Satan finds Jesus at the door he merely says that he guesses he has made a mistake, and has come to the wrong house."

After the meeting a lady who had just attended some large religious gathering handed me a tract, saying she felt sure I would be interested in it. Now, to tell the truth, so many "tracts" are piled up on my desk unread I feared this would only add to their number; but when I saw it was from my good friend Trumbull I changed my mind. I have now read it thru three times, and "then some." The title of the tract is, "The Life that Wins." There are 20 pages in the tract, and I give you below the contents of the first two.

AN ADDRESS (REVISED) BY CHARLES GALLAUDET TRUMBULL BEFORE THE NATIONAL CONVENTION OF THE PRESBYTERIAN BROTHERHOOD OF AMERICA, 1911.

There is only one life that wins; and that is the life of Jesus Christ. *Every man may have that life; every man may live that life.*

I do not mean that every man may be Christlike. I mean something very much better than that. I do not mean that a man may always have Christ's help. I mean something better than that. I do not mean that a man may have power from Christ. I mean something very much better than power. And I do not mean that a man shall be saved from his sins and kept from sinning. I mean something better than even *that* victory.

To explain what I do mean, I must simply tell you a very personal and recent experience of my own. I think I am correct when I say that I have known more than most men know about failure, about betrayals and dishonorings of Christ, about disobedience to heavenly visions, about conscious fallings short of that which I saw other men attaining, and which I knew Christ was expecting of me. Not a great while ago I should have had to stop just there, and only say I hoped that some day I would be led out of all that into something better.

Please note above what he says about "power." In these days of automobiles, when not only boys but *girls* too learn to run them; when you feel you have at the tips of your fingers *power* to go just as fast as any one can want to go, and, too, by practice, run almost to a hair's breadth of where you wish to go, who has not felt the thrill of being entrusted with such power? Well, Trumbull speaks from experience of something "much better than power." I read the above part of the tract to our large Bible class in our Sunday-school here, and they wanted me to go on with it, just as

* See page 557, July 1, 1915.

many of you, dear friends, would have me do; but you really need the whole of the tract to get the writer's secret. The little girl mentioned in Huber's letter had touched the point. I will give just one more extract from p. 13.

What I mean is this: I had always known that Christ was my Savior; but I had looked upon him as an external Savior, one who did a saving work for me from the outside, as it were; one who was ready to come close alongside and stay by me, helping me in all that I needed, giving me power and strength and salvation. But now I knew something better than that. At last I realized that Jesus Christ was actually and literally within me; and even more than that: that he had constituted himself my very being (save only my resistance to him), my body, mind, soul, and spirit. Was not this better than having him as a helper, or even than having him as an external Savior—to have him, Jesus Christ, God the Son, as my own very life? It meant that I need never ask him to help me again, as tho he were one and I another; but, rather, simply to do his work, his will, in me, and with me, and thru me. My body was his, my mind his, my will his, my spirit his; and not merely his, but literally a part of him; all he asked me to say was, "I have been crucified with Christ, and it is no longer I that live, but Christ liveth in me." Jesus Christ had constituted himself my life.

Now, here is something that took hold of me more than almost anything else on the whole 20 pages. Read below:

Do not think that I am suggesting any mistaken, unbalanced theory of perfection or sinlessness in what I have been saying. The life that is Christ reveals to a man a score of sins and failures in himself where he saw only one before. He is still left the free will to resist Christ; and my life, since the new experience of which I speak, has recorded shamefully many failures and sins of such resistance. But I have learned that the restoration after failure can be supernaturally blessed and complete.

As I write on this 3d day of Feb., 1916, I feel that I have made a little start on "The life that wins," and the first revelation that comes to me is, as expressed above, where I saw only *one* sin before, there are now "scores." Sheldon, in one of his books, suggests, "What would Jesus do" were *he* in your place? Dear friends, you have given me scores of kind words. They are coming all the time. As I think of it, the chorus of the old hymn that the good woman wrote comes to mind.

Lord, lift me up and let me stand,
By faith, on heaven's tableland,
A higher plane than I have found;
Lord, plant my feet on higher ground.

NON-RESISTANCE AND LAW ENFORCEMENT.

The two letters below explain themselves.

Did A. I. Root ever consider that the plan of salvation brought to us by Jesus Christ teaches us non-resistance? He suffered all patiently to redeem mankind from their sins, and wishes his followers to follow in his footsteps. L. A. R.

I am a reader of GLEANINGS, and am pleased with the Home department, and have frequently thanked God for the spirit of boldness he has given

you to express your convictions on religious and other important subjects. Of course, I do not approve of all your ideas; but in such cases I turn your idea over to the Lord and tell him to let the light on you and also ask him to search me; and, if I am in the dark, let the light on me. I often say, "Lord, do not let me be deceived on any line." The psalmist prayed that way. He also prayed, "Keep back thy servant from presumptuous sins; let them not have dominion over me," etc.

In looking over the Home papers of June 15, I notice Bro. Poister's admonition. Thank God for such men. Now, I think that carries the spirit of the Master. Brother Root, do not pass that admonition lightly by. Paul says to the Romans, "If any man have not the spirit of Christ he is none of his." Now, if you find in any of Christ's teaching the spirit of fight or defense, use it. But if you cannot find it, beware of your own ideas.

I was surprised to notice that you regard the scripture quotations the brother referred to are merely for neighborhood differences. Are we to understand you that the Son of God left the Father's throne and shed his blood merely for neighborhood differences? Was it not that he came to save that which was lost? Brother Root, let us take the Lord Jesus for our example in suffering in any shape or form, and I then am sure we shall not miss the blessing. In conclusion, please take this in the spirit it was given—not in malice or any ill feeling, but in love; and if you want to defend yourself give us a "thus saith the Lord."

Ahlsene, Kan., June 20.

N. G. HERSHEY.

My good friends, I do not know but we are all getting into "deep water" when we undertake to discuss this question. Our Lord and Master once drove the money-changers out of the temple with a whip; but it has been claimed that this whip was only harmless cords. Again he says, "I came not to bring peace on earth, but a sword;" and I suppose sermons have been preached and books written on this very passage. My opinion is that it refers particularly to the enforcement of law. Again, Jesus came to earth on a special mission; and that mission was summed up, I believe, by the words "Peace on earth, good will to men." And, once more, it is my impression that this refers to law enforcement. How about making counterfeit money and passing it? Counterfeiters almost always fight with guns and pistols when their gang is broken into. And, once more, in regard to the liquor-traffic. Shall we apply non-resistance to this and let the business go on? God forbid. Once more, it is quite a different matter whether the sin affects the individual alone or humanity in general. When a blow comes to me individually on the right cheek, I believe it is my duty to turn the other cheek also. But in case of a blow against all humanity, like counterfeit money, or against suffering men and women and children in consequence of the liquor-traffic, then I believe our Lord and Savior would have me fight to the best of my ability for the suffering ones.

NON-RESISTANCE; AND DID JESUS MEAN TO SAY THAT WE SHOULD NOT PROTECT OURSELVES AS A PEOPLE AND AS A NATION?

A. I. Root:—Properly speaking, Jesus did not say, "Resist not evil." The Greek word which is translated "resist" in Matt. 5:39 is translated elsewhere in our English Bible either "resist" or "withstand." It is used in fourteen places in the Bible—Matt. 5:39; Luke 21:15; Acts 6:10, 13:8; Rom. 9:19, 13:2 twice; Gal. 2:11; Eph. 6:13; 2 Tim. 3:8 twice; 4:15; James 4:7; 1 Peter 5:9. An inspection of these places will show that the word cannot be supposed to carry in itself any particular reference to the use of physical force. A fuller study of this Greek word (which is just as open-faced a compound as the English "overthrow" or "outrun") shows that it does not express the idea of any activity at all, but simply of taking an attitude or staying in an attitude, while "resist" necessarily expresses the idea of an activity directed against the antagonistic person or thing. In this respect "oppose" would be a more exact translation, though "oppose" would not be very perfect either.

Since the word does not express anything so particular as the use of physical force, we have to judge of its force in this passage from the connection. The connection is along such lines as these: Do not make a point of seeing to it that every misdeed is paid off, but bear petty outrages without setting yourself in opposition. It is very important to note that all Jesus' instances are of petty outrages. Now, a man chooses his instances so as to be appropriate to his meaning. It would be perfectly ridiculous if a man meaning to say that we should not resist an attempt at murder or the robbery of a lifetime's savings were to express this by saying, "Do not resist a slap on the cheek or an extortion of half an hour's work." Now, even among those who are (as Anacharsis Clootz said of himself) "personal enemies of Jesus Christ," nobody denies that Jesus knew how to express himself tellingly. If Jesus knew

how to express himself as intelligibly as ordinary men, then by those words about a blow on the cheek, etc., he did not mean the most serious outrages.

My understanding of the meaning is like this. A Christian is concerned in this world with things he is to recognize as much more important than standing up for his rights; properly, standing up for his rights is no object at all to him; and if he is to stand up for his rights whenever they are violated he will have no time left for his Christian duties; besides, the fact that standing up for his rights will sometimes work against the objects that he as a Christian is pursuing. So he should not make it a rule to stand up for his rights. But if the things that are being done to him are such as to interfere with his doing the things that it is his Christian business to do, then it is a part of his Christian business to put out of the way whoever and whatever interferes, provided that it does not cost more in time, nerve-force, and arousing of hostility, than it is worth.

At present a mighty attempt is being made in the world to give war the right of way; to insist that, when war is started, interests of peace must give way to interests of war. If this attempt should be successful, it would set back the cause of peace at least a century. Anything that we can honestly and lawfully do to defeat this attempt, whether by selling arms or otherwise, is well done. A great deal of the talk about the exportation of arms leaves out of account the fact that the actual exportation of arms is simply helping honest and peace-loving people to defeat violent crime. It is as if I saw John Doe jump up and begin shooting at Richard Roe because Doe had heard Crazy Joe say that Roe meant to steal Doc's chickens, and I should hand Roe a gun, since the circumstances were such that Roe must fight or go under, and the people should tell me I was doing—well, very unchristianly by helping to arm a fight.

STEVEN T. BYINGTON.

Ballard Vale, Mass., June 25.

POULTRY DEPARTMENT

HOW TO MAKE HENS STOP LAYING?

"Whew!" says some one. "Why should anybody want to make hens *stop laying*?" Well, it's something like the boy who wrote a composition on pins. He said pins had been the means of saving many lives. When the teacher asked him to explain in what way *pins* saved lives, he replied, "By not swallowing of 'em." Again, don't you know that, when our great doctors want to get control of an epidemic, they first proceed to *cultivate* the bacteria, and when they can get it to growing in their "pure cultures" (I think they call it) they can then formulate an antidote. Now to business.

When I first got here, as usual our 60 hens began to increase in laying; but after they got up to about 18 eggs a day, to my surprise (and disgust) they dwindled back to only five or six a day. I told neighbor Abbott about it, and when he found I was giving them a mash of shorts and hoiled

sweet potatoes he said at once that *sweet potatoes*, either raw or cooked, would "*stop hens laying*." He added further, "You can give them to your growing stock, sitting hens, or hens with chickens, or to a pen of roosters, but never to laying hens."

I stopped the *sweet potatoes*, and soon I had toward two dozen eggs a day. Let me explain further.

A year ago we set out *sweet potatoes* in December and January, and I didn't get back here to dig them for almost a year. They were not only very large, but very poor. We used the best for the table, and boiled the rest for mash, as explained; in fact, some of them were partly decayed; but as the fowls ate them greedily I thought it would do no harm. Now, is it only *bad sweet potatoes* that stops laying? Mr. Abbott thinks not. A neighbor's hens got into the *sweet potatoes*, dug them up, and ate them raw, and very soon he did not get an

egg. Can our readers tell us more about this? I feel pretty sure that too much of a certain diet of many things will cut down the egg yield, and it is also true that a change in diet will often *add* to the egg yield. Plenty of sprouted oats, or even green oats a foot high, will often do it.

SPURS ON MALE FOWLS; HOW TO REMOVE.

I will tell you my way of taking spurs off, and you can do it in a few minutes. Put on the fire, in a pan of water, two potatoes about the size of a nice apple. Boil till nearly cooked, and then push each potato on a spur and keep it there for a minute or two, when the spur will come clean off.

JAMES SMITH.

Kirkmahoe, Dumfries, Scotland, Nov. 9.

HEALTH NOTES

COTTAGE CHEESE OR "DUTCH CHEESE," AND HOW TO MAKE IT.

Mr. A. I. Root.—In your Home department, you occasionally make mention of "cottage" cheese as a very wholesome article of diet. I wish you would, in an early number of this magazine, describe the process of making this kind of cheese. From what you have said about it from time to time, the writer's mouth waters for it, and he is anxious to try his hand at making it.

Halls, Tenn., Jan. 15.

J. C. SAWYER.

My good friend, I supposed every housewife in the land knew how to make cottage cheese, or what is called in many places "Dutch cheese." Mrs. Root says, set sour milk on the stove until it is about as hot as you can bear your finger in. Then pour it into a cloth bag, strain out the whey, and season to taste.

CURING BEESTINGS, POISON IVY, ETC.

More than forty years ago, when I first made the acquaintance of the honeybee, beestings were very painful, and swelled on me, and I listened with very much interest to everybody who had a remedy for beestings. The juice of different plants, a piece of onion, potato, a little bit of mud, etc., were carefully tested; but I soon decided that it was only a notion or the effect of the imagination. Then somebody advertised something in a bottle. In fact, a beesting cure had been advertised in the bee-journals more or less; and as good a man as Dr. A. B. Mason, of Toledo, declared that the essence of peppermint or some other essence, I cannot remember what, was a *sure* cure. I said first, last, and always, "Pull out the sting. Do not rub the place, nor meddle with it so as to diffuse the poison, but get busy, and get your mind off from it, and the pain and swelling will soon go away;" and my impression is that the beekeepers of our land gradually came to the same conclusion I did. Get out the sting, and get it out with a knife or a pair of tweezers so as not to squeeze the contents of the poison-bag into the wound.

Well, of late our agricultural papers have been giving cures for ivy poison, and I have all the time felt confident that a careful experiment would prove about the

same as with the beesting. The matter was brought to mind by a clipping, but I cannot tell just now what periodical it came from. The closing words, which I have put in italics, are what caused me to give it a place here:

CURES FOR IVY POISONING.

The *American Botanist* publishes a letter from a Brookline, Mass., correspondent stating that fishermen along parts of the Massachusetts coast find a prompt cure for the effects of poison ivy and poison sumac in the fireweed (*Erechtites hieracifolia*). The poisoned parts are rubbed with the leaves of this plant, which must be fresh each time, bruised and crushed so that the sap moistens the skin freely. An editorial note mentions the fact that a large number of other plants have been recommended for ivy poisoning—notably touch-me-not and burdock—but that "*it seems doubtful whether any of these herbs can do more than take the attention of the patient from his troubles and cure him by mental suggestion.*"

Let me call attention to one point in all these remedies. If it were true that the juice of fireweed is an antidote for poison ivy, how did anybody happen to discover it? Edison has been called the greatest inventor of the age; and here comes the point—how does he accomplish his inventions or make his great discoveries? Why, he did it by making thousands of tests, on storage batteries, for instance. I think I have seen it stated how many combinations he made with chemicals before he brought out his present storage battery. Now if catnip, fanny, and a great lot of weeds have power to cure diseases, the only way to settle it would be to get a hospital full of patients suffering from one particular ailment. Then bring on your herbs—a hundred, or, better, a thousand. Squeeze out the juice or make some tea and give to the patients, and notice the effect. If catnip tea gives relief to thirty or forty, and the other patients are not helped, then we may be pretty safe in saying that catnip possesses medical qualities for certain diseases. Has such an experiment ever been made? Not that I know of. Of course our grandmothers gave catnip tea to the children that were ailing, and they got better, forgetting that nine times out of ten they get better without catnip tea, and so on.

"HOW TO JUDGE ENGINES"

A Valuable Book Free!

EVERY man who has any idea of buying a Kerosene or Gasoline Engine should have this book.

Discusses different types of engines; how constructed; how operated; how cylinders and other parts should be made to give greatest efficiency.

It has taken 30 years of engine building experience for me to learn the facts in this book. Yours for the asking.

My 1916 Model Engines are the greatest value I have ever offered. All sizes pull from 30 to 50% over factory rating.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it **Powdrpaint**. It comes in the form of a dry powder; and all that is required is cold water to make a paint weather proof, fire proof, sanitary, and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone, or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 58 North St., Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

SQUAB BOOK FREE

Make money breeding PR squabs. 1916 demand biggest ever. Squab book free, telling money-making experiences. How to sell by parcel post, to \$8 doz. Start small, grow big. Many women customers. See today. **PLYMOUTH ROCK SQUAB CO., 615 HOWLAND ST., MELROSE HIGHLANDS, MASSACHUSETTS.**

Free for Testing

A pair of mated EVERBEARING STRAWBERRY PLANTS FREE if you will report as to your success with them. Will bear loads of big, red, berries from June to November. We have counted 480 berries, blossoms and buds on a single plant. A postal will bring the plants, also enough seed of the new CEREAL FETTERITA to plant a red square of ground. Also a pkt. of perennial ORIENTAL POPPY seed. Send 10 cts for mailing expense or not, as you please. Write today and get acquainted with **THE GARDNER NURSERY COMPANY Box 749, Osage, Iowa.**

"Next Door to Everything"

Reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

The best goods and service justify us in promising our customers the fullest measure of satisfaction. Our office and warehouses are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction. March cash orders are subject to a special discount of 1 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to prepare carefully the bees for winter, and anticipate all possible requirements.

This Washer Must Pay for Itself

A MAN tried to sell me a horse once. He said it was a fine horse and had nothing the matter with it. I wanted a fine horse. But I didn't know anything about horses much. And I didn't know the man very well either.

So I told him I wanted to try the horse for a month. He said, "All right, but pay me first, and I'll give you back your money if the horse isn't all right."

Well, I didn't like that. I was afraid the horse wasn't "all right," and that I might have to whistle for my money if I once parted with it. So I didn't buy the horse, altho I wanted it badly. Now this set me thinking.

You see I make Washing Machines—the "1900 Gravity" Washer.

And I said to myself, lots of people may think about my Washing Machine as I thought about the horse, and about the man who owned it.

But I'll never know, because they wouldn't write and tell me. You see, I sell my Washing Machines by mail. I have sold over half a million that way.

So, thought I, it is only fair enough to let people try my Washing Machines for a month before they pay for them, just as I wanted to try the horse.

Now, I know what our "1900 Gravity" Washer will do. I know it will wash the clothes, without wearing or tearing them, in less than half the time they can be washed by hand or by any other machine.

I know it will wash a tubful of very dirty clothes in Six Minutes. I know no other machine ever invented can do that without wearing out the clothes.

Our "1900 Gravity" Washer does the work so easy that a child can run it almost as well as a strong woman, and it doesn't wear the clothes, fray the edges, nor break buttons the way all other machines do.

It just drives soapy water clear thru the fibers of the clothes like a force pump might.

So, said I to myself, I will do with my "1900 Gravity" Washer what I wanted the man to do with the horse. Only I won't wait for people to ask me. I'll offer first, and I'll make good the offer every time.

Let me send you a "1900 Gravity" Washer on a month's free trial. I'll pay the freight out of my own pocket, and if you don't want the machine after you've used it a month I'll take it back, and pay the freight too. Surely that is fair enough, isn't it?

Doesn't it prove that the "1900 Gravity" Washer must be all that I say it is?

And you can pay me out of what it saves for you. It will save its whole cost in a few months in wear and tear on the clothes alone. And then it will save 50 cents to 75 cents a week over that in wash-woman's wages. If you keep the machine after the month's trial, I'll let you pay for it out of what it saves you. If it saves you 60 cents a week, send me 50 cents a week till paid for. I'll take that cheerfully, and I'll wait for my money until the machine itself earns the balance.

Drop me a line today, and let me send you a book about the "1900 Gravity" Washer that washes clothes in six minutes.

Address me this way—H. L. Barker, 1624 Court St., Binghamton, N. Y. If you live in Canada address 1900 Washer Co., 357 Yonge St., Toronto Ontario.

Notice to Northern Beekeepers!

We are making a specialty of the pound-package trade, and will ship from our yards at Fitzpatrick and other points in Alabama packages and queens during April and May at the following prices:

Pound package with queen, \$2.00; without queen, \$1.25. Untested queens, single, \$1.00; six, \$4.50; dozen, \$8.50; in lots of 50 or more, 60 ets. each. Select tested, \$2.00. Breeders, \$3.50. A special price quoted on packages of 50 or more, and 5 per cent discount on all orders by March 15.

We have improved on the pound package, making it larger and lighter, also giving it more ventilation. The vast experience of our Mr. A. B. Marchant with The A. I. Root Company enables us to know what the trade wants and needs, and we are well equipped to take care of any and all orders, regardless of size.

Our aim is to carry a surplus so as to be enabled to fill orders by return mail, and on the day they fall due. Our stock of three-band Italians has stood the test for 20 years. **There is no better.** We have sold The A. I. Root Company two carloads of bees and several hundred queens, and will sell them again this season. We guarantee safe arrival free from disease, pure mating, no inbreeding, and your money refunded if not satisfied.

After March 15 our address will be Fitzpatrick, Ala.

The Rarest and Best Offer Yet

A daughter of one of Dr. Miller's best honey-getting queens and the *Beekeepers' Review* one year for only \$2.00. Every one will want a daughter of those famous World Champion Honey-producers. Listen to the record: A yard of 72 colonies produced in one season 17,684 finished sections of comb honey, or an average of 245 sections per colony. This is without a doubt the world's record crop from a yard of that size. Start breeding up a honey strain of bees by using one of those famous daughters this season. This is the first time stock from this noted yard has been on sale. Our breeder, one of the very best in the Gulf States, will breed from one of those best queens; and as his original stock is of the best three-banded stock, wonderful results are to be expected. Let us book your order at this time for one of those fine queens, for we have for sale only something like 500 for June delivery. The queen is well worth all we are asking, \$2.00 and the *Review* for a year.

1000 Pound Packages of Comblless Bees for Sale with Queen

Did you ever ask a breeder to quote you a price upon a thousand pound packages of comblless bees? If you did, you will have noticed that he took his pencil from his pocket, and began to figure what such a sale would save him in advertising, postage, office help, etc., and the results would be that he would make you a very close price. Now we have that very close price on one-pound packages of bees; and, as is usual with us to charge no profit on supplies furnished subscribers of the *Review*, none will be charged upon those; but our subscribers will get all the advantage of this good buy. Notice that this close price is not for a late fall delivery, but April and May delivery, later deliveries at a less price that will be quoted later, or by mail for the asking. Upon this deal we have two big points: First, the price; second, an old experienced breeder who has spent his life breeding bees and queens for the market. We mention this so you will not get it into your heads that this is a "cheap job" lot of goods, but that they are as good as money can buy, no matter what price you pay. The price is \$16.00 for ten pound packages of those comblless bees, each containing a young untested three-banded Italian queen of this season's rearing. Additional pound packages, without queen, one dollar each.

For larger lots ask for special price, stating how many you can use and when the delivery is to be made. They are shipped from Alabama, in light well-ventilated cages, by express. Just a word to the wise: Book your orders early! Address?

THE BEEKEEPERS' REVIEW, NORTHSTAR, MICHIGAN

RELIABLE POWER

Nearly 100,000 Galloway engines in daily use. Long stroke, large bore, heavy weight. Built for hard, continuous engine-users' satisfaction. All sizes, prices, styles. Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Geo. L. Emerson, Manager, 948 East Second St.

Where the Weed foundation-machines are making perfect non-sag foundation. Send us your wax to be made into foundation. We buy wax too.

Root Redwood Hives.—A sample hive body with cover and bottom KD, \$1.00. Quantity prices on application. We cut hive parts to order.

New machinery for manufacturing hives and frames has been added. Extractors are now shipped "knocked-down" from the factory at Medina.

Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier if necessary.

THE HYDE BEE Co., Floresville, Tex.

QUEENS.—Italians exclusively; golden or leather-colored. One select, untested, \$1.00; 6, \$4.25; 12, \$8.00. Tested, \$1.25. Best breeder, \$5.00. Early swarms of young bees in light screen cage a specialty. One 1-lb. package, \$1.25; one 2-lb., \$2.25; queen extra. For ten or more, write for price. Also nuclei and full colonies. I am booking orders now, with 10 per cent deposit for delivery March 15 and after. Safe arrival, prompt service, and satisfaction guaranteed. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

FOR SALE.—1-lb. swarm (shipping weight 3 lbs.) Italian bees, \$1.50, without queen, March 20 or later. Untested Italian queen, 75 cts. after April 10; tested Italian queen, \$1.25 after March 20. No reduction for less than 50; 1 to 49 2-lb. bees in package, no queen, \$2.50 each; 50 to 500 2-lb. bees in packages, no queen, \$2.37. Bred from best honey-gatherers; no disease. Safe arrival and satisfaction guaranteed. We are now booking orders with ¼ payment, balance before shipment. "The early swarms get the honey." We can care for your wants for 1916. W. D. ACHORD, successful package shipper and queen-breeder, Fitzpatrick, Ala., U. S. A.

FOR SALE.—Italian bees by the pound, and select-bred Italian queens. One-pound swarms without queens, \$1.25 each; 2-lb. swarms without queens, \$2.35 each; 3-lb. swarms without queens, \$3.35 each, and 5-lb. swarms without queens, \$5.35 each. If queens are wanted with swarms, add price as according to price list below. Untested, warranted purely mated queens, 75 cts. each; tested queens, \$1.25 each. All queens are bred according to our plan of breeding only from colonies or queens of the highest standard—those that have made the best record in pounds of honey. These select colonies are the choice of over 1000 hustling honey-producing colonies. Every queen we warrant to be purely mated or we replace her, free of charge. Every pound of bees we guarantee to deliver alive and in good shape, and full weight. We have no disease. Safe arrival and satisfaction we guarantee on both queens and bees in packages. For wholesale prices on either queens or bees by the pound write us. Let us book your order now. Only a small payment down required. M. C. BERRY & Co., Hayneville, Ala.

FOR SALE.—25 colonies of Italian bees, frames wired, combs built on full sheets of foundation; 8-fr. colonies, \$5; 10-fr., \$6, with queen. HENRY SHAEFFER, 2860 Harrison Ave., Cincinnati, O.

HELP WANTED

WANTED.—An experienced apiarist. State wages, experience, and give references as to ability. Board furnished. THE STOVER APIARIES, Mayhew, Miss.

WANTED.—Man, single preferred, to take charge of apary, 200 hives, and assist in orchard work. HAWTHORNE FARMS Co., Barrington, Ill.

WANTED.—Two young men to help in the apiaries for 1916; prefer young men who want to learn the bee business and are willing to work for reasonable wages and board. I want no one who smokes. Address P. O. BOX 124, Wapato, Wash. 12658

WANTED.—Experienced beeman familiar with conditions in Georgia or Florida, to handle 75 to 100 colonies, on share basis. Can be employed in orange-grove work, regular terms, when not busy with bees. Good opening for the right man. References required. BOX 896, Sanford, Fla.

HELP WANTED.—Can take two clean minded and bodied young men as student help for the season of 1916. Board free for help given, and something more if a good season and help does well. One understanding an auto preferred. Address R. F. HOLTERRMANN, Brantford, Ontario, Canada.

WANTED.—Young man with a little experience; fast willing worker—as student helper in our large bee business of over 1000 colonies; crop last year over 105,000 lbs. Will give results of our long experience, and small wages; every chance to learn. Give age, height, weight, experience, and wages, all in first letter, or expect no answer.

E. F. ATWATER, Meridian, Idaho.

SITUATIONS WANTED

Single man, age 29, beekeeper, wants position in apary. No bad habits. All letters answered. M. McLOVICH, Box 243, Rock Springs, Wyo.

Young married man desires position, thoroly experienced poultryman and beekeeper, also understands farm work; references given. PAUL S. PATTERSON, Rt. 2, Horseheads, N. Y.

Experienced honey-producer and helper wants to work bees on shares this spring. Nothing less than 200 colonies in good section considered. Write H 6268, care of GLEANINGS, Medina, Ohio.

BEEKEEPERS' DIRECTORY

Well-bred bees and queens. Hives and supplies. J. H. M. COOK, 70 Cortlandt St., New York.

Nutmeg Italian queens, leather color, \$1.00; 12 for \$10.00, return mail. A. W. YATES, 3 Chapman St., Hartford, Ct.

QUIRIN's superior northern-bred Italian bees and queens are hardy, and will please you. More than twenty years a breeder. Orders booked now. Free circular. H. G. QUIRIN, Bellevue, Ohio.

QUEENS.—Improved three-banded Italians bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00 each; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.

H. C. CLEMONS, Boyd, Ky.

You can have your beeswax made into *best quality* foundation; also the wax from old combs or slumgum. We get it all out. On shares or very cheap for cash. New factory. Old liberal terms. Cheapest and handiest transportation for all Northern beekeepers. You always get your own wax back. J. J. ANGUS, 454 Fulton St., Grand Haven, Mich.

Convention Notices

STATE BEEKEEPERS' ASSOCIATION TO MEET AT LANCASTER.

The annual meeting of the Pennsylvania State Beekeepers' Association will be held in the Chamber of Commerce Building, Lancaster, on Friday and Saturday, March 3 and 4. Arrangements have been made by the Secretary, Professor H. C. Klinger, of Liverpool, Pa., and the President, Professor H. A. Surface, Harrisburg, to have a complete program, by scientific and practical beekeepers, that will be interesting to all persons who keep bees, or contemplate doing so. There will be discussions of methods of handling bees to get the best returns, methods of producing comb honey, methods of producing extracted honey, methods of treating bee diseases, and an address by President Surface on "The Habits of the Honeybee."

The Pennsylvania State Beekeepers' Association is the next to the largest beekeepers' organization in America. It has accomplished a great deal of good for the beekeepers and fruit-growers, and has secured legislation and appropriations for the inspection of bee diseases. This work has already resulted in eliminating the dreaded diseases of bees in several counties. The State Bee-inspector will be present and tell something about this service. There will be a full discussion of the State law in regard to marking honey sections, and future legislation will be decided.

Governor Brumbaugh and Secretary of Agriculture Charles E. Patton have been invited to attend. The meeting will be open to the public, and there will be exhibitions of honey, bees, bee products, and bee fixtures. Persons desiring to contribute to these exhibitions are invited to bring their products, supplies, or specimens with them.

PROGRAM

BEEKEEPERS' WEEK, MARCH 13 TO 18, 1916, MICHIGAN AGRICULTURAL COLLEGE, EAST LANSING. MONDAY, MARCH 13.

- 12:40 P. M., Beekeeping as an Occupation, F. Eric Millen, State Inspector of Apiaries.
- 1:35, First Steps in Beekeeping, F. Eric Millen
- 2:30, Apparatus, F. Eric Millen
- 3:25, Assembling Supplies.

TUESDAY, MARCH 14.

- 8:00 A. M., General Discussion.
- 8:55, The Colony and its Organization, F. Eric Millen
- 9:50, The Cycle of the Year, Ira D. Bartlett, East Jordan, Mich.
- 10:45, History of Hives and Frames, F. Eric Millen
- 12:45 P. M., Life History of Queen and Drone, F. Eric Millen
- 1:35, Life History of Worker, Morley Pettit, Provincial Apiarist, Guelph, Can.
- 2:20, Comb Foundation, Manufacture and Use, F. Eric Millen
- 3:25, Assembling Supplies,

WEDNESDAY, MARCH 15.

- 8:00 A. M., General Discussion.
- 8:55, Races of Bees, Morley Pettit
- 9:50, Artificial Increase—Use and how Made, Ira D. Bartlett
- 10:45, Relation of Beekeeping to Fruit-growers, F. Eric Millen
- 12:40 P. M., Home Manufacture of Bee-supplies, Ira D. Bartlett
- 1:35, A Beginner's Outfit, Morley Pettit
- 2:20, Anatomy of the Honeybee, F. Eric Millen
- 3:25, Assembling Supplies.

THURSDAY, MARCH 16.

- 8:00 A. M., General Discussion.
- 8:55, Making a Start with Bees, Morley Pettit
- 9:50, The Manipulation of Bees, F. Eric Millen
- 10:45, The Production of Extracted Honey, Ira D. Bartlett
- 12:40 P. M., Spring Management, F. Eric Millen
- 1:25, The Production of Comb Honey, Morley Pettit

- 2:20, Wax Production and Comb Building, F. Eric Millen
- 3:25, Selecting a Location for Beekeeping, Ira D. Bartlett

FRIDAY, MARCH 17.

- 8:00 A. M., General Discussion.
- 8:55, The Causes of Swarming, Morley Pettit
- 9:50, The Prime Swarm and its Location, F. Eric Millen
- 10:45, Methods and Principles of Swarm Prevention, Ira D. Bartlett
- 12:40 P. M., Taking off Extracted Honey and Extracting, Morley Pettit
- 1:25, Bee Diseases, Symptoms and Treatment, F. Eric Millen
- 2:20, Requeening and Introducing a Queen, Morley Pettit
- 3:25, Assembling Supplies.

SATURDAY, MARCH 18.

- 8:00 A. M., General Discussion.
- 8:55, Robbing—Symptoms and Control, F. Eric Millen
- 9:50, Methods of Queen-rearing, A. D. D. Wood
- 10:45, Literature on Beekeeping, F. Eric Millen

ANNUAL BEEKEEPERS' CONVENTION, MASSACHUSETTS AGRICULTURAL COLLEGE; FARMERS' WEEK—SECTION 8, BEEKEEPING. MARCH 14-16, 1916; ALL SESSIONS IN ENTOMOLOGY BUILDING, ROOM F, UNLESS OTHERWISE DESIGNATED.

TUESDAY, MARCH 14.

- 9:10—10:10. Demonstrations:—Methods of winter protection; the latest winter cases, unit and multiple; cellar wintering. M. A. C. beekeeping staff—at the apiary.
- 10:10—11:00. Demonstrations:— The rendering process of wax and wax products. B. N. Gates and J. L. Byard, wax laboratory, basement of entomology building.
- 11:10—12:00. Demonstration of apparatus on display. Concessioners and members of M. A. C. beekeeping staff, beekeeping museum, basement of entomology building.
- 1:30—2:20. Beekeepers' Round Table. Spraying practices versus beekeeping. I. The beekeepers' standpoint, Dr. B. N. Gates, Associate Professor of Beekeeping, M. A. C.
- II. Chemical evidence that bees may be killed by arsenical sprays, Dr. E. B. Holland, Chemist, Experiment Station, M. A. C.
- III. The horticulturist's practices in relation to beekeeping, W. W. Chenoweth, Associate Professor of Pomology, M. A. C.
- IV. The control of insect pests of forests in relation to beekeeping, A. F. Burgess, in charge of Moth Work, Gypsy-moth Laboratory, U.S.D.A., Melrose Highlands, Mass.
- V. Municipal spraying as related to beekeeping, Fred Southard.
- VI. Discussion.

WEDNESDAY, MARCH 15.

- 9:10—10:00. How and when to begin beekeeping, B. N. Gates, M. A. C.
- The care of bees in the spring (demonstration). J. L. Byard, Supt. of Apiary, M.A.C.
- 10:10—11:00. How I dispose of eight thousand pounds of honey, A. W. Yates, Hartford, Ct.
- 11:10—12:00. From among the beekeepers, Mrs. A. H. McCarter, Springfield, Mass. Speaker and subject to be announced later.
- 1:30—2:20. Beekeeping in the counties. I. Essex County, the original beeyard of the United States; the future. E. A. Smith, Director Independent Agricultural School of Essex County, Hathorne, Mass.
- 2:30—3:20. II. Bees on the farms in Worcester County, C. H. White, Manager Worcester County Farm Bureau, Worcester, Mass.
- 3:30—4:30. Lines for county work in beekeeping, III. Beekeeping displays at the fairs, A. W. Yates, Hartford, Ct.
- IV. Sweet clover in Massachusetts, Dr. W. P. Brooks, Director Experiment Station, M. A. C.
- V. The relation of the county agent to the beekeepers' society, O. F. Fuller, Blackstone, Mass.

THURSDAY, MARCH 16.

- 9:10—10:00. Bee diseases. Question-box. Demonstrations will be given, if desired, at the apiary.
- 10:10—11:00. Annual meeting of the Hampshire, Hampden, and Franklin Beekeepers' Association.
- President's address: "Timely Suggestions to Beekeepers," O. N. Smith, Florence, Mass.
- Honey Packages: a Standard, B. N. Gates, M. A. C.

PROGRAM OF THE FIRST ANNUAL BEEKEEPERS' SHORT COURSE GIVEN BY THE WINONA COLLEGE OF AGRICULTURE, WINONA LAKE, IND., MARCH 20 TO 25 INCLUSIVE.

PROGRAM.

MONDAY, MARCH 20, 1916.

- 1:30. Address, Dr. J. C. Breckenridge, President of the Winona College of Agriculture
- 2:00. Beekeeping as an occupation.
- 2:40. Beekeeping apparatus. A laboratory lecture.
- 4:15. Races of bees.
- 6:45. General lecture on bees illustrated with lantern slides.

TUESDAY, MARCH 21.

- 9:25. The cycle of the year in the hive.
- 1:00. Beekeeping in relation to fruit-growing.
- 2:40. Internal anatomy and life processes.
- 4:15. Wax production and comb-building.
- 6:45. The uses of honey in the home.

WEDNESDAY, MARCH 22.

- 9:25. Where and how to begin beekeeping.
- 1:00. The manipulation of bees.
- 2:40. What the State is doing for the beekeeper.
- 4:15. Cellar wintering and spring management.
- 6:45. The evolution of the hive.

THURSDAY, MARCH 23.

- 9:25. Swarm control and increase.
- 1:00. The production of extracted honey.
- 2:40. The marketing of honey.
- 4:15. Methods of queen-rearing and introducing.
- 6:45. Some great men in the beekeeping world.

FRIDAY, MARCH 24.

- 9:25. Fall and winter care of bees.
- 10:15. External anatomy of the honeybee.
- 1:00. Comb-honey production.
- 2:40. Diseases of bees.
- 4:15. Sources of nectar and the location of bee-yards.
- 6:45. The robbing of bees.

SATURDAY, MARCH 25.

- 8:00. Food of bees and feeding bees.
- 9:00. How to handle bees.
- 10:00. Does beekeeping pay?
- 11:00. Educational and research agencies related to beekeeping.

An opportunity will be given for asking questions at the end of each lecture period. A quiz on the lectures of each day will be held the following day.

The lectures will be given by members of the faculty of the Winona College of Agriculture, assisted by experts and specialists along certain lines of beekeeping.

The course as above outlined will be one of value, not only to amateurs, but to veterans as well. It is the desire to teach the fundamental principles, for if these are understood, the details will follow easily. Dr. E. F. Phillips' book entitled "Beekeeping," will be used as a guide, and it is urged that each student provide himself with a copy. It is published by the Macmillan Co., New York, and can be secured from them or from any of the publishers of bee-journals, or from the dealers in beekeeping supplies.

Various kinds of hives and equipment will be on hand for examination and demonstration.

Winona Lake is located on the main line of the Pennsylvania lines running between Fort Wayne and Chicago. It is connected with Warsaw by trolley, and may be reached via Warsaw over the Big Four lines or the Winona Interurban railway.

A fee of \$1.00 is payable upon enrollment. Board and room, from \$4.00 to \$5.00 per week. For further information address J. C. BRECKENRIDGE, President.

TRADE NOTES

PASTE TO STICK LABELS ON TIN.

We have had many calls for a reliable paste to make labels stick on tin. We have something which we have used extensively, and find it good. Price in pint tin cans, 25 cents. When sent by mail it would weigh two pounds, and parcel-post rate would be according to zone. Ask your postmaster.

It is with pleasure that we call the attention of our readers to the new catalog gotten out by The Rawlings Implement Co., of Baltimore, Md., manufacturers of farm implements. Anything required by the farmer, from wrenches or fence wire to gasoline-engines or wagons, they can supply at a moment's notice. They have not forgotten to mention bee-supplies either—everything and anything that a farmer can possibly need. We have done business with this firm for years, and have always found them reliable and prompt. They will send their catalog "U" on request.

BEESWAX WANTED.

We are now, as always, in the market for choice pure beeswax. Our present price is 29 cts. in cash or 31 in trade for supplies for pure average beeswax delivered at Medina, or any of our branches east of the Mississippi River.

Commenting on the price we pay for beeswax a correspondent in St. Louis writes recently: "In calling on one of the commission houses yesterday, the manager of the concern commenced a tirade against your good selves, stating that you were offering the beekeeper more money for his wax than they, the commission people, would pay."

In packing your wax for shipment pack it in double sacks. Put a tag in with your name and address and number of pounds you ship. Use no paper or other packing. Boxes or barrels may be used if burlap sacks are not available; but be sure they are securely nailed so they may not be broken open in transit.

A BETTER DORMANT SPRAY.

The scale, blight, canker, etc., are no longer dreaded by those who do careful spraying with any of the several standard spray mixtures, although some give better results than others with a minimum of labor, and labor is the greatest expense in the spraying game. For this reason, the most desirable spray is the one that will accomplish the most in one operation.

You spray with, say, lime sulphur. If the work is thoroughly done you can hold the minor diseases in check; but there are a number of very serious fungous troubles that are found on the trees in their dormant state that lime sulphur might control if it had the proper powers of penetration; but, unfortunately, it cannot penetrate into the diseased tissues of such troubles as collar rot on apple-trees, apple canker, and the brown-rot spores on peach-trees.

From the foregoing it is apparent that there is a need for a dormant spray that will control all of these pests with a single spraying.

Experiments for the past eleven years have proven that all these diseases can be controlled by the use of a miscible oil known as "Scalecide." In orchards where thoro spraying has been done for years with "Scalecide," various forms of blight and canker have almost entirely disappeared.

The B. G. Pratt Company, 50 Church St., New York, have prepared an interesting booklet, "Proof of the Pudding." They will gladly send this helpful book free on request. Write today for the Department XXX.

A VERY INTERESTING BOOK.

There are probably more fancy chickens raised in the vicinity of Mankato, Minn., than there are in almost any other section of this country. This hobby brought forth a big need for a high-class incubator among those poultry-raisers, and resulted in the establishment of a great incubator-factory at Mankato, known as the Mankato Incubator Co. The president of this company, Mr. F. H. Miller, has written a book on the history and development of the incu-

bator, called "The Story of the Mankato." Mr. Miller is himself a practical poultryman, and knows whereof he speaks. The fact that this machine has made good with the poultry-raisers right at home is sufficient evidence to prove that it will be satisfactory to anybody. This year they are offering a greatly improved type of incubator that should appeal to every progressive poultryman. Detailed information and their interesting book, "The Story of the Mankato," may be obtained by addressing a postal to Mankato Incubator Co., Box 837, Mankato, Minnesota.

THE A. I. ROOT COMPANY, Medina, Ohio.

ON THE BOOKSHELF

Der Gefluegel-Zuechter

Those who are interested in reading German publications printed in the United States in the German language may not be aware that there is a German poultry journal published at Hamburg, Wisconsin, said to be the only paper of the kind issued in this country. The purpose of *Der Gefluegel-Zuechter* is to be of service to all Germans who are raising poultry, pigeons, rabbits, and other pet stock. The publishers have spent about twenty-five years trying to create a wider interest in poultry-raising among the Germans of this country.

The eighteenth annual year book, *The "Jahrbuch for 1916,"* has recently been issued. The publishers of *Der Gefluegel-Zuechter*, Hamburg, Wis., will gladly answer any inquiries about combination price of the publication and "Jahrbuch," or will quote subscription rate on the paper alone.

Simplified Beekeeping

Already looking forward to the time when, after the close of the war, England will attempt to become more self-supporting for her food supply, a new manual of beekeeping has been published to encourage beekeeping in the British Isles. Mr. William Herrod-Hempsall, author of "Producing, Preparing, Exhibiting, and Judging Bee Produce," and junior editor of the *British Bee Journal*, has just written and published a little manual entitled "Beekeeping Simplified for the Cottager and Small Holder."

The book does not attempt to be an exhaustive treatise on the subject, but to give concise rules and explanations for the simple operations in the apiary. It furnishes a very good introduction to more advanced methods. Just like other texts on apiculture, the book opens with a short account of the life of the bee and the curious economy of the colony. Then the author discusses hive and tools, with directions for their use, and finally such matters as marketing, wintering, and diseases.

For one who wishes to keep in touch with the latest British methods, the little work is

well adapted; and it is hard to see how any progressive beekeeper in England can get along without it. Its small size and elementary nature well adapt it to the beginner's use universally. There are 48 pages and a large number of illustrations. The printing has been very successfully done.

"Beekeeping Simplified," by William Herrod-Hempsall, F.E.S. Simpkin, Marshall, Hamilton, Kent, and Co., London, 6d. The book may be secured from the *British Bee Journal*, London, for 12 cents; postage 4 cents.

IS BILLY SUNDAY A GRAFTER?

They hate him that reproveth in the gate, and they abhor him that speaketh uprightly.—AMOS 5:10.

In a hotel recently a traveling man said, "Billy Sunday is a grafter—that is all." A man stepped up to him and said, "What is that?" The traveling man repeated the statement. "Can you prove that?" was the next question. "Why," said the traveling man, "everybody knows it." "Well," said the other, "that may be true. I will give you \$5000 to prove it, however." "Who are you?" asked the traveling man; "one of Sunday's kind?" "No," was the reply; "I am a salesman for a brewery. Billy Sunday is doing our business great harm, and my people will gladly give \$5000 to show him up if he's a grafter, and to stop the harm he is doing our business."—From *Civic League Record*, reported in *The Sunday School Times*.

"Best" Hand Lantern

A powerful portable lamp, giving a 300 candle power pure white light. Just what the farmer, dairyman, stockman, etc. needs. Safe—Reliable—Economical—Absolutely Rain, Storm and Bug proof. \$1000 COLD CASH for Beemen

Make a CLEAN Fortune from UNCLEAN Millions

New - - Brilliant - - Scientific Invention

Solves mighty home problems. People everywhere are waiting for it—wonder why it was never invented before. Supplies enormous demand. Covers new field. Just out—just introduced. Tremendous rapid sale staggers country. Remarkable demonstrations going on everywhere. Agents happy—banking enormous profits daily. \$80.00 clear in 2 days—one man's record. Mighty opportunity for you to get the mighty dollar. Failure impossible.

No Experience Required

Territory free, but going fast—worth fortune—get yours today. Write now. Don't lose by waiting. Win by immediate action—without risk, obligation, or cost—the very chance you have been looking for.

Hailed as a Great Blessing to Humanity

Clean homes demand clean shoes. Dirty shoes with their load of dirt, mud, or snow have been the bane of every woman's life. Women for ages have been slaving to keep the house clean, but it is no longer necessary to endure the hardship imposed by dirty shoes. The time has come when people can and will "wipe their feet before entering." This problem is solved—this longed-for and enjoyable condition is now a happy reality for all. Once again man's inventive genius has conquered and lifted a great burden from women's shoulders.

Every family wants Grab's Automatic Foot Scraper on their doorstep. Replaces unsightly, unsanitary, crude door mat. Mud, dirt, dust, snow, dirt of all kinds, removed in a jiffy. Works like magic—sells like "sixty." (Ramsey, of Mont., writes: "Only 45 families in town—have sold all.") A positive pleasure for any one to use—a source of never-ending comfort to the housewife, to all who value cleanliness.

It

Only
\$1.00

Grab's Scientific Shoe Scraper

Truly a mechanical and scientific wonder. Automatically removes mud, dirt, dust, snow, from shoe in one operation. Cleans sides, sole, heel. For men, women, children. Automatically adjusts itself to any size shoe—any shape. Attaches quickly to any doorstep or other handy place without screws, nuts, bolts. Neat, attractive, always ready to use. Rotates for sweeping. Handsomely enameled. Saves drudgery, time, money, shoes—saves carpets, floors. Mechanical wonder. Weighs less than 3 pounds. Very compact, strong, easy to carry. Has 7 new patented features not found in any other scraper—10 steel blades—10 dirt outlets—twin adjustable and removable brushes—compound springs. Can't clog—practically self-cleaning. Guaranteed satisfactory or money refunded.

Means less dirt—less work—less drudgery—less shoes to buy—longer life to rugs, carpets, floors—better health. Over half million in daily use. It appeals to everybody. High grade, unquestionable merit, something with class, practical and durable value, unique, odd, and pleasing to the eye. Sells on sight. No forcing, no salesman's tricks or deception necessary. Simply tell the truth—that's all. You have nothing to learn—nothing to set up—no dirty work to do. Seeing dispels all doubts, settles all questions, a sale results. So easy because it solves a mighty home problem, costs so little, does so much, is not a luxury, but an actual necessity. Every person who sees it wants one. (J. Rowan, Mont., writes: "Six dozen received. All sold, and more. Find them easy sellers, as they fill a long-felt want.") This invention is right for the public, right for you. The price of \$1.00 retail is insignificant, everybody can afford it, everybody recognizes immediately its great practical value, can see at a glance that it saves labor, drudgery, health, worry, time, carpets, floors. You have no competition. There is nothing else like it. What others have done you can do, but do your part—get started today.

Read These Amazing Cash Records

Walters, Tex., made \$25 first day; never sold goods before. Arnold, N. D., orders one, then 2 gross; sold 160 in 2 days. Hagen, Tex., sold 100 in 2 days. Webb, Pa., averaged 10 sales per hour. O'Connell, Mont., 25 first day. Mike Bock, Minn., 30 first day. Mrs. Windsor, Mo., "Ship 6 dozen more. First 3 dozen all gone. Have orders for 75 more." G. Rauscher, Minn., "Ship 5 dozen. Sold 36 first morning." G. Froom, Iowa, "I sold 30 first hour."

Hundreds like these—many doing better. You, too, can have money in abundance. Just get started. Quit the shirt-sleeve wages—stop worrying with goods that everybody has or nobody wants. Get Grab's. It's new, wonderful, irresistible.

The New "F" Super and Its Advantages

The "F" Super is one of the new improvements which we have added to our line. It consists of a super holding 4 x 5 x 1 3/4 plain sections, and can be furnished in either eight or ten frame size. The eight-frame super holds 28 sections and the 10-frame 32 sections. This super is unlike many of the supers on the market, as it takes standard equipment and offers the beekeeper who at any time might care to change over to extracted honey an exceptionally good item.

It can be used for extracted honey by purchasing 5 3/4-in. frames which will fit the inside of the super, or it can be used for comb honey. This saves the beekeeper from purchasing a whole new outfit should he ever care to change over to extracted honey, and at the same time gives him an A1 comb-honey outfit for the same price as a comb-honey super can be purchased.

Any row of sections can be taken out and replaced with a shallow frame without making any other changes or adjustments. Some of our customers who have been substituting the shallow 5 3/4-inch extracting-frames on each side or in the middle are inclined to believe the bees enter the super much quicker.

Prices of the "F" super will be gladly furnished upon application.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.
COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12 1/2 oz. net or 13 1/2 gross. The top of each section in this grade must be stamped, "Net weight not less than 12 1/2 oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz.

net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells, all together, which must be filled with honey; comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color, and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

Leahy Mfg. Co., 95 Sixth St., Higginsville, Missouri

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES

Adopted at Cincinnati, Feb. 1913

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white or slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified, as, first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

CHICAGO.—There has been a free movement in honey during the past two weeks; but, as stated in a previous report, prices are weak, and the desire to push sales at every opportunity is apparent. Beeswax is steady at 30 cts. per lb.

Chicago, March 2. R. A. BURNETT & Co.

INDIANAPOLIS.—The demand for honey of late is light, more especially extracted. We shall have very little to carry over the summer months, if any. Choice white comb is selling at \$3.75 to \$4.00 per case; No. 2 white comb, \$3.50. Extracted of finest quality is bringing 9½ to 11. For wax we are offering 28 cts. cash, or 30 in trade.

Indianapolis, March 3. WALTER S. POWDER.

NEW YORK.—Very few sales are being made in comb honey, as dealers have sufficient stock. Light extracted has been pretty well cleaned up. Prices range from 7 to 8. There is a fairly good demand for buckwheat extracted at 6 to 6½. West Indian honey is selling at 55 to 60. There is a normal demand for this, but importations are light, hence the high price.

New York, March 7.

ALBANY AND SCHNECTADY.—Lower prices have stimulated the demand for honey, and it looks now as tho the market will be well cleaned up, and no stock to carry over. In fact, there is a scarcity already of buckwheat, both in comb and extracted; this will help out on clover. We quote fancy white at 13 to 15; medium grades, 10 to 12; buckwheat, 12 to 13; extracted, light, 7 to 8; amber, 6 to 7; buckwheat, 6½ to 7.

Albany, March 7. CHAS. MACCULLOCH.

ST. LOUIS.—Our local honey market has been very dull the past two weeks, both in comb and extracted honey. While supplies here are not large, they are fully ample for the small demand. We are getting from the retail grocers for No. 1 white comb honey \$4.00 per case; light amber from \$3.25 to \$3.50; amber from \$2.50 to \$3.00. Extracted honey in 60-lb. cans is bringing from 7 to 9; Southern amber extracted, in barrels, from 5½ to 6½, according to quality and quantity. Beeswax is firm at 28½ for pure; impure and inferior, less.

St. Louis, March 6. R. HARTMANN PRODUCE CO.

B. M. CARAWAY, MATHIS, TEXAS

You Should Earn \$25 a Colony from Your Bees This Season

This can be accomplished if you have a young prolific queen and a strong colony when the honey-flow arrives. Many beekeepers fail to secure the greatest possibilities from their bees because their colonies are not strengthened and built up early in the season, making it possible for them to take advantage of the honey-flow when it arrives. This should be a good season for clover honey, as weather conditions last year throughout the country were the best for securing a good strong stand of clover we have had for many years.

We now have a large queen-rearing outfit in Florida for the express purpose of supplying you with EARLY QUEENS AND BEES IN PACKAGES. We are breeding from queens that gave a surplus of 300 pounds per colony in a 24-day honey-flow. You should have this strain of bees in your yard, and insure the placing of each of your colonies on a paying basis. We have a large supply of queens at this time, but as orders are coming in rapidly, we recommend that you provide for your requirements early.

THE J. E. MERCHANT BEE AND HONEY COMPANY, CANTON, OHIO

The Rarest and Best Offer Yet

A daughter of one of Dr. Miller's best honey-getting queens and the *Beekeepers' Review* one year for only \$2.00. Every one will want a daughter of those famous World Champion Honey-producers. Listen to the record: A yard of 72 colonies produced in one season 17,684 finished sections of comb honey, or an average of 245 sections per colony. This is without a doubt the world's record crop from a yard of that size. Start breeding up a honey strain of bees by using one of those famous daughters this season. This is the first time stock from this noted yard has been on sale. Our breeder, one of the very best in the Gulf States, will breed from one of those best queens; and as his original stock is of the best three-banded stock, wonderful results are to be expected. Let us book your order at this time for one of those fine queens, for we have for sale only something like 500 for June delivery. The queen is well worth all we are asking, \$2.00 and the *Review* for a year.

1000 Pound Packages of Combless Bees for Sale with Queen

Did you ever ask a breeder to quote you a price upon a thousand pound packages of combless bees? If you did, you will have noticed that he took his pencil from his pocket, and began to figure what such a sale would save him in advertising, postage, office help, etc., and the results would be that he would make you a very close price. Now we have that very close price on one-pound packages of bees; and, as is usual with us to charge no profit on supplies furnished subscribers of the *Review*, none will be charged upon those; but our subscribers will get all the advantage of this good buy. Notice that this close price is not for a late fall delivery, but April and May delivery, later deliveries at a less price that will be quoted later, or by mail for the asking. Upon this deal we have two big points: First, the price; second, an old experienced breeder who has spent his life breeding bees and queens for the market. We mention this so you will not get it into your heads that this is a "cheap john" lots of goods, but that they are as good as money can buy, no matter what price you pay. The price is \$16.00 for ten pound packages of those combless bees, each containing a young untested three-banded Italian queen of this season's rearing. Additional pound packages, without queen, one dollar each.

For larger lots ask for special price, stating how many you can use and when the delivery is to be made. They are shipped from Alabama, in light well-ventilated cages, by express. Just a word to the wise: Book your orders early! Address

Honey reports continued from page 2.

ZANESVILLE.—The market is firm, save that western comb, on account of its tendency to granulate, is being offered at some reduction from standard prices. Best white is selling at \$3.50 to \$4.00 a case, according to condition and quantity. There is about a normal demand for extracted, white bringing 9 to 11; off grades correspondingly less. Producers receive for beeswax 28 cents cash, 30 in trade. Selling prices are largely arbitrary, and vary with quality and quantity.

Zanesville, March 4. E. W. PEIRCE.

KANSAS CITY.—The supply of both comb and extracted honey is large, and the demand very light—especially on extracted. We quote No. 1 white comb honey, 24-section cases, \$3.10 to \$3.25; No. 2 ditto, \$2.75 to \$3.00; some sales of No. 1 white comb honey have been made at \$3.00; No. 1 amber comb honey, 24-section cases, \$3.00; No. 2 ditto, \$2.50 to \$2.75; extracted white honey, per pound, 7½ to 8; extracted light amber, 6½ to 7; extracted dark amber, 5½ to 6; No. 1 beeswax, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.
Kansas City, March 3.

MATANZAS.—We are now paying for extracted honey in our city 44 to 45 cents a gallon.

Kind Words

You can discontinue the ad., as the results were very satisfactory.
Helena, Mont. DR. W. M. COPENHAVER.

A KIND WORD FROM A LIFE SUBSCRIBER AWAY OFF IN INDIA.

I am very grateful to you that you are kind enough to send me your paper regularly. The matter it contains is not only beneficial in a business way, but A. I. Root's talk is so full of morals and humanity that whenever the paper comes to me I become so much absorbed in his writings that I feel as if we were face to face. May God bless him with an unusually long life, and greatly enhance his good doings. Reckon me one of your life subscribers, and please say what is the subscription.

MOH'D ABDULLAH HUSSAIN.
Hyderabad, India, Sept. 17.

FROM FAR OFF AUSTRALIA.

Mr Root:—I wish to let you know how I value GLEANINGS. It is a journal that no beekeeper can afford to be without, as it contains all the information he needs to handle bees successfully. We are just now passing thru the hardest time here for the beekeeper, as the weather is very dry and there is scarcely any bloom. Most of the bees are dying. My bees are holding their own with my help and knowledge that I have learned by reading GLEANINGS. When my friends come and look at my bees they say, "Your bees look pretty well," and when I show them the inside of the hive they say, "Oh! I wish my bees were half as good as yours. How do you manage to keep them up to such a high standard with plenty of bees and brood in all stages, and so even? You should see mine. The brood is scattered over the frames in patches, and often there are four or five eggs in one cell. How do you account for my bees being in such condition while yours are in such good order and looking so well? Your workers are as large as my queens. My workers are small and dull-looking."

My first question is, "Do you take GLEANINGS?" The answer is always "No," just as I thought. Then I say, "There is where you make the biggest mistake, as it is the only practicable road to beekeeping. Bees are bees, it does not matter where you are. In Queensland or America they need the same attention. If you read GLEANINGS it will be like having some one tell you what to do, especially the letter from Mr. Doolittle. He has told me many things about beekeeping that I should have never thought of, and I must not forget you. I have tried several of your directions in different respects, and have always been successful. So you see I cannot be without GLEANINGS. The price of it is nothing compared with what it gives back.

Toowoomba, Australia. WALTER LINCOLN.

Do You Farm?

Then you should read these interesting and practical books on agricultural subjects by writers of proven authority.

Our Farming.—By T. B. Terry; in which he tells "how we have made a rundown farm bring both pleasure and profit;" 6 x 9 inches; 367 pages; paper; 50 cents postpaid; cloth, 85 cents postpaid.

Barn Plans and Out-buildings.—A new and revised edition, giving thoroly practical plans and specifications for agricultural buildings. Well illustrated; 5x7½ inches; 388 pages; cloth, 90 cents postpaid.

Irrigation for the Farm, Garden, and Orchard.—By Henry Stewart, C. E. In these days of intensive agriculture, not only the westerner but any one seeking bigger crops will find this book valuable. Illustrated; 5 x 7½ inches; 274 pages; cloth; 90 cents postpaid.

Talks on Manures.—By Joseph Harris. Covers the subject completely, containing numerous analyses of manures and comparative tables. Illustrated; 366 pages; cloth; \$1.35 postpaid.

Manures and How to Make Them.—By Frank W. Sempers. A standard work on the subject, which has gone thru many editions; 5 x 7½ inches; 218 pages; paper; 30 cents postpaid.

Handbook for Lumbermen.—An elementary treatise on sawing and saw-filing. Illustrated; 6 x 9 inches; 100 pages; paper; 10 cents postpaid.

Turkey Secrets.—The advice of Horace Vose, who for thirty years supplied the White House with its Thanksgiving turkeys. Illustrated; 6 x 9 inches; 60 pages; paper; 25 cents postpaid.

GLEANINGS IN BEE CULTURE,
Medina, Ohio

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

remember we carry a full stock and sell at the lowest catalog price. Two lines of railroad—Maine Central and Grand Trunk. Prompt service and no trucking bills.

THE A. I. ROOT CO., Mechanic Falls, Maine
J. B. MASON, Manager

Candy for WINTER STORES

Why not be sure your bees have enough for winter by giving each colony one or two plates of candy? We have it in large paper plates weighing about two pounds, enough to last a colony three or four weeks. Can be sent by post. Write for prices, also catalog of supplies.

H. H. Jepson, 182 Friend St., Boston, Mass.

Equipment purchased during the quiet winter months may be made ready for busy spring and summer months. The early-order discount pays you interest on your money.

“Root Quality” equipment means BEST QUALITY equipment. The Root bee supplies are up to the minute. The most complete line of bee supplies made.

We sell Root's Goods in Michigan. Order from Root catalog, or we will quote on request. March cash discount, 1 per cent. Beeswax wanted.

M. H. Hunt & Son, 510 N. Cedar St., Lansing, Mich.

“If Goods are Wanted Quick Send to Indianapolis”

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apian supplies that successful beekeepers have proved to be *profitable* in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

BLANKE MFG. & SUPPLY CO., Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST LOUIS, MO.

PACKARD ROADSTER

1912 model; cost new \$4200. I guarantee it in perfect condition, and as good as when it came from the factory; has electric lights, new tires, and an extra tire (wonderful car). If interested, write me; will sell at a big sacrifice.

Fred W. Muth, 204 Walnut Street, Cincinnati, Ohio

"Next Door to Everything"

Reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

March cash orders are subject to a cash discount of 1 per cent off catalog prices. Clover looks most promising for the coming season, and it is the part of wise foresight to anticipate all possible requirements.

E. W. Peirce,

22 So. Third St. Zanesville, Ohio

We make an 8 and 10 frame chaff hive, also an 8 and 10 frame single-walled hive. Several styles of supers can be used with these hives.

The prices will please you. Catalog of bees and supplies upon request.

The Whole Country Praises The New Lewis 1916 Beeware Catalog

FROM CALIFORNIA: "Much pleased with your 1916 catalog. Other catalogs are all right for the man who knows the goods and knows just what he wants. Your cuts, descriptions, and arrangements are so good they will give delight to the amateur or the one who wants to know in detail of new things."

FROM MARYLAND: "We are in receipt of your 1916 catalog and wish to compliment you on same."

FROM TEXAS: "Have heard quite a good many expressions from beekeepers who have received a copy of the 1916 Lewis Catalog, commenting on the beauty of this catalog and upon its improvement over any catalog they have ever seen."

FROM WISCONSIN: "Received your 1916 catalog. It is a dandy."

FROM NEW YORK STATE: "Congratulate you on its neat appearance. Each season it is a little better than the preceding one."

Send Right Now for a New Lewis Catalog

Here are Only a Few of the Distinctive Features Contained in It:

Our NEW METAL-BOUND DIVISION-BOARD in the full-depth size is to be found illustrated, described, and listed.

A very good tool in the shape of a KNIFE FOR SCRAPING AND CLEANING FILLED SECTIONS is illustrated, described and listed.

A WOVEN WOOD-AND-WIRE CHEST, which is a low-cost article with many uses, is illustrated and described.

One page is given over to the RAUCHFUSS FOUNDATION CUTTING-BOX, a practical little outfit for the beekeeper.

Two other articles, a SECTION-HOLDER NAILING-FORM and FRAME WEDGE-DRIVER are offered.

Two whole pages of INSTRUCTIONS TO BEEKEEPERS, by C. P. Dadant, will be found interesting to the old beekeepers as well as the new.

One page devoted to the PROSPECTIVE BEEKEEPER is very interesting, and many new thoughts are presented.

EDITORIAL

The Beekeepers vs. the Smelting Company; Case Continued

IN our issue for Dec. 15, page 915, and again Feb. 15, page 134, we referred to a case where the beekeepers had entered suit in the sum of \$30,000 against a silver-smelting company, of Ontario. The case was to come up for trial last November; but owing to a change in attorneys for the beekeepers the case was continued till this spring or some time in May. We will keep our readers advised.

"Facts About Honey"

THIS is the title of a new honey-booklet gotten out by the *American Bee Journal*, on the use of honey as a food. It not only takes up the question of what honey is, its sources, and its flavors, but how it is produced. It closes with a general discussion of honey, showing how it compares with other food, and how it is actually cheaper, and in many cases more wholesome.

This booklet is sold at a very low price by the *American Bee Journal*, the object being to furnish it to producers of honey so that they can furnish it free to their customers.

For particulars address the *American Bee Journal*, Hamilton, Ill., the publishers of which will be glad to send copies on application.

German Poster Stamps

SOMEWHAT along the line suggested by Walter S. Ponder in his article on page 151 of the February 15th issue are the German poster stamps shown on another page. These stamps are beautifully colored in gold, red, black, blue, green, and yellow, and are the work of Max Mandl, printed and published by Verlag, *Sddeutsche Bienenzeitung*.

For the benefit of those of our readers who do not understand German, we give

herewith the title of the various stamps as they appear in order on the page. Saluting the Queen; In the Bee Nursery; Cleaning out the Hive; The Bee as an Architect; A Bee Funeral; The Guards at the Entrance; The Honey-gatherers; Ventilating the Hive; Issuing of the Swarm.

Death of Dr. Henry Wallace

DR. HENRY WALLACE, editor of *Wallace's Farmer*, Des Moines, Ia., died suddenly while attending a laymen's missionary meeting in his own church on Feb. 22. Dr. Wallace was not only an able editor, but an active Sunday-school and church worker. He was greatly interested in bees; and when we spoke in Des Moines on the subject of the relation of bees to horticulture he was a very attentive listener, and afterward invited us out to his home.

On Sunday we had the privilege of hearing "Uncle Henry" teach his men's Bible class, and a rare treat indeed it was to listen to this modern Gamaliel who had done so much to mold the lives of the men and women of this country—particularly farmers.

Fortunately he leaves some able sons who have been for some years the active managers of the *Farmer*, a periodical that has a nation-wide circulation. He will be remembered by thousands upon thousands for his Sunday-school talks in that paper.

The Death of Herman F. Moore

WE desire to chronicle the death of every prominent beeman in the industry as soon as it occurs; but, unfortunately, we did not get the notice of the death of Mr. Herman F. Moore until very recently. This occurred on the 21st of December last, following an operation.

Mr. Moore was a charter member of the Chicago and Northwestern Beekeepers' As-

sociation, and its secretary and treasurer for many years.

He was, perhaps, better known as a honey-salesman. About thirty years ago he distinguished himself by selling honey by sample, and later made deliveries. He was peculiarly successful—so much so that later he went to Chicago where he went into a similar business. Later on he took up the study of law, and, after being admitted to the bar, worked at his profession. But he never got entirely away from bees or honey.

He was one of the best-known beekeepers in northern Illinois. He was a brother of J. F. Moore, of Tiffin, Ohio, a large and successful honey-producer, and formerly president of the Ohio State Beekeepers' Association. The brother, J. F., used to work with Herman F. in selling honey, if we are correct.

Spencer Apiaries Company

THERE have been a number of complaints against this concern, and we have investigated them carefully. We believe that these people are entirely honest, and intend to treat their customers fairly, but for the time being they have been financially embarrassed. During May of last spring their locality was visited by a cold rainy spell lasting some twenty days or more; and as they had some 2000 colonies of bees located in twenty yards in the mountain sections, and the bees being bred up very strong, and having consumed all their honey in breeding, they were unable to get around to all their yards and feed the bees, and hence they lost over 300 full colonies of bees and over 500 queen-rearing nuclei in this cold spell. This caused some of their creditors and help that were working for them to become scared, and they attached considerable of their property, thus tying up all their affairs. As these attachments covered considerable of the money that had been sent them by their customers and deposited in their local bank it put their affairs in very bad shape. They were unable to rear any more queens or return the money for many orders that had been sent them. Their honey crop being very short they were unable to pay all their help, as the prices that could be obtained for their honey were very low. They are holding their crop for a better price. We have corresponded with their local bank, and they have confidence in them that they will make good if given time.

We are placing the advertising of the Spencer Apiaries Co. back into our columns, as we believe they are doing every-

thing in their power to straighten up their affairs, and, so far as we know, they have made adjustments in many cases, and in others they have promised to do so just as soon as possible.

Heavy Snows in the West; Is there a Bumper Crop in Sight?

IN his department in the last issue, Wesley Foster comments on the abundant snow in the hills of Colorado, assuring plenty of irrigation water thruout the warm weather. The snow gradually melts, and the water finds its way into the streams, which are thus kept from drying up.

A prominent lumber company of Chicago, in a circular letter, refers to this condition as follows:

The conditions west of the Cascade Mountains, particularly in Washington and Oregon, also through Idaho, Wyoming, and Montana, are something unprecedented in the extreme amount of snowfall, practically stopping all logging operations. The same conditions exist all through Minnesota and Wisconsin. The side-tracks are all completely snowed in. The snowfall has been three to four feet, with exceptionally cold weather, making it almost impossible for the railroads to operate.

There have been good rains in California. The snowfall in the northwestern states has been exceptionally good, and in the central and eastern states the prospects for clover have never been better. "There's many a slip 'twixt cup and lip," to be sure; but at this writing the year 1916 looks as tho it might be one of the old-fashioned kind—the kind that beekeepers look back on a good many years after when they had that bumper crop.

A Caution Regarding the Use of Bait, Unfinished, and Fed-back Sections

SECTIONS partly filled with honey, and bait sections, should never be sent away to the general market, as they are sure to granulate in a short time; and a single granulated comb in a case of good honey knocks off several cents per section on all the other sections in the case. Comb-honey producers should be exceedingly careful to keep all of these baits and unfinished sections from the previous season out of their best grades of comb honey. Of course dry unfinished combs without honey will not granulate any quicker than those freshly drawn from foundation.

What shall be done with the baits and unfinished sections? If you cannot extract the honey, sell them around home, of course,

or sell them where they will be consumed within a few weeks. But do not, under any consideration, let them go out mixed with the best grades of comb honey into the general market. Better by far to extract the honey and save the dry combs for bait.

To a lesser extent partly filled sections of the same season completed by feeding back diluted extracted honey will granulate more quickly than comb honey produced in the regular way. Such honey should also be sold near home, and sold early.

A New Edition of the A B C and X Y Z of Bee Culture under Way

WE are hard at work on a new edition of the A B C and X Y Z of Bee Culture. The new volume will contain anywhere from 900 to 1000 pages. As far as possible every subject of any importance will be treated fully, taking up all the latest developments. Nearly all the articles on botany will be written by John H. Lovell. Articles on the chemistry of honey will be written by A. Hugh Bryan, formerly of the Bureau of Chemistry, Washington, now of the Arbuckle Brothers, of New York. The anatomy of bees will be handled by Mr. Snodgrass, and the development of the honeybee by Dr. Nelson, as before. The subject of alfalfa will be treated exhaustively. We have gone over carefully the latest works on alfalfa-growing and sweet clover, and the new articles will contain hints on their culture as well as their value as a honey-plant.

While the old volume was the largest bee-book in the English or any other language, the new one will surpass it considerably. It will contain a large number of entirely new subjects as well as large additions to old ones. The old edition is almost exhausted, and it is possible and even probable that the new one will not be ready for the public until some time next fall. The price will be anywhere from \$2.50 to \$3.00; but until Sept. 1 we will accept \$2.00 in advance as the price on the new edition, when it will be advanced to \$2.50 or \$3.00.

The Attitude of Gleanings toward Goldenes

CONSIDERABLE comment has been stirred up over articles appearing in GLEANINGS recently concerning golden Italians. Both sides of the question are represented; but so far the majority have protested against Arthur C. Miller's condemnation of the goldenes.

Strangely enough, one or two have hinted that GLEANINGS suppresses favorable re-

ports of goldenes, and publishes only the unfavorable. It is hardly necessary to deny this, for any one can learn the truth by examining our pages for the last year or two. We received some reports condemning goldenes that we thought best not to publish. Being anxious to give the goldenes a fair chance we accepted a number of interesting reports *favoring* the goldenes.

We can not believe that the great majority of our readers would think for a moment that we could have any ulterior motive prompting us to suppress facts. We would not mention this matter at all, were it not that so much testimony has come in, pro and con, that it will be simply impossible to publish more than a small part of it.

We believe there will always be a demand, and a good demand too, for golden Italians. They are beautiful bees, and there are many strains of them fully the equal of if not superior to the average leather-colored Italian. Our belief in this matter, as we have stated before, is that the *average* goldenes are inferior to the *average* leather-colored Italians, judging from our own experience and the reports that we receive, both the published and the unpublished. Perhaps time will prove that we are wrong.

The National Convention in Chicago

THIS was held at the Sherman House, as scheduled, on Feb. 22, 23, 24. The attendance was not as large as it has usually been, especially for a point like Chicago. There appeared to be an undercurrent of dissatisfaction over former policies, and as a result some were conspicuous by their absence.

The general discussions were spirited and good, however, and, taking it all in all, entire harmony prevailed.

There were only six or seven delegates present, and the question arose as to whether so small a representation could do business. However, they met in separate session and discussed the question whether the organization should not disband, and leave room for another of national scope, to reorganize along national lines. Wiser counsels prevailed, however, and now it is planned to reorganize; and as a means to that end, an entirely new set of officers were elected as follows:

President, Prof. Francis Jager, of the Minnesota State University, St. Paul; Vice-president, Dr. Ernest H. Kohn, Clover Hill, Ohio; Secretary-treasurer, F. E. Mellen, Lansing, Mich.

As we were not a delegate we were not present at the delegate meetings; but we

were informed that entire harmony prevailed; that all were agreed that, in view of the long and splendid history of the old National of nearly 50 years, it should not be disbanded, but that it should reorganize along lines that would eliminate discord, and then put the organization back where it was in former days when its membership ran up into the thousands, and when its meetings were largely attended. The new officers, we understand, will announce their policies later on.

In another issue we shall endeavor to give a synopsis of the discussions, or at least as much of them as we heard.

Beekeeping Statistics in Indiana

DEPUTY State Bee Inspector B. F. Kindig, of Indiana, has prepared an article for the *Farmer's Guide*, published at Huntington, Ind., under date of Jan. 15, setting forth some interesting statistics gathered from the office of the State Entomologist. The first paragraph of the article contains so much of interest that we are glad to place it before our readers:

Statistics regarding beekeeping are surprisingly incomplete. The most accurate figures that are available in the state are in the office of the State Entomologist. Those records show fairly accurate data of more than 8200 beekeepers. There are more than that number of beekeepers; but how many more, and how many colonies of bees they represent, can hardly be estimated, inasmuch as the government census-takers do not consider bees kept in cities and towns. From the records of the State Entomologist's office the average number of colonies per beekeeper is 13.2. This seems to represent a higher average than there really exists, because the smaller beekeepers do not respond readily to statistical inquiries. From figures available there are in the neighborhood of 140,000 colonies kept within the state. Figuring the average yearly yield per colony at 15 pounds of honey makes a total yearly production of 2,100,000 pounds. This figure may be unfair to the beekeepers, as many of the large beekeepers make a yearly average production of over 40 pounds per colony. Again, thousands of colonies in the state do not return to their owners an average of one pound per colony. Obviously the great difference is accounted for by the difference in the way the bees are kept.

Don't Forget to Enclose a Stamp

As we have noted before in these columns, there are many good beekeepers who will not write for publication on account

of the amount of correspondence entailed. Occasionally we hear mutterings of wrath from some contributor who has been deluged with letters concerning a certain article; and his usual complaint is, aside from the time and energy required in answering the letters, that very few take even the trouble to send the postage for the reply which they expect. Surely those who expect the favor of an answer to a question ought to be courteous enough to enclose postage. It is a businesslike thing to do, and failure to observe this business rule is well nigh inexcusable.

While we are about it we may as well put in a personal plea of our own. We receive from fifteen to twenty inquiries a day regarding some phase of beekeeping, which we try to answer to the best of our ability. Of course, it is possible to use but a very small percentage of these in GLEANINGS, and even those which are answered in GLEANINGS we usually answer also by letter, since in many instances if the questioner had to wait until he saw his answer in GLEANINGS he would get over wanting to know about it. We should greatly appreciate it if our friends who write us these letters calling for answers to questions of a personal nature that would not be of much benefit to any one else would remember to enclose a stamp.

Yes, a stamp is a small thing; but a lot of them together look pretty good. We shall not refuse to answer a question simply because the questioner forgot to send a stamp, but we can answer it more cheerfully if we see that pink stamp with the question.

Information Wanted

We have room for a few more good live articles on the question of out-apiaries, for our special number for May 1. As we have stated before, we pay rather more for material used in these special numbers, for we are anxious to get the best obtainable. It is not quantity but quality that we want.

The great majority of out-apiaries are run for extracted honey. Who is running one or more out-apiaries for comb honey? We want information concerning the prevention of swarming in out-apiaries.

So far we believe that Allan Latham holds the imaginary cup for operating bees on the let-alone system. Out-apiaries require a different management altogether in order to reduce the cost of the labor and of the transportation. In the March 1st issue there were several discussions on extracting at out-apiaries and at central extracting-

plants. As nearly as we are able to determine, the central extracting-plant system, perhaps because of the increasing practicability of the auto truck, is increasing in popularity. We should like to hear from some of the larger producers who run out- apiaries, as to the probability of the central extracting-plant spreading foul brood. Is the central plant more dangerous than a separate extracting-plant at each apiary, or than a portable outfit carried from yard to yard?

In a letter received recently from E. F. Atwater, Meridian, Idaho, he stated that there are a good many beekeepers who would like more complete information on the construction of large solar wax-extractors for out-apiary use—extractors large enough to handle the output of a large apiary, also those used at a central plant, somewhat on the order of the large sun extractor described a few years ago by Mr. R. C. Aiken. This is a field which has been somewhat neglected of late; and since a sun extractor is automatic to a certain extent, and, if well constructed, nearly takes care of itself, this is a profitable theme for discussion in the May 1st issue.

All articles should reach us by April 1.

Bee Inspection in Arizona

A VERY interesting report is that from State Apiary Inspector J. P. Ivy, to the Governor of Arizona, for the inspection work during 1915. A copy of the State inspection law is given in Section 1, of which the salary of the inspector is fixed at \$1000 a year, and privileges given for the appointing of deputies, not exceeding three, whose salaries shall be fixed by the inspector, not to exceed \$4.00 a day.

Section 7 is interesting, and is as follows:

Sec. 7.—No colony of bees shall be shipped or transported into the state for delivery to any consignee residing within the state from any state or foreign country having an inspector of apiaries or other officer charged with the duties commonly performed by an inspector of apiaries, unless said colony be accompanied by a certificate in writing from such officer, stating that he has inspected said colony, and that it is free from infectious or contagious diseases. Whenever a colony of bees shall be shipped or transported into the state from any state or foreign country not having an inspector of apiaries or other officer charged with the duties commonly performed by an inspector of apiaries, the consignee shall, upon the receipt of said colony, forthwith notify the state inspector of apiaries of its receipt, and

the state inspector of apiaries shall forthwith inspect the same. No transportation company or common carrier shall accept for transportation into the state, or shall deliver any colony of bees from a state or foreign country having an inspector of apiaries or other officer charged with the duties commonly performed by an inspector of apiaries, to any consignee residing within the state, unless such colony is accompanied by a certificate of inspection as heretofore provided. No common carrier shall be liable for damages to the consignee or consignor for refusing to receive, transport, or deliver such colony or colonies when not accompanied by a certificate of inspection as heretofore provided. No beekeeper within the state shall move bees from one county to another within the state without a permit from the inspector. Nothing in this section shall be construed to prevent the transportation or delivery of queen-bees when not accompanied by brood or comb, or bees shipped in wire cages when not accompanied by brood or comb. Any railroad company, common carrier, or any person that delivers any colony or colonies of bees into the state shall, upon its arrival, immediately notify the state inspector of apiaries and give the name and address of the consignee.

Mr. Ivy's letter to the Governor submitting his report is brief, but full of "pcp."

Sir:—I have the honor of submitting my report as your Apiary Inspector for the year 1915.

We have installed 34,147 swarms of bees this year; 23,208 swarms in Maricopa County, 4124 swarms in Yuma County, 3131 in Cochise County, 2594 in Graham County, and 1090 in Pinal County.

We have had to contend with an outbreak of foul brood in Cochise County, and have four yards under quarantine at this time. We found 43 swarms in one yard, 18 in one, 11 in one, and 1 in another. They were all promptly destroyed by burning them.

One person broke the quarantine during the year, and he was promptly brought into court. He pleaded guilty and was fined 30 days and \$50.00.

We collected from the five-cent inspection fee \$1073.35 during this year, which was turned into the State Treasury for the account of the Apiary Inspection Fund.

I will send you a tabulated report when we have them printed.

Respectfully submitted,
J. P. Ivy, State Apiary Inspector.

We do not quite understand the meaning of the word "install" in the second paragraph. We wonder if this means inspected. Probably not, for the fund collected from the five-cent inspection fee, \$1073.35, would give 21,467 as the number of colonies inspected.

Following itemized accounts of receipts

and expenditures is a list of beekeepers in five counties. It is interesting to note that there are twenty beekeepers who have over 500 colonies, and a good many others who have almost 500.

The Comb-honey Situation; a Reply to Editors Bixby and Townsend

IN the West, comb honey is apparently pretty well cleaned up. In the East there are large stocks of it left, and some medium and fair grades are being offered at retail at 12 and 15 cents. Indeed, we know of one place in the East where a beekeeper was peddling comb honey out at 7 cents a section. Think of it!

Some lots of comb honey were displayed in the streets of Chicago on the sidewalks at 10, 12, and 15 cents a pound. The temperature outside was below freezing, and of course this honey was taken in at night. This change of extremes in temperature, and the constant handling back and forth, will, of course, make it granulate within a short time. Then it will have to be sold at any give-away price if at all.

There is going to be a large quantity of granulated comb honey this year, simply because there is so much of it, and because the dealers do not know any better than to put it in a refrigerator or in a cold-storage room where the temperature goes up and down between great extremes. As soon as these lots of granulated comb honey are sold, the market on good comb honey will improve, and a better demand may be expected later on.

The question may be asked why there is so much comb honey in the market for sale at such low prices at this time of the year, when formerly the market has been fairly well cleaned up. There are two reasons: First and foremost was the large production of clover comb honey after the 15th of August—at least a whole month after the usual crop is off the hive and ready for the market. Up to the first of August on account of the continuous rains up till then it looked as if the crop of *comb* honey would not be heavy and prices good, and we so stated on page 696, Sept. 1st issue, and also on page 783 of our issue for Oct. 1, 1915. We said, "There is probably more comb honey than was expected early in the season. It is now being unloaded, and it will bring a good price." And yet Editor Bixby, referring to this same editorial in his February issue of the *Western Honey-bee*, says, "In GLEANINGS for Oct. 1 the leading editorial said that on account of the

big crops (?) prices would be 15 to 20 per cent below 1914, while at the same time the government's market letter showed prices only 2 to 3 per cent off. This cost the beekeepers of New York state alone thousands of dollars, but enabled the largest buyers of table honey in the country to get the cream of the New York comb-honey crop for about 11 cents per pound, which is now retailing for 20 cents per section or more. Well, 'misery loves company.'"

Editor Bixby did not read our editorial carefully, and Mr. Townsend evidently took what Mr. Bixby said for granted, and copied it in his issue for March 1, page 88.

While we did say that prices on *extracted* honey would run from 15 to 20 per cent lower, we also said that *comb* honey would bring "good prices." But we did not know then, and no one else did, that the late flow of clover after the long rainy spell had yielded so large a crop. Of course when this honey was dumped on the market that was already well supplied prices dropped. It was the late crop after the summer rains that caused the market to sag, and not any editorial in GLEANINGS or any other publication. If editors Bixby and Townsend will read our editorial again they will see that they misquoted us, but not intentionally, as we believe. There was another cause that tended to bring about this condition of low prices—namely, the enormous fruit crop which could not be exported on account of the war. This tended greatly to affect the price of comb as well as extracted honey, for fruit is a strong competitor; and when there is an over-supply of it, the careful housekeeper who has to count her pennies very closely will, if honey is high and fruit low, buy fruit instead.

The lesson that comes to us now is that we should not lose our heads, and sell our comb honey at retail for 7 cents, but look forward to the future, and keep our product in a dry warm room where an even temperature can be maintained at 75 to 80 degrees and sell it after all the stock now on the market has granulated, and when there will be a demand for good comb honey.

As we stated in our last issue, page 176, the pendulum has swung the other way. For several years back there has been a scarcity of good comb honey, and we have urged a more general production of it. So many have now gone into it that, if they produce as much next year as last, there is liable to be a demoralization in prices. Extracted can be carried over till another year; but this is not true of comb honey, except at a loss.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

THAT'S a good story, p. 176, about the bees, melon-rind, and darkey, but for one thing. Did you ever know bees away from home feeding on sweets to sting when disturbed or kicked?

AT a uniform temperature of 85 degrees "there is some danger of the combs sagging and leaking," p. 89. That's new to me. I always thought I'd like to keep my sections at 90 or more. Please tell us more about it.

HONEY that is too thin may be thickened by heating, but that endangers the flavor. W. F. Reid, *British Bee Journal*, p. 11, offers this scheme: Take dried apples and give them an extra drying in a slow oven; then put them in the honey, and the water of the honey will be absorbed by the apples. Stewing the apples will then give a fine sauce.

DR. PHILLIPS, at the Chicago convention, treated some of us beekeepers, among other things, with a dish of dasheens, the first I ever tasted. They're good; but why has no one before told us that the flavor much resembles that of boiled chestnuts? [A. I. R. has several times referred to the fact that dasheens taste like roasted chestnuts. They have really a combination flavor of the baked sweet potato, common potato, and roasted chestnuts.—ED.]

FOR years I had held that a syrup of 5 sugar to 2 water was equivalent to honey because it seemed as thick. Then to please J. L. Byer I backed down as much as I thought respectable. Now J. E. Crane comes at me, p. 141, and I've got to back down some more. Well, I don't know just where to stand, but not with Byer. I don't believe a pound of sugar with more or less water can take the place of a pound of honey. So there!

G. M. DOOLITTLE bequeaths to me the question, "Do you believe the earth is drying up?" page 144. Well, I can testify that for the past 80 years one decade has had about as much wet as another, and I see no reason why it should not continue. Lately I saw the opinion of a scientist that we might expect such continuance; but a higher authority has entirely settled the question for me in these words: "While the earth remaineth, seedtime and harvest, and cold and heat, and summer and winter, and day and night shall not cease."—GEN. 8:22.

A. I. ROOT, p. 214, not every housewife by any means knows how to make *good* cottage or Dutch cheese—"smearcase" as we called it in Pennsylvania. They don't know the "finger test" Mrs. Root gives, and scald it too hard. A safer way is to pour boiling water into the milk, stirring it around, then letting it stand a few minutes before draining. Some use butter with it, making it into balls. We like it best merely salted, with enough rich cream to make it into a sort of mush. For my personal eating I add honey.

ARTHUR C. MILLER in his list of puzzles, p. 146, throws my way Case 1, in which the bees sealed queen-cells in 2 days and 5 hours after brood was given them. That's easy. When all and more pap has been given the young queen than she can possibly use, there's no use to wait for further growth, and in a few cases I've found sealed cells containing very small grubs. But then, like the trouble-maker he is, he must go and open those cells, and find in them grubs of unlawful age. Well, what more would you expect from bees whose owner constantly sets them the example of setting aside all traditions and precedents? By the way, Arthur, Case 2 is not so very uncommon. Bees sometimes endure, and even start, cells in the presence of a virgin, and I *think* that the virgin herself pays little or no attention to cells until near their maturity.

INFORMATION as to shipping bare bees and bees on combs, p. 136, is right to the point. Somehow it's hard to get rid of the idea that bees already on their own combs are in a little better condition to get to work than what the Germans call "naked bees." Then, too, the brood. Even if all the unsealed brood is destroyed, the sealed brood will go right on emerging for 13 days, and in that 13 days the number of bees may be doubled. With bare bees by express no young bee will be added inside of 21 days after arrival.

But when you talk about bees in car lots, not one beekeeper in a hundred—perhaps not one in a thousand—is interested. As to shipping bees by the pound, very many are interested, and every one *may* be at some time. Thousands of beekeepers might want a few pounds who would never dream of getting a car lot. Any one with a few colonies might ship a few pounds of bees, few a car lot. So what's the use of comparing the two when we're interested in only one?

J. E. Crane

SIFTINGS

Middlebury, Vt.

Just fifty years this month since I bought my first colony of bees.

* * *

Mr. J. L. Byer, page 95, Feb. 1, says it takes a full pound of sugar fed to bees in syrup to equal a pound of sealed honey for winter stores, and he is right.

* * *

We have been using the Raufuss foundation-cutting bar put out by the G. B. Lewis Co., and find that it works very nicely for cutting foundation for sections. One can cut up strips of light foundation very accurately and rapidly.

* * *

The foul-brood situation has greatly improved in Vermont. A good crop the past year has greatly encouraged beekeepers. The value of sweet clover as a forage crop and for bees is of increasing interest. It was out of the usual order to hear co-operation discussed in an eastern convention.

* * *

The Vermont Beekeepers' Association met in the Addison Bee House parlor, Middlebury, on Feb. 17. The day was mild, and attendance good, with a good degree of interest in discussions. I notice the attendance at bee conventions follows quite closely the size of the honey crop of the preceding season.

* * *

I believe the name that A. C. Miller has chosen for his method of introducing queens, namely, "the distress method," decidedly good—see page 107, Feb. 1. Doubtless the distress of the bees is a large factor in the success of the use of smoke. We may introduce queens safely by causing distress by other causes than the use of smoke, as, for instance, making the bees suddenly aware of the loss of their queen or their brood and stores.

* * *

That is a decidedly good article on European foul brood by Timberline Riggs, page 102, Feb. 1. He has mapped out very closely the plan I had thought out for our own yards the coming season should this disease again appear, as it doubtless will. If but little disease is found in a hive, reduce the size of the brood-chamber so it will be crowded. If a considerable number of cells of diseased brood are found, remove or cage the queen for ten days and crowd

them on a few combs. If very bad, unite several and remove or cage the queen and make one strong colony. Better give a young queen. All should have good strains of Italian bees, for best results. Really it is little more than carrying into practice that old command, "Keep all colonies strong."

* * *

On page 157, Feb. 15, the short article by H. H. Root is of more than ordinary value. Various experiments have been made in the past to show the value of bees in an apple orchard, but this I believe is the most satisfactory of any I have seen. However, this could be improved upon. Had Mr. Root taken two branches of nearly the same size and carrying the same number of blossom buds as near together as possible on the same side of the tree, and then counted the number of apples maturing on each branch, the one being covered with mosquito-netting and the other without protection from insects, we should be able to learn the exact value of the work of the insects in the fertilization of the flowers, and just what proportion of our crop is to the credit of insects, mostly bees.

This method of experimenting should be made on a large variety of apples, as it seems probable that a great difference will be found to exist in different varieties in their ability to become fertile without the agency of insects. It is also possible that many varieties will show a marked difference in different localities.

It is significant that of the five apples that appeared to have set under mosquito netting in the experiment by Mr. Root three failed to mature. Had these three been cut open it is probable that they would have been found seedless, the result of imperfect fertilization. I was interested last fall in cutting open a small undersized MacIntosh red apple when I found it quite seedless from lack of being properly fertilized when in flower. This led me to examine small and imperfect apples of another variety. Some were of irregular or abnormal shape, one side developed while the other side had not developed. I found on cutting them open that the very small apples were without seeds, while the irregular-shaped ones would have one or two seeds on the side that had developed most, while the dwarfed side contained no seeds. This shows that partial fertilization had caused the fruit to set, and develop in an imperfect way, but did not produce any perfect fruit.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

FRIO COUNTY BEEKEEPERS' ANNUAL MEETING.

The writer had the pleasure of being in attendance at the annual meeting of the Frio County Beekeepers' Association at Pearsall, Texas, Feb. 7, at which an enthusiastic bunch of beekeepers were present. The outlook for honey, altho very bright in the early part of the year, had been somewhat disturbed by a late freeze in the early part of January. The earlier shrubs had already been in bloom, and the famous huajilla (uah-he-ah) was "tagging"—a term used for "budding" by the beekeepers of the southwest-Texas country; but these were destroyed by the frost; and as the huajilla is the principal source for surplus there was considerable gloom in the meeting over the prospects. Prior to the freeze, beekeeping operations were already well under way. There prevailed a hope that at least part of the losses sustained during the preceding year of practical failure might be recouped by a good crop this year. The later-yielding vegetation was not affected, it seems, and there is still hope that even the huajilla and other shrubs injured by the frost so early in the season may again put out with renewed vigor and still yield well.

The officers elected for the ensuing year are, Frank Talbot, Pearsall, President; O. E. Milam, Moore, Vice-president; B. I. Gilman, Pearsall, re-elected Secretary-treasurer; and R. A. Little, Pearsall, re-elected County Foul-brood Inspector. Among other matters before the association was a request to the writer, as a member of the Texas legislature, for an address on the subject of the foul-brood work of the state, and particularly the foul-brood appropriations and the efforts that so successfully aided in obtaining in all \$13,000 for this work for three years.

ITINERARY BEEKEEPERS' MEETINGS IN TEXAS.

There are at present something like twenty county and district beekeepers' organizations in Texas, and a number more organizing. Each of these organizations has a certain stimulating effect in its respective territory toward an uplift of the beekeeping industry. Besides, each of these associations has a county or district foul-brood inspector to aid in the inspection work, and thus not only protect the beekeepers' interests of the community, but to aid in carrying out more effectively the state foul-

brood-eradication work. The gatherings, field days, and beekeepers' picnics all have a salutary effect.

Another valuable step in addition to this great number of organizations will be the holding of consecutive meetings of as many or all organizations in rotation, one following the other in such a manner that a lecturing staff can attend a large number of such gatherings on a single trip.

It is contemplated at present to arrange for such an itinerary in the very near future, actuated by the probability of a visit to Texas of a number of distinguished northern beekeepers. Among them are expected such beekeepers as C. P. Dadant, E. R. Root, Dr. Phillips, Frank C. Pellett, and others. These will be joined upon their arrival in Texas by a number of prominent Texas beekeepers who will make the rounds to the various meetings with them. State Entomologist Paddock, LeStourgeon, and the writer are among those who expect to join on the trip. Dates of meetings and other details are being worked out, and will be made known as soon as completed.

It is to be hoped that this will not be the only itinerary of this kind, but that there may be others during the year.

SPRING CLEANING-TIME HERE AGAIN.

At this time of the year my enthusiasm in apiairy work runs high, and there is nothing I enjoy more than to take trips out to the apiaries on warm days in early spring for the purpose of cleaning up the yards and putting everything in apple-pie order. This spring cleaning is of the utmost importance to us; and preparing for the year's work makes this decidedly more pleasant and agreeable. Both the clean yards, and the finding of the colonies in excellent condition, beginning their yearly operations by the rearing of brood and building up to rousing strength for the honey-flows later, increases our enthusiasm. Under these circumstances the bees must obviously receive the best of care. Examinations of the colonies should be carefully made, primarily for the purpose of ascertaining their probable needs, in stores or otherwise; and allow me to emphasize again the importance of "cutting out" all the useless drone comb as it is discovered during these examinations. It is true that I have repeatedly mentioned this during the last several years; but it is equally true that there still remains much drone comb to cut out. Cut it out!

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The condition of bees in this locality is several per cent better than at the same time last season.

What is "spring dwindling" but the dying-off of old bees faster than young ones are being hatched? The better the weather and the harder they work very early in the season before brood begins hatching, the faster they dwindle.

The amount of stores a colony contains may be seriously misjudged by lifting the hive as a test. When breeding up rapidly in the spring the brood in itself makes considerable weight, which may be mistaken for stores, causing serious results.

The sudden warm weather coming after the heavy rains has advanced the season a little too fast for the best interests of the beekeepers. Orange buds are developing rapidly, as well as sage growth—a little too rapidly for the increase in bee force.

About an inch of rain for February. I suspected just such a condition when the heavy flood rains stopped so suddenly. I should not be surprised, however, to see considerably more rain in March, and some cold, disagreeable days when we need it warm.

The best and safest way that I know for introducing very valuable queens is as follows: Place two or three frames of hatching brood (no bees) in a super over a very strong colony, with a screen wire between the colony and the hatching brood. Turn the queen loose on the hatching brood. After a few days the brood will be mostly hatched, when the super may be set off on a bottom-board, and the young bees allowed to go to work.

Nothing could show the prejudice against the golden Italians more clearly than the article of Arthur C. Miller, page 147, Feb. 15. It is said of John Randolph, that, while making a speech in Congress against a tariff on wool, he made the remark that he would go a hundred yards out of his way any time to get to kick a sheep. Mr. Miller says a queen from golden stock will produce perfectly gentle bees one season and

extremely cross ones the next. [See editorial.—Ed.]

There is a mistaken idea which is by far too prevalent in the East, and I notice at least one bee journal is guilty of the offense; and that is, calling sage honey *white* sage honey. As a matter of fact, a very small percentage of sage honey is produced from the white sage. Honey from the button (or black) sage is white—when pure, extremely white; but it should not be called a product of the white sage.

The sumac growing in the coast district is entirely different from that of the inland foothill district. I have been told that the sumac of the coast region blooms in July, while I know it blooms in this section in May. I have now found that the coast-region sumac differs greatly from the inland variety, the coast variety being more of the nature of the sumac of the East. I am led to believe the coast-region variety is a much better honey-plant than that of the inland.

Mr. Editor, in your comments on my article, page 150, Feb. 15, you say: "If bees can gather a liberal supply of honey within $\frac{3}{4}$ of a mile from the home yard, and that supply keeps up, they will go no further than that." In this you are entirely correct. In 1905, when the honey-flow was at its height, I could not find a bee further than half a mile from an apiary in a fine sage range belonging to my uncle, for the simple reason that they had plenty to get nearer home. You are also correct as to the aroma from the orange. There are very few blooming plants that produce aroma equal to that of the orange, and it is an easy matter to scent it a distance of five miles at night when the breeze is sufficient to carry it on the night air. But that bees will starve to death within one and a half miles of a good honey-flow I can hardly believe.

Hive government is rarely spoken of in our bee-journals, and seems to be as little understood by all as any one thing in connection with bee culture. We know certain laws of nature followed by bees relative to their conduct in certain cases, such as superseding, brood-rearing, and the like; but to understand what force rules their actions seems never to have been solved. That

there is some means of communicating seems probable—or are they like bashful lovers who understand without words? In early spring the first loads of pollen and honey cause an immediate response in the brood-rearing line. The increased flow is followed by increased action in the same line. The queen follows the action of the colony to a great extent, and distributes eggs largely to the extent of the activity of the colony. But why? What is the impelling force that drives them to their best efforts? In the government of man we know the forces are organized to depend on the leadership of others; but with the bee there seems to be no leader of the forces, but all act as with one accord in the proper direction without confusion or loss of time. Yet there are some actions that seem to point to a ruling power. Take, for instance, a colony that has an old queen and the brood-chamber filled with honey. Introduce a young queen and there is immediate action in the direction of getting the honey removed out of her way. There seems to be as much difference in the action of colonies at times as there would be with men in a factory with a change of foreman. Whether man will ever be able to solve the mystery is hard to say; but we do know that the government of the colony seems almost perfect, and we cannot but wonder.

* * *

I have promised a correspondent to give my method of swarm control thru these columns. This correspondent suggested that I give it thru this channel, as it might be of profit to others. He suggests that the very best plans in use are only partially successful, in which I most heartily concur. A plan followed by one beekeeper, and made a decided success, may be turned into a decided failure by another, for the reason they have not had the necessary experience with the plan. If a farmer hires a clerk from a store who has never been on a farm, telling him to go and hitch up the team to the cultivator, and plow corn, the clerk would be at a loss to know how to go at it. The farmer could tell him all about it; but until he saw the work actually performed he would know little; and until he had tried the work he could not become an expert. But I started to give my plans.

In the first place I consider young queens one of the greatest factors in swarm control; the other most essential thing is *room*—plenty of it. By room I mean what the word implies, both storage and breeding. I try to leave sufficient stores on every colony in the fall, not only to carry them thru the

winter but leave a surplus of from ten to twenty pounds on each colony. It is preferable to leave this over an excluder, as the bees will then cluster below, where there is more or less comb room, and not so much on frames of cold honey. With empty comb room within the cluster, breeding will start at the earliest possible date. As soon as breeding is well started the queen-excluders should be removed, and the combs containing the smallest quantity of honey placed in the middle of the upper super, allowing the queen the free range of the hive. When the lower section of the hive has been filled with brood the queen will go into the upper section of the hive and fill all available space, which, if the combs have been arranged as I have said, will force the greater amount of brood into the center of the upper section of the hive, the outer frames containing most of the honey. After breeding has been well started above, drone combs will begin to appear between the upper and lower frames. By this time in this part of California the honey-flow will be approaching, all of which the bee seems to understand fully. The condition of the colony has now begun to assume the proportions of a lack of room. The bee by instinct knows there is plenty of stores; and the brood that is soon to hatch will cause an overabundance of bees for the storage room at hand, and swarming is the logical way out of the difficulty.

But now is the time to thwart their plans by extracting the upper outside combs clean of all honey. This immediately discourages the idea of swarming, and gives them empty combs to store in, which is *very* essential, as it diverts them from the idea of swarming to that of storing.

The honey-flow is now at hand. The brood should be put below to the extent of ten full frames, raising the lower side combs, which will very likely contain part brood and part honey. The excluder should be put on at this period, which, as the brood hatches, will give an additional amount of room above. When the upper section has been well filled with honey, and sealing begun, it should be raised, and a super of empty combs placed beneath. By the time the last set of combs is beginning to be sealed, the upper may be extracted and set back under the partly filled one. In this manner there will always be storage room supplied in abundance, and little thought will be given to swarming. It is much harder to control swarming where a single surplus super is used than with two. With old queens being superseded an additional trouble exists.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

THE FOUL BROODS!

"Have you read what Orel L. Hershiser has to say about European and American foul brood, p. 11, January 1? If I understand Mr. Hershiser he classes the European as the worse. I have not found this to be so. To be sure, this disease will spread in a colony more rapidly than the American. But with two or three foul cells of the American in any colony, that colony is as surely doomed as if the number were five thousand. But I have had many colonies with from 500 to 5000 foul cells of the European kind that got entirely well without any treatment whatever—not even a change of queens. Then I claim that this type of disease travels in a sort of epidemic fashion like scarlet fever, measles, etc.; and after it has once gone thru any section of country that section is nearly or quite free from this disease for quite a term of years."

I should hardly wish to lock horns with so good an authority as O. L. Hershiser; but he seems to be uncertain of his ground himself, in view of the testimony given by the Dadants and Dr. Miller. He says that if the Dadants are right "we are wasting valuable time by employing the shaking and brushing methods." And we are so wasting, as well, if Dr. Miller is right. Right here is something I have tried to get before the beekeeping world for a long time. The older readers of our bee-papers will remember that, thru the columns of the *American Bee Journal* about a score of years ago, Mr. Cheshire, a noted scientist in bee matters in Europe, said that foul brood is not spread thru the honey, as he had been unable to find the bacilli of foul brood in the honey of badly diseased colonies, but that such bacilli are plentiful in the bodies of the workers, and to quite an extent in the queen. This was so contrary to the teachings of our beloved Moses Quinby, and to my experience also in curing my own apiary of foul brood in the '70s, that I wrote an article for the *American Bee Journal* to prove Cheshire wrong.

Later on, our beekeepers in the eastern part of this state were reporting a bee disease around Albany that they called "black brood," and those ordering queens from these parts would have nothing to do with us unless we could prove that such disease could not be found in our apiaries. I was entirely ignorant in regard to this disease until the A. I. Root Co. had their great field meeting at Jenkintown. Then I learn-

ed that black brood, now called European foul brood, was Mr. Cheshire's foul brood. Had Mr. Cheshire lived I would have gladly made him an apology for writing as I did in the *American Bee Journal*, as his foul brood was not the kind Quinby and we Americans had known. And now, after many years of experimenting, I am just as sure that Cheshire was right regarding European foul brood as I have always been that Mr. Quinby was right in saying that American foul brood was spread thru the honey. Therefore it has seemed little less than wicked to insist that the correct treatment for European foul brood is the Quinby-McEvoy plan of shaking the bees and confining them three days, then living them on frames of comb foundation, thus bringing a "mountain" of wasted labor on thousands of apiarists. Scores of colonies having European foul brood (some so bad that half or more of the larvæ were dead) getting entirely well without any effort being put forth toward curing them confirmed my belief that the disease is *not in the honey*.

To be absolutely sure, I conducted one more experiment. Two years ago last spring I got some bees ready for shipment that were being sold to settle up an estate, and in fixing them I found one colony that had a large amount of honey left over in a twelve-frame hive with six combs of brood, two-thirds of which was dead and more or less rotten from European foul brood. We nevertheless had none of this disease in our apiaries. I brought home the six combs of honey from this colony and put them in a hive with four empty combs from our store-room. Then I shook a fairly good colony on them. This was about May 20—a time when the European disease takes hold the most rapidly. There was no sign of the disease that season nor since.

Now, Mr. Hershiser, please do not insist that this disease is disseminated thru bees having occasional access to honey shipped to city markets; particles sticking to containers; garbage-cans or pieces thrown out of car-windows, and diseased honey used for queen-mailing cages. This is all right for *American* foul brood, but cannot apply to the European.

Now about the epidemic matter: The fact that this disease first obtained a foothold in this locality about twelve years ago, no one knowing whence it came, attained its height about five years later, grew less during the next three or four years, and then disappeared, makes this seem reasonable.

GENERAL CORRESPONDENCE

CELLAR VERSUS WINTER CASES

Packing in Long Rows vs. Packing Four in a Winter Case

BY JOSEPH J. ANDERSON

Looking over the editor's comments on my article in the Dec. 15th issue I am led to make a few further observations.

As to cellaring, the Root cellars, as I remember them, are merely rooms partitioned off in the very large basements of their manufacturing plant and warehouse. The one in the manufacturing plant I remember as having a window above ground, heavily curtained to keep out the light. These rooms would be materially affected by the temperature and other conditions prevailing in the very large basements of which they are only part, particularly as these basements are only partially under ground. It seems to me the conditions would be considerably different from those prevailing in the cellar of the average beekeeper, even if large enough to hold several hundred colonies.

My cellar is 16 x 18. It is a log structure set in an excavation in the hillside, with a vestibule or entrance in front, and entirely covered over with dirt. It is provided, of course, with ventilators. The earth floor is sandy. In the winter of 1913 I wintered only 64 colonies in this repository, with bottoms and covers on, and they did not winter nearly as well as those with bottoms removed last winter, when I had 158 colonies in the cellar. It is my opinion that in this cellar better wintering will result by removing bottoms, whether the number of colonies be 15 or 150.

The editor's deductions as to heeling in agree with my own—at any rate, as before indicated, I feel that my experience with that method of wintering has been quite sufficient. The colonies in long rows, straw-packed, wintered nearly as well as did those in winter cases. An objection is mentioned, that bees in long rows drift. This is true, and the objection is not an unimportant one either. It is my experience that, with colonies packed in long rows, drifting will invariably occur.

Another rather serious objection is the danger of fire. A blaze kindled in the straw, either by accident or malice, would spread with almost lightning rapidity, leaving no hope of saving any of the bees in the row. At least two members of our association have had this experience.

The big quadruple winter cases make good fire insurance. Even should one of these take fire, which is very unlikely, there would be very little danger of the conflagration spreading to others.

On page 96, Feb. 15, our good friend Wesley Foster says: "One thing that would be interesting to know is what the loss would have been had Mr. Anderson wintered one hundred of his colonies on their summer stands with no protection."

Now, that is a point on which I have no ambition to shed any light by my own experimenting.

Sometimes bees come thru well in this section without protection—that is, with light losses. Other seasons results are disastrous.

A neighbor of mine went into winter in 1914 with over 130 colonies unprotected. When I inspected his bees last spring he had less than 80, many of them very weak, and quite a number died after I saw them. Some three or four years ago another neighbor lost 22 out of 30, and still another, two years ago, had about 25 left out of 70.

No first-hand experience along this line for me. I'm quite willing to profit by the other fellow's experience, Brother Wesley.

But, say, didn't the printer slip a cog? Your article makes it appear that with young and vigorous queens, plenty of bees, and ample stores not to exceed a five-per-cent loss will result in Colorado without winter protection. Possibly this might be true for the southeastern section. What effect would protection have on the 3 to 15 per cent winter loss in the south?

Yes, Idaho, as a whole has a damper climate than either Utah or Colorado. Arizona and Nevada may be omitted in the comparison, because they are exceptionally dry states. But there is a vast difference between different sections of Idaho. This particular section, the upper part of the Upper Snake River Valley, is blessed with more precipitation than any other section of the state except the Panhandle.

The bees packed in straw with open fronts should winter well, other conditions being favorable, provided they are not taken out of packing too early. I am wondering in what section these 900 colonies are located.

Let us hear later from Mr. Foster the results of wintering the 800 colonies in Colorado without protection.

CONCEALING PRESENCE OF DISEASE UNWISE.

Mr. Root remarks that I make no concealment of my experience with American foul brood. Is it not a mistaken policy for any beekeeper to attempt to conceal the presence of foul brood among his bees? Is it not better that the fact be known if any contagion exists, so that it may be combated, and others protected from its spread? Can any good purpose be served by a policy of concealment?

The editor is of the opinion that it would be perfectly safe to use those frames again, as they had been boiled pretty thoroly, then exposed for months to snow, frost, rain, sun, and wind. What say the contributors to GLEANINGS on this point? Can any one give us the result of experience?

THAT OUTDOOR CAPPING MELTER.

Regarding the wax-melter, it is 30 inches wide, 10 inches deep, 7 feet long, made of galvanized iron. It is raised up about two feet from the ground, something after the fashion of a molasses-boiler, with an opening and a free space at the front end. A budge of the same material as the vat, about four inches from the bottom, extends from about twenty inches from the front end to the same distance from the back end. Under this budge the frames are pushed. There is room between the budge and the bottom of the vat for three frames

laid flat, one on top of the other, and the vat is wide enough for three frames side by side so that nine frames may be pushed in at a time. The next set of frames pushes these on toward the opening at the other end of the budge. This budge serves to keep the frames under the water until all the wax is melted out, then they are taken out at the other end and a little tap on a board crosswise of the vat causes all adhering wax to leave the frames. This is the best apparatus I have seen for melting combs in a large way. Of course, where one is equipped for using steam the furnace would be unnecessary.

Yes, I did have a pretty big dose of foul brood, ignorantly, from the other fellow. As stated in my article of July 15, p. 586, I shook every colony, healthy and unhealthy alike, in three yards. More than 4000 frames were run thru the melter. From this process I obtained about 1500 pounds of nice wax, and I averaged better than 150 lbs. of honey per colony of those shaken.

I am preparing for the readers of GLEANINGS a further discussion of my last season's experience with foul brood, and I sincerely hope that next season the sequel will show that the drastic treatment administered has pretty effectively cleaned things up.

Salem, Idaho.

[In the matter of cellar wintering one must be governed by the conditions in the cellar itself. Mr. Anderson is doubtless right for his conditions.—Ed.]

SPRING—WITH THE FOUR-COLONY CASE

BY A. J. KNOX

In the November 1st issue, page 905, I gave my general way of handling the four-colony case in preparing for winter. In trying to point out some of the snags I had struck as regards packing, entrances, snow, etc., I ran foul of the editor, who backed up H. I. Bernation in stating (Dec. 1, page 964) that the four-colony case as it is generally used, with from four to six inches of packing on the sides, and ten over the top, is probably no better than a single-wall hive in a forty-mile gale in the absence of snow packing.

Now, if we could be assured of plenty of light snow, to come early and cover the hives to a depth of several feet, and stay that way, we should have little need of packing of any kind, so far as the actual winter is concerned. But on the approach of spring, then the shoe pinches. During

the fall and early winter months the bees seem to be less susceptible to outside influences than later in the season. Warm sunny days do not always coax them outside. There has been considerable mild weather this fall, but scarcely a bee has been out. After midwinter, and along toward March, conditions inside seem to change, and a restlessness exists that is absent in the fall. From this time on, depth of snow around the cases, upward ventilation, depth of packing, and sheltered location, all have their effects in stirring up the colony, or in keeping it quiet, as the case may be.

Single colonies with a few inches of packing, and four colonies packed together, are entirely different propositions in the spring. Colonies isolated from each other do not develop heat enough to cause undue excitement, even when the sun shines on them.

A. J. Knox's experimental apiary at Orono, where the swarming took place. Double-walled hives in the foreground.

The four surfaces exposed to the air seem to keep down the heat.

In the four-colony case, even with planer-shavings as packing, the sun's rays on the outside, combined with the heat of four colonies within, raise the temperature to such a degree that the bees spread out over the frames too far in advance of the season. It is at this stage, when clear entrances, little snow, and not too much packing around the sides, combine to keep the temperature inside below the danger-point. It might surprise those who have not tried it, to feel the warmth in the packing of a case that is painted dark or red, and exposed to the sun, even when the weather is quite cold. The packing seems to absorb considerable heat, and retain it after the sun has disappeared. It may be that the danger of overheating, and its consequent influence on swarming, lies in the above condition.

When fall clusters are small, and spring protection is needed for the rapid breeding-up of weak colonies, I have been in the habit, in some instances, of leaving the unpacking of these cases as late as June 7. Usually the plan has worked well, but on one occasion it spelled disaster so far as profits went.

At Orono I have an experimental outfit as follows: 25 ten-frame Langstroth two-story double-walled hives, with from two to six inches of sawdust packing. In winter these all have sawdust cushions about four inches deep. In this yard there are also about 15 four-colony Bartlett or Holter-

mann cases, with from four to six inches of packing on the sides, three on the fronts, and ten over top. All are ten-frame Langstroth except twenty colonies, which are the twelve-frame size. So far I have not been able to detect any difference in the winter mortality, all averaging up about the same.

Last summer I had a most peculiar experience with swarming. In the fall before (1914), clusters were very small, owing to the honey failure, and the colonies went into winter quarters weak in bees. The Orono yard has been requeened with young queens, mostly Italian; and altho they did not build up (owing to the failure of both flows) they should have been in better condition to winter than the rest. In the other yard there had been no swarming, and no requeening. The bees were all left in the cases until June 1.

On May 26 the Orono outfit started to swarm, and kept it up without intermission until Sept. 24, the bees in the cases giving nearly thirty swarms while the twenty-five single hives cast four or five. The strange thing was that the bees were not strong enough to swarm; and from first to last the swarms were small and mostly useless. There was no clustering out at the entrance, no crowding in the hives, scarcely any honey-flow, and practically no swarming at the other yards with the old queens.

What was the cause? So far as I can see it was simply an overdose of heat in the four-colony cases, due to the combined effects of sunshine on the outside and the

heat of four colonies within, packed on the quad system. They had just three inches of packing on the fronts, and entrances half size. The weather was generally cold and bright. The bees did not fly freely, as they were weak, and needed the heat to facilitate breeding. The plan had worked well other years. The material used for packing was planer shavings. There was just one thickness of burlap between the bees and the shavings. There was no snow around the cases, and no bottom packing, and the cases stood on 3x5 scantling, with entrances at least ten inches from the ground.

With the packing that I now use, I shall be obliged to choose between the risk of unpacking too early and the evils following, and leaving them too long with another set of evils just as bad or worse.

The queens were bought from some of the best breeders in the South, and not all from one man. They were all introduced by the Miller smoke method. In the same yard were a few blacks, and also a few Carniolans, and the swarming was equally bad all round (except in the single hives).

The other yards with the old queens, and under the same treatment, were quiet, as

there were only about half a dozen swarms in each yard. They contained 70 colonies each, all packed on the four-colony plan, in the same manner, with the same depth of packing.

The present winter I have four yards packed in the same way; but as the bees went into winter quarters strong I will see that they are unpacked early, and take no chances on a repetition of last season's performance at Orono.

To those who are advocating greater depth of packing than that used at present I would call attention to the fact that the case is now about four feet square, which size is just about the limit for one man to handle with ease, even when made out of light material. Clapboard siding costs here \$25 per 1000 feet, and inch stuff \$40. I have both, and up to now see no advantage in the heavier stuff, but, on the contrary, a number of disadvantages. All that is needed is something to hold the packing, keep it dry, and last a generation or two; and I think we have it in the siding. A commercial beekeeper must consider expense of material and labor as well as some other things.

Orono, Ont., Can.

A MALIHINI IN THE HAWAIIAN ISLANDS

BY LESLIE BURR

Just when and by whom bees were first brought to the Hawaiian Islands I have as yet been unable to ascertain. It is reasonable to suppose, however, that the first bees were brought by some of the numerous missionaries that came to the islands following their discovery by Captain Cook. Most of the plants and animals common on the mainland, but unknown here, were first brought by the missionaries.

In ascertaining who was the first person to practice apiculture on the island of Oahu, at least, I have been more successful, for that particular person is still very much in evidence. That he was the first real beekeeper is not necessary to prove, as he admits it. I refer to Thomas Rewcastle, who resides on Kinau Street, Hon-

olulu. I discovered Mr. Rewcastle in much the same way that I discovered my Japanese friend L. Tamagawa, out on Diamond Head. It happened this way: Honolulu is a city containing many streets that have varied and picturesque names (perhaps atrocious would be the better word), such

Kinau Street, on which Thomas Rewcastle lives.

names as Nuuanu, Ponoahau, Kahauki, Kaimiku, Kahaniki, etc., being just ordinary appellations. On the particular day in question I was wandering about the city with the sole purpose in mind of seeing just how weird a name I could find that had been tacked on a street. As I was going down Kinau Street, noting the varied vegetation that almost hid the houses from view, and wondering if the particular block I was on would ever end, I discovered an apiary of some fifty colonies or so. The hives were huddled together in an algaroba thicket some fifty feet or so from the street. On my discovery of the apiary I considered that Kinau Street was a good place to stop, so I quit my quest of strange names. I had found the home of Thomas Rewcastle, an Englishman by birth and an American citizen by virtue of circumstances. "Lassoed Americans" is the term that the natives of the islands apply to themselves, and it is not a bad term when one considers the manner and circumstances by which the people living in the Hawaiian Islands became American citizens.

Mr. Rewcastle was a mechanic, and came to the islands in 1879. In 1883 he had a desire to own some bees, and purchased two colonies that he discovered. Later on in the same year he caught a stray swarm. By reason of his lack of knowledge of bees he lost the two colonies he had purchased the same year. He tried to buy other bees to replace them, but was unable to do so. As a result he was feeling rather blue. It was when he was in this state of mind that he saw an advertisement by A. I. Root in a newspaper. This advertisement had the same attraction for Mr. Rewcastle that a crippled minnow has to a black bass. Previous to the finding of this advertisement by A. I. Root Mr. Rewcastle had made a lot of inquiries of people in Honolulu for information pertaining to bees, but had been unable to find any person who was better informed than himself.

From the time he got in touch with A. I. Root his progress was rapid, and within a few years he built up from his one stray

Apiary of Thomas Rewcastle, situated in the heart of Honolulu.

swarm to over 500 colonies. During those early years he secured good crops of honey, at times averaging as high as 350 pounds of honey per colony. The surplus flow, then as now, was from algaroba. All his bees were located in the city of Honolulu, and I have an idea that he may hold the record as having been the largest city beekeeper. In 1895 he had three apiaries. At his residence on Kinau Street he had 250 colonies. At the base of Punchbowl, a dead crater some 500 feet high that is in the center of the city, he had 50 colonies. In the southern part of the city, about $1\frac{1}{2}$ miles from his residence, he had 50 more colonies located; and out near Waikiki Beach he had another apiary of 200 colonies. His honey and wax he shipped to England, and there received a good price for them. One thing that he never had to contend with was bee disease, with the exception of paralysis. He stated that in the year 1888, and that year only, his bees were attacked with paralysis and he lost 50 colonies.

Mr. Rewcastle is now seventy-four years of age. Thirty-seven of those years have been spent in Honolulu. At the present time he has disposed of all his bees except his apiary at his residence on Kinau Street, and he is ready to dispose of most of those.

He stated that in years past he had sold bees to many people, and had done what he could to make practical apiarists out of such people; but they all failed with but one exception, that exception being the Gilbert Brothers.

For some years past Mr. Rewcastle has been interested in chickens and pigeons,

his principal income at the present time being from squabs.

In spite of his seventy-four years Mr. Rewcastle is very active, as is his able wife. They live a simple, comfortable life, and, even though the life's shadow has fallen far toward the east, they are too busy to think about having physical ills, and both are enjoying

the best of health. In my opinion they both have many years before them.

Such is a brief picture of the life of Thomas Rewcastle as a beekeeper, the father of practical beekeeping in the Hawaiian Islands—an able beekeeper, a fine example of manhood, and an ideal citizen.

Honolulu, Hawaiian Islands.

TENNESSEE STATE CONVENTION REPORT

BY J. M. BUCHANAN

A notable series of meetings was held in Nashville during the last week in January, when the Allied State Associations of Florists, Fruit-growers, Nurserymen, and Beekeepers held their annual conventions, that of the beekeepers taking place on Jan. 27.

For several years these associations have co-operated along various lines, such as advertising, getting out joint programs, convention reports, etc. An important feature planned for next fall is a combined fruit, flower, and honey show, to be held in Nashville. It is proposed to raise about \$5000 for expenses, premiums, etc. It is expected that this show will be of immense value in advertising our products.

A good attendance was present at the beekeepers' meeting, and much interest was manifested in the papers and discussions. Prof. Francis Turner told of his success in teaching beekeeping in the public schools. Prof. G. M. Bentley gave an outline of the proposed four years' course in bee culture in the Agricultural College of the University of Tennessee. Dr. J. S. Ward read a paper entitled "The Sting of the Bee," and also gave a report of his work as apiary inspector. He said the foul-brood situation in the state is much improved.

An important paper on wintering was read by Ben G. Davis, in which he showed that in this climate it does not pay to go to the expense of providing packing or extra protection for bees in winter, a good hive and plenty of good stores being all that is necessary for wintering. Much stress was placed on the necessity of having the colony strong in young bees at the beginning of winter. Several members reported good success with the plan of wintering in double-story hives. The bees so wintered seem to come thru in better condition, and build up faster in the spring.

Mrs. Allen read an interesting paper, and recited a poem, "We Beefolks," which was greatly enjoyed by those present.

The election of officers for the ensuing year resulted as follows: Ben G. Davis,

president; Prof. F. M. Turner, vice-president; J. M. Buchanan, secretary.

The accompanying photograph shows some of the beekeepers who were in attendance.

Franklin, Tenn.

[Mrs. Allen has supplemented the above report as follows:—Ed.]

Knowing as I do that the secretary of our state association planned to send a report of our annual convention (with our picture!) I scarcely know whether the ethics in the case will allow me also to comment on it or not. But I do think the traditions hold secretaries so severely to prosy minutes that they are almost forced to get the fact rather than the flavor; and while ours was a modest gathering it did have some flavor. Mr. Romine, the president, made a splendid presiding officer. There was Prof. Bentley, the state entomologist, over from Knoxville, proclaiming the dignity and worthiness of beekeeping as a university course, and giving us a vision of what may some time come to be, in the matter of education, both practical and scientific. There was Dr. Ward, the state inspector, always enthusiastic and full of his subject, talking about the marvelous delicacy and wonder of the formation of the bee's sting, as well as about modern methods of practical beekeeping. And there were all the others (this is not a report, you see) with their different messages and comments and suggestions. But, best of all, was the very noticeable feeling of increasing friendliness, unity of interest and purpose, and the recognition on all sides of the open-minded attitude of people eager to improve and develop, and to keep always abreast of new ideas in their chosen work.

One impressively interesting thing was the unanimity of opinion expressed that this section does not require the heavy packing recommended by Dr. Phillips—that it would not bring about sufficient additional profit to pay for the increased labor and

Beekeepers present at the Tennessee convention at Nashville, Jan. 27.

W.P. CENTER PHOTO

expense. Mr. Ben G. Davis, who handled this question in an interesting paper, said in answer to a question that some time ago they made experiments along this line that convinced them that the good to be gained by quadruple winter cases was not worth while for them. And no one was found to take up cudgels in behalf of the recommended method.

WE BEE-FOLK

(Being the conclusion of my paper at the convention.)

The city's mad mornings are discord and din,
With a clash and a roar and a jangle within;
While with mockingbird music the morning
hours come

Caressing our beehives—and how the bees
hum!

The cities go tramping with quick-rushing
feet

That hurry the day thru, and restlessly beat;
But we love to loiter a bit as we pass

A lingering day by the hives in the grass,
In a spell that is woven by shuttle-like wings
That flash thru the sunshiny fabric of things,
While whispers of grasses and winds in the
trees

Come waving around us at work with our
bees.

The drab-tinted cities are murky and gray,
While the greens of the country are running
away

To far hazy blues, and everywhere glows

The purple of iris and red of the rose.
And out from the flowers with indolent air
A fragrance comes floating around every-
where—

Lilac or lilies or locust in bloom,
More delicate far than imported perfume;
And we shrink to remember the dust of the
town,

With stife of crowds and smoke like a
frown.

And we draw a deep breath where the blos-
soming trees

Are showering petals on us and our bees.

Oh! this work of our hand and our heart and
our brain,

And the deep satisfactions our workings
attain—

The long winter evenings to sit by the fire
And delve into books that instruct and in-
spire;

The fitting of hives from the bottom to top
In the litter we love in some improvised
shop;

The honey that hangs in the hive's heart at
dusk,

Like sunshine entangled in odors of musk;
The mornings and noontimes, when all the

world sings,
And our bees flash around us with rapturous
wings,

And old benedictions descend thru the trees
To touch us and bless us at work with our
bees.

Nashville, Tenn.

SHIPPING COMB HONEY BY PARCEL POST

BY J. L. BYER

A few days ago the rural mail-delivery man placed a peculiar-looking parcel in our mail-box. It was three or four inches thick, about double that size in width and length, and the outside of the parcel was of heavy brown paper tied securely but rather loosely with heavy cord—ordinary binding twine if I remember correctly. A glance at the postmark showed me the words "Norwichtown, Ct.," and the very first thought that went thru my mind was, "Well, I am glad that I did not question but that Allan Latham could send comb honey by parcel post successfully." Sure enough, after a whole lot of unwrapping was done, we found a beautiful section of sumac honey—one of the 36 sections illustrated in a recent issue of GLEANINGS. First I shall deal with the quality of this particular section of sumac honey. Some years ago while at the Albany convention friend Latham kindly gave me a section of sumac honey which I brought home with me. For some

reason nearly all the members of the family except the *pater* did not like it any too well, objecting to the rather peculiar flavor common to all who are familiar with sumac honey. In the case of this section just received by parcel post, whether it was because of the novel way it reached us or some other reason unknown to me, every one of the family pronounced the honey very fine indeed. As to the condition of the honey in so far as the long trip thru the mails was concerned, briefly I might say it was just as perfect in every way as any section of choice honey could well be. In acknowledging receipt of honey I told Mr. Latham that in my opinion it would have gone to the front at Flanders without injury, and, judging by the resiliency of the package coupled with the substantial nature of the packing as well, I believed a shell from a "75" would have done it little harm. When I describe the method of packing used I think all will agree with

friend Latham that comb honey can be sent successfully by mail. Whether it can be done in a commercially successful way is another question.

First of all, the section—one of the four-beeway variety used by friend Latham—was carefully wrapped in a good grade of paraffined paper. This was then placed in a comb-honey carton, the same having a lot of attractive advertising printed on it. Then on each side of the carton there was placed blocks of a scant half-inch in thickness and of the exact size of the carton. This was carefully wrapped with three thicknesses of rather light-grade brown paper, and then around this was placed excelsior averaging probably two inches thick when not compressed. Outside of this again was the last wrapping, consisting of two or three thicknesses of heavy wrapping paper, all securely tied with heavy cord. This rather lengthy description of the package may make it appear to be a difficult job thus to prepare a section, but I can believe Mr. Latham, that, after wrapping a few, the job would be an easy one. As to cost of sending honey this way, of course that is the great problem standing between the producer and the buyer of honey by mail. I regret that I forgot to weigh the package, but Mr. Latham tells me that 7 cts. postage will carry it inside first two zones, so any one interested can readily tell what the weight would be approximately by referring to the schedule of rates. In sending it to my address, thirty-six cents in stamps were affixed. Package did not go to custom-office, so possibly that was partly duty charges. At any rate, that was the most expensive section of honey that our family ever ate, altho it really cost us nothing, and I am still wondering how to get even with friend Latham. As before mentioned, the section was perfect in every way, and if he can produce honey like that without using separators, then I do not blame him in the least for not using them at all. The four-beeway section at first

glance does not appeal to me, but then I am not a comb-honey producer; so comments in that line from me are of no value. Even if Allan Latham can produce section honey without separators like the sample sent me, do not forget that all comb-honey men are not "Allan Lathams." That factor will, in my mind, pretty well dissipate all ideas of having the bulk of our comb-honey men produce unseparated honey. The same argument holds good in the matter of sending comb honey by mail. Friend L. says he never expects to send out honey that way to any great extent, but often parties wish him to send some friend a section, and for that purpose it is rather nice to be able to send honey by mail successfully. But many might try to send honey by mail and not take the elaborate care to prevent accident that he does, and then there would be trouble.

Markham, Ont.

[In the course of a year we receive a good many glass photographic negatives by mail. Probably three out of four are broken when they reach us. A pane of glass eight by ten inches, or even one only five by seven inches, is easily broken. About the only safe way to send such a negative is to wrap it in several thicknesses of soft paper, and then in heavier paper, finally placing the package inside a strong flat box.

What is true of pieces of glass is true also of comb honey. An egg is hardly as fragile as a piece of comb honey, and yet quite a number of beekeepers, desiring to experiment, have merely wrapped the honey, and then enclosed it in a pasteboard box. Such a package is not fit for the mails.

Mr. Latham's plan is safe, but the expense will probably be in the way of shipping comb honey by parcel post in a commercial way. If the cost of the packing material and labor amounts to three cents it would cost ten cents, therefore, to mail a section to the second zone.—Ed.]

BEEES DRIFTING; CAUSE AND PREVENTION

BY G. C. GREINER

Since the subject of bees drifting has been occasionally mentioned by some of our most prominent beekeepers I have at different times tried to make such observation as would explain its prevailing conditions. Many times have I watched the flight and general behavior of the bees, sometimes standing in front of the yard or at other

times lying on the lawn in front of certain hives.

It seems that there are two main causes that produce this undesirable feature: First, abnormal excitement; second, location of home insufficiently marked. But as the first is really the cause of the second, there is only one cause, the second, the actual

cause of drifting. As a rule, the most detrimental drifting takes place when bees are moved from the cellar to their summer stands, and it does not make much difference if any whether they are placed on the same stands they occupied before they were moved into the cellar or not. The usual way of moving bees from the cellar to their stands outdoors is the most enticing inducement to cause drifting. After a long confinement of four, five, or even more months, which has been forced upon them against their wishes they long for the time to have an open-air fly they so much need for their future welfare.

To prevent bees leaving their hives, the moving is done some cool night; and it is done when there is a fairly certain prospect of a fair day following, that bees may not venture out on an inclement day and be lost. Next morning, as soon as the climatic conditions will permit a bee to fly, a few of those suffering most begin the rush for this long-wished-for cleansing flight, and, without paying much attention to the exact location of their home, the whole swarm is in the air in a very short time. But it does not end here. The roar and commotion of the first few colonies soon attract the attention of the others. They, too, in the excitement of the occasion, leave their hives without taking the precaution of marking their location; and before many minutes the whole apiary is in the air, a confused mixed-up multitude that knows not where to go or whence they came. When they finally quiet down and begin to look for their home they are a lost and unguided set. There happens then what the editor describes on page 922, with the closing sentence: "The result is, the stronger grow stronger at the expense of the weaker."

We may take it then for granted that drifting is the result of the undue excitement, when bees take their cleansing flight at the same time, especially when hived close to one another. To prevent it would be a simple affair. By setting out one colony at a time and waiting until it had its first cleansing flight, a second one might be set out; and after this has had its first flight a third one could follow, and so on until the cellar is emptied. I hardly think drifting would occur if managed in this way. But this would not be practical. It would take all summer to empty a cellar of a few hundred colonies. When the times comes that bees need this much-desired flight, and atmospheric conditions favor the change, they must all, or nearly all, go into the open air—the sooner the better.

Now, suppose we compromise, and try to

produce conditions more like the flight of bees wintered outdoors. If a part, say one-half or one-third of a cellar's colonies were moved outdoors at a time, scattered over a beeyard, and placed at reasonable distances from one another until they have their first flight—then at the next opportunity another portion moved out and distributed between the first lot until they have their flight, and the same operation repeated with the remainder, I believe, altho I cannot speak from experience, the unpleasantness of drifting would be reduced to a minimum. In a way this would resemble the condition of bees wintered on the summer stand. It hardly ever happens that adjoining neighbors are out at the same time. Even after a longer confinement we generally see one flying here, another a little further down the line, a third one still further, and so on; and when these are quieting down, the intermediates follow suit. Being at some distances from one another, and thoroly knowing their location, little drifting occurs.

If it is not caused by the beekeeper himself bees will drift very little when wintered in long straight rows or quadruple sheds outdoors. The main point to be observed is, bees must be thoroly acquainted with the location of their own hives. To insure this it is necessary that bees should fly a couple of weeks (the longer the better) from the location they are to occupy after they are placed and packed in their sheds. If moved any distance at all, even if only a few feet from their accustomed place to the sheds when being packed, drifting is sure to result. It requires quite a little strategy and systematic manipulation to wean a colony of bees from one place and teach them to find another with unfailling certainty unless they are moved miles away.

To illustrate the certainty with which bees know and find their home by location I present to the readers the accompanying drawing made to represent one of those roaring bee days in September when it seems as tho bees are bringing honey, honeypants, soil, and all. If an instantaneous photo could be taken the drawing would not resemble it very much; but it demonstrates fairly well the point I wish to make. The roar and multitude of flying bees resembles an absconding swarm coming toward you, with the exception that they are flying in a straight line while an absconding swarm moves more like a rolling ball.

The hives face the east, and the direction from which bees are supposed to be bringing honey is northwest. When coming home they have to pass over pear and apple

orchards, so that, when reaching their hives, they are from ten to fifteen feet in the air. When the line of descent is reached they suddenly drop, not straight down, but in every imaginable direction to bring them nearest to their respective homes. Altho the excitement at the hive-entrances is at its highest pitch, no confusion can be noticed. Occasionally a heavily pollen-laden

not so liable to drift is because they generally have an occasional flight during the winter; and when spring comes they are not so hard pressed for exercise. They leave their hives in a more nearly normal condition, and consequently return in the same way.

One more point I wish to mention. The drawing proves my claim which I have always defended, that bees are guided more by location than by looks or appearances. No matter how conspicuous a hive may be made by color, shape, or size to the human eye, it has little to do with bees entering their own hive. The drawing represents only five hives in a row, while in reality there are from twenty to twenty-five, all as uniform in appearance as a basketful of eggs laid by one hen. But along the whole

Fields of Astor and Sweet Clover about 1 mile distance.

bee enters a hive somewhat hesitatingly, reappears after a second or two, takes wing, and enters the next hive and remains.

The action of the bees in this case may differ somewhat from their compelled flight after a long confinement; but even then perfect knowledge of location has a tendency to prevent confusion and drifting. Another reason why outdoor-wintered bees are

line the home-coming crowds are evenly spread from side to side, and every bee seems to know exactly what direction to take when aiming for its hive at the line of descent. A row of equally uniform-appearing hives a mile long would not cause any more confusion than the five represented in the drawing.

BEE CULTURE IN LOUISIANA; MAKING INCREASE

BY J. F. ARCHDEKIN

There are only two crops of honey gathered here that are worth working for; namely, the spring and fall crops. The summer flow, as I have shown in a previous paper, is dark and bad-flavored, and, consequently, of little market value. But for raising bees it is, of course, as good as any honey, and the purpose of this article is to show how it can be utilized.

The bees are more valuable in many ways than the honey, and can be more readily disposed of. The pound-package trade is growing rapidly, and I look for it to surpass even the fondest expectations of the southern beemen before many years. There is absolutely no foul brood here, and this gives us an advantage that is not to be smiled at.

During the spring flow it is, of course, desirable to hold all the colonies together as much as possible; but at its close the hives are full of bees and brood. Unless some practical use is made of this material it will go to waste to a great extent. Unlike the central states where I was raised, there is a long slow flow ahead, lasting for months. Under these circumstances the most profitable thing to do is to divide. Three frames of brood with the adhering bees can be lifted out of each brood-chamber and put in a hive on a new stand. A cell is given, and they will draw the remainder of the combs needed to fill the hive and store a super of honey in the fall flow. Occasionally it may be necessary to give a few of them that have had bad luck a frame

or two of brood or honey during the summer; but for the most part they will need no further attention.

By the last of July the old colonies will have lots of honey stored in the extracting stories. Instead of taking this honey, the upper stories with what bees they contain can be set on a new stand, together with a couple of frames of brood and a cell. Having their combs already drawn, and plenty of stores, they build up rapidly and are in good condition to take advantage of the fall flow.

I have demonstrated the above methods to my entire satisfaction, and proved that it is easy to treble the number of colonies spring count, and secure two crops of honey at the same time. All this makes the queens hustle, and wears them out very quickly. I believe it is good practice to requeen every year to secure the best results "in this locality." Besides, a young queen will lay all winter, and in the spring jump in and fill the hive in no time.

Bordlonville, La.

WHERE THE BEES KEEP THE HOME

BY HENRY HOGRAVE

During the years that I have been a reader of *GLEANINGS* I have read more than one story in which it was stated that bees paid for this or for that; but in this little narrative of mine I want to describe how they managed to keep that which I had already secured.

From my earliest childhood days it had always been my ardent wish to live in the country, even trying to persuade my parents when a mere boy to move away from the city. So, after having been engaged in the retail dairy business for a dozen years or more, and after having taken a better half unto myself, I thought the opportune time had arrived in which to materialize one of my most cherished hopes.

Accordingly, in the fall of 1909 I purchased for cash a ten-acre tract with good buildings, located about twelve miles from the metropolis of the state. My city friends all predicted my early return to the city, and for the first year or two it seemed as tho their prediction would be fulfilled. Luckily, however, and thanks to the busy little bees, I am still on the place, prosperous and contented.

When I moved to the country I did not even think of bees, much less dream of keeping them so that I could keep the place. I had planned to do truck-gardening, as I had often helped my mother in the backlot garden; but, owing to the too great distance from town, it was not a paying prop-

Home of Henry Hograve, Waukesha, Wis., which the bees "keep."

Part of Mr. Hograve's 115 colonies.

osition. It was not long before I concluded that a change in management must be made if that prediction of my friends were not to come true. It has remained a mystery to me to this day how it came about; but my friends all know that I am keeping bees, and that the bees are keeping me where I so longed to be.

In January, 1911, I bought three colonies from a farmer some miles away; transferred them to ten-frame dovetailed hives; increased to eight colonies; but secured no surplus that year. Since then I have steadily increased them in numbers, and have

getting it, altho some other producers have advertised and offered their product at 10 cts. per lb.

Of course I have not laid away a fortune during this time, but I have made a comfortable living, made several improvements, chief of which, among other things, is the installing of a furnace, and this fall the acquiring of a new automobile.

Waukesha, Wis.

A side line that goes well with beekeeping.

always secured more or less extracted honey per colony, having as many as 115 colonies during the past season, and having had with me a nephew who has now decided to embark in the bee business for himself.

I retail all the honey I produce, in the cities of Milwaukee and Waukesha, at 12 cts. per lb., and have found no trouble in

300 lbs. of extracted honey from one colony.

M. S. Nordan's apiary on the Pike Road, 23 miles southeast of Montgomery, Ala.

BEEKEEPING IN ALABAMA

BY M. S. NORDAN

My home apiary consists of fifty colonies, all in ten-frame hives. All the bees are pure Italians, three-banded.

I started this yard in the spring of 1912. At that time I was in poor health, having gone thru three operations which nearly took my life. When I got to working with the bees I commenced getting better and have been improving ever since. This apiary is only 60 feet from the gravel road, which is the main road leading to Montgomery. Altho the road is used constantly I have yet to hear the first complaint. I did have 100 colonies, but moved half of them to outyards, putting 25 of them three

miles east of this place, and another 25 five miles west.

My son, 14 years old, is my helper, and is a fine beeman. His pet coon is lying on a branch of the tree in the foreground of the picture.

My crop was a little over 300 gallons last season. I am planning to increase the business, and will build up the outyards to 50 colonies each. I started with only 20 colonies. I have never shipped any honey, for I have always had a market at home for all I could produce. I have never sold it for less than \$1.00 a gallon.

Mathews, Ala.

WATERING BEES AUTOMATICALLY

BY A. C. GILBERT

Having kept bees right beside a mill-stream of sparkling spring water until last year I moved to a location where I had to resort to artificial means for supplying water. I planned a labor-saving way which I think cannot be improved on very much.

The first desideratum is a well to furnish the water for a force pump. The pump has an opening at the back, opposite the spout. A pipe with valve is connected thereto. The spout has a valve also. When properly adjusted most of the water will flow thru

the spout-valve, and just the amount needed for the bees can be controlled by the valve at the back of the pump.

I think it a great advantage to have water for bees right near the apiary, for it certainly saves the lives of a great many; for when they are compelled to fly very far, especially on a chilly day more are lost than one is aware of. Furthermore, brood-rearing will go on at a more rapid pace where water is near by.

I have a large trough filled with floats, and it is surprising how fresh and pure the water keeps for a long time without emptying. All there will be is a small accumulation of slime and moss. Perhaps it might be a good plan to clean out the trough occasionally. It is a sight to see the way the bees swarm around the trough, and the stream of bees going back and forth during

dry weather and when brood-rearing is at its height.

I use water from the same pipe to water the poultry by having another valve at the lower end of the pipe. The fowls have had plenty of fresh water constantly all summer. I would not carry water to chickens all summer for the price of two force pumps. Little chicks need fresh water several times a day during the hot summer days. Every time water is used at the pump the bees and fowls get some too. During the summer months some member of the family will be imbibing freely, or there will be a pail or two used otherwise. By closing the valve at the back, the force pump can be used for washing cars; and if near buildings it could be used in case of fire by attaching a hose.

East Avon, N. Y.

EUROPEAN AND AMERICAN FOUL BROOD

Their Differences, History, and Methods of Treatment

BY OREL L. HERSHISER

Continued from page 162, Feb. 15.

In the summer of 1912 I treated for European foul brood over half of the colonies in one of my apiaries by shaking, according to the McEvoy plan, and requeened many of them with the resistant Italian stock described in Feb. 15 issue. In the fall 82 colonies were prepared for winter, 80 of which came thru to the following season in excellent condition. About the middle of May the apiary was moved, and, soon after being established in the new location, 42 of the 80 colonies became reinfected. But, with few exceptions, those requeened with resistant stock the season before were unusually strong, and showed no trace of the disease.

When white clover commenced to yield honey the treatment of the diseased colonies was undertaken. These were shaken or brushed upon starters, and three and four days thereafter placed on full sheets of foundation *a la* McEvoy. The diseased brood was stacked up four and five stories high over *healthy* Italian colonies, care being taken that the queen was confined to her own brood-chamber by an excluder. A good clover-honey flow was on, and, as anticipated, the diseased combs were thoroughly cleaned out, filled with honey, and no trace of the disease was ever discovered in the brood-chambers of these healthy colonies.

A number of the diseased colonies that had been shaken swarmed out, eventually

reducing the number in the apiary to 72. In all other respects the treatment was successful, which was shown by an increase in the number of colonies from 72 to 105, 101 of which wintered, and a crop of 9500 lbs. of extracted honey, the individual yields running all the way from nothing, in some of the colonies treated, to past the 300-lb. mark in several of the healthy colonies of resistant Italians.

There is surely a bright side to this whole European-foul-brood situation. It is this: When you have Italianized all your colonies with vigorous, resistant stock, the better condition of your apiary and the valuable experience you have gained will add so much to your proficiency and enable you to produce so much better crops of honey that you will not seriously regret that the disease overtook you.

The essentials for the treatment of European foul brood may be summarized as follows:

Head all colonies with resistant Italian queens, or rear them in the process of treating.

Treat only strong colonies; if not strong, unite until those to be treated are strong.

Treat only during a good honey-flow that is sufficient to prevent robbing, except that strong colonies, that are diseased late in summer, may be given the fall treatment, after breeding has stopped for the season,

by placing the colony on combs of honey that are not contaminated with infection.

DZIERZON'S DESCRIPTION OF THE TREATMENT OF THE "MALIGNANT FORM" OF FOUL BROOD (AMERICAN FOUL BROOD).

"With this the question at most is how the owner of the diseased stocks may come off with least loss. First of all, the queen may be made use of, and must be caught as quickly as possible, if the whole stock is not immediately cashiered. But if the bees that have been made queenless should have removed all the foulness up to the time of the hatching and fertilizing of the queen it does not do to rely on having obtained a healthy stock. The disease would soon appear in greater severity than before, because, in the mean time, the poison has probably permeated the accumulated brood food all the more completely. We hasten, therefore, to take out the queen again as soon as she has become fertile, and after some time we put a queen-cell into the stock again, or clear out the hive, using the honey for any purpose other than bee-food, which might be given to brood.

"But if we still cherish the hope of recovering a healthy stock from the bees they must be subjected to a similar but longer treatment than that already described. After they have been kept two or three days shut up in an airy vessel without food, or with food given very sparingly, they are put into a new hive, the queen being kept caged for some time, partly for the sake of preventing the laying of eggs, partly to hinder their going off, to which such a stock is much disposed. But to put in a comb of brood, or even larger combs, is not advisable, because the stock ought to work up all the nutritive material it has by it as much as possible into wax, so as not to deposit it in the cells. Notwithstanding that, the stock may at last be up and away, or show itself again foul-broody so that all the time and care bestowed on its cure is lost. It is better, therefore, to make short work of it, break out the contents of the diseased hives, make the best you can of them, and buy in their place healthy breeding-stocks."

The prime essential in the treatment of the "malignant form" (American foul brood) as described by Dr. Dzierzon is, avowedly, to have all the diseased food the bees may have with them, when deprived of their combs, consumed or made into wax during the time they are caged and before the queen is allowed to deposit eggs. With the aid of comb foundation the same end is accomplished by placing the bees and

queen on very narrow starters of comb foundation for three or four days and then shaking on to full sheets after McEvoy, or by shaking the bees directly on to the full sheets, omitting the first shake, as recommended by other operators, the latter being less exhausting to the colony, but probably not so sure a cure.

The fundamental principle upon which the treatment of European foul brood depends is the suspension of brood-rearing for a time sufficient for the bees to clear the combs of diseased matter, or for conditions to obtain in which the brood will not be fed with contaminated food and bees sufficiently vigorous to do a thoro job of cleaning. That of American foul brood is the destruction or sterilizing of all combs that have ever contained diseased matter, and by forcing the bees to consume, or convert into wax, all honey they may have with them, when deprived of their combs, before breeding is resumed, thus destroying all traces of the disease.

It will be observed that these principles were recognized and described by Dr. Dzierzon, and that modern methods of treatment are but variations and elaborations of those described by him.

Foul brood, like most infectious diseases that attack animal life, loses half its terrors, and more, when effective means of abatement or cure are available. Most states and provinces have enacted good laws, backed by liberal appropriations, to safeguard the interests of apiculture, under which capable bee-inspectors are brought to the very door of the apiarist "without money and without price." Practical educational demonstration in the treatment of these diseases is, therefore, within the reach of all, when the disease is present, wherever such laws are in force.

Besides all this, and what should be more fruitful of encouragement and confidence than all else, many beekeepers, including some of the most extensive honey-producers, have demonstrated in their own apiaries that the foul-brood situation can be mastered; that the good crops of honey that they secured before the disease overtook them are still obtainable, and that expansion of their apicultural business may be undertaken with certainty of success. Why, then, need any beekeeper quail at the approach or appearance of the disease in his apiary?

The way of the transgressor is hard, for troubles rarely come singly.

AS GLIMPSED THRU THE CAMERA

The Best-laid Plans o' Mice and Men Gang Aft A-gley

BY H. H. ROOT

Here is a common picture of an uncommon sight. I tried hard to write an article on the subject; but after saying that mice do much damage to honey, and that every beekeeper ought to set traps, I could not think of anything more, and yet the article did not seem finished. But I have decided to write an article any way, not on any particular theme, and then if I ramble somewhat no one can accuse me of getting off the subject.

The picture itself is suggestive. It reminds one that some mice are like some people in that they get into trouble, no matter which way they turn. It reminds one also of the old saying that So and So jumped from the frying-pan into the fire. In the picture I am not sure which is the frying-pan and which is the fire. I believe, however, that this particular mouse, feeling himself hugged tightly about the neck from above, attempted to move away by using that part of his anatomy not so held, and, unfortunately, stepped on the trigger of the other trap. I think this is what happened, for I cannot imagine an intelligent mouse caught in the small trap (especially across the stomach) showing any great amount of interest in the cheese on the trigger of the larger trap, and so I believe

the larger trap should be labeled the frying-pan, and the smaller one the fire.

This picture reminds me of the time I attempted to use a butcher-knife for uncapping. It worked quite well, but on the second comb I cut a large piece of myself from one finger. While observing this unexpected result, I decided to move away from there, and then discovered that I was standing in honey. The pail under an eight-frame extractor had overflowed; and, altho the time had been short, there was a thick layer of honey gradually spreading itself over the floor and finding its way thru the cracks to the ground beneath, where the bees outside could get it. This was during a honey dearth. If we had had a better floor in that honey-house the bees would not have got to robbing, or, better still, if I had not cut my finger I probably should not have let the extractor-gate remain open so long. If this mouse had not been too nervous to think, he would have reflected that if he had not got his chin caught in the large trap he could easily have avoided the other one. Troubles rarely come singly.

Job had several troubles all at once. Mr. Holtermann has only one among his bees—European foul brood, and for this reason it seems to me that he should not have likened

himself to Job, even tho he does have friends who try to comfort him. If Mr. Holtermann, in casting about to find a reliable cure, had discovered that two-thirds of his bees were afflicted also with American foul brood, I can see that he might have felt like Job and—like this mouse. Getting caught once is not such a terrible thing; but getting into another trap at the same time, and a worse trap too, is a somewhat serious matter.

While viewing the remains of this mouse I happened to remember H. F. Strang's exciting experience in moving a car of bees, as told in the June 1st issue of *GLEANINGS* for 1914. After all sorts of unexpected delays, requiring 52 hours to make a trip of 42 miles, he finally reached Chicago

with his car of bees where he was told that his choice Jersey cow which he had in the car would have to be inspected. This kept him in Chicago over two whole days with his bees shut in the car; and when he finally got started again the train ran into a severe blizzard, got stuck in the snow, and the engine ran off the track. I don't remember what else happened, but that was surely enough to make Mr. Strang and everybody else suspect that, when moving bees, the unexpected may happen.

I believe the sad fate of this mouse has reminded me of enough predicaments for the present. Yes, it rarely pays to make the same mistake twice. After all, this is merely a little story of real life. I mean of real death.

SECURING A COLONY OF BEES FROM THE WALL OF A HOUSE

BY RUDOLPH OSTHEIMER

A farmer living near here came to me and asked if I could take a colony of bees out of the wall of his house. The bees had been there five years, right between two windows, and next to a door; and, with people passing constantly, the bees got pretty cross and were inclined to sting.

I had to take off considerable of the siding before I had the combs all uncovered. They covered a space 54 inches in height, 18 inches in width, and the entire space of 6 inches back to the plaster. There were

five large sheets of comb containing brood, and there were also eight queen-cells. I took two empty hives and placed the combs in the same position just as they were hanging in the wall. Other combs held about 150 pounds of honey.

I have been transferring colonies of bees from old trees and houses for the last few years, and have increased my apiary up to 85 colonies in this way. I wish I could get about 100 more.

Sandusky, Ohio.

Five long combs of brood, eight queen-cells, and 150 pounds of honey.

EUROPEAN FOUL BROOD, CHRONIC AND ACUTE

BY G. W. JOICE

On page 102, Feb. 1, Timberline Riggs describes a plan that I once thought would revolutionize the foul-brood question. I did that crowding stunt as Mr. Riggs recommends it, and it worked in some cases. It did very well where the colony was in fair shape so that it was not necessary to crowd lower than two Hoffman frames.

I am surprised that Mr. Riggs never heard of a case of European foul brood in bees taken from trees. I have found plenty of it in the combs and the brood. Mr. Riggs seems to have the opinion that, owing to the bees being closely confined in trees, they are able to cope successfully with the disease. I have seen hollow trees occupied by bees that contained more vacant space and a larger spread of combs than any domestic colony, and there was no disease. I have also noted a fair-sized colony cooped up in a hole containing no more space than four Hoffman frames, and with plenty of European foul brood.

With all due respect to Mr. Riggs, I wish to state that, after trying his cure for two seasons, I will positively guarantee that it will not cure in all cases, altho it checks it to a certain extent in most cases, and probably cures in some cases. In this location European foul brood just hangs around, sometimes a few cells here, sometimes there, and occasionally we have a season without seeing any. Thus far it has never been a serious pest, altho it may break out in an acute form at any time.

I feel very sorry for Bro. Holtermann; and with the number of colonies he usually has on hand, and the disease such as I have had in a few colonies, I should be looking at the dark side of the cloud also. Here is hoping for things to turn out for the better.

Page 107, Arthur C. Miller tells us why we fail in using his "distress" method of introducing queens. Arthur may have his system perfected for himself, but I cannot make the queen behave at the same time the bees are behaving. He speaks as tho he knew just how to do the stunt—he is always so sure of a thing when he tells about it—but with this "distress" method I am unable to succeed as well as with the cage and candy method. He says, "Create the distress; see that it is continued for ten minutes; and you never need worry as to the safety of the queen." Correct. When I bury a hen I never need worry as to her safety. I know where she is. But with the queen it is different, for she may be missing.

I should be willing to accept my results and keep quiet, but I think of the time when I was an amateur (perhaps I am yet), experiencing all kinds of mistakes. Then I would have thanked some one to tell me to go slow on the new idea; but I waded right in and got my experience with my knowledge, something like Dr. Miller.

Edon, Ohio.

GLEAMING MOMENTS

BY GRACE ALLEN

<p>Oh! I greet you all with singing, and I come to you rejoicing; Of those moments I come chanting when your hearts were like a flame. All your glimpses of life's glory in my verses I come voicing, And I would that I could celebrate each one of you by name.</p> <p>One and all—oh! you have had them— moments high and unforgotten, When a sudden sweetness stirred you or a sudden wideness thrilled, Or a sudden vision swept you with intensity begotten Of your longings and your yearnings and the things you would have willed.</p>	<p>Just a blossom may have brought it, or an orchard in the budding, Or a poet or a prayer, or the sunlight on the trees— But it came, dear hearts, it came! perhaps in spring when life was flooding, And the morning was a-tingle with the witchery of bees.</p> <p>So I come to you with singing, and I hail you with rejoicing, And those moments I come chanting when your hearts were like a flame; And I would that I could fold them in a verse forever voicing All your ecstasy of answer when your gleaming moments came!</p>

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Mother got all excited last week over a story she read where a man made his tax money by pickling his combs and marketing them in glass jars. Come to find out he was in the chicken business.

Beekeeping in Florida; Schools, and Price of Land

Mr. E. R. Root:—I have known for some time that you have traveled considerably in Florida, and have been in position to learn a great deal from other sources. If it would not be asking too much of you I should like to submit to you some questions, and you may answer them by number. In order that you may better understand matters, I will give you an outline of the situation:

We have a farm of 140 acres, fine improvements; have improved the place with the intention of living and dying here. I have five children—a boy 18 and a girl 20 who will graduate from high school in June; the other three are younger. We are quite sure we have a buyer for this farm at \$225 per acre. If we sold everything but bees and fixtures and household goods we should probably have \$30,000 cash in hand.

We started 25 years ago with about \$400, and have always been on the conservative order, because we had nothing to lose. I have lived here all my life. It is a good bee country, good farming country, but I have thought for some time that I should

like to live in Florida; and when land is selling for \$225 per acre it becomes a problem as to whether a person can afford to keep it. Now for the questions:

1. Is Florida a good place to go if one wants to make beekeeping his business? If so, where would you go?
2. What outlet is there for honey, and what do producers usually realize per pound? Is it of good quality?
3. Would it pay to ship 120 hives and fixtures—a fine outfit—to Florida? or would you sell them and buy there?
4. What do you know about the trucking business, the pecan crop, and fruit business, as a proposition for a good bright boy just out of school? Would a location for the above lines be a good one for bees?
5. How about the schools in Florida as compared with those schools in the North?
6. Could a person live there as cheap as here?
7. Is the majority of the population white or black? What can you say of the society in general?
8. Is beekeeping in Florida so much different that a beekeeper from the North would have the business to learn over?
9. What does land sell for that would be adapted to the above lines?
10. Would you go to Florida if you were I?

11. What would the opportunities be for a young man or young woman, as compared to the North?

Iowa.

W. S. P.

[1. This question cannot be answered by a direct yes or no. Florida is a good place to keep bees, but you must get a location that is fairly good. The best parts of Florida for the production of honey are the northern parts up around the Apalachicola River, southeast Florida among the Keys, parts along the east coast, and spots along the west coast. The region in and about Bradentown is among the citrus groves and is likewise good. To get a good location we would advise your buying out some beekeeper who is already stationed, and who has his bees and outfit for sale.

2. The outlet for honey in Florida is usually the New York market. The price realized is not large, and most of it is extracted, usually sold by the gallon between 50 and 75 cents, or about five cents a pound. This is, of course, for the usual grades of honey, not orange. Orange honey will bring as good a price as ordinary northern clover, anywhere from eight and nine to ten cents, and usually sells very readily. Of course, this is for a pure orange honey. The mixture of a little palmetto or a little mangrove probably would not do any harm. The fact that a considerable amount of orange honey is produced around Bradentown would make this district a rather good one, provided the

yield from that source was always good, which it is not.

3. It would not pay you to ship 120 colonies and outfit to Florida. You had better sell them where they are, and buy bees after you get there. You could hardly ship bees to Florida unless you send a whole carload of between three and four hundred colonies, then go in the car with the bees.

4. We do not know anything about the trucking business or the pecan crop; but as a general proposition we may say that where fruit-growing is extensive it is generally fair for bees—that is, for a limited number. If you keep too many bees in an orange grove the yield per colony will be correspondingly reduced.

5. The Florida schools, generally speaking, are good, especially in the larger towns. They are the equal of any of the schools in the North. 6. Yes.

7. The majority of the population is white and mainly northern people. As one Florida cracker said, "Most everybody is from everywhere else." There are a good many colored people in the state, but as a rule they live in isolated districts.

8. Yes and no. A practical beekeeper of the North would very soon be able to learn the conditions in the South, so that he would be able to handle the keeping of bees profitably—that is, provided he could do so in the North.

9. We could not name any general figure, but the price of land is anything you care to pay. The closer the land is to towns or to water frontage the higher the price. It runs all the way from \$2 and \$3 an acre to \$10,000 and \$50,000 an acre. Usually the land in the large towns is rather expensive, but a mile or so out it is comparatively cheap.

10. This is a hard question to answer. We doubt if you could do any better by going to Florida than where you are. If you have made a success under the conditions in the North with which you are familiar it is doubtful if you would do any better in the South, and it is probable you would not do quite as well.

11. Generally speaking, the opportunities for a young man are better in the North than in Florida. On account of the large number of people who are compelled to go to Florida for lung trouble or other diseases the labor market is rather poor there. The same is true of California.

We would suggest that you spend two or three months in Florida traveling about, asking all the questions you can; but be very shy about accepting the statements made by the average real-estate man. Take, rather, the statement of some conservative person who goes down to Florida every year for his health and is not in any way interested in the sale of land. There are plenty of honest real-estate men there whose statements you can rely upon; and while Florida has its land-sharks that state is no worse

than any other state where development is going on. You will find conditions just as bad in Texas, New Mexico, Arizona, California, where there is a great onrush of people on account of supposed get-rich-quick propositions, or because people have to go into other climates on account of their health.—Ed.]

What Section or Sections are the Leaders? The Pound Section No More

I have been ill for a few months, and improved the opportunity of looking over Gleanings for the last twenty years. It made me notice more than ever before the tremendous advance and improvement in the bee industry, and especially in Gleanings. It is a high-grade magazine, and I am sure you may be congratulated for bringing it to such a high standard.

It has been about twenty years since I have been in touch with the comb-honey market. I am thinking of going or changing into comb-honey production; and should ing into comb-honey production, and should ent-day sections.

Do the markets in Ohio and adjacent states still prefer the tall section, such as 4 x 5? If not, what size has the preference?

Under the net-weight law, is it likely that the heavier 4 x 5 x 1½ will have the preference over the lighter 4 x 5 x 1¾? Or is the latter about the right net weight?

Do you know of any section besides the 4 x 5 and 4¼ x 4¼ which is likely to come into the lead? I like the 4¼ x 4¼ but don't like the fixtures. Besides, there are too many varieties already.

I want to be sure to receive your opinion as to be best thickness of the 4 x 5 under present conditions of markets and laws—for instance, whether there are any signs of a change in the future.

Fremont, Ohio.

Dr. C. G. Luft.

[While the 4 x 5 plain section is very popular, yet, taking the country as a whole, it is not the leader. The 4¼ x 4¼ x 1½ beeway section is sold more than any other; but the 4x5 section is gaining in popularity everywhere it is sold, and we prefer it to any other style of package for comb honey.

So far as the net-weight law is concerned, there is no advantage in the 4 x 5 x 1½ over the 4 x 5 x 1¾. Since the net-weight law went into effect, sections are not sold by the pound any more, but by actual weight, or minimum weight in ounces. We do not know of any sections besides the 4 x 5 and 4¼ x 4¼ regular beeway, 1¾, that is likely to come into lead. The last-mentioned section is already in the lead, and very possibly may hold its lead. In the western part of the country the 4¼ x 4¼ square section is used almost exclusively.

As to the best thickness of the 4 x 5 we recommend the standard 1¾ plain section. There is no likelihood that the 4¼ x 4¼ will come into any general prominence.—Ed.]

A. I. Root

OUR HOMES

Editor

The voice of one crying in the wilderness.—JOHN 1:23.

And their works do follow them.—REV. 14:13.

A sad task lies before me. T. B. Terry, whose name has been before our readers more or less for 40 years, is no more. From the *Ohio Farmer* I clip as follows:

T. B. TERRY DEAD.

T. B. Terry, well-known agricultural writer and lecturer, died at his home, Hudson, O., Jan. 1, aged 73. Mr. Terry had been in ill health for some years; in fact, about 20 years ago the doctors gave him only a year or so to live. Then he began a persistent system of dieting, exercise, bathing, and pure-air treatment, which was successful until his last illness began about eight weeks ago. He had lived for 45 years on the farm where he died. He went to Hudson in 1860, and entered the creamery business. Later he devoted his time entirely to farming, writing, and lecturing, receiving his first Ohio institute appointment in 1880, from secretary W. I. Chamberlain. Years ago he was a well-known writer for *The Ohio Farmer*. Of late years he has confined his writing entirely to one paper, and has specialized on health topics. His last book was entitled, "How to Keep Well and Live Long." He is survived by his wife and four children.

And again from the *Practical Farmer* as below:

It is with great sorrow that we announce to our readers the death on New Year's Day of our good friend, and theirs, Mr. T. B. Terry. For over twenty-five years Mr. Terry has contributed regularly to this paper, and "Terry's Talks" have been eagerly read by nearly every reader of *The Practical Farmer*. During his connection with this paper Mr. Terry has written on a broad range of subjects, covering every phase of agriculture, and in addition has contributed a most valuable series of health talks thru which a great many of our readers have profited in renewed good health.

Mr. Terry's death resulted from the recurrence of a malady which afflicted him twenty years ago, at which time his doctors told him that he could not recover, and expected his death in a very short time. In this emergency Mr. Terry exerted his indomitable will and courage; he studied his own case carefully, and thru a strict system of dieting, exercise, bathing, etc., he restored himself to perfect health. It was the knowledge and experience thus gained which Mr. Terry put into his health articles which have done so much good to readers of this paper. It was only when the weakening effect of advancing years joined hands with his old malady that he succumbed.

A host of our readers will join us in mourning for this wise and kindly gentleman whose highest aim always was to aid others and give them the benefit of the experience which he himself had gained thru years of toil and a valiant fight against ill health.

From a kind letter from Mrs. T. B. Terry, dated January 1, I learn that, since his sickness of about two years ago, he had often complained of a sore spot in his bowels, and remarked he feared it might give him trouble some time. Not long before he was taken sick he painted the roof to that "covered barnyard." Altho he worked at

it only three or four hours a day he always complained, when he came in, of feeling badly. The good wife tried to have him get help, but he wanted it done "just right." A little later, while the wife was away he carried several boxes of apples into the cellar. This proved "the last straw." Mrs. T. thinks if he had not insisted on painting that roof and carrying those apples himself he might have been enjoying fair health today.

Let me pause a little right here. While there is danger that some of us may get in a hurry to think we are "too old to be of any use," there are doubtless many who, like our departed friend, shorten their stay here by unimportant matters. One of the firm of the great nursery of Storrs & Harrison lost his life by lifting on a barrel of water that was to be used for irrigation. He had means enough to buy a whole pond or lake of water, and have it put where he wanted it.

Two most able physicians and two trained nurses were employed for Mr. Terry, but to no avail. His trouble was kidney disease and inflammation of the bladder.

I first met Mr. Terry at a farmers' institute in Medina toward 50 years ago. He gave a talk on potatoes. It so impressed me I insisted on putting it into book form. His great theme was big crops of clover, all plowed under, as "green manuring" for the crop to follow. Later on he astonished the world with strawberries, grown by turning under clover and nothing else in the way of a fertilizer; and this brought out the book "The A B C of Strawberry Growing;" and, still later, other farm books. Soon after the farmers' institutes found out, as I did, that, no matter what Terry "talked about," it was always interesting to an audience. It was not only the farmer himself he was glad to help, but his institute talk on "The wife's share" brought crowds of women out to his lectures. While I was away down in Missouri on one of my wheel rides I ran across him lecturing to crowds of farmers, with the wives and children also in attendance. As Medina is only about 30 miles from Terry's home I went over often to get pointers, and very soon I too was surprising the world with potatoes and strawberries grown by plowing under the biggest growth of clover I could produce.

Terry's health failed; and the doctors told him, if I am right, he had but a few weeks to live. He went clear to New York

city to get the best expert advice. Then he turned to nature and to nature's God. I was pretty close in touch with him all this time, for I was pretty nearly in the "same boat." The doctors said I could "never be a well man." As Terry climbed away from grim Death, he told about it in the *Practical Farmer*, and afterward, at my special request, he put it in book form. From a multitude of testimonials I will select just two letters.

During the spring of 1910 I was taken sick. Our family physician was called in. He treated me several weeks. I continued to get worse. I could walk around and work some during the first part of the treatment, but finally I had to stop all activity. I suffered day and night. Then I called in another doctor and continued to get worse until I was reduced in weight from 156 to 128 pounds. Then I went to a nearby town and entered a hospital for treatment. I was there five days without taking a dose of medicine; was examined by two doctors. The fifth day I asked them why they did not treat me. I was informed that they had just located my complaint and were ready to begin treatment. I asked the amount of charges during the time I had been there, and was presented with a bill for \$26. I paid it and started for home. In the meantime I had ordered Mr. T. B. Terry's book, "How to Keep Well and Live Long." On reaching home I determined to study it carefully and follow its teachings, which I did from that day to the present date. The 4th, 5th, and 9th chapters were my chief studies. I followed instructions closely. I cut out everything that Mr. Terry advised, even my tobacco, which I had used for 30 years, and today I feel as well as I ever felt in my life. My present weight is as usual when I have good health. I am fully convinced that one who will read, study, and live according to instructions of Mr. Terry's book, "How to Keep Well and Live Long," will never have occasion to call in any but a surgical doctor, as they will have no sickness, barring accidents. And to those who are sick I beg to persuade you to secure Mr. Terry's book and follow its teachings and cast aside all drugs, and you will surely have health.—C. C. LONDON, Emmerton, Va.

In the March, 1910, issue of GLEANINGS IN BEE CULTURE I first read the introduction of your book, "How to Keep Well and Live Long." The description of Mr. Terry's case, as given there, struck me as being very similar to my own at that time. I was suffering with a general breakdown of health, and under the care of a good doctor, but did not seem to get much better. I ordered a copy of "How to Keep Well and Live Long," and after a careful reading was very favorably impressed with the plain and forcible manner in which things pertaining to health and illness were explained and set forth. Also the plain, inexpensive instructions and suggestions toward right living. I became convinced that I had been working, breathing, eating, and drinking very carelessly, and began to set about to make some corrections and put into practice the teachings of the book, gradually, at first, adding one after another change as I re-read and studied it and became familiar with details. My first move in the right direction was for better air by opening windows top and bottom. How easy and simple! Strange I could not have thought of it myself, years ago, but did not—too busy and hadn't time. Then came the water-filter, then later the flesh-brushes (a long-handled one too) and sponge bath. Then the cutting down of improper foods and substituting prop-

A. I. Root's one-third acre Florida garden consisting mostly of Irish potatoes.

er ones instead. Thus I kept gradually working into better and more healthful ways of living until I got everything about right according to the book. As the days and weeks went by I very slowly and surely began to improve, and now, after several months following the advice as taught in "How to Keep Well and Live Long," I can say that I have been greatly benefited in health, and expect to keep

on gaining until fully restored to health. My greatest regret is that I did not have or know of these things sooner in life. I feel, personally, full of gratitude to Mr. Terry for the book and for what it has done for me. He certainly has accomplished a great work which will be a blessing to the human race if it will but follow the truth Mr. Terry has put before them.—A. W. McMASTER, Jacobsburg, Ohio.

HIGH-PRESSURE GARDENING

GLIMPSES OF OUR FLORIDA GARDEN, TAKEN ABOUT FEB. 15.

No. 1 shows how it is thrown up in beds, with deep wide paths between. These paths not only answer to some extent the place of tile draining, but they run the *cold air* down toward the canal, so that when we have a moderate frost or freeze my stuff is mostly unharmed, when garden truck on dead-level land is often killed outright. Nothing has been harmed in our garden so far (Feb. 21), except sweet potatoes. We are just now digging and selling our Irish potatoes at 25 cts. per half-peck basket, and the demand is ahead of the supply.

No. 2 shows the rhubarb that here in Florida must be planted in the fall and harvested before the summer rains. Just back of it, next to the fence, are some fine potatoes on new ground just reclaimed from the wilderness. In fact, said "wilderness" was just chopped up and put under ground to furnish humus. Potatoes seem to thrive better on new ground the first year than almost any other crop. On the upper right-hand corner you get a glimpse of what we call our "barn," with the shed on the south

side, where we have poultry-netting shelves on which to cure the dasheens.

No. 3 shows our method of growing "sprouted oats." The bed originally had five rows of oats, such as you see. Just before the picture was taken we pulled and fed to the chickens every other row and planted potatoes in their stead. The potatoes are not yet up; but when they are, we shall pull the remaining oats and cultivate and hoe the potatoes. Our chickens have learned to devour eagerly oats a foot high. It is an easy matter to pull them, root and all, out of the soft sandy soil.

Everything has been described in picture No. 4, except the great cassava roots. I might say, however, that one of the dasheens in the little basket in the foreground weighed over 4 lbs., and that the Red Bliss Triumph potatoes shown are two of the 25-ct. half-peck baskets set in a half-bushel basket. Now for the cassava:

Just about two years ago we set out (4 x 4 feet) some sprouted cuttings in one of the beds on our poorest sandy ground, giving them a very little fertilizer. The weeds were kept out until the cuttings were

Burbank Giant rhubarb with beets and carrots on the right.

well started, and almost no cultivation (and no fertilizer) since. When Wesley dug up those three roots I was astonished. The three were about all I wanted to carry; but I carelessly neglected to weigh them.* They are good nourishing food for man or animals; and as we have more on that one bed (perhaps 100 feet long) than the chickens can ever use, I have been seriously considering some pigs to utilize the crop. They can stay in the ground winter and summer until you are ready to feed them. In our soft sandy soil it is but a minute's work to reach down and "yank" out a root like those shown above. A drouth doesn't seem to hurt them at all. You may recall I have already printed extracts from a Government bulletin in regard to cassava for pigs, poultry, and other farm stock.

Near the basket of dasheens you will notice a small bundle of the bleached dasheen shoots that we call "dasheen asparagus." The other basket near the potatoes contains leaves of the Giant rhubarb.

* I am told indirectly I got the first premium on cassava, altho almost every county exhibit has cassava, more or less.

THE WILD CACTUS OF TEXAS AND MEXICO, AND SOMETHING ABOUT THE SPINELESS.

We clip the following from *The Times Union*:

CACTUS IN TEXAS; GOVERNMENT OFFICIAL SAYS
CATTLE ARE RAISED AND FINISHED ON IT THERE.
J. M. Doyle, manager in charge of United States

Winter turf oats, grown for poultry.

demonstration work in Texas, writes from San Angelo, Tex., as follows to American Spineless Cactus Inc., in answer to a query concerning the use of cactus as a stock food:

"All that territory from Beeville, Tex., on the east of El Paso, Tex., and on thru New Mexico, Arizona, almost to the eastern border of California, and on a line east and west thru San Antonio, Tex., on the north, to the Gulf of Mexico on the south, is, as all the people throughout that territory will attest, a wild-cactus-bearing country, and is used now and has been for many years by the ranchmen to feed their stock on, spines and all, and latterly, with the aid of the pear-burner, to burn the spines off. The cattle in nearly every case are fed on the wild cactus until it is finished and ready for the market; and this has been going on for years; but, as Mr. Dougherty well knows, it is more expensive to feed the wild cactus on account of the sharp spines than it would be to feed the spineless variety of cactus, and the wild cactus does not by any means produce the tonnage per acre that the spineless variety does.

"This is no secret. Any one can investigate and see for himself if he only would.

"This wild-cactus territory is many times larger than Florida, and thousands of stock of all kinds, but principally beef cattle, are fed on it the year round in many sections of it, and in large portions of this territory there is almost absolutely nothing else that can be used for feed than this wild cactus.

"There is no question at all as to the commercial status of feeding cactus. There is no feed in the world that can match it for economy and results when the cost is considered."

We have the wild cactus of Mexico in our garden by the side of the spineless, and they started to grow several weeks sooner than the spineless. They are now, Feb. 24,

A. I. Root's exhibit of garden truck at the South Florida fair held at Tampa in February.

in bloom, and some have fair-sized fruit, not yet ripe. The very first cactus to start down here was Malta, the one I pictured last summer (p. 690). I pulled off the eight slabs, packed the whole in my trunk, and in less than 30 days every one was budded, and now we have from that one slab, sent to Medina last July, 30 growing slabs, counting "children and grandchildren."

A GASOLINE TORCH FOR BURNING WEEDS, AND SPINES ON PRICKLY PEAR CACTUS.
I have been over a year trying to find out where

I could buy a gasoline torch to burn weeds and dodder in alfalfa. It was used a few years ago in the San Jacinto Mountains to burn the spines off cactus for cattle to eat.

The tank of the torch is strapped across the shoulders, and is easily carried. A pipe about 4 ft. long is furnished so as to have the blaze at a distance. It will throw a blaze about 6 inches in diameter, and from one to four feet long if desired.
DAVID CHRISTIE.

Veterans' Home, Cal., Sept. 2.

I think I have seen something of this kind advertised. Can any reader of GLEANINGS tell us where it can be found—cost, etc.?

TEMPERANCE

DID ABRAHAM LINCOLN EVER USE, SELL, OR RECOMMEND "BOOZE"?

The following came to me from my son, H. H. Root:

I am enclosing a bulletin put out by the Methodist Church Temperance Society, which gives the first denial that I have ever seen of the oft-repeated statement by Lincoln that prohibition works a great injury to the cause of temperance, etc. Every campaign we have had in Ohio, the wet leaders have flooded the state with this statement, supposed to be by Lincoln. I have never believed it, and have tried to find some one who could give the truth about it. These Methodist men have gone to the trouble of ferreting out the whole shameful process by which Lincoln's temperance utterances were twisted into arguments to favor the wet side. I thought you would like to see this.

The article mentioned is too long for our use here; but the whole story may be had by addressing Deets Pickett, 1-6 Shawnee Building, Topeka, Kansas. It covers the whole ground so completely, there is no possibility of mistake.

"GOD'S KINGDOM COMING."

Here is another good thing in that same Methodist Bulletin. We clip as follows:

NEW YORK TRIBUNE SOON WILL CEASE TO ADVERTISE LIQUORS; NEWSPAPERS IN ALL PARTS OF THE COUNTRY ARE CLEANING THEIR COLUMNS IN RESPONSE TO THE BIRTH OF A NATIONAL CONVICTION.

In a letter to Rev. Clarence True Wilson, D.D., General Secretary of the Temperance Society of the Methodist Episcopal Church, the New York Tribune announces that after April 1st, next, it will no longer accept advertising of any alcoholic liquor. The letter reads as follows:

"February 7, 1916.

Clarence True Wilson, D.D.:—After April 1st, next, we shall not carry the advertising of any alcoholic liquor. At present we carry this advertising on a non-solicited list entirely, barring all statements which present any such beverage as having food or tonic value.
RICHARD H. WALDO."

This act of the Tribune will send a thrill of gratification thru millions of prohibitionists of the United States, and will have the approval of millions of other men and women who are not prohibitionists.

The Indianapolis News and the Scranton Republican are two other papers which have recently taken this step.

In response to an inquiry sent to all of the daily newspapers of the United States, the Methodist Temperance Society has received more than 1000 replies. There are 2123 daily newspapers published in the English language in the United States, according to the American Newspaper Directory for 1916.

The result of this inquiry will be announced in a special bulletin issued by the Temperance Society in a few weeks. It is already apparent that the year 1915 brought about an astonishing revolution in the attitude of the newspaper world toward alcoholic leverages.

May God bless the Methodist Temperance Society.

"GOD'S KINGDOM COMING" IN RUSSIA IF NOT IN AMERICA.

Dear Mr. Root:—The enclosed clipping may be of interest and good use to you in your worthy work.
WM. A. HUNTER.

Terre Haute, Ind., Feb. 14.

The good friend who sends the above gives no clue as to where he clipped it, so we are unable to give proper credit. Below is the clipping:

RUSSIA DRY FOREVER AS RESULT OF YEAR WITHOUT HER VODKA.

PETROGRAD, Feb. 10.—Russia has taken a long breath, raised her solemn right hand, and sworn: "Never again!"

A year without vodka has convinced the officials, from the czar down, that prohibition will always be the rule in Russia. Here are some results of the first twelve-month without liquor, as reported officially and semi-officially from all over the country:

Crime (all kinds) has decreased 62 per cent.
Absenteeism in factories has fallen 60 per cent.
Suicide rate has dropped enormously.
Hospitals formerly overcrowded are not filled.
Efficiency in factories increased 10 to 15 per cent.
Practically every inhabitant is at work.
Savings deposits have increased 8 per cent.
Fire damage has fallen off 38 per cent.
Wages in some districts raised 500 per cent.
(This applies to peasants working as day laborers.)
People are eating better and costlier food.
Better clothing is worn by the poorer classes.
Agricultural-implement sales 60 per cent larger.
Imprisonment decreased 72 per cent.

OVER FIFTEEN THOUSAND BARRELS OF BEER LESS IN 1915 THAN THEY SOLD IN 1914.

The *Plain Dealer* informs us that The Dayton Breweries Co., Dayton, O., sold 15,185 barrels of beer less in 1915 than 1914, and I think most of the breweries could make a similar report. Even if Cincinnati did keep Ohio wet, God's kingdom is steadily "marching on," even in Ohio.

MICHIGAN'S SPLENDID RECORD; HAVE KNOCKED OUT ONE SALOON A DAY FOR PAST EIGHT YEARS.

Michigan drys are well organized for the campaign for statewide prohibition to be conducted this year. Hon. R. H. Scott, manager of the Reo Automobile Company, of Lansing, is chairman of the Michigan dry committee. The whole campaign organization is well manned and equal to the work. Summarizing the results of the work done by the Anti-saloon League in Michigan, Mr. Scott says:

"The results of the work of the Anti-saloon League in this state are 2934 fewer saloons than there were eight years ago. The decrease in saloons averages 366 a year, or one for each day for the past eight years. There are 3236 left, and about half of this number are located in Wayne County, in which is the city of Detroit."—*American Issue*.

Good for the "Reo" folks!

SOMETHING TO MAKE YOU OPEN YOUR EYES.

We clip the following from the *Youth's Instructor*:

WAR'S BLOODY TOLL.

If the European war continues at the present rate of destruction until April, 1916, it is estimated by a distinguished war writer that 19,700,000 men will have been killed or permanently disabled. This means that thirty-seven of the chief cities of our country, according to the government's 1912 estimate of their population, would have to be depopulated of men, women, and children to furnish a number of persons equal to the war victims of Europe's bloody battlefields. The cities are: New York, Chicago, Philadelphia, St. Louis, Boston, Cleveland, Baltimore, Pittsburgh, Detroit, Buffalo, San Francisco, Milwaukee, Cincinnati, Los Angeles, Newark, New Orleans, Washington, Minneapolis, Jersey City, Seattle, Kansas City (Missouri), Indianapolis, Providence, Portland (Oregon), Rochester, Denver, Louisville, St. Paul, Columbus (Ohio), Toledo, Oakland (California), Atlanta, Worcester, Birmingham, Syracuse, Little Rock, and Lincoln (Nebraska).

QUEENS WANTED IN WINTER.

Mr. Root:—I wrote your agent at Savannah for an Italian queen; but he informs me it is too early for shipment. Could you advise me of any one in your vicinity who has queens for sale now, as I am very anxious for one at once!

I have a very populous colony that I wish to divide. The palmetto and orange are beginning to bloom. I suppose I am your furthest-south "bee-woman" subscriber. My bees are making a great deal of honey, and have made quite a bit since September.

I am a beginner with bees; but I love to work with them. The Italians here are much gentler than those my father raised in Kansas. I shall increase my colonies as fast as possible.

ROSELLE OR JAMAICA SORREL.

I read your article about Jamaica sorrel. I have raised it for three years, and am much pleased with it. I have quite a bit of seed if any one desires it. Homestead, Fla. MRS. CLARA KILLINGER.

So far as I can discover, no one has ever undertaken to furnish queens, either here or in California, before March 15 or April 1, and yet my two neighbors Ault and Abbott have both had queens hatched and fertilized every month in the year. I have been expecting every year some one would advertise queens in winter time—of course at a large price. There would, perhaps, be some risk in mailing them very far North; but I feel sure it *can* be and *will* be done soon. Of course no one should undertake it without previous large experience in queen-rearing.

NUCLEI BY EXPRESS FROM YORK STATE TO FLORIDA.

Our neighbor, E. A. Redout, had four six-frame nuclei sent by express in January from his home in York State down here at a cost of only \$3.00; and as he had here hives of empty combs they promise to make good colonies soon. The charge of only 75 cts. per nucleus he thinks quite reasonable. They came in perfect condition.

ANOTHER CHRISTMAS PRESENT.

In token of my brotherly love and friendship, and in appreciation of your several favors, and in approval of the good work you are doing, and heping your appetite for meat is good, I am sending you by mail a little fresh meat for Christmas. It is a little early, perhaps, but this kind of meat won't spoil. Besides, it is *canned*, and was canned *alive* at that, and as it wasn't butchered it is genuine fresh meat, sure enough. You may open the cans any time, and it won't die nor putrify before Christmas. And you won't have to disguise it nor pepper it nor salt it and stuff it with sage, nor smother it with onions to make it go down, nor take dyspepsia tablets to hold its breath down! And, best of all, it springs forth from the bosom of Nature like the succulent herbs of the garden, the waving grain of the field, and the luscious fruit of the vine, supplying rich and palatable food for man, free from disease and impurity, and without causing pain or death to any innocent creature.

"Behold I have given unto you the fruit of a tree; to you it shall be for meat,"
Monticello, Fla., Dec. 10. SAMUEL KIDDER.

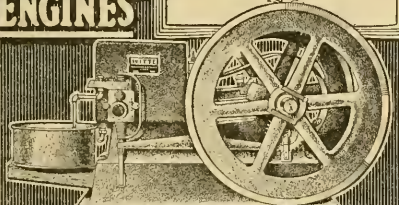

And now, dear friends, what do you suppose came by parcel post, that fulfilled to a dot the above "specifications"? A box of extra-fine large paper-shell "pecans!"

I wish to thank the publishers of GLEANINGS for sending it to me this year, altho I did not send in any money for it. I was unable to do so, as Russian postoffices do not accept money orders out of this country since the beginning of the war. Now the year is again drawing to its close, and I am at a loss how to send the subscription money. If the publishers will continue to send me GLEANINGS I shall be very thankful, and, of course, will send the money as soon as possible—that is, as soon as the war ends. It would be a great disappointment to me not to get GLEANINGS, as I am an old subscriber, and have a large apiary. GLEANINGS is very interesting to me, as well as useful. I hope I shall not be deprived of the pleasure of receiving it.

Aria, Russia, Nov. 18. MISS M. OULIANINE.

"HOW TO JUDGE ENGINES"

A Valuable Book Free!

EVERY man who has any idea of buying a Kerosene or Gasoline Engine should have this book.

Discusses different types of engines; how constructed; how operated; how cylinders and other parts should be made to give greatest efficiency.

It has taken 30 years of engine building experience for me to learn the facts in this book. Yours for the asking.

My 1916 Model Engines are the greatest value I have ever offered. All sizes pull from 30 to 50% over factory rating.

WITTE Engines—built by experts. **Free Trial—Easy Terms.**

MYERS HYDRO-PNEUMATIC PUMPS

FOR HOME WATER SUPPLY

MYERS HYDRO - PNEUMATIC PUMPS are rapidly growing in popularity, for they are ideal for the home water supply. Made for hand or power operation, in numerous styles and sizes, they meet everybody's requirements. Air and water are pumped through the same discharge line into the pressure tank. The air, compressed in the top of the tank, forces the water through the distributing lines.

Write for our catalog of Home Water Supply systems. It is free for the asking.

NEW KEROSENE LIGHT

BEATS Electric or Gasoline

10 DAYS FREE

SEND NO MONEY CHARGES PREPAID

Don't ask you to pay a cent until you have used this wonderful modern light in your own home ten days—we even pay transportation charges. You may return it at our expense if not perfectly satisfied after putting it to every possible test for 10 nights. You can't possibly lose a cent. We want to prove to you that it makes an ordinary oil lamp look like a candle; beats electric, gasoline or acetylene. Lights and is put out like old oil lamp. Tested by Government and 35 leading Universities show it **Burns 50 Hours on One Gallon** common coal oil, and gives more than twice as much light as the best round wick open flame lamp. No odor, smoke or noise; simple, clean, no pressure, won't explode. Several million people already enjoying this powerful, white, steady light, nearest to sunlight. It's **GUARANTEED.**

Men Make \$50 to \$300 Per Month with Rigs or Autos

delivering the ALADDIN on our easy trial plan. No previous experience necessary: Practically every farm home and small town home will buy after trying. One farmer who had never sold anything in his life before writes: "I sold 51 lamps the first seven days." Another says: "I disposed of 37 lamps out of 31 calls." Thousands who are coming money endorse the Aladdin just as strongly. **NO MONEY REQUIRED.** We furnish capital to reliable men to get started. Ask for our distributor's plan, and learn how to make big money in unoccupied territory. **Sample sent for 10 DAYS' FREE TRIAL.** We want one user in each locality to whom we can refer customers. Be the first and get our special introductory offer under which you get your own lamp **FREE** for showing it to a few neighbors and sending in their orders. Write quick for **10 DAY ABSOLUTELY FREE TRIAL.** Address nearest office.

More Profit

THROUGH better, more intelligent, more economical use of good tools will come the profit that is so hard to find each year on many crops. Plant right so you will get full benefit. Work faster with better tools so you can cultivate and spray often. Study whether there isn't some tool that will do your work better.

IRON AGE

Potato machinery, spraying machinery, garden tools, etc., are built to give you just what you need to do things right. Almost any combination you can think of in each line. Eighty years of factory and farm experience behind their manufacture.

Ask your dealer to show them, but write us for separate booklets fully describing lines in which you are interested. Let us make good our claims.

Describes over 70 tools including 12 entirely new ones, and improvements to our Seeders, Wheel-Hoes, Horse-Hoes, Harrows, and Corn, Potato, Orchard, and Beet Riding-Cultivators. Write for it today!

S L Allen & Co Box 1106S Philadelphia

No. 4 Planet Jr Combined Hill and Drill Seeder, Wheel-Hoe, Cultivator and Plow pays for itself in a single season in the family garden as well as in larger acreage. Sows all garden seeds (in drills or hills), plows, opens furrows and covers them, hoes and cultivates easily and thoroughly all through the season.

No. 11 Planet Jr Combined Double and Single Wheel-Hoe, Cultivator, Plow and Rake. Straddles crops till 20 inches high, then works between. The plows open furrows and cover them. The cultivator teeth work deep or shallow. The hoes are wonderful weed-killers. The rakes do fine cultivation and gather up trash. Unbreakable steel frame. Strong high steel wheels and specially hardened steels—new this year. The greatest hand-cultivating tool in the world.

No. 11

We make 32 styles of seed-drills and wheel-hoes—various prices.

Three-band and Golden Italians

The Secret of
Success

in beekeeping is to keep your colonies strong. To do this you must have good healthy laying queens.

1 untested queen, \$1.00; 6 for \$5.00; 12 for \$9.00.
1 tested queen, \$1.50; 6 for \$8.00; 12 for \$15.00.
½ lb. bees with untested queen, \$2.50; tested, \$3.00.
1 lb. bees with untested queen, \$3.50; tested, \$4.00.
1-fr. nucleus with untested queen, \$3.00; tested, \$3.50.
2-fr. nucleus with untested queen, \$4.00; tested, \$4.50.
If more frames are wanted than we list, add \$1.00 each per frame wanted to above prices.

Satisfaction guaranteed

W. J. LITTLEFIELD

618 W. Seventh St. Little Rock, Ark.

Yes, "By their fruits ye shall know them," and that is why I have recommended your queens. Where European foul brood is found, the stock proves itself disease-resisting as well as or better than any other we have tested. When a beekeeper having a good apiary where European foul brood was taking the apiary when inspected, and he told me, after testing your queens, he would not take \$25.00 for the last queen you sent him, it speaks for itself. His apiary, now cured, is proof of the pudding.
N. E. France, Plattsville, Wis.

Martine Foundation Fastener

Patent applied for.

Latest and best device invented for fastening foundation securely to the frame or section with a tiny stream of hot wax. Prevents breaking down of foundation with the weight of the bees.

Saves expense, time, and labor.

One filling of the fastener is sufficient to fasten the foundation in five frames and can be done in one-third the time required by any other device.

Price 50 cents, postage prepaid. Satisfaction guaranteed.

Three-band Italian Queens

My queens are bred from imported mothers. They are the best for honey-gathering and gentleness. I fill orders as promptly as possible. GUARANTEE that all queens will reach you in good condition, to be purely mated, and will give perfect satisfaction.

PRICES --- April 1 to July 1

Untested	one, \$0.75; six, \$1.25; doz., \$8.00
Select Untested	.90 5.00 9.00
Tested	1.25 7.00 13.00
Select tested	2.00 11.00 20.00

L. L. Forehand, Fort Deposit, Ala.

Do You Need a Queen for that Queenless Colony?

We can furnish tested Italian queens by *return mail*, \$1.00 each. These queens are not cull nor inferior in any way because they are cheap. They were reared last September and October, and wintered in four-frame nuclei expressly for our early spring trade in tested queens. We expect to have untested queens ready to mail about April 10; \$1.00 for single queen; \$9.00 per dozen. We began rearing queens for sale in 1886. Our strain of three-band Italians is well known to leading beekeepers. We have never had a case of foul brood in our apiary, and we guarantee every queen sent out by us. We solicit your orders.

J. W. K. Shaw & Co., Loreauville, Louisiana

ITALIAN QUEENS THREE-BANDED

Ready April 1. Of an exceptionally vigorous and long-lived strain of bees. They are gentle, prolific, and the best of honey-gatherers. Untested, \$1.00; 3, \$2.75; 6, \$5.00; 12, \$9.00. Tested, \$1.25; 6, \$6.50; 12, \$12.50. Send for my free circular and price list, and see the natural conditions under which my queens are raised. Will book orders now.

Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier if necessary. THE HYDE BEE Co., Floresville, Tex.

Carniolan, Golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, box 135, Buffalo, Texas.

QUEENS.—Italians exclusively; golden or leather-colored. One select, untested, \$1.00; 6, \$1.25; 12, \$8.00. Tested, \$1.25. Best breeder, \$5.00. Early swarms of young bees in light screen cage a specialty. One 1-lb. package, \$1.25; one 2-lb., \$2.25; queen extra. For ten or more, write for price. Also nuclei and full colonies. I am booking orders now, with 10 per cent deposit for delivery March 15 and after. Safe arrival, prompt service, and satisfaction guaranteed. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

FOR SALE.—Swarms of Italian bees in packages, 1 lb. of bees, \$1.50; 2 lbs. of bees, \$2.50; for 50 or more they are 12½ cents less. Untested Italian queens 75 cts. each; tested Italian queens, \$1.25 each. No reduction on quantity of queens for April and May. Quality, service, safe delivery, and no disease, I guarantee. We spare no labor nor money to produce the best for you is why we cannot make a lower price. Early swarms get the honey. We can deliver the goods with pleasure to both of us.

W. D. ACHORD, Fitzpatrick, Ala.

The successful package-shipper and queen-breeder.

BEES AND QUEENS.—Doolittle's Italian stock speaks for itself. They are gentle, resist disease, and are fine honey-gatherers. We breed this stock only, and guarantee delivery only to points west of the Rocky Mountains. Untested queens, 75 cts. each; \$8.00 per dozen; \$60 per 100; tested queens, \$1.25 each; \$12 per dozen; \$85 per 100. Three-frame nuclei, \$2.25 each; \$200 per 100. Bees, ½-lb. packages, 75 cts. each; \$6.00 per 100; 1-lb. packages, \$1 each; \$85 per 100. Add price of queens to above packages. Complete catalog free on application.

SPENCER APIARIES, Nordhoff, Cal.

FOR SALE.—Italian bees by the pound, and select-bred Italian queens. One-pound swarms without queens, \$1.25 each; 2-lb. swarms without queens, \$2.35 each; 3-lb. swarms without queens, \$3.35 each, and 5-lb. swarms without queens, \$5.35 each. If queens are wanted with swarms, add price as according to price list below. Untested, warranted purely mated queens, 75 cts. each; tested queens, \$1.25 each. All queens are bred according to our plan of breeding only from colonies or queens of the highest standard—those that have made the best record in pounds of honey. These select colonies are the choice of over 1000 hustling honey-producing colonies. Every queen we warrant to be purely mated or we replace her, free of charge. Every pound of bees we guarantee to deliver alive and in good shape, and full weight. We have no disease. Safe arrival and satisfaction we guarantee on both queens and bees in packages. For wholesale prices on either queens or bees by the pound write us. Let us book your order now. Only a small payment down required. M. C. BERRY & Co., Hayneville, Ala.

HELP WANTED

WANTED.—Able-bodied experienced beemen for season of 1916. W. W. FAIRCCHILD, Heber, Cal.

WANTED.—A queen-breeder of experience, April 1. Give references, salary wanted, etc., in first letter. M. C. BERRY & Co., Hayneville, Ala.

WANTED.—An experienced apiarist. State wages, experience, and give references as to ability. Board furnished. THE STOVER APIARIES, Mayhew, Miss.

WANTED.—Experienced beeman, familiar with taking extracted honey, and to help handle 450 colonies. Give experience, and wages expected in first letter. Will commence April 1. D. B. ELLIS, Benson, Ariz.

WANTED.—Young man to assist in outyards and on small farm when not working bees. Board and lodging provided. State age, weight, wages, experience, etc. A. L. COGGSHALL, Groton, N. Y.

WANTED.—Single man, experienced, extracted-honey producer or assistant, at once; farm-raised, and of good habits; must be willing at odd times to help at light farming. Good home and permanent position to right party. One acquainted with autos preferred. THE HOFMAN APIARIES, Janesville, Minn.

WANTED.—Man with some experience to take care of 150 colonies of bees for 1916, and who, if conditions suit him, will buy bees or take them on shares for 1917. German with some experience in farming preferred. Give all particulars in first letter.

CHAS. BENTRUP, Deerfield, Kan.

WANTED.—Can take two clean minded and bodied young men as student help for the season of 1916. Board free for help given, and something more if a good season and help does well. One understanding an auto preferred. Address R. F. HOLTERMANN, Brantford, Ontario, Canada.

WANTED.—Young man with a little experience; fast willing worker—a student helper in our large bee business of over 1000 colonies; crop last year over 105,000 lbs. Will give results of our long experience, and small wages; every chance to learn. Give age, height, weight, experience, and wages, all in first letter, or expect no answer.

E. F. ATWATER, Meridian, Idaho.

SITUATIONS WANTED

WANTED.—Position in beeyard. I have a diploma and 5 years' experience. Good reference; apply at once. JAMES A. MAINS, Nile, N. C.

College student, wishing to learn the bee business thoroughly, desires position in an apiary after May 2. Habits good. W. J. NOLAN, 2100 Adelbert Road, Cleveland, O.

H. C. CLEMONS, Boyd, Ky.

ON THE BOOKSHELF

The Apple.

The claims of the honeybee upon the fruit-grower come in for acknowledgment in a new volume entitled "The Apple," by Albert E. Wilkinson. Not only does the author warn against spraying at the wrong time, lest it kill the bees, but at another part of the book he thoroughly sums up the relation of bees to the pollination of the apple-blossom. No other work on orchard methods that we have seen treats these important subjects with more practical thoroughness.

"Every large orchard" writes Mr. Wilkinson, "where the trees are numbered by the thousands, should have near by a beeyard of at least fifty swarms to help in thoroughly pollinating the blossoms and

obtaining the best results. Bees will not be poisoned by the spraying of fruit-trees with poisonous substances if the work is done at the right time, which is just after the blossoms fall. No sensible orchardist will spray his trees while in full bloom, and thus poison one of his best friends—the bees."

Honey-producers have a practical interest in getting this book into the hands of the orchardists near them, or into the local public library for the sake of the directions on spraying.

The author is a member of the faculty of the Department of Horticulture in Cornell University. The aim of his book is to bring together and boil down the great mass of literature dealing with the various aspects of the apple business—growing, harvesting, and marketing. The entire subject has been studied in every phase from one end of the country to the other. The text contains many helpful illustrations, including four full-page color plates.

The Apple, 492 pages. Ginn & Co., Boston, \$1.00 postpaid.

Automobile Questions and Answers

How can you adjust a carbureter by the color of the gases? How are valves timed? What is the difference between double and dual ignition systems? Answers to such questions as these the ordinary driver of automobiles often wants to know, and usually has no better way of absorbing the information than to stay around garages and quiz the workmen.

Books there are, but most of these have been written by the expert for the expert. A thoroughly practical text-book, working from elementaries to technicalities, has long been wanted. Such is a new volume by Victor W. Page, entitled "Questions and Answers Pertaining to Automobile Design, Construction, Driving, and Repair." In this treatise of 622 pages the author has explained from every angle all the driver of a car needs to know about his machine, and gives a good technical education in automobile repair. The matter is made clear by 329 illustrations and plates.

The Norman W. Henley Publishing Company, New York, \$1.50 postpaid.

Convention Notices

The twenty-fifth anniversary of the Connecticut Beekeepers' Association will be held in the old Supreme-court room, State Capitol, Hartford, Ct., Saturday, April 8, 1916.

MORNING, 10:30.

Reports of officers and committees; election of officers; collection dues; new business, etc.

"Reminiscences, and Progress of Beekeeping in Connecticut, George H. Yale.

Mr. Yale was third president of the association, and presided continuously for five years. His address will deal with the early history of our association.

"History of Foul Brood in Connecticut," Stephen J. Griffen.

Mr. Griffen was the pioneer in inaugurating laws in this state for the control and suppression of this scourge.

"Can a Woman Manage an Apiary?" Mrs. D. R. Bristol.

Mrs. Bristol is one of our ardent beekeepers. Her address will be of special interest to the ladies.

Recess, 12, for lunch.

AFTERNOON, 1:30.

"Beekeeping in Hungary," Alexander Luko.

Mr. Luko will tell us of the interesting methods and appliances in use in Hungary. He possesses a number of certificates and medals for beekeeping, awarded by the government at various competitions.

"Ventilation Affecting Storing and Swarming," John T. Cullen.

Question-box.

Our association is twenty-five years old this year. In commemoration of the event, the program committee is offering a program of unusual interest. From a membership of 11 we have grown to more than 150, and we continue to grow. It is planned to make this meeting a reunion, and it is hoped the entire 150 members will make a special effort to be present. As a special inducement, a hot dinner will be served, free of charge, at noon, to all members in attendance. This should be the largest meeting in the 25 years of our existence, and the most enjoyable and profitable one as well. Let us not forget about the prompt payment of dues. If GLEANINGS fails to arrive, it is because dues remain unpaid.

Hartford, Ct.

L. WAYNE ADAMS, Sec.

Kind Words

"AS LONG AS I AM ABLE TO READ."

I wish you to continue to send GLEANINGS until further notice, or as long as I am able to read Mr. A. I. Root's excellent Home Talks. I first began to be interested in them as long ago as 1879.

Chicago, Ill., May 17.

R. R. MCGILL.

SOME KIND WORDS FROM A NEAR RELATIVE OF ABRAHAM LINCOLN.

Mr. A. I. Root:—I have often wanted to write to you. Back in the 70's I read of you, and, strange to say, your apiary was the first I ever saw a picture of. Now to the point:

In GLEANINGS for January 1, page 41, you give some very good advice; and now I want to give you grandmother (Lincoln) Bowman's prescription for attaining great age. She says, "Have a purpose in life. Have something to keep yourself occupied at. Never worry nor let anything make you weary. When we find that anything is making us weary, we should stop at once—pick up a paper or book, and read awhile; then we shall feel fresh, and can go right at that work again. My grandmother was 88 years old in October, and works almost every day. She is very spry for her age; and, by the way, she is a first cousin of President Abraham Lincoln. Her great grandfather was killed from ambush by Indians not far from Louisville, Kentucky. He once owned the site on which Louisville now stands. His name was Abram Lincoln. He had four sons. But only three are recorded in history. They were Mordeah, Harry, Thomas, and James. Thomas was the grandfather of Abraham, and also of grandma Lincoln (Bowman). Grandma's father's name was James B. Lincoln. So much for the aged people. I love them. I feel the greatest pleasure in listening to them when they tell of their thrilling experience. I am almost 60, and am yet a young man.

Now, brother Root, I will soon open my maple-sugar camp (and I thought you said you had a lip for maple sugar), and I am going to send you some. I was raised to boyhood at Nelsonville, Athens Co., Ohio. I lived there when General Morgan came thru town. Father was then at the front in the 116th Ohio volunteer infantry. Those were days and nights of terror, and I pray the allwise Creator that I may not see the like again.

J. C. SCHAUFFELE, M. D.

Colchester, Ill., Feb. 14.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Geo. L. Emerson, Manager, 948 East Second St.

Where the Weed foundation-machines are making perfect non-sag foundation. Send us your wax to be made into foundation. We buy wax too.

Root Redwood Hives.—A sample hive body with cover and bottom KD, \$1.00. Quantity prices on application. We cut hive parts to order.

New machinery for manufacturing hives and frames has been added. Extractors are now shipped "knocked-down" from the factory at Medina.

1632.—Ladies' Apron. Cut in 3 sizes: Small, medium, and large. It requires 5 yards of 36-inch material for a medium size. Price 10 cents.

1658-1659.—Ladies' Costume. Waist 1658 cut in 6 sizes: 34, 36, 38, 40, 42, and 44 inches bust measure. Skirt 1659 cut in 6 sizes: 22, 24, 26, 28, 30, and 32 inches waist measure. It requires $7\frac{3}{4}$ yards of 44-inch material for the entire gown for a 36-inch size. This calls for two separate patterns, 10 cents for each pattern.

1650.—Girl's Dress, with or without overblouse. Cut in 4 sizes: 8, 10, 12, and 14 years. It requires $3\frac{1}{2}$ yards of 44-inch material for a 10-year size for the dress with $1\frac{1}{2}$ yards for the overblouse. Price 10 cents.

1652.—Girl's Dress. Cut in 4 sizes: 4, 6, 8, and 10 years. It requires $2\frac{3}{4}$ yards of 44-inch material for a 6-year size. Price, 10 cents.

1636.—Ladies' Dress. Cut in 6 sizes: 34, 36, 38, 40, 42, and 44 inches bust measure. It requires 6 yards of 44-inch material for a 36-inch size. The skirt measures about $3\frac{1}{4}$ yards at the foot. Price 10 cents.

1638.—Ladies' House Dress. Cut in 7 sizes: 32, 34, 36, 38, 40, 42, and 44 inches bust measure. It requires $7\frac{1}{4}$ yards of 36-inch material for a 36-inch size. Price 10 cents.

1501.—Ladies' Shirt Waist with convertible collar. Cut in 7 sizes: 32, 34, 36, 38, 40, 42, and 44 inches bust measure. It requires $2\frac{3}{4}$ yards of 40-inch material for a 36-inch size. Price 10 cents.

1644.—Child's Rompers. Cut in 5 sizes: 1, 2, 3, 4, and 5 years. It requires 3 yards of 27-inch material for a four-year size. Price 10 cents.

“Hats Off to the New Management”

writes a Mission, Texas, customer

The old reliable line of Root's Beekeepers' Supplies with our new system of business management assures Texas beekeepers of service such as they have never before experienced.

Mr. B. I. Solomon, who is now in charge, has been with The A. I. Root Company for some years and knows their method of doing business.

We intend to carry a large and complete stock of supplies, and we also have our Weed foundation machines in shape to care for all orders promptly.

Give us an opportunity to convince you of our service.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hand. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

17 CENTS A DAY! Remember this grand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY---Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

The Oliver Typewriter Co., Cleveland, Ohio

946 Prospect Avenue

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

Valuable Book to **FREE** "Gleanings" Readers

GOOD HEALTH is fifty years old. We want to make our fifty-first year the biggest in our history, and to give our campaign a good start, we make you this special offer, good for thirty days only. Fill out and mail the coupon on this page and you will become a subscriber to GOOD HEALTH for one year, and we will send you, *absolutely free*, the 140-page book, "Constipation—How to Fight It." After you receive the book and the first number of the magazine you can remit the small amount of \$2 for your subscription or, if you are not satisfied in any way with either the book or the magazine, you can return the book at our expense, we will cancel your subscription and your examination will have cost you nothing.

GOOD HEALTH

is the magazine which teaches you how to fight the causes of disease, improving, protecting and preserving health by the most up-to-date methods. Though strictly a scientific magazine, it is not dull, dry-as-dust, nor technical, but every page is intensely interesting and written in simple, convincing English readily understood by anyone. You cannot afford to miss this opportunity to get the magazine which will help to keep you and every member of your family healthy and happy by sane, sensible methods of health reservation.

Dr. John Harvey Kellogg

who is the Editor-in-Chief, has been for forty years Superintendent of the Battle Creek Sanitarium, the largest institution of its kind in the world, which is recognized by leading medical authorities everywhere as the greatest in existence for teaching the principles of preventive medicine.

Your Health Questions Answered FREE

Every subscriber to GOOD HEALTH has the privilege of asking as many health questions as he wishes of the Specialists who are connected with this magazine. Every one of your questions will be answered immediately by mail. This is a great advantage to busy men and women who have some trouble which they feel it is not necessary to see a doctor about but which can be easily corrected by following the advice of a Specialist. The answer to one single question may enable you to avoid sickness and suffering and save you many dollars.

Send the Coupon Now. Do not put off taking advantage of this opportunity. Fill in and mail the Coupon before you forget it.

GOOD HEALTH PUBLISHING CO.

1003 Main St. Battle Creek, Mich.

Enter my subscription for one year to GOOD HEALTH and send me FREE the 140-page book, "CONSTIPATION." If I am satisfied I will promptly remit \$2. Otherwise I will return the book within 5 days and you will cancel my subscription.

"Constipation"

How to Fight It

The worst disorder which afflicts humanity, which is most prolific in symptoms—is intestinal inactivity—or constipation. Nearly all chronic ailments, especially disorders of the heart, arteries and kidneys are the result of the absorption of poisons from the intestine, which are produced through the action of germs upon undigested food remnants.

In "Constipation—How to Fight It" Dr. Kellogg tells you how to rid yourself of this affliction—and stay rid of it—by steady attention to daily habits, diet and exercise. The book is the result of Dr. Kellogg's successful treatment of thousands of cases of constipation and resulting ills. Every word is *fact*, not theory. It is a book you cannot afford to be without.

Here is your opportunity to
 get this beneficial book **FREE**
 —but you must be prompt.

Gleanings in Bee Culture

The Double-walled Massie Bee-hive

Surest Protection for Bees---Increased Supply of Honey---the Best Hive for any Climate

T 1. Massie Hive for Comb or Extracted Honey

Furnished in the clearest of lumber, in either Cypress, White Pine, or red-wood; all brood and extracting frames are made from White Pine.

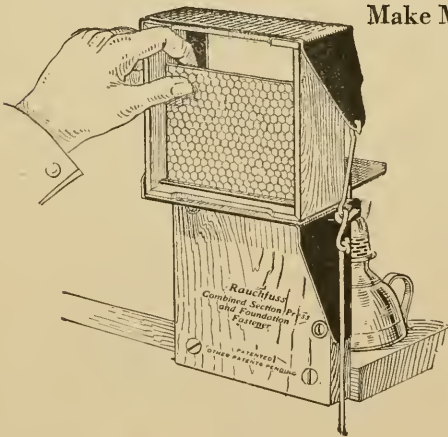

The Dovetailed Hive for Comb Honey

THE VENTILATED BOTTOM admits fresh air into the hive, lessening the chance for swarming, and gives renewed energy to the bees. It is also equipped with a feeder without extra cost. Fifty years in the bee-supply business has shown us that the MASSIE is THE VERY BEST HIVE, and testimonials to this effect are received daily from those who are using this hive.

Why not give us a trial order? Satisfaction fully guaranteed. Early Cash Order Discounts..

We are also extensive manufacturers of DOVE-TAILED HIVES and all other apiarian supplies. If you are in the market for supplies be sure to get our prices before buying elsewhere. We will mail our large illustrated catalog and SPECIAL price list to any one upon request.

KRETCHMER MFG. CO., 1000 3d St., Council Bluffs, Ia.

Make More Profit by Reducing Cost of Production

Comb-honey Producers, large or small, find our labor-saving devices save them valuable time during the busy season.

The Rauchfuss Combined Section Press and Foundation-fastener enables the beekeeper to fold sections and put in foundation at one operation. It is guaranteed to do more and better work than any other device on the market. Any child can operate it. Made for 4¼ x 4¼ sections and also for 4 x 5 sections. Price \$3.00, complete with lamp and treadle, delivered postpaid anywhere in the United States.

The Colorado Honey-producers' Association, 1424 Market St., Denver, Col.

Send for 68-page illustrated catalog of the best bee supplies made.

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

BLANKE MFG. & SUPPLY CO., Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST. LOUIS, MO.

EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A post card will bring it to your address free.

Red Catalog, postpaid.

Dealers Everywhere.

"Simplified Beekeeping," postpaid.

where the good beehives come from

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.
Honey in badly stained or mildewed sections.
Honey showing signs of granulation.
Leaking, injured, or patched-up sections.
Sections containing honey-dew.
Sections with more than 50 uncapped cells, or a less number of empty cells.
Sections weighing less than the minimum weight.
All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroughly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.
Honey contaminated by excessive use of smoke.
Honey contaminated by honey-dew.
Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (P-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

KANSAS CITY.—The supply of extracted honey is large, and the demand very light. The supply of comb is not large, and the demand is light. We quote No. 1 white comb, 24 sections per case, \$3.00; No. 2 ditto, \$2.50 to \$2.75; No. 1 amber, \$2.75 to \$3.00; No. 2 ditto, \$2.50 to \$2.75; extracted white, per pound, 7½ to 8; extracted amber, 6 to 7; No. 1 beeswax, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.

Kansas City, March 15.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: Fancy white, per case of 24 sections, \$3.15; No. 1, per case, \$2.93; No. 2, per case, \$2.70. White extracted, per pound, 8½ to 8¾; light amber, 8 to 8¾; amber, 7 to 8. We pay 25 cts. per pound in cash and 27 cts. per pound in trade for clean yellow beeswax delivered to us here at Denver.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, March 20. Frank Rauchfuss, Mgr.

ALBANY.—The honey market is quiet, with considerable comb honey unsold, and will have to be carried over the season. Stocks of extracted are worked down.

Albany, March 18.

H. R. WRIGHT.

INDIANAPOLIS.—The market for honey has been very encouraging the past week, and extracted honey is moving much better than comb honey; however, the honey business is naturally declining as spring draws near. We are quoting choice white comb at \$3.75 to \$4.00 per case; No. 2 white comb at \$3.50. Extracted of the very best quality is selling at 9½ to 11. For wax we are paying 28 cts. cash or 30 in trade, delivered here.

Indianapolis, March 18. WALTER S. POWDER.

ZANESVILLE.—The market is firm, save that western comb, on account of its tendency to granulate, is being offered at some reduction from standard prices. Best white is selling at \$3.50 to \$4.00 a case, according to condition and quantity. There is about a normal demand for extracted, white bringing 9 to 11; off grades correspondingly less. Producers receive for beeswax 28 cents cash, 30 in trade. Selling prices are largely arbitrary, and vary with quality and quantity.

Zanesville, March 20.

E. W. PEIRCE.

CHICAGO.—During the past three weeks there has been quite a free movement of honey, and stocks have been greatly reduced, as also the prices, because holders have become anxious to realize, and much of the honey has shown a tendency to granulate. Fancy comb honey is held at 15 cts. per lb., and anything off from this grade is from 1 to 5 cts. per lb. less. Extracted honey, white grade, sells at from 7 to 9, according to the kind and quality; but sales have been made mostly at 8, for the clover and basswood, with the amber grades at from 6 to 7. Basswood is selling freely at 30, if clean and of good color.

Chicago, March 18.

R. A. BURNETT & Co.

ST. LOUIS.—We have had very little demand for comb honey lately. Extracted honey is moving a little better with a certain trade, we suppose, on account of the high price of sugar. Stocks of comb honey are quite ample for the little demand, but the market is not overstocked in either extracted honey in barrels or cans, and we believe very little will be carried over into the coming season. We are still getting for No. 1 white comb honey, 4.00 per case; light amber, \$3.25 to \$3.50; amber, \$2.50 to \$2.75; extracted honey in 60-lb. cans, 7 to 8½; amber in barrels, 5½ to 6. Beeswax is firm at 29 for pure; impure and inferior, less.

R. HARTMANN PRODUCE CO.

St. Louis, March 20.

MATANZAS.—The price of honey in this market, at the present time, is 45 cts. per gallon, including barrel.

Matanzas, Cuba, March 22.

ADOLFO MARZOL.

Add price of queen to bees by the pound if queens are wanted. Safe arrival guaranteed on bees by the pound within six days of Mathis. Orders booked now, and queens shipped when wanted.

B. M. CARAWAY, MATHIS, TEXAS

You Should Earn \$25 a Colony from Your Bees This Season

This can be accomplished if you have a young prolific queen and a strong colony when the honey-flow arrives. Many beekeepers fail to secure the greatest possibilities from their bees because their colonies are not strengthened and built up early in the season, making it possible for them to take advantage of the honey-flow when it arrives. This should be a good season for clover honey, as weather conditions last year throughout the country were the best for securing a good strong stand of clover we have had for many years.

We now have a large queen-rearing outfit in Florida for the express purpose of supplying you with EARLY QUEENS and BEES IN PACKAGES. We are breeding from queens that gave a surplus of 300 pounds per colony in a 24-day honey-flow. You should have this strain of bees in your yard, and insure the placing of each of your colonies on a paying basis. We have a large supply of queens at this time, but as orders are coming in rapidly, we recommend that you provide for your requirements early.

ISLAND-BRED ITALIAN QUEENS

Shipments begin March 1.

ON THE BOOKSHELF

Now that so many beekeepers own automobiles, and so large a proportion of the automobiles have electric starting and lighting systems, we should like to call attention to a new book by Victor W. Page, "Starting, Lighting, and Ignition Systems." All automobiles and trucks use electrical ignition, in fact; and since this book gives a very comprehensive review of all the ignition systems in common use it is a valuable addition to the automobilist's library. Like "The Model T Ford Car," by the same author, it is profusely illustrated with specially made drawings and halftone engravings. The book may be obtained from The Norman W. Henley Pub. Co., New York. Price \$1.50.

BANKING BY MAIL AT 4%

Saving Safety

These two words should be inseparable in the mind of every person who wants to win success and prosperity.

SAVING money is the first step; the next is to put that money where it will be in absolute SAFETY.

Ample Capital and Surplus, capable management, strict state supervision, enable this bank to afford the highest degree of protection for the funds of its depositors.

We pay 4 per cent on savings, and deposits may be safely sent by mail in the form of draft, check, or registered letters.

We invite your patronage.

ASSETS OVER ONE MILLION DOLLARS

A KIND WORD AND SOMETHING MORE.

Mr. A. I. Root:—I feel very well acquainted with you, altho I have never seen you. I appreciate the great work you have done, and are doing in helping to lead the people upward into the "safe and sane" atmosphere you enjoy so much. There are so many evils that you can barely do justice to all of them; but I wish you would give a little attention to those "farm" and "home" newspapers that prate so much about their moral influence, and the "elevation" of the farmer and his family, while selling their space for the advertisement of tobacco and cigarette tobacco. I assure you I always feel insulted by those advertisements when I open up a paper that comes into our home pleading "moral influence."

Mantua, O., Feb. 26.

Woodman's Section-fixer Gold Medal

for the finest comb honey at the recent Michigan fiftieth anniversary convention was won by Floyd Markham, of Ypsilanti, Michigan. He says:

"We have several kinds of machines for folding sections and putting in the starters, but since we got one of your Section Fixers, about two years ago, no other machines for the purpose are used in our shop. It pays to use bottom starters, and your Section Fixer is the only machine that I know of that will do the job at any rate of speed and do it right."

DO YOU KNOW that with this machine you always handle large pieces of foundation, which makes the putting in of bottom starters easy? Special circulars will tell you all about it. Price \$2.75 with lamp and one form block, shipping weight 5 pounds, postage extra.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---
30 cts. cash, 32 cts. in trade; wax delivered to Lansing.

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

SWEET - CLOVER SEED

Quick Germination

Get our "Scarified" Sweet-clover Seed, which will germinate from 85 to 95 per cent the first year, and thus insure you a good stand right from the start. By sowing our seed you will save money, as it takes only about half as much scarified to sow an acre as ordinary hulled seed.

PRICES	1 lb.	10 lbs.	30 lbs.	100 lbs.	60 lb. a bu.	5 bu. a bu.	10 bu. a bu.	Lbs. per acre
Unhulled White, re-cleaned	\$0.25	\$2.00	\$5.10	\$16.00		\$4.80	\$4.50	25 to 30
Hulled White, re-cleaned and scarified	0.30	2.75	6.75	22.50	\$13.50	13.00	12.50	6 to 10
Hulled Yellow, re-cleaned and scarified (<i>Melilotus Officinalis</i>)	0.20	1.80	5.10	17.00	10.20	9.50	9.00	8 to 12

When seed is wanted by parcel post, be sure to include postage. Bags will be included in the weight in parcel-post shipments.

Please Note.—All of our seed is thoroly cleaned. The scarifying process usually breaks some of the seeds, and we remove all broken seeds. This is an important saving to you. Samples on application.

Dadant & Sons, Hamilton, Illinois

YELLOW SWEET CLOVER.—Many people fail to recognize the value of the biennial yellow sweet clover as a honey-plant. The fact that it blooms two weeks earlier than the white variety makes it especially valuable to the beekeeper. Be sure, however, to get the biennial variety as quoted above.

NO. 7

EDITORIAL

The Area of Sweet Clover Spreading

WE have already reported how sweet clover is occupying some of the hill country of Kentucky; how land that was good for nothing there is now worth as much as any other farm land, because it will grow sweet clover, honey, pasturage, and hay. What has been taking place in Kentucky is making a start up in the Ozark Mountains. See article by Otis A. Griffith in this issue.

Why Gleanings is Late Again

WE are under contract with a big paper concern which supplies the paper on which GLEANINGS is printed regularly. GLEANINGS is not one of the great magazines, by any means, and yet it takes nearly three tons of paper to get out a single issue. Because of the influence of the great war on the paper industry a carload of paper that should have reached us weeks ago was not shipped until March 24. It is needless to say that we did everything in our power to get paper elsewhere; but under these trying times paper is simply unobtainable on short notice. We hope that our readers will bear with us, for of course matters of this kind are entirely beyond our control.

Prospects for 1916 Honey Crop

PROSPECTS for a large crop of honey the coming season were never brighter. Reports continue to be favorable in California, Colorado, and many parts of the West; and the prospects for clover thruout the United States have not been as good for years. The winter was mild, and there was considerable snow during the latter part of it. So far as we can ascertain, there was little or no winter-killing, and clover honey will be much in evidence next season—that is, provided, of course, we do not get a reversal of last season, and that is, a drouth. If it should be very dry in the late spring or early summer, the clover that is now so

very abundant will be of little or no use to the beekeeper.

Death of One of the Gleanings Office Force

WE are more than sorry to be obliged to record the death of Miss Bessie Templeton, who for more than ten years has been at the head of our subscription department. There is an endless amount of work, correcting and changing addresses, and it is not a small task to see that each subscriber of GLEANINGS receives his copy regularly. Miss Templeton has done this work most faithfully and well.

For a time there is bound to be some delay in entering new names and making corrections necessitated by changes of addresses. We hope our subscribers will be patient with us until this work can be reorganized once more.

Wintering Thruout the United States

It is a little early yet; but so far the average of the reports regarding wintering are favorable. But one man in Montana says the losses will be the severest in years. Another, from Ontario, Canada, says he is fearful that they will be very heavy. By consulting Weather Bureau maps we find that it has been much colder relatively in Ontario than in that portion of our country south of the Great Lakes. Indeed, up till March the winter was very mild. But March was a little cold, and it is probable that there will be some losses reported yet.

Our own bees, so far as examined (and we have gone over about 300), especially those in the big quadruple cases, have wintered with a loss of 7. None died in the big winter cases except one, and that starved; and not only that, they are in splendid condition—the best we have known in years. This is gratifying. We put the bees in winter quarters very late last fall. The home yard of 174 shows no dysentery and almost no spotting of the hives.

The Distance Bees Fly, Again

IN this issue, in his regular department, Mr. J. L. Byer evidently had not read what we said about the flight of bees, page 150, Feb. 15, or he would have seen that he was more nearly in accord with our own views than his statement implied. He finds that there is a condition in a level stretch of country under which bees will fly further than $3\frac{1}{2}$ miles. So have we. He cites one year (1913) when a dearth visited the section in which the apiary was located. Nearly three miles away from the apiary was a strip along a river-bank where alsike clover kept in bloom. The bees went to this strip, and some of them went as far as five miles away. By turning to page 150 it will be seen, in referring to a place where bees ordinarily would not fly more than three-fourths of a mile, we said, "When there is no natural nectar which the bees can gather less than three to five miles away, it is not an uncommon thing for them to fly that far. But they do not always do so."

Testing the Soil for Sweet Clover, and Something about the Largest Grower of it in the United States

IN this issue, page 284, appears an article from Mr. Frank Coverdale, of Delmar, Iowa, on how to test soil—in short, how to make a sure catch of a seeding of sweet clover. Mr. Coverdale is probably the best authority on this plant in the United States; and when the farmers in the country begin to wake up to the value of this wonderful legume as a foliage plant, and want to know something more about it, they will be asking for Frank Coverdale at farmers' institutes all over the United States.

We would suggest that beekeepers and farmers make a general request that Mr. Coverdale be employed next winter to speak at farmers' institutes on how to grow sweet clover. The first state that gets him will be fortunate. Any one who has heard him talk will be convinced that he knows sweet clover from A to Z, for he is the largest grower of it, probably, in the United States.

Summer Beekeeping Course of the Iowa State College

A COURSE in beekeeping is to be offered during the first six weeks of the summer session at the Iowa State College. This course will consist of three lectures and recitations a week, and three periods of practical work a week for the six weeks.

The course will not occupy all the students' time, and they will have opportunity to take other studies that may be related to apiculture in other departments of the college.

This course will fill a long-felt want among the beekeepers of Iowa as well as those interested in beekeeping. It is offered in addition to the new four-year course in apiculture which will be offered for the first time at the beginning of the next college year in September, 1916.

The Iowa State College is to be commended for the recognition it has given to the value of teaching apiculture, and the opportunity it is offering to students who may be interested in the subject of beekeeping. It will offer an opportunity for school-teachers and beginners to obtain information for successful beekeeping, and it will offer to beekeepers the chance to learn the latest and best methods as well as to gain information they could seldom gain from practical beekeeping.

Information in regard to this course may be had by writing to the Director of the Summer Session, Iowa State College, Ames, Iowa.

The Lament of Job, Again; or the Silver Lining to the European Foul-brood Situation

Two articles in this issue will give our friend Job (Holtermann) a few crumbs of comfort. We refer to one by Geo. H. Rea, on page 272, and the other by L. A. P. Stone, page 274. Mr. Rea's method is somewhat drastic in that it involves the destruction of combs or melting them up. According to most of the evidence in hand it appears it is not necessary to do this for European foul brood, altho possibly such drastic means would have to be applied provided *every* trace of the disease is to be wiped out as Mr. Holtermann stipulates.

The article by Mr. Stone promises relief by simply using Dr. Miller's method of cure, dequeening for ten days, and using vigorous Italian stock, and saving the combs. In fact, there are so many reports endorsing Dr. Miller's treatment for European foul brood we really believe that the disease can be handled without very much difficulty provided a good strain of Italians can be secured. In any case, neither Mr. Holtermann nor anybody else need fear that European foul brood will cut down the honey crop.

The Miller treatment, boiled down in a nutshell, quoting from Mr. Stone, is very simple. He covers it in one sentence; name-

ly, "Make the infected colony queenless, and unite as many together as will make one strong colony; and then introduce choice queens after a ten-day period; but first make sure of destroying all queen-cells started by the colonies." He commences treatment at the beginning of the clover harvest.

Another crumb of comfort for Mr. Holtermann is that European foul brood will eliminate all the black colonies and the old-fashioned beekeepers who do not and will not keep up with the times. This will give him a larger field for operations, and, of course, more honey per colony, as there will not be the overstocking as a result of old-time neighbors keeping a few bees and cutting prices. Cheer up, Bro. Holtermann! Don't you see the silver lining in the skies?

The Beekeepers vs. the Smelting Company in Canada Again

ON page 215 we stated that this case had been continued to some time in May. We are now advised that it will come off May 17. It is to be presumed, of course, that the company against whom the action is taken will leave no stone unturned to prove that the gases from their plant or plants are not the cause of the death of the bees in that locality. At all events we are informed that they are taking testimony in Utah, Washington, and California.

It will be remembered that the smelter people in a similar case in Salt Lake Valley, Utah, are said to have settled with the beekeepers in the sum of \$60,000. Of course the attorneys for the beemen will use this case as a precedent.

The beekeepers interested in the case are desirous of hearing from other beekeepers in the United States, particularly the Salt Lake Valley, who can give any information regarding this settlement. If they have anything to offer they are advised to correspond at once with Lewis Minor, Smithville, Ontario.

Regarding the case, Mr. Minor writes:

The smelter people evidently intend putting us in a position to state whether the bees get the poison from the flowers when they ask for particulars, or how else do they come in contact with the gas from their plant? We contend that the bees are killed by flying in contact with their gases in search of honey.

The first summer the smelter was operating, and all the bees were yet in the district, there were over 1000 colonies more than I thought there were, until I looked them all up this winter. Those closest to the smelter died as soon as they began work-

ing in the spring. Further away they lived until the season was over. As soon as the honey quit they likewise were all dead in two weeks. There seems to be something in the gases that attracts bees.

Since the first summer there have been only a few colonies in the place, only what swarms came in from the outside, and what we have taken in for a test. Their flight is always in the direction of the smelter when they are dying.

Lewis Minor.

Smithville, Ont., Can., March 11.

Slightly Exaggerated, Again

THE average reporter, especially if he be a "cub" reporter, in writing about bees, often gets the facts horribly twisted. There has been going the rounds of the press from Los Angeles to New York, and from Portland to Jacksonville, a story to the effect that "E. R. Root, the bee expert," while giving a lecture on bees, was "stung on the mouth" by one of his "untrained bees," and that his "mouth swelled so horribly" that the lecture was "brought to an abrupt close." With almost every newspaper story there is almost always a scintilla of truth; so in this case. While giving a demonstration before the students of the short agricultural course of the Ohio State University, a bee did sting us on the mouth. We brushed it off, scratched out the sting, and went on. The incident was noted by a student who sat in the front seat, and he happened to be a cub reporter for one of the afternoon papers.

The facts are, there was no swelling beyond a slight welt, and we continued our talk and demonstration until the lecture closed. The aforesaid cub reporter added to the other statement that the bees stung Mr. Root and the audience so that there was a "grand rush for the door."

After the lecture had closed, and perhaps two-thirds of the audience were gone, a bunch of boys jammed around the platform and tried to get a taste of granulated honey or honey butter. The jam was so tight that some of the outsiders could not get inside, and one of the outsiders picked up our hat, which contained about a pint of bees, and threw the bees all over the other boys that were fast absorbing the butter. They immediately scattered and a few rushed for the door; but no one was stung. After the laugh was over, some of the outsiders got a taste of granulated honey.

At first we thought we would pay no attention to this oft-repeated yarn; but it is being copied everywhere, in a dozen different versions, presumably as a good joke on the aforesaid "bee expert."

One of our newspaper friends made the remark that this write-up with its "screaming head lines" was worth to the Root Co. thousands of dollars, because the Root Company, Mr. Root in particular, their Airline honey, and bee supplies had been heralded all over the country thru millions of papers. Possibly our newspaper man was right; but this poor little "bee expert" can't help feeling a little humiliated to have it told about him when it wasn't so that he was put out of business by a single bee in one of his recent lectures before the university students of a state university. Josh Billings used to say, "What's the use of knowin' so much when so much you know ain't so?" Some of these cub reporters ought to absorb a little of this truth. But then the truth wouldn't have made a "good story."

=====

The National Convention at Chicago

THE secretary, Mr. F. Eric Millen, page 277 of this issue, gives an official statement of the policies of the new National as recommended and adopted by the delegates at the last meeting in Chicago. As Mr. Millen says, the thing to do is to forget the past, wash the slate clean, and begin all over with the new men who have been in no way identified with the past. If we understand it, no blame is attached to individuals; but the general opinion seemed to be that a single organization national in its scope cannot perform a dual function—educational, commercial, or both—at the same time. The new organization will attempt to do only one thing, work along educational and social lines.

The editor of GLEANINGS during late years has repeatedly refused to take any part in any discussion relative to the policies of the National. In Cincinnati, when he was asked to express even an opinion, he respectfully declined, saying that he did not believe that any bee-journal, supply dealer, or supply manufacturer had any business to dictate or even suggest what any beekeepers' society, national or local, should do; that each organization should be absolutely independent of any commercial interests outside of the mere business of honey production. Any other policy would be fraught with danger.

SOME THINGS THAT WERE SAID AND DONE IN CHICAGO.

We were not present at all the sessions, and therefore can give only a limited review of the proceedings. After the business of the morning had been transacted, the actual discussions began on the afternoon

of the 22d in one of the assembly rooms of the Sherman House. Mr. G. W. Williams, editor of the *Booster*, and secretary of the United Honey Producers of America, delivered an address on teaching the uses of honey in our public schools. Domestic science, he said, was being taken up in all of our best schools; the opportunity was now ripe for the beekeepers of the country to carry the subject of beekeeping and the uses of honey as a food direct to the domestic-science teachers as never before. He found that the various boards were receptive—glad to take up the matter if properly presented. Beekeepers are distributed all over the United States, and it would be an easy matter for each beekeeper to explain the uses of honey by handing out booklets, giving honey recipes to the domestic-science teachers. He closed by giving a statement of the food value of honey as compared with other foods, especially cane sugar. He recommended that these comparisons be presented to the domestic-science teachers and they in turn to the pupils.

Mr. Williams was followed by Mr. E. H. Bruner, of Chicago, on the uses of honey in cooking. There were two important things to be considered—first, a fine quality of honey, and, second, to get the housewife to understand the value of honey as a food. There was no use in getting her interested unless she could be supplied at any time with good honey. The use of honey in baking should be brought to her attention. There are thousands who would eat honey if they could get it and know of it. The business of getting honey into our homes has only just started. It was important now he said to set people to thinking about honey. Let them understand that it can be used in ninety places where sugar is now used. Show them, for example, that honey is good to use on grapefruit and bananas; fine on cold cereals, and excellent in lemonade. He deprecated the policy of selling honey in a retail way at wholesale prices, or cutting prices, as many beekeepers were doing, in order to "introduce the sale of it." Whenever low prices were established it would be difficult to get them up again. The whole policy of cutting prices to the consumer direct was wrong. Our grocers were our best friends. If we protect them, they would protect us.

Mr. R. M. Spencer delivered an address on selling and advertising ripe honey. He recommended that all honey sold should be entirely sealed before being extracted. Such honey would bring good prices, whereas the half-ripened article would bring a low price. He asked for all his honey thoroly ripened,

8 cents, while a neighbor sold an inferior article for 5 cents, as that was all he could get. Honey could be sold by parcel post in suitable containers. He urged a national campaign of advertising. If a fund were raised by assessing only ten cents per hive an enormous amount of money could be raised for advertising. It would create a demand and sale for honey. If beekeepers could only get together on a proposition of this kind it would mean much, because in union there is strength.

The next forenoon we were not present at the sessions; but we were told that Dr. Miller, among others, gave a little talk on olden days. Dr. E. F. Phillips, in response, paid him and some others of the old patriarchs some very high encomiums. We regret that we did not hear this; but apparently all the beekeepers were glad to welcome and see Dr. Miller and his assistant, Miss Emma Wilson. Dr. Miller has arrived at the age of nearly 85. He, with Mr. Wilcox, and Mr. M. M. Baldrige, St. Charles, Ill., carried us back to the olden days. The latter, between sessions, gave us some very interesting history of the Langstroth hive and the introduction of Italian bees into this country. This, doubtless, will be made public some day.

Dr. Phillips, of the Bureau of Entomology, Washington, D. C., in the afternoon delivered a stereopticon address. He showed a number of interesting pictures which he and his associates took; and among the number none called forth more interest than beekeeping in the South Atlantic states. There were more bees and beekeepers there, he said, than anywhere else in the United States. But the trouble was, bees were blacks and kept by the old primitive methods in box hives. He went on to describe some of the superstitions that were rife among some of these plain mountain folks, the purest of the pure Anglo-Saxons, many of whom had never been away from home more than a few miles. Nearly all of them kept a few bees, and they kept them just as their forefathers did three centuries ago. If a death occurred in the family, the bees would have to be "informed" of it. On Washington's birthday their colonies have to be moved an inch or two or else calamity will follow. When asked how many gums they have, they don't know. If the visitor proceeds to count—"No! you mustn't count them, for that would bring trouble. There are about so many." 'Nough said.

They know nothing of hiving prime swarms back on the old stand, thus retaining the flying bees of the parent colony. The swarms are hived in another gum

placed anywhere, and the parent colony is allowed to swarm itself out of existence. The moth miller is rampant over all that part of the country. It finds these parent colonies, second and third swarms, an easy prey. Practically no returns are received from anything except the prime swarm. The rest die off, either during the winter or are despoiled by the moth miller, or both. If disease should ever get into this Southland, beekeeping would be entirely wiped out because there are nothing but black bees there. Dr. Phillips hoped that some day the state extension workers would be able to instruct these people along the lines of modern methods.

Subsequently in the proceedings a resolution was introduced urging Congress to increase the appropriation now expended for bee culture by \$35,000, making a total of \$50,000 all told. This resolution was subsequently submitted to the Committee on Agricultural Appropriations in Washington with the result that \$5000 increase was granted by the Committee. The whole Agricultural Bill has been temporarily held up in favor of the Military Bill. In the mean time beekeepers should write their congressmen urging their support of the increased appropriation for apiculture. After the Agricultural Bill passes the House it will go before the Senate, with the probability of adoption by that body. Beekeepers should write the senators also. If adopted this will make a total appropriation of \$20,000. The recommendation was made that whatever increase was granted, if any, should be used by the Bureau of Entomology to send experts down into this Southland to instruct those simple mountain folks on how to keep bees in the modern way; how to know bee diseases and how to control them if they ever get a start. It goes without saying that Dr. Phillips will do his part in the Bureau.

Dr. Phillips was followed by Mr. F. G. Snooks, freight claim adjuster in the traffic department of the Erie Railway Co. Mr. Snooks' address was one of the most useful that has been given, provided that the honey-producers of the country will heed his suggestions. We obtained from Mr. Snooks a digest of his address, which we are glad to present here.

Beekeepers and Railroads

I am a beekeeper. Bees are a source of my enjoyment. I am connected with a railroad which is the means of my livelihood, and I should like to call your attention to some interests in common, not as a railroad employee, but as a beekeeper.

First, let us consider the railroads. Railroads have been in the limelight of legisla-

tion for a considerable length of time, not as dictators, but as the target for every politician who thinks his one mission in life is to secure for the people something at the expense of transportation companies.

While we admit that some of this legislation has been beneficial to all concerned, still, if continued, the pendulum will swing past its arc of usefulness and destroy what good has been accomplished. The failure at the present time to sell railroad bonds at par is withholding the placing of large orders for new freight cars.

Beekeepers are interested, with the public at large, in well-maintained and bountiful passenger service, fast freight schedules, fine railroad depots and freight houses, enlargement of terminals to prevent congestion in an adequate supply of fine rolling stock, and, in fact, everything that makes a railroad.

A recent new venture on the part of railroads is the organization of bureaus for the prevention of loss and damage claims. This is of vital importance to all shippers. The men handling this matter are chosen for their long terms of commendable service, and it is their duty to see the packages accepted for transportation are strong enough to withstand ordinary handling; that placards on packages requiring special handling are observed, such as "Comb Honey," "Very Fragile," "Handle with Care," "Glass," "This side up," "Inflammable," "Explosive," etc.; to see that large transfers and small stations do not delay, improperly handle, nor poorly stow any freight. Switching in yards, also freight trains, are watched both day and night.

These bureaus not only decrease the loss thru claims, but the prevention of every claim is the elimination of a complaint from a customer to a shipper. Customers have frequently been known to cancel orders due to continued claims resulting from poor packages.

Railroads are frequently rebuked for declining to accept insecure packages at the owners' risk. This is wrong. Take, for instance, an insecure can of extracted honey. All the releases a shipper could execute would not repay a carrier for the loss it would sustain by damage to silk or other high-grade freight loaded in the same car, due to the leaky can.

The successful shipping of comb honey begins with its production. The foundation should first be securely fastened to the sections. The comb honey should then be placed in factory-made shipping-cases (notice I emphasized factory). First, factory-made shipping-cases are the exact size, thus avoiding any play. Furthermore, they are usually equipped with corrugated cushions which absorb much of the shock of transportation without damage to contents.

The shipping-cases should then be placed in carriers with the sections all running the same direction. That is, when the package is finally placed in the car all the sections in

the package will be parallel to the rails of the track.

The carriers should be constructed of sound lumber, secured with cement-coated nails. I much prefer a box to a crate, one which holds from 175 to 200 lbs. The carrier should be cushioned on the bottom with about three inches of straw, and provided at the top with pieces which extend beyond the crate in such a manner as to form handles with which to carry the package.

Stencil your carriers with a mixture of lampblack and oil in the following manner:

From	Stingless Apiary, Beeville, Texas.
To	Mr. Eatmore, Wellsville, N. Y.

Do not use tags written in ink and fastened on with tacks, as ink blurs, and tags are very easily torn off. Placard your packages "Comb honey, very fragile." There are good advertising features in this method of marking.

For carloads, anticipate your wants. See that suitable cars are used—those free from noxious odors, leaky roofs, and journal-boxes improperly packed. Avoid shipping comb honey in extremely cold weather if possible, and avoid shipping small packages of comb honey.

Do not use old rusty second-hand cans for extracted honey.

Do not load carloads of bees without first ascertaining the time of your departure.

Do not expect trainmen to place your car free from the smoke and gas of the engine unless you request it. They do not understand the peculiarities of bees.

On less than carload shipments patronize railroads that make long haul thru package cars. This avoids unnecessary handling.

Patronize railroads that pay legitimate claims promptly.

Patronize railroads that advertise schedules and maintain them.

File your bills of lading and expense bills. They are valuable, and should not be destroyed.

Remember, continued claims on the same commodity have a tendency to increase the rate.

Tell the railroads your trouble; ask their help; they are your friends.

F. C. Snook,
Inspector for Freight Claim Dept. Erie R. R.

To be continued

=====

A Correction

IN our last issue, page 217, we say that Dr. Kohn was elected vice-president of the National. The name should be W. M. Coppenhaver, of Helena, Mont.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

FRED W. MUTH says: "If you scratch the tin first, flour paste will stick as good as any; or if you put sugar in paste you need not scratch the tin. We do it."

WHEN considering the pros and cons as to house-apiaris, don't forget one very important point: The man with a house-apinary loses the health-giving advantage of an outdoor life.

D. W. MILLAR has mailed me a sample of campanilla honey so clear, so excellent in flavor, and so daintily put up, that there ought to be a law against allowing such honey to enter from Cuba to interfere with my trade.

J. E. CRANE is learning. He says, p. 145, "I found what I did not know before, that bees will not build up on sugar syrup as well as on honey." Good! I confess that, until lately, I had not realized—perhaps don't fully realize yet—how much better honey is than sugar for man or bee.

"DON'T be a kicker!" That's another lesson, Huber, you might have drawn from that mouse-and-trap affair, p. 244. Some people are always ready to kick, no matter what happens, only making more trouble for themselves and others. If that mouse, instead of kicking, had lain still and quietly died when caught by the one trap, it would not need to have been killed the second time by the other trap. After all, why was any one so careless as to set two traps so close together?

VERY interesting is the discussion of bees drifting when set on their summer stands, p. 235, by G. C. Greiner. Years ago I had trouble galore from drifting. A hive at one end would have the bees for three colonies, and too often the queen would be killed—nowadays no trouble at all. I can't be sworn just why, but I'll tell you just how we do. On a bright morning when bees can fly they are all brought out of the cellar as rapidly as possible; and before the bees have time to fly, each entrance is closed to one square inch or less. I *think* that small entrance is the secret of no drifting.

AN OHIO correspondent has abundant dandelion and fruit-bloom, and then an interval of two weeks before clover. He intends to take from a colony the queen with two or three brood, and when the queenless colony has ripe cells to divide it into nuclei which shall grow into full colonies. He asks

whether to begin operations in the early or the clover flow. The earlier he begins, the longer time there is to build up. But unless the colony is very strong in dandelion, better wait for the stronger colony in clover. Moreover, in localities like mine, where bees rarely swarm before clover, the chances are that early queens will be poor, so in such places I'd wait for clover. But where swarming is mostly before clover, I'd begin just before that swarming.

WHAT is the best cellar temperature for bees? We don't know as much about it as we did 25 years ago—at least we're not so well agreed. At that time all agreed that the orthodox thing was 45 degrees; now we're divided in opinion. George H. Rea, p. 208, says 43. I think Dr. Phillips favors 50. Asked why it was that 45 was so generally held years ago, he thought it was because cellars generally happened to be that temperature. Formerly I had good wintering at 45; now my bees do well at 50. No doubt bees may winter fairly well at different degrees, yet no doubt there is some one degree that is *best*. [Our best success in wintering has been with the higher temperatures; but with them there must be increased ventilation, or the bees will become very uneasy, and fly out on the cellar bottom and die—at least that has been our own experience. Our temperatures ranged from 50 to 55, some of the time going as high as 65; but when we secured fresh air by means of an electric fan going into the room the bees did not appear to be uneasy.]

One reason why 45 has been considered the orthodox temperature is because, years ago, when that dictum was put out, comparatively little attention was paid to ventilation. Prior to that time, sub-earth ventilators were recommended; and then it was concluded these were of no use because they carried in too much dampness and cold air. Then later the slogan was no ventilation except what percolated through the cellar walls, doors, and windows; and the advice was given to close these up as tightly as possible; and, strange enough, there was some fair wintering; but when the temperature hovered around 42 to 45, and a closed cellar, nothing was thought of two or three inches of dead bees on the cellar floor, and weak colonies in the spring. To-day we can not regard it as good wintering when the bees fly out in large numbers and die on the cellar bottom an inch or so deep; and the main cause of this is not bad food but bad ventilation.—[E.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Apparently we have all wintered satisfactorily here in Tennessee, tho at this writing the hives in our own yard have not yet been opened, as we prefer to wait till fruit-bloom. Last year the fruit-bloom came April 7, unusually late; to-day, March 13, it looks as tho another day or two would see both the earlier plum and peach trees in full bloom. Yet I am compelled to admit they have looked like this for nearly three weeks, the result of unusually warm weather in February followed by a cold blustery March.

What a season it has been, anyway! Here came Spring dropping purple violets in our neighbor's yard and golden daffodils in ours, filling us all with the delight of her coming and the hope of her staying; and then while she was coaxing the tight fisty little peach-buds to show their crumpled pink, quite suddenly out of the north old Winter came roistering back. He pelted us with a wonderful storm, with big north winds and hours of swirling snow. And poor little Spring, for all her singing as she came, had merely "walked right in and turned around and walked right out again!" Can you blame her, with snow on her daffodils? She had a deal of tidying-up to do when she finally did come back, for Winter, careless old fellow that he is, left many a mile of slush puddling up our roads, and many a brave-hearted blossom dead by our fences. But she has done it well, and now once more there are violets like bits of sky in our neighbor's yard, and daffodils like stars in a corner of our own.

It was during those early warm days in February that there were so many bees flying low around our yard, some of them alighting on the ground, especially on bare worn places fifty feet or more from the hives, seemingly drinking the moisture from the damp earth, while others were slipping into the little brooder-coops of the baby

chicks, apparently after bran. I put out water, which promptly became popular, and then, lacking a better kind, some plain graham flour, which also drew some attention. I watched them for a long time one warm Sunday afternoon, alighting on the shallow edge of the flour for a busy instant or two, then hovering just over it while brushing the flour back to the carrier legs, and finally going off loaded with big light-colored balls in their pollen-baskets.

FOR BEGINNERS.

When spring is quite surely here, and the weather pretty well settled, you will want to look thru all your colonies to see the conditions in each hive. You will make sure of stores. If they are in need, give them food, a comb or two of sealed honey if you have it—sugar syrup from a pan in the super, if you have not. You will notice now brood-rearing is coming on. If they are crowded, give them room by removing a comb or two of honey from the sides or raising it to the super. The queen must have plenty of room to lay, but do not spread what brood she has. You will make sure of the queens themselves. Of course, where you find eggs or young brood, you will know your colony has a queen,

even tho you don't happen to see her.

However, when you get ready to clip your queens you must hunt for each one, thru frame after frame if necessary to find her—even tho your record shows you clipped last year. It may easily happen you will find an unclipped queen where you left a clipped one—the bees having superseded the other without either your advice or knowledge. As to the actual clipping itself, it may be done in several ways, but is always a matter of great delicacy and care. The method probably generally used is to pick up the queen by the wings, with the right hand; then with the thumb and first finger of the left hand take hold of her body—you will see by trying that it works out that the thumb goes under the

Bees in April

Drifting down the ages
On the wings of time,
April dawn comes rippling in
Like a little rhyme,
Rippling in and dancing
With her daffodils,
Dropping unexpected things
Over startled hills.

April with your treasures,
Have you ever guessed
Which of all your graceful gifts
My heart loves the best?
Not your lilting birdsong,
Not your swelling trees,
Not your brimming buttercups—
Bees, dear! Bees!

How you set them humming!
When their gauzy wings
Flash across my world, ah! then
My whole world sings.

thorax and the finger above, which is as it should be. The right hand is now free to do the clipping. Take off both wings from one side—not too close, however. The abdomen should not be touched at all; and the less handling the better, as sometimes the bees ball the queen when she is returned to them with the new strange taint. Be careful, too, to return her gently, avoiding dropping her, as she is easily injured.

The following extract from a letter received last year from Mr. O. J. Jones, of Urbana, Ohio, is interesting in this connection:

"Pick the queen up by the wings with the index finger and thumb of the right hand. Place her on the index finger of the left hand (end of finger); she will take hold with her feet. Place your thumb on the three feet next to it. Take the scissors in the right hand and clip one of the large wings. I always clip the right one. Place her back on the frame from which she was taken, not on the tops of the frames yet in the hive. (I have lost some valuable queens by following book directions and placing her on top of frames on account of her running in frightened; or the bees, detecting a foreign odor, ball their own queen.) By placing her on the frame yet out, if there is any excitement leave her out until she resumes her normal dignity. I have clipped hundreds of queens, and never taken a queen in my hands except by the feet and wings."

Aside from doing these necessary things, don't open the hives and fuss around with them very much. To be sure, that is an excellent way to observe, and to add to your familiarity and ease and experience, and most of us started in that over-zealous fashion, but it is rather hard on the bees.

* * *

We have known all along that this particular neighborhood of ours is not very good bee country, being too thickly built up. There are some stretches of commons, to be sure, but not very large, and constantly diminishing at that, and with too many cows taking advantage of the free pasturage. There are a few low outlying hills with some slight growth of locust; but to reach pasturage of any extent our bees would have to fly two and a half or three miles. Now, if Prof. Baldwin and the editor are going to limit their flight to a mile or even a mile and a half, we are even more restricted than we thought, and we can scarcely expect the bees to accomplish very marvelous things for us.

In this connection I remember that Mr. J. C. Parks, of Scottsboro, Alabama, said

in a letter this past summer that his experience shows the eight-frame shallow supers superior for a poor locality. His bees are located where there is neither clover, basswood, nor buckwheat—the main flow being from tupelo, poplar, locust, persimmon, and sourwood. It is not, he says, a good honey section. Well, last year he contracted a few colonies to eight frames, and these averaged 60 pounds of extracted honey better than the colonies in ten frames. Mr. Parks wisely declines to draw too positive a deduction from this experience, but is sufficiently impressed to make the experiment next year on a larger scale. All of his supers, by the way, are the shallow variety, but most of them ten frames. I know this past season we wished several times that we had shallow supers, for it was a poor year, and hence many of the large frames were only partly filled.

Another unfortunate thing about our particular neighborhood is that there are so many little apiaries scattered through it. You see this used to be a "half-in-the-country-half-in-the-town" section; and tho the town keeps elbowing the country further and further out, the simple countrylike ways are still in vogue. Nearly every family has its own little home, its own little garden, and a few hens. Then a goodly number keep a cow, some of them a pig or two, and still others a flock of geese or ducks. The ducks and geese and the pigs and cows have the run of the commons—likewise the streets! so it is not strange that bees are often added to other interests.

Of course the worst feature of so many such small yards is the carelessness and ignorance often shown in their handling, and the consequent danger of disease getting a hold. Noticing one row of hives while on a ramble walk one day last week we wandered into the yard to introduce ourselves and chat beetalk a bit. We learned that right there, within fifteen minutes' walk of our own home, they had had foul-brood troubles, but which kind or when, or what was done about it, we did not ask, being such utter strangers. But I shivered all the way home.

Then a few days later came GLEANINGS with Mr. Crane's encouraging article, "European Foul Brood not Formidable to the Efficient," page 985, Dec. 1, whereupon I gritted my teeth and made big plans for a thoroly efficient future; for if just plain efficiency or practical proficiency or any other ish-ency can strengthen our defense, there should be no deficiency, but adequate sufficiency, of genuine efficiency — that's simple common sense.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The warm open spring will be beneficial in reducing paralysis to a minimum.

My bees are in fully 25 per cent better condition than at this time, March 13, last year. Wherever an old queen has been carried over, the results are not so satisfactory.

The orange will bloom fully two weeks earlier than last season if the weather continues warm. The sage is little if any ahead of last season's growth. Should good weather continue it may cause a prolonged season, the sage following the orange rather than blooming at the same time.

Word has just reached me that Prof. A. J. Cook has been forced to resign as State Horticultural Commissioner on account of ill health. It is my sincere wish that he will not be incapacitated any length of time. His value to the beekeepers alone has been worth while, yet beekeeping has been only a side issue.

The *Western Honeybee* for March contains the announcement that a New York concern will loan money on California honey if stored in a warehouse and guaranteed by a state certificate. I have never had the least trouble in getting a loan on any honey I had stored in a warehouse where the warehouse receipt was presented at my local bank. In fact, the local banks are always ready to take honey for security on a loan. I should very much prefer to get my loan at home, even if I have to pay a little more for the use of it. If you treat your local banker properly you will be much more likely to get a loan in time of need when you have no honey to secure it.

Editor Bixby, in the *Western Honeybee* for March, page 53, says: "A. I. Root, in a recent number of *GLEANINGS*, inspired by notes of Editor Chadwick, waxes eloquent over sweet clover in the orange groves of southern California." Mr. Bixby, kindly read that matter over again, p. 130, Feb. 1. See if the questionable matter was not credited as a clipping from the Redlands *Daily Facts*. The words "orange groves of southern California" do not appear at all. While you are at it, observe the words "sweet clover" are taken from the clip-

ping, also that the word *honey* does not appear any place therein. The question of honey-producing was not the point at issue. The item appeared in Mr. Root's High-pressure Gardening department. The laugh is on you, Bro. Bixby.

Mr. P. G. Snyder, of Aibonito, P. R., wrote asking me if I knew of any bulletin on the value of bees as pollinating agents for citrus fruit. As I had no data on the subject I began a search on that line. But the very first round I was shocked by the following:

I am unable to give you the definite information on this subject that is very much needed. The following notes may be of some interest in this connection:

The navel orange, which is so commonly grown in California, is, as you know, practically sterile, and develops no pollen or seeds. I have never seen a perfect grain of pollen developed in a navel flower. Again, we know by careful experiments that the navel develops fruits when the flowers are bagged and no pollination is possible. Also, the pistil of the navel is very abnormal, the pollen-conducting tubes, thru which the pollen-tubes grow normally, being closed at the top, which does not allow the entrance of the pollen-tubes as in the case of the normal orange.

All of these facts would seem to indicate that pollination in the case of the navel, by either the honey-bee or any other insect, would be of no particular value. To determine this matter finally, however, would require experiments in which bees were used on navel trees in comparison with other trees which were protected, giving as nearly natural conditions as possible. Such experiments have not yet been carried out.

There is more evidence in favor of bees being necessary and desirable in connection with the other varieties of citrus fruits, but here again we have no definite experiments on which to base a conclusion. We do know that many varieties of citrus fruits have the power of developing without pollination. On the other hand, in the varieties where seeds are normally developed, we might expect that there would be less set without the pollination. In such a case bees might be an important factor.

H. J. Webber,
Director Citrus Experiment Station,
Riverside, Cal.

I cannot believe the foregoing letter is correct, however, as I am quite sure the bees gather pollen from the orange, for I have seen them in the act. I am not positive about the variety from which it was gathered, but I will make some investigation.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

In looking at that photo of G. Frank Pease's work-tent and auto truck I am wondering if the sweet-clover bloom furnishes Mr. Pease with much of his surplus. At any rate, he bought several hundred pounds of seed of me some time ago. It is the progressive beekeepers who look to improve their pasturage in every way possible.

THE ADVERTISING OF HONEY.

I think that many of our beekeepers are wrong in the assumption that nothing is being done to extend the use of honey. The fact is, a great deal is being done. Take conditions in the Southwest, in the West and middle West. Very few farm papers there are but carry from one to half a dozen honey advertisements. True, the classified columns are most largely used; but everybody reads the classified columns. I verily believe that thousands of dollars are spent annually by the beekeepers in this form of advertising. Of course, it is not general publicity, but it must get results or it would not be persisted in. This kind of advertising could be wonderfully improved by aid rendered the beekeepers in wording their advertisements, and something should be done at standardizing the goods offered. Honey is offered at from 5 to 12 cents a pound; and while much of it is very variable in quality and color it is no doubt true that honey of equal value is sold at a wide range of prices.

If the beekeepers would follow the methods used by some of the livestock associations and fruit-growers, better results could be secured. Suppose twelve beekeepers join together and each put up \$200 for a winter advertising campaign. There would be \$2400 to spend. The twelve beekeepers before the campaign began would all be prepared to put out, say, 10-lb., 30-lb., and 60-lb. cans of honey of the same quality and at the same prices. Then a two-inch advertisement with as much taste in the way of illustration as could be secured in this space with effective copy, and the names and addresses of all the beekeepers at the bottom; or instead of the names and addresses of all the members might be the name and address of the secretary to whom orders and inquiries could be sent. My idea of an advertisement of this kind would be one with the effective appeal to the people to use more honey, and also the prices at which it can be secured.

Each beekeeper would need to be pro-

vided with circulars, price lists, honey booklets, and a record system to keep track of inquiries and orders.

The amount of money mentioned would carry on a very nice winter campaign from October to March, and would cover the agricultural press of most districts of the United States. It would pay for two-inch space in from ten to fifteen weekly farm papers for five months. I have found that farm papers of 50,000 to 100,000 circulation are better mediums than those with 200,000 up, for the amount of money expended for space in each class of publication. Beekeepers who advertise will find what papers pay them best by a trial of a few months. It is rather expensive to gain the knowledge of the best mediums, but there is no royal road to marketing one's crop.

Floods in California and snow-slides in Colorado indicate what we may expect in 1916. Prospects are good, and bees are wintering well. I believe that the amount of honey carried over will not be large, and it would do the heart of beekeepers good to see the way honey is coming into its own in many localities. People are eating more honey—it is getting more publicity, and the lower prices have induced wholesalers to handle carloads where, in the past, little if any has been handled. In the future these districts will call for honey; and while the prices received this year have been ruinously low, it has made it possible for honey to be introduced into markets that before took little if any. Honey is being retailed at five cents a pound in some districts, and it seems to be a fair quality too—at any rate, it gives satisfaction.

WHAT BEEKEEPERS COULD DO.

Take, as an example, a county producing ten cars of extracted alfalfa or sage honey for export shipment. Suppose, instead of the owners of this honey taking \$15,000 for it, or 5 cents a pound, that they set aside (or, rather, borrow, which they will have to). \$5000 to put into an advertising campaign. The honey would bring, I believe, \$24,000, or eight cents a pound on the average. It would not be well to put the entire amount into newspaper advertising. Some could be used in trade papers (grocers), and in a house-to-house canvass. A few salesmen could be put on the road selling to grocers direct. With the advent of cheap runabouts, double the territory may be covered at no additional expense provided the roads are passable.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Generally speaking, our climate averages pretty well one year with another. In other words, if we get a drouth, quite likely a wet spell will then follow; if we get milder weather than usual during early part of the winter, extreme cold may be looked for later on. Certainly the latter has been true here in Ontario this winter, when a very mild January was followed by a February three degrees colder than the average (official), while March to date (15th) has been very severe. The first five days were all below zero, and on the 10th five below. As we have had only thirteen days during the winter that have shown below zero temperature in our locality, it is easy to see that March has more than done its share in furnishing us cold weather.

On page 81, Jan. 15, A. I. R. asks, "How many years and even centuries has it taken the *bee* to learn the trade of making the beautiful honeycomb?" The answer is real easy, but I won't give what I think is the correct solution of the problem, as it would be too simple for modern scientists to consider a moment. Instead of answering the question, allow me to ask another one along the same line: While the bee was *learning* how to make the "beautiful honeycomb," where were all the *baby* bees being reared in the meantime?

Some time ago I stated that the common dandelion came as near to being an all-the-year bloomer as any plant we have in Ontario, as I had found blossoms in nine months of the year. On Jan. 25 I found a fully developed blossom in front of a hive, so now I shall have to say ten months instead of nine. But the common garden pansy is a close second for the honor of being our hardiest plant—indeed, it may even lead the dandelion. On the same day that I picked this dandelion blossom, different parties near us gathered pansy blossoms in their gardens. But bees do not work on pansies, and they do on dandelions. That is enough to make any beekeeper give the latter plant the preference.

Misery loves company, they say, and on that basis I am inclined to agree to a certain extent with friend Holtermann in his lament regarding European foul brood, p.

116. While I dread this disease I am losing no sleep over the matter, and I take comfort from the fact that men like Warrington Scott and others in Ontario who first had the disease among their bees, while they do not claim to have entirely gotten rid of the disease, yet have so mastered it that it in no way interferes with getting big crops of honey when there is any nectar in the neighborhood. I am hoping that, when we get the disease among our bees, as we are sure to do sooner or later, we shall be able in time to do likewise. That is the grain of comfort I chew at when I allow my mind to think of this "curse of bee-keeping."

This question of how far bees fly will never be solved to my satisfaction, as there are so many things to be taken into consideration, such as strains of bees, topography of country, etc. For years I was inclined to take a view similar to expressions on page 965, Dec. 1, and, in fact, I seriously doubted that bees very often go more than a mile and a half in search of nectar.

Our apiary north of Orillia is in a flat wooded country similar to that described by the editor, Dec. 1, and observations taken in 1913 prove how erroneous are the views that, under such conditions, bees fly but little over $\frac{3}{4}$ of a mile. That year a terrible drouth visited the section in question, and all the clover on high land was literally burned up. Nearly three miles southwest of the apiary of over 200 colonies was a strip along the river bank that was kept moist enough so that alsike clover was kept in bloom. The river had been dredged out, and this strip of clover was only a few rods wide and ran along the river for about two miles still further from the apiary. Our bees came to this strip of clover by the hundreds of thousands, and they were on the clover to the further end, so that many were nearly five miles away from the apiary. There was no question about the matter at all, as one could stand at the north end of the strip and see thousands of bees coming and going to the yard, and there are no other bees in that locality.

That same year there was some white clover west of the apiary across the bay. It is two miles direct to the bay, and more than half the distance is forest. Yet our bees, under these forced circumstances, flew the two miles to the bay, and then another two miles across the water. You will un-

derstand there was no pasture near the apiary, owing to the drouth having burned everything up. And yet right here in York County for years our bees would get nothing during August, when less than four miles away there was quite an acreage of buckwheat and bees near it were storing surplus. Clearly this matter of how far bees fly in search of nectar is a complicated one. [As we have stated, bees have been known to go seven miles, and a great many times two and three miles; but our contention is (see page 149), when flora is within a mile or a mile and a half, bees will not go further as a rule. It is only in peculiar cases that they go from two to three miles. Then, as Dr. Miller points out elsewhere, the matter of odor probably has some bearing. The aroma from clover or buckwheat fields probably can be carried by a breeze several miles; and if there is no clover or buckwheat in the immediate locality bees will keep on flying in the direction of odor mellifluous until they arrive at its source. The question then of how far bees fly for stores depends on the locality and conditions. See editorial.—Ed.]

Bees have had no flight to amount to anything, altho bright sunshine is coaxing many to leave the hives, never to return. Present indications are that there will be quite a loss in many apiaries from dysentery. Colonies were unusually full of young bees last fall; and altho the latter part of winter has been cold, yet we have had colder seasons more than once. The cause would seem to be bad stores, probably caused by excessive moisture during late summer and fall. Another reason advanced to explain the cause of dysentery is that January was so mild that much brood-rearing was started, and then so much cold weather followed, with no chance for a flight, that naturally such conditions would follow. Personally I noticed young bees in the pupa stage being cast out of a number of hives early in February. That was *prima facie* evidence that brood-rearing was going on in January all right. Whether that is the correct diagnosis as to the cause of dysentery or not, I am not sure; but certainly for some reason we have more of the disease in our York Co. yards than we have had for a number of years. As to the north yard, as we have not been there since last October, and do not expect to visit the apiary for a few weeks yet, we know nothing as to its condition.

Any beekeeper knows that, when cold weather comes, the bees in the hive form

a cluster, the size of said cluster being determined by the severity of the weather. No doubt many a beginner has turned back a quilt of a colony known to be strong, and if the temperature was down below zero the smallness of the cluster would cause him to think that the colony had become very weak. On the other hand, if the weather moderated to the freezing-point or higher, a look in the hive again at that time would make things appear that the colony had just as suddenly become very strong again. This is orthodox, and up to the present season I think that possibly I would have said there are no exceptions to this rule. Early in the winter my attention was called to one particular colony in the home apiary when I noticed cappings, dead bees, etc., on the fresh snow in front of the entrance when all other colonies had no such evidence of activity. The colony was in a hive equal to 12 Langstroth frames in capacity, a single packed hive having an entrance five inches wide and one inch deep. Looking in this deep entrance I was surprised to see the bees quietly hanging below the frames, even tho the thermometer was but a few degrees above zero. This was unusual, to say the least; and when I next lifted off the cover of the hive and took a peep under all four corners of the quilt, and found bees in every corner, it is needless to say my surprise increased. Altho they were not at all uneasy I prophesied that there would be something doing before spring. To make a long story short, scores of times during the winter I examined that hive; and, no matter how cold the weather, the bees could be seen from the entrance, quietly hanging below the frames, and every corner of the hive would be packed full of bees, as would be revealed when packing was lifted up and the quilt carefully turned back. I am not sure whether this queen will prove to be a genuine "find" or whether the colony will yet go to pieces during the spring; but the fact is, they have been as described for over three months; and today, March 13, the colony is quiet, sweet, and clean when other colonies in the same yard are showing signs of dysentery. Probably about ten per cent are thus affected.

The queen in this colony is a dark Italian, and was purchased last July from one of our well-known breeders. Don't ask me any questions about her for a while yet. For a month or two, perhaps, I shall not want to mention the matter at all if the colony should yet prove to be a "four-flusher." However, you may be assured that this hive will get its share of my attention for the next few weeks anyway.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

THE BEST BEES.

"I am a comparatively new beginner with bees, but wish the best bees for comb honey I can possibly get. In time I may conclude to work for both comb and extracted honey. Are some bees better for extracted and others for comb?"

Volumes have been written on this subject, and the matter is not fully settled in the minds of many, even at the present time. Some claim that the black bees are preferable to any for comb honey, especially the large gray kind that they have in the South, while the smaller jet-black bee is nearly worthless. After trying in vain to get that large strain of black bees, all proving nothing better than the black bee of my first fifteen years of beekeeping, I have concluded that some one was mistaken. The black bee is superior in only one point for comb honey; and that point is, the *white capping* of the section honey which they produce. Comb honey sells mainly by the nice appearance of the sections; and the blacks, by leaving a greater air-space between the honey and by their heavier coating of wax, give the best possible appearance to section honey. And at all times of a bountiful flow of nectar, long drawn out, they are as good as any bees for honey; but with a slow intermittent flow of nectar the golden Italians are far ahead as to the amount gathered, while they cap their honey nearly as beautifully as do the blacks. However, some of our very best apiarists tell me they do not know which are the best.

If I were producing extracted honey altogether I would select the darker Italians, those produced from queens from an imported mother, or the most superior strain of leather-colored Italians which I could find bred by some breeder of known integrity. I would allow the young queens to mate with whatever drones there were in and about the apiary, paying no attention as to whether these drones were from Italian, hybrid, or black stock. Bees from such queens would use much less wax in capping combs than from any other strain which I know of; and as the capping of combs cuts no figure in the taste or looks of extracted honey, I should be so much ahead, as, for the most part of the time in the average surplus season, wax secretion is possible only by a larger consumption of honey.

If I were working for comb or section honey exclusively, then I would procure a

good queen of the golden variety, rearing all queens from her, and allow them to mate with any drones they might chance to meet, the most of which, without doubt, would be from an entirely different "blood" from themselves, which would give a direct cross. Such direct cross always gives greater vigor than anything I know of; and, as the question is asked, I should not care very much whether my yellow queens mated with drones from black or hybrid stock, as all of my experience goes to prove that thoroughbred golden Italian queens, mated to drones of either black or hybrid stock give bees equal to the very best for comb-honey purposes. If I could conveniently hinder it I should prefer not to have these queens meet drones from young queens reared from imported mothers—not because they would not give queens just as vigorous, and of just as good honey-gathering qualities, but for the reason that, as a rule, workers having much imported blood in them do not cap their honey nearly so nicely and captivating to the eye of the consumer as do those having more of the golden, hybrid, or German blood in them.

From the lot of young queens reared from this same golden mother I would select one or more queens which give the best results in section honey, considering amount produced, color, and smoothness of the cappings, disposition and wintering qualities, and use them to breed from for a year or two. Or I would get another golden queen from another experienced breeder in whom I had faith, and go over the ground again.

To sum up I would say, first have your young queens mate with drones as distantly related to your queens as possible. Second, use queens as closely related to imported Italian or leather-colored stock as possible, where working for extracted honey, for there are no better bees in the world, in my opinion, than those two or three generations from imported stock for securing all the honey there is to be had from your locality. Third, where white capping of combs becomes one of the great objects to work for, as is the case where working for section honey, choose the golden Italians, on account of their qualities in that direction. At the same time they are in no way second to Italians from imported stock, or the dark leather variety as to their honey-gathering qualities. Lastly, put your own self into this breeding business, using all the energy and vim you possess.

GENERAL CORRESPONDENCE

PERFECT POLLINATION OF CITRUS GROVES

BY PROF. E. G. BALDWIN

Your timely discussions of the proper number of colonies to fertilize a citrus grove, in various pages of GLEANINGS, have greatly interested me. While it does not seem to be *imperative* to know *how few colonies* will do the work, still it may be useful on occasion; for it will often happen, probably, that some groves will have a minimum quota of colonies in their vicinity. In such instances, if the number of colonies present were below the accepted and proved minimum, the owners of such groves could easily bring in sufficient to insure fullest fertilization. So it is wise to discover, if possible, what number will do effective work, where more can not be had. But I have always held, here, that "the more the better," and that seems to be the idea that is crystallizing in the minds of the growers hereabout, and even further south, about Bradentown, for example, and Tampa.

The blossom of the citrus (orange or grapefruit, for instance) is a so-called "perfect flower"—that is, has both pistils and stamens on the same stem, more or less united at their bases. The pistils rise a little higher from the base than the enveloping stamens, which stand outside of and lower than the pistils. There are, hence, three ways in which the blossom can be fruited—gravity, wind, and insects. Gravity carries the dust from some stamen above the particular blossom in question down upon the pistils of the blossom below. Wind carries the dust from other blossoms on the same or nearby trees, over upon the pistils of blossoms within wafting distance. One citrus tree usually has many blossoms out at one time tho not with anything like the same evenness as the blossoms on apple-trees. The orange-blossoms come out much more irregularly and far less simultaneously. Nearby trees also add their contingent of fertile stamens to fertilize the pistils of any trees that are near enough; therefore, even were wind and gravity the only fertilizing media or agencies, there would be some fruit, often heavy crops of it, from these agencies alone. The fullness of the fertilizing would in all such instances depend on, first, the fullness and evenness of the bloom on the particular tree under consideration, the proximity of other trees, and their simultaneous blossoming period, etc.; second, on the weather during the time of bloom.

It is this latter point that we have studied most carefully. In our latitude (29th degree) the citrus-blooming time is at the end of February and thru March. In the latitude of Tampa, for example, it is the latter half of February and early March. Our conclusions are based largely for our personal deductions—that is, on data recorded by us in and about Deland. Here we have on an average, say, five weeks of blooming time. That means that from the time the earliest blossoms come out on the first and most advanced trees and varieties (tangerines are much later than others), to the end of the "last lingering rose" of the tangerine blossom, on latest groves (and land and location alter the time much), we have an average of about a five-weeks' bloom-period. That gives an outsider a very erroneous impression, I fear, about the length of bloom of a single blossom. I have watched this very carefully, and I think a blossom seldom hangs on more than three days, on an average. In hot dry weather one good day of sun seems to "cook" it, and it is done for the second day. For that particular blossom, then, the fertilization would have to be done within about two days, say, to be effective and best. Of course one day is sufficient provided the pollen from some stamen is wafted to the pistil in that time. But a season of damp foggy weather, when pollen wafts but little during the bloom of the particular blossom, would likely prevent full fructification of that blossom. A dead calm, too, in that time, would make gravity the only means of fertilization. For such blossoms as happened to come within the wet or calm weather only, would fullest fertilization be impossible. The succession of blossoms on other stems of the same tree would give opportunities for their fertilization outside of the periods of calm or dampness. But, taking our average springs here, one with another, we do not average more than half the time really favorable weather. Much is either damp, or a dead calm. And were gravity and winds the only agencies for fructification, we feel sure that many blossoms would not be fertilized at all. Of course, you may say that, usually, every tree sets enough fruit to insure a sufficient crop. But would it do so with these two agencies alone? I must confess that I am not in position to state dogmati-

eally or with finality on this point. I am planning now to make a test of the question by covering certain branches during their time of bloom, and test by actual observation the effect on a large number of blossoms, kept from all visits of insects.

That brings us to a discussion of the observed data from the increase of bees among our groves. Six years ago one could hardly find a dozen men to the county in Florida who kept bees, and most of those were small holders. Now the number has grown by leaps and bounds. Then, too, many fruit-growers had an antipathy to bees, thinking they damaged their bloom. But enlightenment is coming. Now, those same growers who objected to bees in their groves are asking beemen to place apiaries in their holdings. Here, for instance, one of the largest growers of this section, Judge Stewart, has made a request to have bees placed in his large groves north of town, seeing what has been done in the increase and quality of fruit in and about town, where so many bees are flying. Half the grove men here have bees in their groves, either their own (largely so), or sometimes from neighboring beemen. Mr. C. F. Spaulding, of Deland, was the first, ten or twelve years ago, to see the importance of bees among his trees, and located a small apiary in his grove at his own expense, not for honey, but for fertilization. No one has had better fruit nor more even-bearing nor fuller carrying from setting to maturity than he has had for a decade past. His grove is pointed out as one of the most even-bearing. That was even ten years ago. Now, with hundreds of colonies to ten then, he has not found it necessary, as I have taken over his apiary. But I have 100 colonies within a block of his grove. There are probably over 400 colonies within flying distance of any one grove in and about town. If, as seems to be the growing idea, bees do not fly more than a mile and a half, on an average, then we need more bees rather than fewer. That is my contention. From a pomologist's point of view, not that of the apiarist, we seem to be coming to this view. "The more the merrier." Too many bees there cannot be; all will admit that. Too few there can easily be, all are coming to admit. Just how many make the minimum is the problem. I wager it is impossible to do more than determine this point roughly from our present data, at least.

One point I should like to add: I can easily see why Editor Root should insist that fewer bees per acre are needed to fertilize orange-trees than fruit-trees north,

for two reasons—namely, first, the shorter time of blooming in the fruit-trees; second, the comparatively weak condition of colonies in the North at the time of fruit bloom. Perhaps a third element might be added, the fact of bad weather at the time of fruit-tree bloom. My statements in our local papers were all directed toward encouraging an understanding of the matter, and a favorable attitude among our growers toward bees in their groves. So I stated a large number as the necessary one. I wrote the following for the local paper two years ago, since which time a marked change in attitude among growers here has been noted. I may be allowed to repeat that closing paragraph:

"For best results there should not be fewer than five hives to an acre; even more are better; for in stormy weather, when bees fly for only a short time during the day, or for only a short distance from their hives, a larger number of colonies will insure perfect fertilization, where a smaller number might not."

So, in absence of accurate data as to the minimum of safety in numbers, I have pleaded for the maximum. The idea also is growing among beemen further south in the state, I note in some instances. I refer notably to the Manatee Fruit Co., of Palmetto, and to the groves of Mr. Z. Goddard, of Terra Cea, Fla.

The final point I wish to make is this: That growers are at last coming to admit the Darwinian theory as true in their fruit, that the fertilization of blossoms from trees remote gives stronger buds, and young fruit, and makes better mature fruit, which in turn improves the strength of the seed, and makes for constant improvement in vitality all thru the entire life of the tree, and thru succeeding generations of stock. The growers in and about Deland and Brantown and Tampa and Arcadia and Orlando, hold this idea, "The nearer the bees to their groves the more fruit they have, and the better the quality."

Editor Root says, that on his visit to Florida he found the growers unaware of any bees in their groves, often, and yet they secured large crops of fruit. He adds that he found bees flying there, and always told them that they probably knew little of the real number of bee-visitors they really had among their trees. His remarks were most pertinent, and showed the accuracy of his observation; and it might be well to remark that there are a dozen—yes, twenty—bee-trees in the average flying distance of any grove in Florida, compared with one such bee-tree within flying distance of the usual

orchard in the North. That would make a difference; for it would insure fertilization, even in bad weather, in cases where the grower thought there were no bees about. Few men, till their attention is called to it, notice whether bees are on the blossoms or not.

I was glad to read the article, p. 92, Feb. 1, taken from the *Hemet News*, of California. It seems to corroborate what I have been forced to conclude from my own observations along this line.

Deland, Fla.

[Prof. Baldwin states the peculiar conditions in Florida so clearly that we consider if his estimate of the number of colonies needed per acre were too high ours was too low. As he says, it is far better to err on the safe side—that of having too many, rather than too few to do the work of pollination, both in the orchards of the North and of the South. The last paragraph in the article referring to the item on page 92 is somewhat at variance with the following article. Who is right?—Ed.]

FROM THE CALIFORNIA STANDPOINT

BY M. C. RICHTER

As for California, it can be stated positively that all of our commercial varieties of citrus fruits are able to set and mature fruit without pollination. The navel orange has no pollen, and very rarely contains a seed. If, perchance, a seed has formed in the navel orange, it means, in all probability, that a bee has brought some pollen, *e. g.*, from a Valencia tree, to the stigma of the navel orange. It has happened at times that navel oranges in some orchards have had a considerable sprinkling of seeds in them. This phenomenon, however, is of rare occurrence.

On the other hand, about half of the Valencia oranges contain seeds; but it rarely happens that there is more than one seed in an orange. The seeds are, of course, the result of pollination. But if all the bloom of a Valencia orange-tree were protected from insects, there would nevertheless not be the slightest diminution of set and mature fruit.

The same is true of lemon-trees. Dr. J. Eliot Coit, Professor of Citriculture of the University of California, and the leading authority on the Pacific Coast, performed the following experiment on a lemon-tree. Just before the buds opened he cut off all the upper portion, *i. e.*, the petals and the stigma of the pistil that receives pollen. The bloom, nevertheless, set and matured good fruit, which did not contain a single seed. This experiment, altho made for another purpose, *viz.*, to ascertain whether the lemon-tree could produce seeds parthenogenetically, also proved that pollination is not necessary to set and mature fruit.

The honeybee in the citrus orchards of California is not an unwelcome guest, however. She does not harm the orange-grower, but she does enrich the state by thousands of dollars annually.

San Francisco, Cal.

[The conditions in California, especially when seedless fruit is grown, possibly are quite different from conditions in Florida and in the Isle of Pines. A Florida orange and a Florida grapefruit are quite different from the same fruit in California. If we are correct, Florida oranges all have seeds, as the seedless variety apparently doesn't do well there. There are a great many seed oranges and grapefruit grown in California; but the grapefruit in California is very much smaller than that from the Peninsular state. Many colonies of bees are in the vicinity of the orange and grapefruit groves in California. They gather a large amount of honey from the groves. The presence of the nectar would seem to indicate that Nature has an object in seeking out the visitation of insects in the citrus groves. While it is probably true that seedless fruit can be grown without bees, it is possible that larger grapefruit could be grown in California providing there were more bees to the acre.

At the present time the citrus-fruit growers of the Isle of Pines are discovering that they need bees; and we happen to know that certain concerns furnishing bees are having calls for bees. Bees in Cuba are so badly affected with disease that the residents of the Isle of Pines do not care to import from their nearest neighbor and are, therefore, seeking the breeders in the United States.

From the best advices at hand, the Isle of Pines is greatly in need of bees because the fruit-growers there are waking up to the fact that they probably could grow more and better fruit if they had more bees.

This is a rather interesting question, and we hope that some time the Bureau of Entomology, Washington, can give us scientific data on it.—Ed.]

JUST HOW IMPORTANT IS THE WORK OF THE BEE?

BY J. E. CRANE

We have all doubtless seen apple-trees that blossomed profusely, and that apparently set full; but when the young apples were as large as beans, they began to drop, and kept on until not enough apples were left for half a crop. Now, what proportion of this dropping is caused by lack of the proper fertilization of the flowers? I believe a much larger share than we think. It seems evident that there is a wide variation in the ability of fruit-trees to become fertile. Some may produce from the pollen of the same flower, while others may set fruit with pollen from other flowers from the same tree, while still others may require pollen from some other tree.

Plants have many ingenious ways of scattering their seeds over the earth. The dandelion, with its winged seeds, the burdock with its burrs that stick to everything that comes in contact with them. The "tumbleweed," by breaking off at the surface of the ground at the approach of cold weather, and rolling over before the wind, which scatters its seeds everywhere in its path. Fruit-trees cover their seeds with a pulp enjoyed by man and other animal life, and just as the fruit ripens gives the skin a bright color to attract attention, the object of which is doubtless that the fruit may be plucked and the seed scattered. Fruit-trees seem to know by instinct what the pulp of the fruit is for, and just the object of surrounding the seed with it, and when the embryo seed does not develop in the ovary they seem to know the utter uselessness of developing the pulp, and absorb the

cells that connect the stem of the fruit to the twig of the tree, and let it drop to the earth. If the tree could speak I think it would say, "It is useless to produce fruit unless it contains seed." How wonderful it all is! We are accustomed to think that the young fruit drops because of the dryness of the earth, or very hot weather, or because the tree had set more than it could carry to maturity, and doubtless these may have a part in causing the young fruit to drop; but there is reason to believe the imperfect fertilization, or complete lack of fertilization, is more often the cause of the dropping of young fruits.

But there are some surprising exceptions to the rule. There is the seedless banana. The navel orange, some varieties of grapes, and even some apples and pears, will mature without seed. Here is a large field for experiment by boys or girls. Let them take two branches on the same side of the tree, of nearly equal size; count the blossoms on each. If not the same, make them so by removing some from the branch having the most; then cover one with mosquito netting, leaving the other without cover. Remove the netting after the petals drop. When the fruit ripens, carefully count the number of fruits on each branch. Observe if other insects than bees are at work on the flowers—what kinds, and the proportion of them to the bees. Also we should like to know the variety of apple or pear experimented with. Peaches, plums, cherries, and even currants and gooseberries might come in for a share of our attention.

Middlebury, Vt.

CAN EUROPEAN FOUL BROOD BE STAMPED OUT?

Encouragement for Mr. Holtermann

BY GEORGE H. REA.

I don't wonder that Mr. Holtermann can not derive much comfort out of his Jobshite friend's advice regarding European foul brood. While it is Mr. Holtermann's bees that are "boiling" instead of himself, yet there is some analogy between the cases after all. If Eliphaz and Bildad and Zophar were not much comfort to Job, they did one good thing—they stirred up his fighting blood.

To control a disease and exterminate it are two different things. Like Mr. Holtermann, I am not satisfied with merely controlling the disease. I am satisfied with no-

thing less than its extermination, so that it will not be eternally cropping out in my apiaries and keeping me in hot water lest it break out seriously at any time. I can not afford to spend half of my time looking for it.

Mr. Holtermann is hunting for "the one who has stamped out the disease after it has spread among his bees." I will essay to offer my services in that capacity. If any one has doubt up his sleeve, pay me a visit and look up my records. Besides cleaning up the disease from my own bees I have helped to rid it from this community. It has been prac-

tically stamped out of several other badly infected areas also. I am now serving the state in the capacity of apiary inspector.

Any one conversant with the bee literature of today knows that more confusion is resulting every day from the many so-called treatments for the cure of European foul brood, and all the time the disease marches triumphantly on. It has swept over whole counties and states, and bids fair (as I understand) to sweep over the whole of Canada. Some of the best beekeeping counties of Pennsylvania are practically depleted of bees by its ravages, and the end is not yet. This is true of other states also. Shall we ever be able, then, to conquer and bring under control this scourge among bees, or shall we throw up our hands and give up beekeeping as a bad job? I say, give up—never! It can be stamped out of an apiary or community.

As to eradicating this disease from the country, that is a question of right legislation backed up by adequate funds and the employment of experts who will use radical methods of treating it. Up to date I know of no state that possesses that happy combination. But I have faith enough in the bee business to believe that the time will come, at no distant day, when it will be recognized and cared for adequately.

I do not wish to add anything to the confusion and losses resulting from the improper treatment of European foul brood; but I do wish to pierce Mr. Holtermann's cloud of gloom with a ray of hope and comfort. Before I knew how to handle this disease, and while experimenting with many so-called cures, I lost hundreds of dollars' worth of bees. Others have done the same thing. I know it is a serious pestilence; but, on the other hand, I know positively that it can be stamped out. To do this involves the fundamental principle used in fighting many diseases with which we are familiar—i. e., sanitation. Sanitary measures used in combating epidemics of typhoid, cholera, smallpox, etc., need no discussion. The simple expedient of removing the bees away from all infected material into a clean hive where they can build up anew, if properly done, will positively cure European foul brood with no danger of its recurrence unless the bees rob it somewhere or have it carried to them.

I want to go on record, without fear of successful contradiction, that the beekeeper who treats his bees infected with European foul brood exactly as he would for American foul brood (two shakes) will eradicate the disease from his apiaries. Those who advocate many of the so-called short cuts

(most of them long cuts) have not been able to prove to the satisfaction of the beekeeping world that they can eradicate the disease. The very fact that they are continually looking for it and expecting it to break out again shows that something is wrong, either with the men or the methods. Why don't they get rid of it?

I might give my long list of experiments and failures as well as the ruined apiaries I have found as a result of unsuccessful treatment, but it would take too long. We have had it in this locality as badly as anywhere, but it is here no longer.

We must all admit that some experts in some localities and under some conditions may do some things that we common mortals can't do. Now, if they can cure European foul brood by dequeening and requeening, etc., that is the thing for them to do. I must admit that I can't do it without a feeling that it is pretty sure to recur some time in the future. From what I have seen in my visits in hundreds of infected apiaries, I know that the rank and file of beekeepers can't do it either. I could show that the shaking treatment is the most economical, anyway. Dequeening and requeening, Italian bees, etc., are of no avail so far as a sure cure is concerned. They are helps, and should be used in connection with a cure, but helps only. In order to keep your bees clean it is necessary, of course, to have the surrounding territory clean so that your bees will have no place from which to carry it by robbing.

MY METHOD IN BRIEF.

Any colony showing the disease is shaken at once. If the infection is general in the apiary, which is probable in an outbreak of European foul brood, all colonies are shaken in order to run no risk on those that do not show it. Good combs of honey are extracted, and the combs, with all other empty combs, are melted up. Combs containing diseased brood, if bad, are burned. Enough bees are left on the brood to care for it, and this brood is then stacked up two, three, or four stories high, in an isolated corner of the yard to be shaken in 21 days. The entrances to these stacks of brood must be small so that the bees can protect them. The cover and the whole thing, in fact, must be bee-tight excepting the small entrance. There is no danger of robbing if well done. Strong colonies will result from this brood when shaken. The combs are then to be melted up.

The first shake is on starters attached to strips of lath. Three or four are all that is necessary. The second shake at the end of three days is on full sheets of foundation.

Any colonies, at the first shake, not strong enough to make good colonies, are shaken together.

If a honey-flow is on, the bees may be supered as in the regular method of forced swarming practiced by some, and a crop of honey harvested. If no honey is coming in they must be fed.

The wax from the melted combs will pay for the new foundation and the work. The bees are now absolutely clean, and on new combs, and practically nothing is lost but the time necessary for the work, and that is really paid for. Do not lose sight of the fact that other bees in that locality must be looked after too.

By the shaking treatment the bees lose practically no time. In fact, they will work with the vim of new swarms. All colonies headed by old or failing queens, or those not pure Italian, are replaced with young Italian queens. Methods of treating that involve a period of queenlessness make a serious break in the life of the colony. The bees will practically loaf thru that queenless period. A colony left queenless or without a laying queen for two or three weeks will be of no particular value for the rest of that season. I trust that no one will misunderstand me. I recognize the many good and valuable things in other methods of treating; but fifteen years' experience with this disease has taught me

that radical treatment is not only the safest but the most economical in the end, and the only sure way to stamp it out.

There is much talk just now about strains of Italian bees that are immune. It would not surprise me if some would-be queen-breeders (?) would start advertising such bees. Will the gullible public bite? There is much evidence that Italian bees are resistant to the disease because of their vigor, and should be introduced generally as a help in the fight. But *immune*—not yet. I venture to say from the very nature of things they never will be, but that is another subject. We all know how Italian bees will clean out the bee-moth and keep them out. That is because they are a hardy and vigorous race of bees, and not easily discouraged. They will work at European foul brood the same way, and tend to keep it down; but while they are doing so in many cases they are losing out at the same time. The beekeeper who thinks that he will never have European foul brood just because he has a good strain of Italian bees may wake up with a sudden jar some fine morning.

I know what it means to handle more than one thousand colonies of bees with little competent help, and to treat hundreds of cases of foul brood, and I offer my experience for what it may be worth to others.
Reynoldsville, Pa.

TO THE RESCUE OF MR. HOLTERMANN

BY LAURENCE A. P. STONE

Poor Mr. Holtermann! I wish I could sympathize with his sad remarks on page 116, Feb. 1; but, unfortunately, my feelings concerning the menace of European foul brood among the bees do not disturb me, altho I have had to contend with this disease among my bees ever since I have been in the bee business. It has been more of a blessing than a woe, for it has improved conditions among the beekeepers of my locality, and made it possible to get decent prices for honey.

Situated as I am, in Canada, just across the river from Buffalo, I have had the full benefit of European foul brood ever since it crossed Niagara River. Before the disease arrived, almost every farmer in the vicinity had one or two hives of vicious black bees; and when any surplus honey was made they sold it for a song. It was impossible for any bee specialist to compete with these people, as the latter would invariably undersell. Since these farmers never gave any time to their bees, what honey they

received was in the form of a bonanza, and what they could not eat themselves was promptly sold at the first price offered, or, rather, just a little below the one they heard the regular beekeepers were offering. No care was ever taken of the bees; the hives were made of any kind of material, and I doubt if one person in ten of these had ever seen the inside of a hive.

Then came the disease; and the way it wiped out these beekeepers was a caution. Before long a hive of live bees was almost a curiosity in the neighborhood. Luckily for me I had started right, and had mostly Italians. The disease used to touch my yards now and then; but with one exception it never took a firm hold in any colony of pure stock. Only the hybrids suffered, and I requeened these as fast as I could with good stock imported from the United States, and in but one case was there trouble with the queens purchased. These queens came from a very prominent breeder, and I was pained with the results obtained from their

bees. They gathered but little honey, and were very poor resistors of European foul brood, while experiments with them cost me a number of colonies before I awoke to the fact that they were not what I wanted.

Keep up your spirits, Mr. Holtermann! You'll find European foul brood much less serious than you think, if you have Italianized, and I feel sure that you have. I do not agree with Mr. Selwyn when he says that the Italians must first suffer from it too. Mine did not, and that is reason enough for me to disagree. It does not take much trouble to find the disease in a yard, and requires very little more inspection than should ordinarily be given a normal apiary. In the first place, if bees get thru the spring months and to the clover flow without contracting the scourge, it is almost a sure thing that there will not be any until a scarcity of honey again; so, outside of treating the colonies that contracted it before this time, one need not be looking for new cases but devote his time to the honey harvest. One need not be so expert as Arthur C. Miller in understanding the conditions inside of a hive from outside appearances, to know foul brood is present. It is easily noticeable without tearing the hive to pieces to find it.

I have tried many methods of treating European foul brood, and I don't blame Mr. Holtermann for feeling the world on his shoulders if he is considering many that are recommended. To follow the instructions of many bee-doctors, one would have to destroy all combs and hives in the infected area, and do nothing but treat sick bees. I don't destroy any hives, and but very few combs; yet I manage to clean up the disease and get a good crop of honey. My treatment follows Dr. Miller's, except that I kill the queen from the diseased colony and introduce fine Italian stock, so as to have a new queen laying at the expiration of the ten-day period. I never attempt this plan during the spring or fall, but only during a good honey-flow, as the bees very rarely clean up the disease unless plenty of nectar is coming in. I attribute this to the fact that bees always seem, during a flow, to feed the fresh honey to the larvæ; and as this honey, as a rule, is free from the germs, there is very little reinfection in the colony. In the fall or early spring, more radical treatment is necessary. If the combs in a hive have more than one-eighth of the unsealed brood diseased at a time more than two weeks in advance of the clover flow, I shake the bees off on to full sheets of foundation, giving them one comb of *sealed* brood from a good Italian colony; and after a week I kill the old queen and intro-

duce Italians. If the colonies to be treated are fairly strong, and there are more than one of them, instead of destroying the brood I stack it up two stories high, leaving enough bees adhering, after the shaking, to hatch out the sealed brood. At the end of ten days I open up these stacked queenless colonies, cut out all queen-cells that have been built, and introduce good Italian queens. The infected combs should be melted up and the hive burned out with gasoline.

In the fall I simply destroy the colonies as stated, for it has never paid me to keep a diseased colony over until spring.

However, the nicest way to use Dr. Miller's method, and still get a crop of honey from the bees (unless the disease has gone too far), is to commence treatment at the beginning of the clover harvest. Make the infected colonies queenless, and unite as many together as will make up one strong colony and then introduce choice queens after the ten-day period, *but first make sure of destroying all queen-cells started by the colonies*. Instead of laying queens I prefer introducing choice cells, because I have plenty of choice drones flying, and cells are much more easily accepted by hives that have been queenless for ten days than frisky young queens. Dr. Miller's plan works all right with me, and I think it will with others, provided they use it as I do.

Mr. Holtermann, in my opinion, will not find European foul brood such a calamity after he has dealt with it a year or so, especially if he uses the afore-mentioned treatment. Henceforth, because of a little more watchfulness he will get bigger crops of honey and have finer bees. Where there are now ten beekeepers to compete against in his vicinity, there will soon be but one. Nothing but the right kind of beekeeper will be left in the business, and better prices will be obtained for honey. In short, fight the plague now and reap the harvest later, for virtue, in this case, will surely give a reward.

The time is not far off when, because of European foul brood, there will be no finer bees nor better class of beekeepers in the country than in my own county of Welland. However, I see no reason why all other counties, including Mr. Holtermann's, because of these diseases, cannot correspondingly improve. The wintering problem right now is far more troublesome to me than any bee disease; and our good friend, since he has mastered the former so well, certainly will not have much trouble with the latter. Therefore, Mr. Holtermann, be not pessimistic. Better times are surely in store for you if you care to work for them.

HAND'S CONVERTIBLE HIVE—A WINTER CASE WITH LITTLE EXTRA EQUIPMENT

BY J. E. HAND

Economical methods of winter protection of bees outdoors is a hobby of mine. My colonies are all in 14-frame hives with supers to match, but we have no difficulty in contracting a 14-frame colony into an 8-frame wintering-chamber, and all our colonies are wintered that way, partly to economize equipment, but more particularly because I regard extreme contraction fully as important as external insulation.

After an experience of forty years in outdoor wintering in the North I have come to regard external packing as inadequate unless coupled with extreme contraction of the wintering-chamber. In northern Ohio it is better to provide a moderate amount of packing with extreme contraction than to resort to excessive packing without adequate contraction of the wintering-chamber. An ordinary colony is poorly protected in a non-contracted hive in spite of packing—like a small heater in a large room. A two-story hive in a winter case will do no harm if the honey is all in the top story, neither will it do any good. Every wintering hive should have a three-inch space below the frames, and, of course, a packed bottom-board would be superfluous.

Undoubtedly the quadruple case will winter bees well in most locations, but it is not perfect. 1. It is expensive. 2. It is idle capital six months of the year. 3. It requires too much lifting of heavy hives (to eliminate the nuisance of handling heavy hives I adopted a hive so heavy that one man can't lift it, and I've been happy ever since—no more hive toting for me). 4. The basic principle is wrong, for a thick-walled inner chamber non-contracted invites condensation and humidity, and a thin-walled outer case invites radiation.

It is more economical and practical to make hives protect bees than to make winter cases to protect hives. By a system of hori-

J. E. Hand's 14-frame hive.

zontal expansion in summer to the capacity of 14 frames, and contraction in winter to eight frames, the hives proper are converted into winter cases with no extra equipment save a thin-walled inner chamber costing barely 25 cts., useful in summer for nuclei, increase, etc., therefore not idle equipment.

Fig. 1 shows a 14-frame convertible hive as used in the summer with frames hanging parallel with the entrance. The external appearance is the same in winter except the entrance, which is contracted to $\frac{3}{8}$ by 6 inches. Fig. 2 shows the inner chamber in position inside of a regular hive-body, with frames hanging at right angles to the

The hive containing the inner wall for the contracted colony in winter.

entrance, thus providing adequate spaces for packing. The extra depth of the inner chamber (12 inches) provides a deep space under the combs, and a full-depth upper story holds sufficient packing on top.

These hives cost but little more than good winter cases, and we have the satisfaction of knowing that every hive is a winter case, and *vice versa*. To prepare for winter, place eight combs, having the most honey, in the wintering-chamber, which is then placed on the floor inside of a regular hive-body put on the top story, and feed until every comb is solid full of honey and syrup; then apply the packing in the regular way, and let them alone until they become crowded for room in spring. Eight combs will hold approximately 40 lbs. of honey, which we regard as the minimum limit for best results in northern Ohio, where the weather is so uncertain in spring that it is unsafe

to depend upon nectar secretion for a food supply much before June; therefore we find it more economical and practical to provide sufficient stores to last until June than to fuss with feeding in April and May, and our spring work is thereby greatly facilitated. By this method every brood-comb is handled separately and inspected carefully in spring and in autumn. It means work, but not heavy lifting, and we know the exact condition of every colony.

The convertible hive is 20x24x9½ inches outside. Supers and brood-chambers are alike and interchangeable. If more packing is wanted at the ends it can be made longer; but for our location 24 inches is sufficient with our system of extreme contraction. The inner chamber is 13 x 19, 12 inches deep, made of half-inch sides, and ¾-inch ends. I have no hives for sale.

Birmingham, Ohio.

DELEGATES' SESSION OF THE NATIONAL BEEKEEPERS' ASSOCIATION

BY F. ERIC MILLEN, SEC.

At the forty-sixth annual meeting of the National Beekeepers' Association, held at the Sherman Hotel, Chicago, Ill., on February 22, 23, 24, the delegates present made an effort to place the National on a more stable foundation.

For some reason the National has not made much headway during the past few years, and it seems to have receded somewhat from the prominent position it formerly held. The past is gone, and it would serve no good purpose to dig up differences which we hope are safely buried. All of the officers did their best; but with a lack of unity progress was impossible.

There is room and need for a national association of beekeepers, and an immense amount of good work can be done by the National body for the good of beekeepers individually and collectively. Dr. C. C. Miller, America's grand old man in beekeeping, fittingly expressed the sentiments of those present when he said that it would be a pity to see the National break up. The doctor recalled many profitable conventions in days gone by, and these meetings had been the source of much pleasure in the meeting of brother beekeepers, and the exchange of greetings one with another. I am sure the doctor's remarks made every one of us feel that the National must live; and now that the doctor has diagnosed, let us make the prognosis favorable.

The sentiment was strongly expressed that the new officers should avoid commer-

cialism in the form of selling supplies, etc., and that they should confine themselves to helping the beekeepers along other lines, educational, fraternal, etc., which they thought were just as profitable, and more needed by the beekeeper.

With the exception of Mr. E. J. Baxter, Nauvoo, Ill., a new set of officers was elected as follows:

President, Professor Francis Jager, University Farm, St. Paul, Minn.

Vice-president, Dr. W. M. Copenhaver, Helena, Mont.

Secretary-treasurer, F. Eric Millen, East Lansing, Michigan.

These three officers, together with Mr. E. J. Baxter and Mr. E. S. Miller, Valparaiso, Ind., are to act as directors.

Mr. E. D. Townsend, editor and owner of the *Beekeepers' Review*, resigned as director, so that the new officers would feel free to inaugurate new policies without being tied in any way. Those who are personally acquainted with Mr. Townsend know that he has the interests of the beekeepers at heart, and that he would sooner remove himself than oppose any measure that seemed to be for the good of the cause.

While the *Review* is still the official organ of the National, it is now owned by Mr. Townsend, who dictates its policies.

The National Beekeepers' Association will work under the articles of the constitution as printed in the December number of the *Review* for 1915,

Membership dues to the association are \$1.50, which includes the *Review*. We cordially invite all beekeepers to join the National Beekeepers' Association. Members are eligible, whether their state association is affiliated or not. We hope the beekeep-

ers will show their confidence in the officers elected, and aid us in building a national that will be a source of pride and a credit to one of the greatest beekeeping countries in the world, America.

East Lansing, Mich.

SOURCES OF HONEY IN THE OZARK MOUNTAINS

BY OTIS A. GRIFFITH

Beekeepers here in the mountains are looking forward to 1916, as the prospects are excellent for the main honey-producing plants, white clover and sweet clover.

We are looking forward to the time when white sweet clover will take the place of all other hay crops. Besides being the best for honey, it is a soil-builder, and also the best for hay and silage. On many old wornout

It furnishes early pollen for the bees. Red cedar and red elms of the bottoms come next. By March 30 we have glade moss, buckeye, sarvis bush, maples, pawpaw, dogwood, and redbud. These furnish some honey. By this time there is a wealth of bloom of all kinds. The south slope furnishes an abundance of wild buckwheat, which begins blooming in May. After this

Cutting the first crop of buckwheat on the "Heights," a part of the Ozark Mountains, near Verona, Mo.

clay fields it is grown successfully. I have scattered many pounds of seed along the roadside. Five years ago I offered to give sweet-clover seed away, but today I have no trouble in getting rid of it at the market price.

Altho this locality here is nearly level it is in reality the highest point in the Ozark Mountains. The valley and the hills are covered with a natural growth of all kinds of timber, and there are many wild flowers blossoming thruout the season, which furnish either honey or pollen. The mountain elm blooms first of all, about February 20.

comes the white doe, a natural honey-plant. It is snow-white, grows about two feet tall, and has a white flower in a compact form. When a bee alights on one of these flowers it apparently does not leave until it is ready to start back to the hive with a load. The flowers last about thirty days, and the honey is water-white.

We have also what is called the fox-grape and the bluevine. While the blooming period of these vines is short, the yield of honey is good. The fox-grape grows along the streams and on every bluff. In some places it is impossible to walk because of

the tangle of these vines, all a mass of bloom, and the perfume of the flowers can be smelled for many yards.

I have never failed in getting two crops of Japanese buckwheat from the same land each year. I get from ten to fifteen bushels per acre at each crop. I had the third crop in full bloom when our first hard freeze

came last fall. If the first crop fails to mature, or if it blasts, as it often does, I plow it under and smooth the land down. I always plow under more than enough seed to reseed the second crop. Buckwheat plowed under makes a fine fertilizer, and gets the land in fine condition for a meadow.

Verona, Mo.

DO BEES PREVENT DAMAGE TO FRUIT-TREES BY FROST?

BY G. W. ADAMS

There has come to my knowledge a matter concerning the fertilization of fruit by bees which I have never seen touched upon, but which, if true, is of great importance.

Here is the claim, and it is made with a good deal of confidence after several seasons of careful observation, and on a rather large scale. *Bees will, to a very considerable extent, prevent damage by spring frosts.* The experiment has been mostly with peach, but applies to all blossoms.

The large orchard I have in mind was greatly damaged about one year in three, and to some extent every year. An apiary was established, and in a three-year test there has been no appreciable loss, altho the frosts have been (as proven by a local weather-bureau station) fully as late and severe.

Two reasons for this appear at once.

1. Every day, before the chill of evening arrives, the ripe blossom is fertilized, and the life processes transferred from the extremely delicate and exposed parts of the blossom to the protected ovary which is sheltered and closely covered in the base.

2. From the observation and study of vegetable temperature, we get evidence that there is a slight development of heat accompanying these vital processes. A careful and technical study of this will show its importance more fully.

I think no fruit-grower who has observed with care will dispute that most fruit damage by cold is to the open blossom, the freezing of the bud being the less common; and if the bees will protect us from this as well as by their prompt action, lessening the loss by heavy rains, we should realize and appreciate it.

Rowley, Mass.

[Several times there have appeared statements to the effect that, when proper and complete pollination takes place, the ordinary light frosts of the spring will do little or no damage. Prof. F. A. Waugh, author of numerous books on fruit culture, and probably as good an authority as there is in the United States, to whom this was forwarded, makes the following reply:—Ed.]

Mr. E. R. Root:—The letter from Mr. Adams is very interesting. I have never heard this claim made before, and of course do not know of any practical or scientific observations bearing on it. It is true, of course, as a general statement, that bees assist very materially in the pollination of fruit-blossoms; and in critical times, such as partial damage by frost, this assistance would count for a good deal. Aside from this indirect and wholly problematic assistance, it is difficult to see how the bees could accomplish the results claimed.

Amherst, Mass.

F. A. Waugh.

MANY A BEEKEEPER CAN MAKE HIS OWN HIVES

BY E. E. COLIEN

The article by Lewis L. Winship, page 1022, Dec. 15, contains some rather exaggerated statements. His illogical expressions, such as "the average home-made hives are fit for nothing so much as kindling-wood," invite contradiction.

In defense of the home-made goods, and of the ability of the ordinary workman to produce an article in every way as good as the factory-made, I herewith present a picture of one of my own make of hives and

supers. Mr. Winship admits that a few beekeepers can make their own hives, but charges that they usually try to economize in every possible way; and the hive, when finished, usually looks like the one in his illustration. He says, further on, that "the hive shown is *better* than the average run of home-made hives, and you must be quite a carpenter to make one as good."

I deny his theory, and call attention to the hive herewith presented in refutation of

his statement. I am not a carpenter, have never shingled a square, nailed on a piece of siding, nor hung a door. But I *have* been a farmer. I am past 70 years of age, and farming has been my occupation from boyhood.

Fifteen years ago I started gardening, and eight years later I added beekeeping to my employment. I started with two colonies; had never managed or seen bees managed, but subscribed for GLEANINGS and bought an A B C of Bee Culture; studied carefully and kept bees profitably on the information thus gleaned.

Five years ago the present winter I made up 30 hives and 60 supers, and you have in the picture before you one of these hives after five years of service on the summer stand. You will observe its still prime condition. The nailing was done with cement-coated nails, and every hive was painted at once. Today you can scarcely find an opening at any of the joints that will admit a pin to the interior.

I am producing comb honey exclusively, and my crop the past season exceeded a ton and a quarter from 40 colonies, spring count, and I made an increase of thirty colonies. My honey, all white, netted me 15 cts. per pound on the Chicago market, or \$375. I sold 13 colonies of bees for \$45.00 more, making in all \$420, and an addition of 17 colonies for the season's work in my apiary.

The foregoing is from an amateur who makes his own hives and supers, and advocates economy, not only as a privilege but as a duty.

If what I have done as an ordinary workman proves to the unbiased mind what the average beekeeper can do, does it not appeal

Not a bad job for a home-made hive.

to common sense that all over this country may be found beemen who, during the long winter months of otherwise enforced idleness, make up their own hives and supers, in which the bees find comfort and safety despite the deplorable picture by Mr. Winship, and his statement that ninety per cent of the home-made hives are not fit to keep bees in?

Manana, Wis.

FASTING VS. SMOKE

BY J. M. BUCHANAN

A writer in the New York *Sun* gives the following simple method of writing poetry:

Webster has the words, and I
Pick them up from where they lie,
Here a word, and there a word,
It's so easy it's absurd,
Merely range them in a row—
Webster's done the work, you know.

Thus it seems that anybody ought to be able to write poetry.

A writer in GLEANINGS gives the following simple method of introducing queens: "Close the entrance, all but an inch; blow in plenty of smoke; close entirely for a quarter of a minute; then run in the queen,

and close again for ten minutes." Easy, isn't it? "It's so easy it's absurd"—until you try it. Then follows a page or more of "qualifying conditions," a sort of *sine qua non*—page 108, Feb. 1.

Let's look at some of these. First, the hive must be smoke-tight. How many hives in a thousand, taking the average apiary, will you find perfectly tight at all joints and corners? Possibly two or three. Second, the smoke must be just the right kind, just thick enough, but not too thick. Third, there must be just enough smoke, but not too much. How is the average beekeeper to judge these things? Then the hive to be

requeneed should be without supers or upper stories. Does the author of the smoke plan know that in some parts of the country supers or upper stories are kept on the hives the year round, and it is not considered poor beekeeping, either?

Now, I have the highest regard for Mr. Miller. He is an original customer. He has the courage to leave the beaten paths, and go forth and find. For that I admire him. And he generally finds something worth while. No doubt, with his intimate knowledge of bee behavior he can make use of the smoke-in method with a very small per cent of loss. But the average beekeeper does not realize the qualifying conditions, and so he fails. At least, so many have failed that this can hardly be called a successful method.

Let us look at the so-called "starvation" or fasting plan. As I use it, this plan differs somewhat from the Simmins plan. The essentials are these: See that the colony is without queen or queen-cells; confine the queen alone, and without food, for forty-five minutes; push the hive cover or super over an inch or so, blow a puff or two of smoke into this opening, and let the queen run

down among the frames; then replace the cover, and the work is done.

Now for results, and that is what counts. Out of hundreds of queens introduced by this method, my loss has been less than one per cent; and there are hundreds of beekeepers in this and other states who are using this plan with uniform success, and who will bear me out in this experience. I have failed a few times in trying to introduce to laying-worker colonies; but, as Mr. Miller well says, that is poor beekeeping. I would not advise this nor any other method in that case, nor when the bees are engaged in robbing.

You don't have to wait till dark. I introduce any queen, any time, anywhere I want to, and the beauty of it is that anybody else can do the same. Under the best conditions I have lost twenty per cent of queens introduced by the antiquated cage-and-candy plan, and I don't believe others who use it have much better success. That may be a good thing for the queen-breeders so long as they don't guarantee safe introduction. If you are looking for a safe and sane method, try the fasting plan.

Franklin, Tenn.

A LARGE PRODUCER MUST BE A SMALL PRODUCER AT THE START

BY J. B. DONOHO

In 1912 I found a bee-tree near my home. I sawed off the section of the trunk containing the colony, and brought it to the house and set it in one corner of the yard. I watched them as tho I had a gold-mine, but they swarmed in a few days, and all left the stump. I don't blame them much when I think of the house I had provided for them. Then I bought some bees in box hives—five colonies in all. I soon found, however, that I had started beekeeping the wrong way.

The following winter I bought enough hives to transfer all my colonies, and transferred the first one March 4, and by the last of March I had all five in new clean hives with full sheets of foundation, using what young brood they had in good straight combs also. You see I had bought an A B C and X Y Z of Bee Culture, and had learned a little about bees.

As soon as possible I divided and made ten colonies, getting a fair yield of honey that season.

In 1914 I increased to 23, reserving 5 to be run for honey, and running the other five for increase. I succeeded in getting some honey from some of the colonies run

for increase. I got over 200 pounds from one of the colonies run for honey, making a little over 1000 pounds of honey from my apiary that year.

I lost 3 colonies the following winter; but in the spring of 1915 I increased to 45 and got a fair yield of honey, about 50 pounds to the colony. I hope to increase to 100 colonies next spring.

It takes a little common sense and backbone to start into beekeeping. Mr. Scholl thinks the one-horse beekeeper ought to quit and go away back and sit down. I agree with him, since by his ignorance he runs prices down; but I want to know how any man, not knowing much about bees, can start in the business without starting the one-horse way. If some one had given me 200 colonies before I learned anything about them I should not have known what to do with them, and the whole thing would have gone to the scrap-pile. I just wonder how many colonies Mr. Scholl himself started with.

I sell all of my honey in my home town, and cannot fill all of the orders I get. For comb honey I get 18 cts. a pound, and for bulk comb honey 12½.

Grandview, Texas.

THE APIARY FROM WHICH THE BEES STING(?) THE GRAPES.

My apiary is in the center of a town—Twin Grove—having a population of 40. I have never had any trouble with the neighbors with the exception of one man at the far end of the town who complains of the bees bothering his grapes. He tries to make out that the bees sting the grapes, and then take out the sweet.

JAMES D. BENSON, Juda, Wis.

HONEY PRODUCTION AS A BUSINESS IN THE HAWAIIAN ISLANDS, AS SEEN BY A MALIHINI

BY LESLIE BURR

Beekeepers sometimes move from one location to another; and while they do not move very often, yet they are always talking about moving. In fact, I do not remember any beekeeper with whom I am well acquainted but has expressed the idea that he thought that, if he were in some other and distant location, he could make more out of his bees. For the benefit of those who want to move from their present location to some distant land, I am going to describe the conditions here at the Paradise of the Pacific, the Hawaiian Islands.

The Hawaiian Islands are a territory of the United States, within the tropics, and at a distance of over 2000 miles from California. There is no foul brood nor any other disease to be contended with, nor winter losses. The beekeepers do but very little of the actual work themselves. They hire Japanese to do it for them, and the Japanese make good help, and work at very low wages. The principal honey-plant is the algaroba, and there is plenty of it.

Now, all those who want to come to Honolulu, hold up your hands. Well, I see my old friend Summerford, Hickox—yes, and there is Claude Hill, but he says that his

better half says he had better stay in Ohio, and several others.

Now that I have you fellows hooked, I will tell you some more about the Hawaiian Islands: First, that while the country in and about Honolulu is good bee country, it is overstocked. At the present time there are twice as many colonies as there should be. The apiaries are owned by Japanese, and they have an apiary just about every place where they can put one. If you desire to work outside of Honolulu, you are in worse luck. Everything here is big corporations, and that applies to honey production. One company has 5500 colonies, and there are others almost as large. Those corporations control all the good locations, and they have bees on them. But then, I know that some of you fellows, if you were here, would get an apiary or so located somewhere, so I will tell you what other troubles you would meet. So here is the second batch of difficulties: Ants are a pest, so that special hive-stands have to be constructed. These stands are of two parts—an upper part and a lower one, the upper section being placed upon iron supports, and the supports being covered with oil so

that the ants cannot climb them. As to the quality of the honey produced, aside from the algaroba honey, which comes in the summer, it is all vile stuff. Perhaps I had better say that it is the poorest grade of honey I ever saw. As to the market, prior to the war in Europe the honey went to Germany, but now there is no market for it, and at the present time the crop of the past season is in storage in Honolulu, and indications are that it is going to remain in storage for some time.

In my opinion the outlook for the honey-producers at the present time—well, it is not dark. The only word that will suffice

is *black*. What will the outcome be? Well, I am not bothering my head, neither should you fellows. You have troubles of your own.

As to local markets, there is a market here, and no doubt it could be greatly increased. As a matter of fact, people are at work, and honey in bottles has within the last few weeks been placed upon the market. The honey is bottled by a bottling company on the Pacific Coast, and the honey in the bottles is California honey. You see the Hawaiian honey is in storage awaiting the end of the war in Europe.

Honolulu, Hawaiian Islands.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sightings

BY H. H. ROOT

Did you ever stop to think that most photographs of an exhibit of honey show what looks to be more like an exhibit of ink? Even light-colored honey takes very dark, and a photograph of dark honey makes black ink look pale. The trouble is due to using the ordinary photographic plate on which to take the picture, and neglecting to use what is known as a filter. The average photographic plate and film is oversensitive to blue and violet, and under-sensitive to yellow and orange. This means that the plate does not record much reflected light from the yellow honey—not much more, in fact, than if it were black, hence the very dark appearance of the honey.

Panchromatic plates, on the other hand, are sensitive to all colors, as indicated by the name; and when used with the proper "filter" the true shade or tone of the color desired can be preserved. While I have not tried them, I believe that good orthochro-

matic plates would answer just as well for honey as the panchromatics.

The illustration shows four pictures of the same jar of honey, photographed and printed under exactly the same conditions, aside from the use of different plates and filters. The honey in the jar was very light—very light yellow, in fact—and it was placed on a pure-white card so that it would show as light as possible. Even under these favorable conditions, taking the picture on an ordinary plate (Seed 23) as shown in the first illustration made the honey appear like a dark amber. If the honey itself had really been an amber honey, this first picture would have shown the honey very dark—almost black. The second picture of the series was taken in exactly the same way, except that a panchromatic plate (Standard Panchromatic) was used. Notice that the honey appears a little lighter. The third picture was made with a panchromatic

Four pictures of the same jar of honey. No. 1.—Photographed on Seed 23 plate, no filter. No. 2.—Photographed on Panchromatic plate, no filter. No. 3.—Photographed on Panchromatic plate, K1 filter. No. 4.—Photographed on Panchromatic plate, K3 filter.

plate, but with a very light-yellow filter over the lens, known as the "K-1." The last picture was taken on a panchromatic plate with a "K-3" filter, which, as can be seen, has the effect of making the honey appear almost water-white. The "K-3" filter and the panchromatic plate is the right combination for average photographing of honey; but under very favorable circumstances where the honey is very light, and has a

white background, the "K-1" filter gives about the right tone. Beekeepers who own cameras might not be able to use just this combination, especially in case of film cameras; but if a photographer is employed, insist on his using a "K-3" filter and a panchromatic plate. Your picture will then look like your exhibit, and not like an exhibit of Carter's ink. Figures may not lie, but pictures can.

SOWING SWEET CLOVER WITH OATS

BY FRANK COVERDALE

1. I have a piece of land from which a corn crop was taken last fall. I wish to get it seeded to sweet clover as soon as possible. Will it do as well if sown with oats as if sown broadcast alone in the spring?

2. If sown alone will it be better to sow it without breaking up the ground in any way (ground being firm and quite even) or would it pay me to disk it and harrow once? I have to hire all work done, so if disking is not necessary it would be an advantage financially.

Granville, Mich. W. M. P. Jerrett.

Mr. Jerrett is located at Granville, Mich., where I rather think his land will not be so dry as to prevent him from getting a good growth. I would recommend making a test for acid, however. To do this, secure from a druggist a few sheets of litmus paper. Stick a spade three inches into moist surface soil; withdraw the blade and put in a sheet of litmus and press the soil tightly against the paper for ten minutes. After removal, if the litmus paper has turned pink, lime is needed for best results. However, if there is only a slight pink color on the paper it is possible to get along without the lime.

In either case, Early Champion oats is the best variety to seed with. Sow a third less than the usual seeding of oats. It is a pretty good plan to inoculate the seed. I prefer the glue and dust method when it is

done right. Select some soil three inches under the surface, where sweet clover has grown for years. Dry it in a cellar—not quite dry, but so it will pulverize nicely. Moisten the seed well with glue water that is just a little sticky when put between your finger and thumb. Mix thoroly, allowing all the dirt possible to hang to the seed. I have had the best results by sowing this inoculated seed by hand, because in this way the dirt sticks to the seed, whereas a seeder rubs and grinds it loose. None of the extras need be put on where sweet clover has been growing in late years. Do not allow the sunlight to strike the seed before covering.

Referring to the second question, it will pay Mr. Jerrett to make a seed-bed on the surface, cultivating it quite well, as the white sweet clover always makes a stronger growth on such prepared land. It is always the poorly cultivated as well as the corners that are missed that do the poorest.

If the soil cuts in well, one good harrowing will be sufficient. If not, double and harrow. It probably would not pay to plow unless the land is a tough sod. I always plow such fields with good results, and secure a good deal of seed or hay the first season.

If Mr. Jerrett should not want to disk or plow the ground I would advise sowing the seed in March just as the snow is going off. Delmar, Iowa.

TWO FORMS OF BEE PARALYSIS IN JAMAICA

BY C. N. EDDOWES

Having read two articles recently on the subject of paralysis in bees, the last by Mr. M. Y. Calcutt, page 990, Dec. 15, I was induced to take up the subject again. In an article on page 881, Dec. 1, 1913, will be found my experiments, and the results obtained by breeding to obtain stock immune to this disease. As Mr. Calcutt does not

give a full description of the appearance of the bees when suffering from paralysis, and as there will probably be a question whether paralysis in Jamaica is the same as that in the United States, I will give a full description of the bees as they appear when attacked by the disease here.

There are two forms of the disease, the

first being very fatal, and, so far as my experience goes, impossible to cure. In the second, the bees in some cases appear to recover without any external aid.

I will now proceed to describe the two forms. In the first, the abdomens of the bees are not distended; in fact, they are somewhat shrunken, and have a smooth sticky appearance, and are darker in color than healthy bees, and have the characteristic quivering of the wings and legs, but are able to fly to a certain extent. In consequence of this, the number of bees seen dead in front of the hives, and clustering on the grass, is not as great as in the second form, as the majority of the bees fly for a short distance before collapsing. In this form the drones are very often attacked, and sometimes, but rarely, the queen. In the second form, the bees' abdomens are greatly distended by accumulated feces. Their coloring and appearance, other than that of the trembling of the wings and legs, do not differ from that of a healthy bee. None of the bees are able to fly and crawl out of the hive and fall to the ground. In bad cases they cluster in bunches of from ten to thirty.

In neither form is there any sign of dysentery. Both these forms of disease have existed in Jamaica for a sufficient length of time for the native bees to have become to a very great extent immune; whereas the progeny of imported queens are generally

more or less susceptible. I am not able to say whether this disease is caused by the parasite *Nosema apis* or not, as I have not been able to have any bees examined, up to the present, but intend doing so as soon as possible.

As *Nosema apis* is known to affect bees in Brazil and the northern parts of South America, and the West India Islands, the probabilities are that *Nosema apis* is responsible for bee paralysis in Jamaica. There is, so far as I know, no cure.

In the second form of the disease mentioned in a former paragraph, where an apparent cure has been effected by the bees, it invariably breaks out again, and the colony eventually dies. Most commonly both forms are found in the same hive. It appears the only further help I can offer is to refer enquirers to the former article written by me. My subsequent experience since that article was written has justified my still adhering to my statement that the only cure for bee paralysis is to select and breed immune stock.

Half Way Tree, Jamaica, B. W. I.

[Instead of there being two forms of bee paralysis, we are inclined to think it is all one and the same disease under different stages of development. Possibly environment has a tendency to modify the form and the symptoms. See answer to Mr. Cox in this issue.—Ed.]

THE NEW BEE DISEASE AND AN ALLEGED SURE CURE FOR IT

BY ADAM A. CLARKE

I have been reading all the descriptions of what you call the new bee disease, in GLEANINGS for Jan. 15. I have also read the editor's comments on it, and will say that, in my opinion, he has not missed it far when he says it is only paralysis. I have had a good many cases of this disease the past ten years, and, like all the rest of the beekeepers who give a description of it, have found it hard to cure, for, if not treated successfully in the first stages, it will soon cause severe loss, for it not only destroys the colony but your chance for securing a crop of honey is at stake also.

I notice that our oldest experts in the business are at a loss to find or give a cure for it, but say that it will disappear with the advent of warm weather. This is partly true; but a good many colonies will also disappear before it warms up. I have no fear of it any more. I can treat it successfully, after trying everything recommend-

ed in all the bee literature I could get hold of, and, not getting any satisfactory results, I experimented according to my own ideas, and have hit the nail square on the head. It costs next to nothing to stop it. This is the cure:

As soon as you see the effects showing up in any colony, take common lime fresh slaked, and keep this all around the entrance of the affected colony, using some (fresh) every day. Be sure to get it on all the bunches of bees that get some distance away from the hive. Do not use too much lime at one time—just enough to kill all the sick bees and keep the entrance of the hive disinfected. In a few days there will be no more dead bees around the hive. Then I open the hive and note the conditions inside. If only a few bees and the queen are left I take them with the combs they are on, putting them in a fresh hive, leave them in the same place, at the same time giving

them a frame of hatching brood from some other colony. Thus I have not had it fail to cure. The rest of the combs I have used in any place in the yard, and have never seen any ill effects from using them thus.

If the disease is of long standing the combs have a very foul smell. They should first be exposed to the light and air, when, in a few days, they will have lost this smell, and are ready to use. I notice that where there are only a few bees left with the queen the brood hatched from the frame given them will soon supersede the queen;

so in severe cases the queen becomes weakened.

I hope that all readers of this the coming season will give it a trial; and if my directions are minutely carried out, there is no need of losing a single colony.

Le Mars, Ia.

[From what we have read of this disease in other localities we are not so sure that the lime treatment would be an infallible cure. It is worth trying, however, as it is so simple to apply.—ED.]

NOSEMA APIS, OR BEE PARALYSIS; A NEW WAY OF APPLYING THE SULPHUR CURE THAT SEEMS TO BE A SUCCESS

BY J. SAMUEL COX

On page 784, Oct. 1, I came across the following question: "Nosema apis, Bee Paralysis, or what?" and reading the subject following I was surprised to see that, altho far away in another country, I am not alone, but like those who have suffered and are suffering. Altho I am not altogether out of the woods I can safely say, "Thank you, that the worst is over, for my workers are no longer dying as heretofore by this strange disease. On the contrary, all my weak colonies are getting strong again, from many of which I am now extracting a full-depth super of honey, and, from a few others, two. The only thing I have not yet got rid of altogether is the dying of the brood; but even this I have reduced to about 5 per cent, and I am confident in a very short time I shall get rid of the disease entirely."

According to descriptions given, my apiary has suffered from the same thing, and I can confidently say that the brood of this apiary has not died either from neglect or starvation; for as soon as I noticed this dying of the bees I made a general examination of all my colonies; and while some were greatly reduced in bees, the majority were still crowded with busy workers; and even among these very strong ones the dead larvæ and some brood were found in some combs more than others. Just a little before this a light flow started, and the bees were working fairly well, inasmuch that, when I first saw the bees crawling on the ground in the morning, I concluded that they had come home laden with honey and had fallen on the ground; and as my hives are about 6 or 7 inches from the ground I got strips of board cut to convenient lengths and leaned them up from the ground to the alighting-board; but none of the bees would

go up or showed the least desire to return to their hives.

I do not remember exactly what date I first noticed this dying of workers; but some time about the last week of June I noticed here and there a few bunches of dead bees which increased daily until the ground of the entire apiary was nearly covered.

Seeing the victims crawling on the ground much the same as with paralysis, I was inclined to think it was that disease. Altho I have had to do with that disease several times years ago, I have never seen such a scourge among bees as I was then having in all my beekeeping days; for surely if I had not found a cure, this apiary must have been wiped out ere this.

I went from hive to hive, watching the entrance to see the bees taking out their sick ones, but never could I see any. It seemed as if as soon as they felt sick they rushed out, and, not being able to fly, dropped and walked around until they died.

I examined the brood-nests, and found several greatly reduced in bees; and in some colonies I found one or two combs with dead larvæ here and there; in others, more; but these dead larvæ were not confined to weak colonies alone, for even among the strong ones, upon examination of these larvæ, not the slightest sign of ropiness was visible. When pierced with a pin a liquid of a light brown color would drop out as freely as a drop of water. This color was not confined to all, but each had its own, according to age. The larvæ of about four to six days are perfectly white. In some frames I found the larvæ were perfectly dry, and did not stick on to any part of their cells, as they would shake in the cells if the frame was shaken.

Seeing the bees dying out so rapidly I

thought the best thing to do was to try to find a remedy as soon as possible. Remembering that sulphur is good in case of paralysis I resolved at once to give it a trial. I looked up the A B C and X Y Z, and this encouraged me to give the sulphur a trial. I concluded, however, that, as sprinkling the combs is injurious to the larvæ, I would try another plan. Accordingly, I opened the hives and took out all affected brood, and gave full sheets of foundation in their place. I sprinkled on top of the frames of the brood-nest a mixture of honey, sulphur, and water, putting enough honey to sweeten, so that the bees would feed on it readily, and for the further reason that the bees that do not leave the hive had indoor feed. I also gave them a general open-air feeding of this same mixture every day for two weeks. This, for two reasons, they did not seem to notice for a whole day. First, I put in enough sulphur to give the feed a slight smell. This in a measure destroyed the honey odor. Second, as already stated, there was a light honey-flow on, especially in the morning, and all beekeepers know that bees work more readily on nectar than anything else. After a few days, however, they drank up all that was given each day. This worked with great success, for at the termination of a week the death-rate was greatly reduced, and in three weeks not a bee was seen bumping about, ready to die.

The curing of the dead larvæ is the most difficult, for even in the new frames I had given were found later on the same dead larvæ here and there. The only cure I have

found for this is to give each colony a new and vigorous queen.

Guayama, Porto Rico.

[There have been numerous reports to the effect that sulphur in some form or other has not only helped but in some cases cured the peculiar disease known under various names such as *Nosema apis*, bee paralysis, Isle of Wight disease, etc. Mr. O. O. Poppleton, of Florida, a conservative and careful beekeeper, and who has had a very large experience with bee paralysis, stated that powdered sulphur sprinkled on the combs and bees would effect a cure; but the process is rather slow. Sulphur is a well-known antiseptic, and we see no reason why it might not effect a cure if applied in the manner described by Mr. Cox.

The disease has been so rampant and destructive in some parts of the world that we can well afford to grasp at every straw, especially as the reports regarding the use of sulphur as a cure have been favorable.

This fact also lends color to the theory that the Isle of Wight disease, *Nosema apis*, and bee paralysis are all one and the same thing, but modified by environment and the peculiarities of the season. In damp climates and in damp seasons, and particularly in tropical climates, this three-in-one disease, if we may so call it, is much worse than when it breaks out in localities further north in a dry atmosphere.

Taking it all in all, we would request our readers to try out Mr. Cox's remedy; and if that fails, try out the one recommended by Mr. Clarke.—Ed.]

MY FIRST SEASON'S EXPERIENCE AS A BEEKEEPER

BY DR. A. P. BETTS

In April, 1915, I bought twenty colonies of bees from one Joseph Smith, a veteran beekeeper. The colonies were in eight-frame hives and in good condition. Smith had 160 colonies, and sold me a score of them for \$100, because he said he had more than he wanted.

I had never opened a hive nor hived a swarm nor seen a queen or a frame of brood. I told him just how things were, and he said I was "taking a pretty big contract," but if I wanted the bees he would take my money. "But, honest, Doc, I would advise you to take two or three colonies for the first year."

I gave Smith his money, and said I would take my chance, and that all I ever got was by doing something that some one else could not do. So he brought over the bees in a

spring wagon, twelve miles. It was very early in the morning of April 24, 1915. I remember it very distinctly. The day was clear and warm. Smith helped me set the bees in place, gave them a little smoke from his own pipe, and took the screens from the entrances. He chatted awhile, and then drove off.

Just before leaving he turned his head and said that if I needed any help I should let him know, and he would help me all he could. I thought I saw a flicker of a smile on his face as he drove away. Now, if there is anything more than another that put "pep" into me it was that grin on Smith's face. I think it was worth more than money to me as the months went by. Whenever a difficulty arose or a new problem had to be solved, when I was almost at my wits' end,

there was Joe's face with that incredulous smile.

The stimulating effect was wonderful. I bought all the bee journals and books about bees that I thought would help me and read them on every occasion that I had time. As this article is principally for the benefit of amateurs and not for the amusement of the professionals, I will speak of some of the difficulties to be overcome.

When Joe left I put on my veil and gloves and sat down to think it over. The warm sun came out, so did the bees. I didn't think we could buy so many for \$100. They made me think of a lot of Indians that I once met on the plains. They were about as careless with their weapons. The first thing I did was to open a hive. It looked very interesting to me. There were three or four frames of brood, but at that time I could not understand what all that brown capping meant until I opened several.

There were many little burrs of comb between the frames which I decided to clean off. Cleanliness is next to godliness, so in the next day or two I cleaned up the rest of the hives. Here is where I made my first mistake, for in my tinkering I lost four queens as I afterward discovered.

As I intended to run my apiary for comb honey the swarming question was all the more absorbing for me. I concluded to try the Alexander plan of increase on the sixteen remaining colonies. This was my second mistake. It afterward turned out, how-

ever, that it was a good thing I did it, for the season was poor for June honey, and I got the increase but no June honey. There was no swarming to speak of in the sixteen colonies divided nor in the increase, but those four colonies with queen-cells were surely a caution. In the future, when I need a queen for increase or any other purpose I will buy a laying one. It is more economical and less bother, especially when they can be bought for 50 or 75 cts.

In a good fall flow the bees got enough for winter (all except a few which I united in the fall), and a fair surplus for a beginner, considering the season and other things.

The honey sold at 15 cents per pound. Adding the value of this to the value of increase at \$5.00 per colony, deducting \$12.00 for Italian queens, and not counting my time, I have made \$3.40 each, or \$68, on the twenty colonies, and a world of experience which money can't buy. The \$100 at interest would bring me only \$6.00. To sum up, I think I made a good investment, especially when one considers that I now have thirty good colonies in the cellar, which are wintering well.

In the future I shall run for extracted honey. I believe that, with the help of Joe's grin (which still haunts me), and the A B C and X Y Z, and Miller and Alexander and several journals, I may give a good account of myself and the bees this coming summer.

Wauseon, Ohio.

MAKING FRAMES EASIER OF ACCESS

BY L. E. KERR

Some of the most pleasant hours in all my beekeeping experience have been spent in working over new problems in hive construction. Langstroth did not expect others to work out all the fine points of removable frames; tho, as yet, the best of them at times come remarkably near being unmovable.

In an apiary of no more than a few colonies one soon learns to realize the difference in the way frames loosen from the various hives. One of the very first colonies that I ever owned was in a home-made telescopic hive the frames of which could be removed far more readily than those of the much lauded factory-made hive of today. Tho having ever since considered, more or less, a means of adapting its unusual frame rests to a cheaper and simpler hive, no entirely satisfactory solution has been forthcoming, and it is here submitted to the beekeeping public in hopes that an-

other may show how a plain (or at least plainer) hive may be so provided.

Upon this rabbit the frames are raised above the hive-ends, tho not necessarily the sides. As the cut plainly illustrates, frames are consequently tenfold more easy of access.

Supering with the rabbit shown is more complicated, and has, so far, been accomplished by substituting $\frac{1}{4}$ -inch wooden rests for the customary flat tins.

Fort Smith, Ark.

Heads of Grain From Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Mother says it is all right to give rye flour and oatmeal for pollen in the early spring, but if it is for the baby bees it ought to be pasteurized.

How the Climate of Florida Differs from that of California.

I have been reading your articles in *Gleanings*, and have been especially interested in what you say regarding Florida. Will you kindly write me a line, stating how southern Florida compares with California as to climate and fruit and vegetable products in your estimation, as I understand you have been in both places?

Chicago, Ill.

D. Zinser.

[In a general way the climate of Florida is a little warmer, taking the state as a whole, than that of California. California will have any climate you desire, either by going northward up the state, or by going up into the mountains. Florida, on the other hand, is comparatively level; and the fact that it is surrounded by water makes the climate very moist or humid. Those persons who cannot very well stand dampness, especially nights and mornings, would find that the Florida climate would not be adapted to their conditions.

In Florida, for example, if a sheet or clothing of any sort is left out on a line over night it will be dripping wet by morning. Of course, this is not invariably so, but is very apt to be so during the dryer part of the year when the dews and fogs are very heavy.

In California the climate is comparatively dry; and while it does not get so warm as it does in Florida, the temperature of southern California, at least, is more uniform. There are certain kinds of fruit and other vegetation that can be grown in Florida that cannot be grown in California, and the reverse is also true.

When we speak of California we must remember that it is large enough to comprise the area of several ordinary states in the East, so that everything depends upon what is meant when we speak of California. The territory, say fifty miles north of Los Angeles and down to San Diego, comprises the warmer part of the state, and is a good deal like that in Florida, with the difference that it is dry, and more uniform from one year's end to the other. Both states have rainy seasons. Central and northern California is more like Georgia and Alabama. It would pay you to go to Florida, at least, and spend a month or so, and then go to California. You can then better decide which state suits you best.—Ed.]

Shall a Successful Farmer Give up Farming and Go into Beekeeping on a Large Scale?

I am seeking a little advice; and as you know of the possibilities of beekeeping I want to ask you if you think from a financial standpoint a young man can do as well as to engage in general farming. Men who bought land 10 to 15 years ago have made considerable thru increase in land values; but any desirable land here is from \$100 to \$150 per acre, and I question as much of an increase in the future.

I am married—have three children; am 34 years old; weigh 135 lbs.; have \$2100 on interest and \$1200 worth of stock and machinery. I sold my farm last spring and am renting at present. I have 40 colonies of bees and a good location, and there are several good unoccupied places for outyards.

I am naturally a good beekeeper, I believe, and have been fairly successful with my bees, but have always been rushed for time on account of farmwork. I love a farm and outdoor life, and enjoy the beework better than any other; but my duty to my family is to follow the course which will give them the best opportunities.

I have a chance to buy the 50 acres, good soil I am renting one mile from town (my home town) for \$7500; \$2000 down, long time on balance. Now, of course, I know it will take a good many years to pay for this; but I could do it, tho it would mean a great deal of heavy work at times. We are hustlers, all of us; and as my boy will probably not be large he will be a better help in the apiary than on a dairy farm. We are good savers; and, altho we aren't as husky as a farmer and his family should be, we are

contemplating buying this; but if we can do as well with more bees, we may extend our bee operations and buy a smaller home.

Kilbourn, Wis. H. W. Loomis.

[Your question is a hard one to answer, as so much depends on your locality, your farm, yourself, as well as the members of the family. Generally speaking, we would say that, if one has made a success of farming, he had better stick to it. In any event, we would not advocate a radical change all at once. In your case we would advise you to continue on in your farming on your rented farm where you are, gradually expanding your beekeeping operations. This you can do without very great expense by taking bees on shares, and managing a series of outyards. In that way you will secure a certain amount of increase and some honey. Operate this way for two or three years, hiring the work done on the farm, but be sure you keep a direct supervision over all the work done.]

Our belief is that the right kind of man in a good locality will make more money by keeping bees than by running a small farm. A fifty-acre farm intensively operated can be made to yield large returns; but as a general thing the average farmer seems to think he must have a hundred acres.

If you have an eye to going into beekeeping some time, continue making increase until you can get all you can handle; but you should not have less than 400 or 500 colonies; and if you operate more than this number you will probably have to hire help a part of the year. Everything will depend on you, your locality, the character of your soil, and whether you keep abreast with the times.

If you have growing boys who are enthusiastic with you, you will have a big advantage; but if you have to hire all your help, and that help is incompetent and high-priced, you will have to confine your operations down to what you can do yourself. In that case, a fifty-acre farm or 400 or 500 colonies will be all you can handle. You cannot very well work more than 100 colonies in connection with a fifty-acre farm, and then you would have to have pretty good help from your boys, your wife, and your daughters.

No one can succeed in either line of business unless he takes several papers relating to those lines, and carefully planning so that there will be no waste movements. After you have read up, unlimited patience will be essential, because your full returns will not be forthcoming the first season nor perhaps for several seasons.—Ed.]

Is It Necessary to have an Inspector's Certificate on Every Package?

I wish to make some inquiries about shipping bees. Our agent of the express company tells me that I cannot in the future ship any bees unless they are inspected by an inspector, and each shipment is accom-

panied by the inspector's certificate. We have no foul-brood law nor inspector in Maine. I have in the past had quite a large trade in bees from Massachusetts. According to his statement, as there is no inspector near, if I have to get that on every shipment, my bee-trade is entirely cut off.

J. B. Mason.

Mechanic Falls, Me., Feb. 23.

[While it is true there is no bee-inspection law in Maine, and while it is true you do not need any inspection card, or certificate of inspection, for shipments of bees in Maine and a great many states of the Union, yet you do need such certificates for states like Massachusetts that have rigid bee-inspection laws. As a general precaution it is wise to have such a certificate go out with every package of bees.]

In your case you are placed in an embarrassing position for the simple reason that you have no inspector who can furnish you with the necessary statement. We don't know what you can do except to get a foul-brood law before your legislature and get it passed. It will be difficult for you to get a large appropriation the first year. If you asked for a mere nominal appropriation and then had some one appointed inspector who could inspect your bees you would then be able to send out a certificate like all the other bee-raisers of the country.—Ed.]

Feeding by Filling Combs with Syrup

Last fall I had the same experience that many other beemen had. In mid-summer I removed all the honey from my bees that I could get, and extracted it, expecting my bees to gather enough more from the fall flow to run them thru the winter; but on account of the incessant rain the fall flow failed to materialize, and so I had to buy barrels of sugar and go to feeding.

I used the Boardman entrance feeder, and had considerable trouble because of robbing. Perhaps I was a little careless, however. I wondered why I could not put the syrup in the comb for the bees. Therefore I got one of my extracting bodies and frames which had the empty comb in. I then melted the sugar and made a thin syrup. I took the frame of empty comb and laid it flat and poured the comb full of the syrup. I then turned it over and held the comb at an angle of about 45 degrees, and poured the other side full. I filled as many of these frames as I wanted a colony to have, put them in the extracting-body, and set the body on the hive.

On examination I discovered that some of the colonies had scarcely any honey at all. When I found a colony in such a condition I would lift out an empty frame from their brood-chamber and put in one or more frames filled with syrup. My bees up to date are all healthy and strong; and if they continue to do so well I shall keep up this method of feeding for the young brood.

Brookville, Ind. Darlie M. Hanna.

Form for Putting Starters in Sections

Some one else may have a form for putting in starters like the one I use, but I have never seen any mention of it. I have a rack as shown in the illustration, which holds four sections at a time, and which has spacing-blocks which center the foundation at exactly the right place.

The thumbscrew at each end of the rack holds the four sections tightly together so that they may be slung up or down on the hinges, and then when the melted wax is applied to one side of the foundation four sections may be swung around so that the wax may be applied to the other side if desired.

Cabot, Pa. Wm. F. Ebert.

How Much Sugar Does It Take to Make a Pound of Bees?

Can you tell me about how many pounds of sugar it takes to make a pound of bees?

Isn't there a better way to hold Benton cages together in mailing queens than tying with twine? Wouldn't a paper tape such as you use to fasten the metal-spacer boxes together hold them?

Mayhew, Miss. D. D. Stover.

[We have no accurate data. The nearest we have is the work done by Mr. W. A. Selser. He made the statement based on some experiments he made, that it took about \$2.00 worth of sugar to make a colony of bees. By colony he probably meant it would have four or five frames of brood, and possibly three pounds of bees. This \$2.00 worth of sugar was based on the valuation of sugar before the war came, or about \$5.65. The brood would be equal, probably, to two pounds of bees more if it were all allowed to hatch out, and this would make five pounds of bees for \$2.00 worth of sugar.]

We do not know of any better way to hold mailing-cages together than by the use of strong string. If you nail little wooden cleats along the end they are liable to split, and one of the cages lose out. We have had some trouble where the cages were held together by little wooden strips and the nail driven thru into each cage.—Ed.]

Does It Pay to Feed in the Spring?

In reading "Fifty Years among the Bees" I conclude that Dr. Miller's location is very much like my own—that is, his honey sources are about the same, with the exception of cucumber bloom which he has from the fields of the growers for the pickle-factories. He is two degrees north of me, or about 150 miles, which makes his season a little shorter and a little later in the spring.

I wish to ask him if he believes it pays to stimulate bees between fruit bloom and white clover—that is, feed a little every day, no matter whether the bees have plenty of stores or not. If his location is like mine there is nothing yielding honey then except dandelion, and I have always practiced feeding at that time; but I am doubtful if I am any the winner for it. My doubts are aroused by other bees in the neighborhood being about as strong as mine without the feeding. Of course, if the bees were short of stores they would need to be fed. Would it be best to feed in that case a little at a time or a big feed all at once?

Sabetha, Kan. Frank Hill.

[Dr. Miller replies:]

In a locality where there is a dearth so long that the queen stops laying entirely, it is important, not only that the bees shall have on hand a good store of supplies, but that they be fed every day or two. The break between fruit-bloom and clover, at least in this locality, is not enough to stop the queen laying, provided abundant stores are in the hive, and I don't believe anything would be gained by frequent feeding. Of course, any shortage should be supplied; but it is just as well to give it at one time.

An Unusually Good Report from a City Apiary

I began with five colonies. I have sold honey to the value of \$45.75. Honey for home use, \$20.00. Sold the increase for \$20.00. Total income for the season, \$85.75. Expenditure was \$20.00. Net gain, \$65.75, or \$13.05 per colony, spring count, and this on a city lot 40 feet wide.

Des Moines, Ia. R. R. C. Grantham.

[Lest some beginner should think that such a record is always possible, perhaps we should add that Mr. Grantham has gone far beyond the average, almost the record, we should say, from a city apiary.—Ed.]

The First Flight in the Midst of a High Wind.

My bees had their first flight January 21: and because of a very strong south wind many of them were unable to get back to the hive, and so were chilled to death. The ground in front of each hive was covered. There are about forty hives in my apiary, so you can see the loss was great.

Sheldon, Ill., Feb. 11. C. L. McNealy.

Honey Necessary even for Prepared Paste

I see by *Stray Straws* that Dr. Miller has trouble in making labels stay on 5-lb. pails. A home-made paste with a little honey added will make it stick, but it will sour and mold under the label, and so is not very satisfactory.

The best thing I have found so far is a paste made by the National Can Co., which is made for labels, and which they say will stick to tin; but it would not always stick for me, however, until I added a little honey to it. It will not sour or mold, even after the honey is added, and will always stay. About a tablespoonful of honey is added, and if, upon trial, it will not stick, a little more honey is added. To make a label that goes half way around a can stick is a different proposition from one that goes all the way around, and the ends lap, or a label on glass when almost anything will stick.

Grosvenordale, Ct. Ernest Ryant.

A Good Paste for Labeling Tin

To make one cup of paste, melt a piece of glue about the size of a medium hazlenut, or two white beans. Next stir in a large tablespoonful of wheat flour. Mix in cold water, then bring it to a boil and stir. We never had this fail or come off. But if too much glue is used the label will get stiff and peel off.

The greatest tool ever used to clean frames, hives, and sections, is Dr. Miller's large overgrown putty-knife, or piece of a handsaw, two to three inches wide. But I have been waiting ten or fifteen years for some one to tell how to sharpen the edge. The old shoemaker's way of dulling his steel for scraping soles is simply to put it in the vise and rub the edge heavily until the corners turn over, making a flatter edge. It works best in cool weather. This tool will keep right on to the wood, and will plane the very varnish off, and will not lead into the wood. Try it.

Listowel, Ont., Can. C. Mitchell.

Another Paste for Labeling Tin

To make paste sufficient for 30 or 40 labels, take about four tablespoonfuls of cold water, a small pinch of saleratus, and a lump of laundry starch about the size of a large walnut, and dissolve them together; then put them on the stove and cook to a paste. Use paste while warm, and you will have no trouble about labels coming off.

Ticonderoga, N. Y. George H. Adkins.

Wash the Tin with Soda

Tell your readers that they will have no trouble having labels stick to tin if they will first wash the tin with strong soda water, and then use good mucilage.

Forkville, Pa. W. L. Norton.

94 Pounds Per

Mrs. Allen, page 969, Dec. 1, 1915, speaks of the average yield per colony in North Carolina being very low, and the quality being nothing to boast of. Yes, that is the general cry; but I think I did pretty well for a poor season. I got an average yield of 94 lbs. per colony of honey that sold for 18 and 20 cents per lb. (this was comb honey) and an increase of a little over 57 per cent. Our main honey-flow, the sourwood, was a complete failure.

Hazel V. Boukemyer.

Randleman, N. C.

Blessing in Disguise, after All

I had muscular rheumatism in my right leg and arm, and so much that for two years I took electric treatments. My trouble would come and go—come so hard sometimes that I limped when walking, and my shoulder would ache so that I could not sleep nights.

The first year I had bees I was not troubled so much, the second year less, and so on until now for over two years I have had no trouble with it at all. I think that the stinging of the bees counteracted the poison that was in my system—any way, it is gone, and I assure you I had plenty of stings to do it, for the bees certainly got at me in good shape.

Rutland, Vt.

J. H. Davenport.

Eucalyptus Tempting even in Bad Weather

My bees have been carrying in both honey and pollen every bright day all autumn and winter, and they even fly out into the rain and try to work, as a number of eucalyptus-trees are in bloom, and it is a great temptation to them. I am sure that I am losing quite a number from this cause, but see no way of preventing it. I can catch the odor of new honey when near the hives.

Millbrae, Cal.

W. O. Graeber.

A Prayer

My Father, I thank thee for this day
Wherein a task was set for me,
That I might labor, and in my way
Share the blessings sent by thee.

My work may seem quite humble, Lord,
To those who do not understand;
For I care not for worldly hoard,
Nor noted fame throughout the land.

O Father! I'm content with these—
My simple home, my garden-plot,
And daily care I give my bees—
Dear Lord, I thank thee for my lot.
Elsa Rosalind Howell.

Indianapolis, Ind.

[This prayer was written by a little girl and was sent to *Gleanings* by Walter S. Powder. We are very glad to give it a place here.—Ed.]

OUR HOMES

Editor

EVOLUTION AND THE HONEYBEE; SOMETHING FROM ONE WHO IS NOT A BEEKEEPER.

As a rule I do not think it best to give very much space to theories in place of practice; but the following kind letter from one who has never kept bees commends itself, as it brings before us once more matters so much discussed years ago when the Dzierzon theory first came out.

The writer is nearly 55 years young, and has preached the gospel 36 years. Early in life he heard in New Zealand a course of lectures on "World-making," by a noted scientist. He saw them ably reviewed. I have ever kept an open mind, adopting the following as a principle of action in life:

Listen, read—not to contradict or confute, nor to believe and take for granted, but to weigh and consider.

I have occasionally seen GLEANINGS. Yesterday I ate with a beeman. Of course we talked bees, read some after you, and, as usual, liked you for your writings. I decided to write to you. You can set me right if I am wrong. Assure me in my belief if I am right. I am interested in my problem because of its far-reaching meaning, as it touches the problem of the universe, of man and destiny.

I put it in the following form as the plainest and simplest one I know.

1. Bees are of three kinds—father bees, mother bees, and worker bees. (I do not pretend this to be accurate, but only for the purpose of this problem.)

2. Neither parent bee ever makes cells or gathers honey. (Is this quite true?)

3. Those which make cells and gather honey never become parents of young bees.

4. As those who have had experience in the work of making cells and honey never become parents, whatever experience they may acquire is lost in their death. It is never transmitted, there being no offspring from them.

5. Father bees, mother bees, parent bees, having no experience in making cells and gathering honey cannot transmit to their offspring what they have not got. What they do transmit is natural, not acquired.

6. The first bees that ever were must have had just as much ability as the present generations.

7. The first bees must have been created, and so the evolution of bees is impossible.

8. If these premises are correct, then this is a clear fact in nature, unaccounted for by the hypothesis of evolution; for then the bee must have been a direct creation.

My question now addressed to you as an expert beeman is to know whether it is true that the parent bees never work, never make cells, and never gather honey.

In other words, is it true that the transmission of acquired tendencies is impossible?

In asking you for a reply I am not looking for an extended letter. I know you are busy; but a few words from you will be very gratefully received. This I ask in a private letter rather than in your paper. I see GLEANINGS but rarely, not being myself a beeman. H. GOODACRE.

Wolcott, Ind., July 26.

After reading the letter I submitted it to Ernest, who advised sending it to Dr. Miller, and asking for his reply. Below is Dr. Miller's answer:

The drones do no work of any kind in the hive, neither do they gather anything outside. The same

is true of the queen, except that she lays eggs. That is her sole function. So it is quite true that "the parent bees never work, never make cells, nor gather honey," with one slight exception. It happens in rare cases that a worker lays eggs, which never produce anything but drones, in which case that parent does all the work that any worker does. Yet that can hardly be said to have any bearing on the case, since practically that laying worker has no progeny, and so can transmit nothing.

So, on the face of it it would seem according to reason to conclude that the parent bees, having no experience in the work of the hive, can transmit nothing different from what they received from their parents, and that "the first bees that ever were must have had just as much ability as the present generation," or, in other words, that all honeybees to-day are exactly the same as the first bees, and that all are exactly alike.

Against any such reasoning, however, stands the very troublesome fact that bees are not by any means alike, and that there is just as much difference among bees as among folks. They differ in temper, in color, in habits, in diligence—in fact, name any difference that may be between two members of the human family, and it is likely that a difference in the same respect may be found among bees. Moreover, that difference is transmitted. Rear queens from the queen of a very cross colony, and you will have cross colonies resulting. So with other traits.

So against the *theory* that a queen cannot transmit, we have the *fact* that she *does* transmit.

Not being a scientist, but only a practical beekeeper, it might seem presumptuous in me to attempt to explain how a parent can transmit something that apparently is possessed only by her children. But there is no law against giving my guess. Take the one matter of temper. A colony may be so irritated by rough treatment or in some other way as to become very cross. Is it beyond belief that the queen may share that same irritable feeling, and transmit it not only to her worker progeny but also to her royal offspring? If that be true, then it may also be true that if any change takes place among the workers, that change may in some subtle way have such an influence upon the queen that a trait acquired by the workers of her colony may be transmitted by her to her royal offspring.

I am inclined to the belief that the first colony of bees was a direct creation, but it can hardly be proven in the manner suggested.

Is any of this of practical importance? Surely—of vast importance to the practical beekeeper. The beekeeper who believes no acquired trait can be transmitted by the queen will make no effort to improve his stock, although, strangely enough, he may thoroughly believe that bees will "run out." The one who believes that the queen can transmit acquired as well as inherited traits, good as well as bad, will be making constant improvement in his bees, and his slogan will be, "Breed from the best."

Marengo, Ill.

C. C. MILLER.

I am not sure that I entirely agree with my good friend Dr. Miller—for instance, in regard to cross bees. A colony that is handled almost every day, and properly handled, will, I feel sure, become so accustomed to it that they take it as a matter of course, and after awhile they will hardly stop work. In fact, the queen will keep right on laying. But take an apiary that

has been neglected, even though it has good movable-comb hives, and if you try to open it without smoke you will have trouble, and perhaps trouble even with smoke. I appeal to beekeepers as to whether I am right or not. And I have been of the opinion that queens do not transmit irritability. At one of our Chautauqua gatherings a speaker of note said that mankind transmits physical qualities but not mental; and he gave some pretty strong facts to support his assertion. Our great inventors and men of great education are frequently from parents who have shown no great mental powers in either direction. He asked us if this was not true. This hits on the old question as to whether it is environment or inherited tendencies that make a man good or bad. We can do very much, and the whole wide world is doing much, to help environment; but we cannot very well help the other *after* people are born.

=====

SHALL THE UNITED STATES INVEST MILLIONS
IN ANTICIPATION OF WAR?

On page 42, January 1, I said I *might* change my mind in regard to the above; but at this date, March 1, I have not changed it, and I have done a great amount of reading in order to keep fully posted. I hope every one of our readers will have a chance to read Henry Ford's articles which he is to have placed in the advertising columns of many periodicals.

We clip below from the *New York Evening Journal*:

The very men who pile up the armament of all nations—and it is true that the same firm will often arm both sides in a conflict—will find an enemy for any country they arm. And they will arm that enemy, too, for the profits on arms are great, and the industry is a monopoly.

We ought to realize that it is the people who not only pay the bills of these munitions makers, but pay the penalty also in the death and misery the use of these arms must bring.

The following from the *New York Times* of February 9, printed prominently by the *Times*, but not conspicuously treated by the great majority of city newspapers, give some idea of the facts:

WASHINGTON, February 8.—Testimony that pleased the pacifist element in the House was furnished to the Committees on Military and Naval Affairs today by General Nelson A. Miles, U. S. A., retired, and Rear Admiral Victor Blue, Chief of the Bureau of Navigation. General Miles said he did not fear an invasion of the United States, and that an invader Admiral Blue declared the navy was now ready to meet any enemy it might be called upon to encounter in the Pacific.

I am having this statement printed in the advertising columns of newspapers and magazines throughout the United States. Others will follow. I have no other purpose than to save America from bloodshed and its young men from conscription. I feel that if this militaristic burden is assumed by the country, the United States within ten years will be

in turmoil, its industries paralyzed, and its men, instead of being at work in peaceful industry, will be dying in trenches. And I feel, too, that these men will not be dying to defend their country, as we are now being told, but will perish in the conquest of other men who have a right to live in happiness and peace.

I am hoping and praying that Henry Ford and Billy Sunday may get in touch, and that God may be enabled to use *both* in hastening "the coming of his kingdom."

So good an authority as Prof. Harvey W. Wiley has the following in *Good Horse-keeping* for March, in regard to saving life instead of taking it:

Do we really want to live? As I mingle with my fellow-men I begin to doubt it. Our conversation is of war, commerce, society, music, clothes, athletics, Congress, preparedness, taxation, occasionally of books, and once in a long while of life. That which is dearest to us we apparently think least about. Where one man is studying how to prolong life, thousands are seeking means to put a speedy end to it. The advisory committee to the Secretary of the Navy has suggested building a laboratory costing five million dollars, and equipping and manning it, which would probably take about as much more. Its purpose is to study the best methods of killing our fellow-men from other countries, and preventing our own sailors and citizens from being killed. I am not inclined to protest against this action, but merely to ask, What of guarding against disease and preventing the half-million of preventable deaths every year? Who will provide the five million dollars for that? Ten dollars used for prevention will save a life.

God hasten the time when the whole wide world shall discover how much better it is to *preserve* life than to destroy it; and not only physical life, but the kind the dear Savior had in mind when he said, "I am come that they might have life, and that they might have it more abundantly."—
JOHN 10:10.

PREPAREDNESS; BRYAN SUGGESTS MILLIONS
FOR GOOD ROADS INSTEAD OF MILLIONS FOR
MUNITIONS.

The following, clipped from the *Times-Union*, is a part of Bryan's address delivered at Tallahassee, Feb. 29.

Scoring those preparedness advocates who think the country must spend billions upon billions immediately, Mr. Bryan said: "There are two organizations in this country which together claim a monopoly on all the patriotism of the nation. They have taken upon themselves the task of getting the country ready for war. The Security League says, spend three hundred millions a year on the navy and one hundred and fifty millions on the army. The Navy League is older, has more ciphers at its disposal, and had the advantage of making its bid after the bid of the other had been known. It insists that five hundred million is necessary for the army each year, and that a standing army of one million men is an absolute necessity. This program would cost about \$750,000,000 yearly.

"If we are so near war, as the jingoes claim, then let us get ready by preparing our roads. Get them in condition so we can transport our armies from one place to another without delay. It will greatly increase our defensive power by being able to mo-

hilitze quickly and transport it rapidly to the point threatened. And there is an advantage about this kind of preparedness; if, after we have prepared ourselves and the war does not come, we shall be able to make good use of the preparation on the work of production. If, however, we divert the money from useful channels and spend it all on battleships and arms and ammunition, we shall have wasted our money if the war does not come; and if it does come, chances are that before it comes changes in warfare will very much reduce the value of preparations in which we have invested.

"We cannot single out a nation and begin to prepare to fight it without cultivating unfriendliness toward that nation, and we cannot make hatred a nation's policy for a generation without having our people anxious to fight as soon as they are ready to fight. If the nations at war had spent in the cultivation of friendship but a small percentage of the amount they have spent in stirring up hatred, there would be no war in Europe today. We should not transplant upon American soil this tree of hatred unless we are prepared to eat of the fruits of the tree, for it has been bearing its bloody fruit thruout the years."

WAR, WHAT IS IT?

Years ago, when I had one of the first automobiles built, down in southern Ohio, while on the road away from any town, my machine suddenly gave out. A thunderstorm was coming on. There was neither time nor place, even if I had the tools, to take the machine to pieces and find the trouble. A heavy peal of thunder reminded me something would have to be done, and that quickly. My little prayer, "Lord, help," welled up of itself. Then I discovered the machine would go backward, even if it would not go forward. By going backward I got into a nearby town and in the shelter of a blacksmith shop just as the big drops began to patter on the roof. There was no repair shop in the town, and the blacksmith said there was only one man in the village who could tackle a disabled automobile, and he had just gathered up his tools and gone down to catch a train to take him back to his home in Columbus. Somebody lent me an umbrella and I caught the man just as he was stepping on the train. He and his brother went back to the blacksmith shop, pulled my machine all to pieces, found the break, and put it in order. You may be sure I thanked the great Father for helping me to get under shelter just in the nick of time, and then again to secure the only competent mechanic just in time—the man who *happened* to be there just by accident.

But what has all of this to do with our present war? Well, just this: It illustrates how important it is to find some one just in the nick of time, a skilled expert, if you choose, in mechanical work, especially for a stranger in a strange land. What a boon to humanity it is to run across ex-

perts, even mechanics! Now try to think how much greater it is to be able to get experienced surgeons and physicians, when the human machine happens to be suddenly marred or thrown out of commission. The Red Cross organization is now trying to place skilled doctors where human beings are torn and lacerated in this wicked war. A little pamphlet comes through the mails entitled "Wounded. By Arnold Bennett;" and to give you a better understanding than you have had before of what *war is*, I am going to make some extracts.

The primary object of this war and of all wars is to lacerate human flesh, to break bones, to inflict torture, to paralyze, and to kill. Every army in the field to-day is out for maiming and homicide, and nothing else.

We do not see a thousand prisoners led away in despair, nor a thousand decaying corpses lying in strange, contorted attitudes on the ground, nor eight thousand tortured, bleeding men, whose torn and pierced bodies have in a few moments exuded hogsheads of blood. You protest that I ought not to use such a phrase as "hogsheads of blood"—it sickens you. And why should you not be sickened? Those hogsheads of blood, lacerated limbs, smashed bones, glazing eyes, screams of pain, are exactly what we all in every country asked for when we voted supplies.

The shrapnel rips, tears, lacerates, and penetrates the human tissues in a horrible manner, and our work consists in repairing and making good as best we can. Our best, alas! is too often of little avail in the face of the anatomic devastation produced. One man, for instance, had his lower jaw shattered to a pulp, and his tongue cloven in two. Another man had his skull smashed, and his brain welling over his face. Another is made completely blind. Another has the front of his abdomen ripped open, and his bowels protrude. Another has a knee joint blown open, a hand smashed, an ankle shattered, and so on; and so on. One could multiply and enumerate without end.

The wounded man has suffered a horrible and tragic disappointment, for he, like every soldier, hoped to escape damage; very probably this hope amounted to a belief. He knows that he has done his duty, and the mere fact that he is wounded proves that he has affronted risks. But he knows also that he is useless, for the time being, if not for life. He knows that he is only in the way, a dead weight, a source of possible danger, a drag on the operations. Further, his mind is perhaps perturbed by sudden anxieties about his family. Lastly, he is in great pain, he is acutely enfeebled, and he is helpless. If ever a human being needed comfort, special attention, and the full aid of medical science, apparatus, and highly skilled nursing—if ever a human being needed to feel that he was the center and chief object of all activities in his neighborhood—the wounded man is that human being.

But on the other hand, the army, like the wounded man, knows that the wounded man is useless and a dead weight. The army cannot help wishing that it might be freed of the immense incubus of its wounded.

"At once they rallied and forced us back, and now it was our turn to lose heavily. That was nearly three weeks ago, and since then the ground over which we fought has been debatable ground, lying between our lines and the enemy's lines—a stretch four miles long and half a mile wide that is carpeted with bodies of dead men. They weren't all dead at first. For two days and two nights our men in the earthworks heard the cries of those who

still lived, and the sound of them almost drove them mad. There was no reaching the wounded."

Nobody deserves succor as a wounded man deserves it. His need is a thousand times greater than that of the average person for whose benefit the National Relief Fund was established.

In the last paragraph quoted above, suppose we read it, "is now a thousand times

greater than that of any automobile or any number of automobiles on the face of the earth." Shall we not do all we can to assist the armies or army of the Red Cross, and at the same time stop the foolish and wicked waste of human life caused by the war?

HIGH-PRESSURE GARDENING

SELECTING SEED CORN; A NEW WRINKLE.

For the past two seasons I have gone into the field and selected ears for seed, and placed them near a furnace in the cellar, where they would always be warm and dry. Well, when I tested each ear before planting time *every ear* gave good germination. Right here comes a suggestion from *The Independent Farmer*, Lincoln, Neb. Before you take the time to test each ear, do this: Say you have 100 select ears. Shell four or five grains from each ear, and mix them all up. Now sprout the lot, between dampened cloths (or any other way); and if *every kernel* germinates satisfactorily there is no need of the expensive single-ear test. One who has had practice can, in a field of good corn, select 100 ears with seldom a poor one.

JUST WHAT I HAVE BEEN EXPECTING.

That the boys of a dozen or more years, in our corn clubs, would be teaching their old fathers. See the following clipped from the *Plain Dealer*:

Statistics compiled from the records of the past years show the boys found large profits in their corn contests. The showing is given as illustrating the possible profit to be made from growing corn. On that subject Clark says:

"The average number of bushels raised per acre by the junior corn-growers in 1915 was eighty bushels. The average cost of raising was 25 cents a bushel. If the selling price were 60 cents a bushel, then the \$48 receipts, less the \$20 cost of raising, would be the net profit of \$28 per acre of each acre of corn. The men in Ohio raised an average of 38.8 bushels per acre, and no one knows what their expenses were, neither their losses nor profits."

In some countries *senior* corn contests have been started among the grown men. The contests of the boys have started the men into the game actively.

ROSELLE OR JAMAICA SORREL.

In addition to what I have said about the above, see the following from the *Florida Grower*. Our plants are now (Jan. 24) starting on a second crop.

We call it Florida cranberry. It is far better and far more useful than the cranberry. Some call it "lemonade plant," because it makes a drink similar to lemonade. Another name for it is Jamaica sorrel. But it matters not by what name you know it, I am sure it will become one of the most useful and profitable crops grown in Florida. A friend writes from

California that they often realize \$1000 per acre there for this fruit. I say if they make \$1000 off an acre in California, where they have their water to buy, what ought we not to make here, where conditions every way are so much more favorable? We have 15 plants scattered promiscuously around "Eukalypta Kabin," that came up voluntarily last spring. From these 15 plants we have sold and given away more than fifteen dollars' worth of products; besides, more than half the pods were left for seed, and the third crop is now coming on. The end is not yet. We shall be glad to tell your readers how we come out. We are sufficiently encouraged to try an acre or two this year. Mr. King, the canning man, at Fort Meade, says he will be pleased to contract now for all he can utilize next fall and winter at 12½ cents per pound. Think of it! Another gold-mine about to be discovered! When Florida is discovered, won't it be a great country? When you want the prettiest and best in jelly, jam, marmalade, sauce, pies, drink (better than grape-juice), just try Florida cranberries. "Tastes more."

R. J.

Note.—We have grown "Roselle," made jelly and "lemonade" from it; also used it as cranberry jelly is used with meats, and it is very fine. The only question is in creating a market for it. That done, a profit is assured, for the cost is little.

AN ALIGHTING BOARD MADE OF CLOTH.

I wish to ask your opinion of a new device for an alighting-board—an awning like wire frame covered with various-colored cloth, the cloth a single thickness kept tight by a spring on the under side. The wire frame springs into an adjustable holder on the outside edge of the bottom-board. Advantages? Well, one of the chief ones is the comfort of the laden bee, as she returns weary from her flight. Did you ever observe their hesitation as tho dreading to drop on the hard board? Further, this thin cloth would be cooler in the summer and warmer in the winter than the wood. It would not hold puddles of water during rainy weather. Cloth of various colors could be used. The number of the colony could be marked on the cloth.

Mantua, O., Feb. 28.

D. B. HUSTED.

Years ago I had a cloth alighting-board; but it flopped about so much when it was windy I was compelled to give it up. The wire springs mentioned in the above would surely fix that. Just this very morning, when the bees were rushing out to work on the orange bloom, there was a puddle of water on the painted alighting-board, caused by the damp breath of the rousing colony, and many bees were soaked and disabled as they tried to get out very early. Will our friend mail us his device, that we may illustrate it?

MYERS House Pumps

Every housewife would be proud of her kitchen if she had a MYERS HOUSE-PUMP. They are handsomely finished and harmonize nicely with the finest surroundings. They are very easy to operate on account of the Patented Cog Gear Head. Ease of operation is an important feature, especially when the pump is much used by women.

We have a beautifully colored circular showing Myers House Pumps in their actual colors, and will send one at your request.

F. E. MYERS & BRO., ASHLAND, OHIO
351 1/2 Orange Street

"Orchard Success"

is a small pamphlet of big ideas that you should send for at once. It tells how thoroughly, quickly and cheaply you can rid your orchard of all scale, larvae, eggs and fungi. It describes "scalecide the one great dormant spray," which mixed 1 to 15, is guaranteed to kill every scale it reaches. One barrel equals three barrels of lime sulphur and there is no spray more simple, safe or effective.

Our Free Service Department is for your special benefit. Question us about any orchard and garden sprays and tools. Our lifetime experience is yours for the asking. Write TODAY.

NEW KEROSENE LIGHT

BEATS Electric or Gasoline

10 DAYS FREE

SEND NO MONEY CHARGES PREPAID

We don't ask you to pay a cent until you have used this wonderful modern light in your own home ten days—we even pay transportation charges. You may return it at our expense if not perfectly satisfied after putting it to every possible test for 10 nights. You can't possibly lose a cent. We want to prove to you that it makes an ordinary oil lamp look like a candle; beats electric, gasoline or acetylene. Lights and is put out like an oil lamp. Tests by Government and 33 leading Universities show it **Burns 50 Hours on One Gallon common coal oil, and gives more than twice as much light as the best round wick open flame lamps.** No odor, smoke or noise; simple, clean, no pressure, won't explode. Several million people already enjoying this powerful, white, steady light, nearest to sunlight. It's GUARANTEED.

Men Make \$50 to \$300 Per Month with Rigs or Autos

delivering the ALADDIN on our easy trial plan. No previous experience necessary: Practically every farm home and small town home will buy after trying. One farmer who had never sold anything in his life before writes: "I sold 51 lamps the first seven days." Another says: "I disposed of 37 lamps out of 51 calls." Thousands who are coming money endorse the Aladdin just as strongly. **NO MONEY REQUIRED.** We furnish capital to reliable men to get started. Ask for our distributor's plan, and learn how to make big money in unoccupied territory. Sample sent for **10 DAYS' FREE TRIAL.** We want one user in each locality to whom we can refer customers. Be the first and get our special introductory offer under which you get your own lamp **FREE** for showing it to a few neighbors and sending in their orders. Write quick for **10 DAY ABSOLUTELY FREE TRIAL.** Address nearest office.

Three-band and Golden Italians

The Secret of Success

in beekeeping is to keep your colonies strong. To do this you must have good healthy laying queens.

1 untested queen, \$1.00; 6 for \$5.00; 12 for \$9.00.
 1 tested queen, \$1.50; 6 for \$8.00; 12 for \$15.00.
 1/2 lb. bees with untested queen, \$2.50; tested, \$3.00.
 1 lb. bees with untested queen, \$3.50; tested, \$4.00.
 1-fr. nucleus with untested queen, \$3.00; tested, \$3.50.
 2-fr. nucleus with untested queen, \$4.00; tested, \$4.50.
 If more frames are wanted than we list, add \$1.00 each per frame wanted to above prices.

Satisfaction guaranteed

W. J. LITTLEFIELD

618 W. Seventh St. Little Rock, Ark.

Yes, "By their fruits ye shall know them," and that is why I have recommended your queens. Where European foul brood is found, the stock proves itself disease-resisting as well as or better than any other we have tested. When a beekeeper having a good apiary where European foul brood was taking the apiary when inspected, and he told me, after testing your queens, he would not take \$25.00 for the last queen you sent him, it speaks for itself. His apiary, now cured, is proof of the pudding. N. E. France, Plattsville, Wis.

Dr. Miller's Strain of Italians

We have made arrangements with Dr. C. C. Miller to furnish us breeders, and therefore offer you the finest queens reared from the best stock on earth, as Dr. Miller holds the world's record for an apiary of more than 70 colonies having averaged 266 sections weighing 244 pounds. These are not queens bred from a mother that has produced one good yield, but it has been bred in them for generations until their honey-gathering is a fixed quality. In GLEANINGS, p. 788, Editor Root says, "Those queens (Dr. MILLER'S) ought to be worth \$10 to \$25 each."

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me. Marengo, Ill., Mar. 1, '16. C. C. Miller.

Virgins, 50 cts.; untested, \$1.50; tested, June, \$2.50. Breeders, August, \$5 to \$10.
 Bees, our strain, 1 lb., \$1.50; 2 lbs., \$2.50; nuclei, 1-frame, \$1.25; 2-frame, \$3.25; 3-frame, \$3.25; 8-frame colony, \$6.00; 10-frame colony, \$7.00.

Prices do not include queens.
 Queens, our strain, 75 cts. each.
 Satisfaction guaranteed as well as safe arrival.
 200 colonies in 10-frame hives at \$6 each.

Preparedness

High-grade Queens
Bees by the Pound

Prepare for a Big Crop of Honey by Getting Bees and Queens from

M. C. Berry & Company

Three-banded Italian Bees and Queens Bred for Honey Production

Price List of Swarms of Bees in Packages ready to ship now.

1-lb. swarms, \$1.25; 2-lb. swarms, \$2.35; 3-lb. swarms, \$3.35; 5-lb. swarms, \$5.35.

If queens are wanted, add price as according to price list.

On lots of five packages or more we will prepay express to your address east of the Dakota, Nebraska, Colorado, and Texas lines, and south of the Canadian boundary. This applies only on orders received in April.

Price List of Queens by Return Mail

Untested, 75 cts.; Select Untested, 90 cts.; Tested, \$1.25; Select Tested, \$1.50.

All queens warranted purely mated. Wings clipped free of charge.

Our queens are bred from *Select Honey-gathering Stock*, the choice of over 1000 hustling honey-producing colonies that produce about two solid cars of honey annually. All orders for either bees in packages or queens will be filled promptly by return mail or express, or as per booking. *There will be absolutely no delay.* We take only as many orders as we can fill and do so promptly. Let us have your orders and get your bees on time, or your money back by return mail. Our capacity is 100 1-lb. swarms a day and 6000 queens a year. We have no disease of any kind. Safe arrival and satisfaction we guarantee. Write for prices on wholesale quantities.

M. C. BERRY & CO., Hayneville, Ala.

Successors to Brown & Berry,
Largest shippers of young Italian bees
in the South.

Do You Need a Queen for that Queenless Colony?

We can furnish tested Italian queens by return mail, \$1.00 each. These queens are not cull nor inferior in any way because they are cheap. They were reared last September and October, and wintered in four-frame nuclei expressly for our early spring trade in tested queens. We expect to have untested queens ready to mail about April 10; \$1.00 for single queen; \$9.00 per dozen. We began rearing queens for sale in 1886. Our strain of three-banded Italians is well known to leading beekeepers. We have never had a case of foul brood in our apiary, and we guarantee every queen sent out by us. We solicit your orders.

J. W. K. Shaw & Co., Loreauville, Louisiana

I furnish a full colony of Italian bees in a complete new 8-frame Dovetailed hive for \$10.50; an S-frame chaff hive, \$12.50; a 10-frame chaff hive, \$14.00. This price includes a tested Italian queen. Catalog of bees and supplies free.

I. J. STRINGHAM, 105 PARK PLACE, N. Y.
Apiaries, Glen Cove, L. I.

Whether you cultivate the smallest door-yard "patch" or the largest market garden you can't afford to work without a Planet Jr.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powdrpaint. It comes in the form of a dry powder; and all that is required is cold water to make a paint weather proof, fire proof, sanitary, and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone, or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 58 North St., Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

I am booking orders now, with 10 per cent deposit for delivery March 15 and after. Safe arrival, prompt service, and satisfaction guaranteed. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

The Beekeepers' Review, Northstar, Michigan, are buying combless bees in pound packages, with young untested queens in large quantities. By so doing they are getting inside prices, and they are giving their subscribers all the benefit of this close buy. Listen: Ten pound packages with queens for only \$16.00; 20 packages for only \$31.00. If you want two pound packages instead of the one, add 95 cts. to each package. They are shipped from the gulf states by express, direct to the purchaser.

FOR SALE.—Swarms of Italian bees in packages, 1 lb. of bees, \$1.50; 2 lbs. of bees, \$2.50; for 50 or more they are 12½ cts. less. Untested Italian queens, 75 cts. each; tested Italian queens, \$1.25 each. No reduction on quantity of queens for April and May. Quality, service, safe delivery, and no disease, I guarantee. We spare no labor nor money to produce the best for you is why we cannot make a lower price. Early swarms get the honey. We can deliver the goods with pleasure to both of us.

W. D. ACHORD, Fitzpatrick, Ala.

The successful package-shipper and queen-breeder.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, untested and gentle. Mated, \$1.00; six, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SON, Wilcox St., Binghamton, N. Y.

BEES AND QUEENS.—Doolittle's Italian stock speaks for itself. They are gentle, resist disease, and are fine honey-gatherers. We breed this stock only, and guarantee delivery only to points west of the Rocky Mountains. Untested queens, 75 cts. each; \$8.00 per dozen; \$60 per 100; tested queens, \$1.25 each; \$12 per dozen; \$85 per 100. Three-frame nuclei, \$2.25 each; \$200 per 100. Bees, ½-lb. packages, 75 cts. each; \$6.00 per 100; 1-lb. packages, \$1.00 each; \$85 per 100. Add price of queens to above packages. Complete catalog free on application.

SPENCER APIARIES, Nordhoff, Cal.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei, with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can, therefore, supply you with the biggest and strongest nuclei you will be able to find anywhere. Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier, if necessary. Bees are all on standard Hoffman frames, and combs are all built on full sheets of foundation and wired frames. We guarantee bees to be free from disease.

THE HYDE BEE Co., Floresville, Tex.

HELP WANTED

WANTED.—Man to take charge of apiary, 200 hives, and assist in orchard work.

HAWTHORNE FARMS Co., Barrington, Ill.

WANTED.—Expert beeman to help in business of 1100 colonies. Work starts April 15. Good wages.

EARL HANKS, Hageman, Ida.

WANTED.—Young man with some experience in handling bees, to assist in large apiary, garden, etc.; married man preferred. Please give full particulars in first letter.

W. D. WRIGHT, Altamont, N. Y.

WANTED.—Can take two clean minded and bodied young men as student help for the season of 1916. Board free for help given, and something more if a good season and help does well. One understanding an auto preferred. Address R. F. HOLTERMANN, Brantford, Ontario, Canada.

WANTED.—Robust western young man, of good habits, honest and industrious, at moderate wages and board, who has had some experience handling bees for extracted honey. State your case fully, give references, and wages expected in first letter.

IRA C. FARNEY, Mesilla Park, N. M.

WANTED.—Young man with a little experience; fast willing worker—a student helper in our large bee business of over 1000 colonies; crop last year over 105,000 lbs. Will give results of our long experience, and small wages; every chance to learn. Give age, height, weight, experience, and wages, all in first letter, or expect no answer.

E. F. ATWATER, Meridian, Idaho.

SITUATIONS WANTED

WANTED.—Position in beeyard. I have a diploma and 5 years' experience. Good references; apply at once.

JAMES A. MAINES, Nile, N. C.

WANTED.—Young man having ten years' experience with bees wants position with extensive bee-keeper to learn more thoroughly the business. Please state wages and all particulars.

L. E. TURNER, Montrose, Minn.

BEEKEEPERS' DIRECTORY

Well-bred bees and queens. Hives and supplies.
J. H. M. COOK, 70 Cortlandt St., New York.

Nutmeg Italian queens, leather color, \$1.00; 12 for \$10.00, return mail.
A. W. YATES, 3 Chapman St., Hartford, Ct.

H. G. QUIRIN, Bellevue, Ohio.

QUEENS.—Improved three-banded Italians bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00 each; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.
H. C. CLEMONS, Boyd, Ky.

TRADE NOTES

HONEY-EXTRACTORS.

If you contemplate buying a honey-extractor, better get your order in without delay or you are likely to pay more money for it. Most of the metal parts entering into its construction have doubled, or nearly doubled, in value during the past few months, and a new scale of prices will be in effect before very long.

BUCKWHEAT SEED.

We have a moderate supply of buckwheat seed, both Japanese and silverhull, which we offer while it lasts at \$1.50 per bushel; two-bushel bag for \$2.75; no charge for bag. If intending to sow, send in your order while the seed is available.

ALSIKE CLOVER SEED.

We still have a number of bushels of alsike clover seed, which we offer, subject to previous sale, at \$10.00 per bushel, with 25 cts. extra for bag to ship in. Any quantity from a peck up at this rate. Lot of two bushels or over, no extra for bags. It will not last long at this price. If you want some, better order promptly.

SWEET-CLOVER SEED.

We have a good supply of very choice hulled white-sweet-clover seed scarified for quick germination, requiring only 10 lbs. per acre for a good stand. We offer this for a short time to reduce stock at \$18.00 per 100 lbs. Now is the right time for sowing with a nurse crop to produce hay or bloom with seed next year. We have also choice hulled yellow which we will sell at \$15.00 per 100 lbs.

ADVANCING PRICES.

The upward movement in prices of materials has become so marked in many lines that we are compelled to figure out advanced prices on finished products, especially in metal goods, and new prices will be announced in the near future. To replace material on hand at present market prices would make the cost of the finished article so high that we should be unable to sell at the prices which have been in effect except at a loss in numerous cases. The best authorities on the situation maintain that, even if the great war closed now or in the near future, it will be several years before production overtakes demand for steel products, and that we must expect a period of several years of higher values.

A POSSIBLE SHORTAGE OF SECTIONS.

Two factories which formerly made sections, hives, and supplies generally, have been closed during the past few months by going into bankruptcy. The factories which remain will have their own trade to supply, and in addition will have to make up for the shortage caused by the closing of the two now idle. A recent investigation discloses the fact that there is a shortage of dry white basswood suitable for making one-piece sections, and the color of many turned

out during the next few weeks will be below the average. Stocks of manufactured sections are below normal for this time of year; and if the season turns out well there is prospect for a short supply. New lumber cut the past winter is usually not dry enough for use till late in May.

COMB-HONEY CARTONS ADVANCED.

Owing to a big advance in white-coated hoxboard we are under the necessity of advancing the price of comb-honey cartons as listed in our catalog, both printed and plain, both styles, 75 cts. per 1000 retail, wholesale, and jobbing prices. This advance represents simply the increase in cost of stock at today's market price. Paper-makers are in a bad way for materials. This issue of GLEANINGS is delayed in mailing because a car of paper ordered in January for delivery by March 10 did not arrive till March 29, which delayed the printing about a week. The label catalogs we are now mailing quote advanced prices on most styles as well as on stationery and other printing. We are working out some new designs in labels to be included in a new edition of the label catalog in preparation.

COMB VS. EXTRACTED HONEY.

For several years previous to 1915 there seemed to be a shortage of choice comb honey and a plentiful supply of extracted. Market conditions at this time seem to indicate an oversupply of comb honey, whereas the available supply of extracted is being pretty well picked up, and there is not likely to be much left when the new crop is ready for market.

Well-ripened extracted honey does not deteriorate with age, and is just as available for use a year or two after production as it is during the first year. Because of the liability to granulate, it is not so easy to carry over comb honey. It is important, therefore, that there be no overproduction of comb honey if a steady market be maintained at a remunerative price. When comb honey granulates before it is used up its market value is reduced 50 to 100 per cent; and the one who owns it during the process of granulation is bound to lose money, and may also lose interest in handling an article subject to such deterioration. There ought to be some reliable method of regulating the relative production of comb and extracted so as to prevent an oversupply of comb. If in doubt, better produce extracted rather than comb. The consumption of extracted honey is on the increase, and we believe it will increase relatively faster than that of comb honey. If there should be an oversupply of extracted, and you store it well ripened, you can feel safe that it will not deteriorate, no matter what temperature it may be subjected to; whereas with comb honey if you can not dispose of it you must keep it in a warm even temperature to prevent granulation, and even then you may not succeed.

SECOND-HAND FOUNDATION MILLS.

We have to offer the following list of foundation machines which have been used but are in fair condition. In many cases they will answer as well as a new machine where you have only a moderate output. Send for sample of foundation from any mill in the list which may interest you.

- No. 0153, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.
- No. 0156, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.
- No. 0165, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.
- No. 0183, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.
- No. 0214, 2½ x 10 hexagonal light-brood mill in poor condition; rolls quite badly pitted; will make fair foundation. Price \$13.00.
- No. 0230, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.
- No. 0231, 2½ x 10 hexagonal medium-brood mill in fairly good condition. Price \$20.00.
- No. 0233, 2½ x 10 hexagonal medium-brood mill in poor condition; cells bruised. Price \$14.00.
- No. 0234, 2½ x 6 extra-thin-super mill in very good condition. Price \$12.00.
- No. 0235, 2½ x 10 hexagonal light-brood mill in good condition. Price \$22.00.
- No. 0237, 2½ x 6 thin-super mill in fair condition. Price \$10.00.

- No. 0238, 2½ x 6 thin-super mill in fair condition. Price \$10.00.
- No. 0239, 2½ x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.
- No. 0241, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0242, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0243, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0244, 2 x 10 round-cell medium-brood mill in good condition. Price \$14.00.
- No. 0245, 2 x 10 hexagonal medium-brood mill in very good condition. Price \$18.00.
- No. 0246, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

THE A. I. ROOT CO., MEDINA, O.

BILLY SUNDAY AND THE SALOON CROWD.

We clip the following (from Ridgway) in the "Busy Men's Corner" of the *Sunday School Times*:

Only this very day I have read an intemperate attack by a minister upon Billy Sunday—to the great joy of every saloon man in the town. This very same paper prints a list of saloons that have just lost their licenses thru this same Billy Sunday's stirring and searching evangelism. This Pennsylvania Pharisee would undoubtedly have heaved his rock at Stephen as joyfully as he stabs his pen into Billy. Billy Sunday draws thousands to strike the sawdust trail. These stone-throwing critics draw little beyond their salaries (Rev. 3:14-18). As I write we are busy fighting rum here in Pennsylvania. The saloon-keepers give us no anxiety. They are in front of us fighting their best. But our "good Christian temperance friends" give us our wounds. In fact, the saloon crowd is printing sermons by "Christian ministers" defending their cause.

The Dollar Hen

My opinion is that "The Dollar Hen" is not only one of the best books on poultry that we have at the present time, but it is worth nearly as much as a dozen other books. Perhaps this is extreme, but we have very few books that are strictly up to date, and still fewer that pitch right into the superstitions and humbugs scattered thru all our poultry books and journals.—A. I. Root.

This book will be clubbed with GLEANINGS for one year at \$1.35; or, if you have already subscribed a year or more in advance you can have the book for 60 cents.

Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication you want.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER.** By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE.** By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES.** Our new complete catalog mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER.** Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES.** The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING.** Just the thing for the up-to-date housewife. Price 10 cents.
- BEEES AND POULTRY,** how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES.** A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE.** A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES.** A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.

"Next Door to Everything"

Reads the advertisement of a great railway terminal. "Next door to everything in Beedom" fittingly describes our location. In the bee-supply business distance is measured, not in miles but in hours and minutes; and the house that gives first service is nearest the beekeeper.

Tho but a short distance from the geographical center of Ohio we are yet so near to West Virginia and Pennsylvania, and so closely connected by transportation lines, that we are truly "next door."

Some idea of our importance as a distributing center may be gained from the fact that more than fifty mails arrive and as many depart daily, and almost a hundred freight and express trains enter and leave the city every twenty-four hours.

Then our location in the city is most accessible. Our office and warerooms are just off the main business thoroughfare, in the heart of the wholesale district, and only a stone's throw from depots, post-office, and the large retail stores. Beekeepers and their friends are earnestly invited to make our store their headquarters when in the city.

The best goods and service justify us in promising our customers the fullest measure of satisfaction.

Clover looks most promising for the coming season, and it is the part of wise foresight to anticipate all possible requirements.

E. W. Peirce,

22 So. Third St. Zanesville, Ohio

To Advertisers of Bees and Queens

The following is addressed mainly to present or prospective advertisers of **GLEANINGS IN BEE CULTURE** who seek customers among the readers of our columns; and while it is addressed especially to those who wish to advertise bees or queens, it may apply in some respects to other advertisers as well. It is prepared in this form so that any one who receives it may understand that its application is general, and that he alone is not made the subject of special requirements or conditions not required or imposed on others.

The supplying of queen-bees, and to a less extent bees in colonies or nuclei or pound packages, is attended with a good many difficulties not readily understood by those who have not actually had one or more seasons' experience in this trade. To explain this, let us relate from our own experience as queen-breeders, and from the correspondence which reaches us both from our advertising friends and some subscribers to **GLEANINGS** who have ordered bees and queens from our advertisers or elsewhere.

At the beginning of a season a queen-breeder may have on hand a fairly good stock of queens; but having been reared very late the previous fall he has not had time to test. Another breeder may have on hand a quantity of tested queens, or perhaps a pretty liberal proportion of select tested, or a number of good breeding queens, worth anywhere from \$5.00 to \$10.00. Now, unless the advertiser is very explicit as to the stock on hand, and as to the probable dates when he will be able to begin deliveries, customers may be disappointed greatly in not being able to get the grade of queen wanted from a certain advertiser or on the date expected, and too much care cannot be taken to make the advertising clear and explicit. A number of new advertisers every year get into serious difficulty because their facilities for raising queens being limited, and the price quoted too low for safety they receive orders early in the season which they *expect* to be able to fill shortly, and accept the money for the same, hoping to supply the stock within a reasonable time. Unfavorable weather may ensue, and they find themselves unable to fulfill their plans, and their customers are indignant and demand their money returned. A good deal of this trouble, which often assumes pretty serious aspects, could be avoided by more care in the wording of the advertisements, occasionally by taking more space. We therefore caution our advertisers to be explicit in their promises as to grades and quantities, and dates when deliveries can be made; and we caution our readers to understand these things before placing orders. It is amazing to learn that beekeepers will order queens from points one or two thousand or more miles away in lots of fifty or a hundred or more, cash with order, without knowing these things. The compliment is appreciated by the publishers of **GLEANINGS**, showing the confidence in which our advertisers are held; but at the same time, where a small breeder will occasionally make very low prices to establish himself in the trade, careful discrimination should be made in the placing of large orders between the breeder with very limited experience or facilities, and those who have had years of experience and ample facilities for handling large orders. It would be unfair for the publishers to refuse space to a small but worthy queen-breeder simply because his output is very limited, for he may have some very fine stock, and it may be a decided advantage to those who are wanting only a few queens to get them from a small breeder at a moderate price. On the other hand, among the small breeders are occasionally found those who either are unprincipled or so inexperienced that they are not worthy of the confidence of our readers; and to make a distinction between these we require of all advertisers the most definite and explicit information in regard to their plans. We must know of every one securing space in our columns how large a yard he has from which he expects to raise queens; what breeding stock he has; when he expects to begin deliveries; and, more than all this, we must have reliable information as to the character of the advertiser; whether he will properly take care of orders placed in his hands, and promise to return promptly on request funds which have been placed in his hands for certain orders. Unless this information is fully supplied we shall decline the use of our columns to any one unwilling or unable to furnish it.

THE A. I. ROOT CO., MEDINA, O.

HONEY - CANS

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

Special Easter Offer

Gleanings in Bee Culture, 1 year . . \$1.00
Pictorial Review, 1 year 1.50
Both Publications at Clubbing Rate 1.60

Canadian postage 55c extra; foreign postage \$1.10 extra

Let us take a glimpse of the Pictorial Review for 1916. One of the new features of this most rapidly growing magazine in America is its book-length novels complete in four installments—each one of which will sell for \$1.50 in book form after its publication in the Pictorial Review. The following are some of them:

THE HEART OF RACHEL

By Kathleen Norris, is a whole evening's reading in itself. Every live thinking woman is bound to be interested in this great serial.

THE CURVE OF THE CATENARY

One of Mary Roberts Rinehart's remarkable mystery stories which will keep you breathless from start to finish.

MAKING HER HIS WIFE

A really great novel, and a credit to the originality, humor, and philosophy of its author—Carra Harris.

SHORT STORIES

In addition to these novels you will get from 60 to 70 of the best stories now being written by living masters of fiction.

The children have not been forgotten either. Dolly Dingle cut-outs will be a delight to children of all ages. The usual household department, showing the latest wrinkles in the home decoration, child welfare, beauty hints, household devices, recipes, and fashions will also create much enthusiasm.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hand. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

17 CENTS A DAY! Remember this grand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY--Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

The Oliver Typewriter Co., Cleveland, Ohio

946 Prospect Avenue

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A post card will bring it to your address free.

Red Catalog, postpaid.

where the good beehives come from

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, CO.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.
Honey in badly stained or mildewed sections.
Honey showing signs of granulation.
Leaking, injured, or patched-up sections.
Sections containing honey-dew.
Sections with more than 50 uncapped cells, or a less number of empty cells.
Sections weighing less than the minimum weight.
All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.
Honey contaminated by honey-dew.
Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES
Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

CHICAGO.—The market continues to drag, there being a heavy supply on sales, especially of comb honey. It is difficult to quote prices under these conditions; but it is seldom that the best grades of white comb bring 14 or 15 cts. per lb., most of the sales being made around 13. Extracted white brings 7 to 8; ambers, 6 to 7. Beeswax is steady at 30 to 32.
R. A. BURNETT & Co.

Chicago, April 4.

NEW YORK.—There is no demand for comb honey to speak of; and while No. 1 and fancy white are cleaned up, there is quite a stock of off grades still on the market for which there is practically no demand, and hard to dispose of at any reasonable price. The market on extracted honey is in a little better shape, and prices now show an upward tendency, especially on fancy West Indian honey; supplies sufficient to meet all demands. Beeswax steady at from 29 to 31, according to quality.

New York, April 6. HILDRETH & SEGELKEN.

INDIANAPOLIS.—The demand for both comb and extracted honey has been light of late, due to the weather condition mostly. Choice white comb is selling at \$3.75 to \$4.00 per case; No. 2 white comb, \$3.50. Extracted of excellent quality is bringing 9½ to 11. For wax we are offering 28 cts. cash or 30 in trade.

Indianapolis, April 4.

WALTER S. POWDER.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: Fancy white, per case of 24 sections, \$3.15; No. 1, per case, \$2.93; No. 2, per case, \$2.70. White extracted, per pound, 8½ to 8¾; light amber, 8 to 8¼; amber, 7 to 8. We pay 25 cts. per pound in cash and 27 cts. per pound in trade for clean yellow beeswax delivered to us here at Denver.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, April 6. Frank Rauchfuss, Mgr.

KANSAS CITY.—The supply of extracted honey is large, and the demand light. The supply of comb honey is not large, but the demand is light. We quote No. 1 white comb, 24-section cases, per case, \$3.00; No. 2 ditto, \$2.50 to \$2.75; No. 1 amber ditto, \$2.75 to \$3.00; No. 2 ditto, \$2.50 to \$2.75; white extracted, per pound, 7 to 8; amber, 6 to 7; No. 1 beeswax, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.
Kansas City, April 5.

ST. LOUIS.—The demand for comb honey in this market has been very light of late, but we have had a fair movement in extracted honey. Stocks here are not plentiful, especially southern extracted honey in barrels; but the stock of 60-lb. cans is larger. We are getting for No. 1 white comb honey \$3.75; light amber, from \$3.25 to \$3.50, and amber from \$2.50 to \$3.00; extracted honey in 60-lb. cans from 6½ to 8½; southern amber in barrels from 5 to 6; dark, 1 ct. less. Beeswax is very firm at 29½ for pure; impure and inferior, less.

R. HARTMANN PRODUCE CO.
St. Louis, April 8.

ZANESVILLE.—At a season when the honey business is usually light, we are having a fair and normal demand. There has been no marked revision of prices. As heretofore, best grades of white comb bring around \$4.00 in single-case lots. Some lots of Western are offered at \$3.75. On quantity orders some concession is allowed, and of course jobbers are given the usual 12 per cent discount from list prices. Extracted in cans is quoted at 9 to 11 for best grades of white, there being little demand for amber. Twenty-nine cents cash, 31 in trade, are ruling prices paid producers for beeswax. Selling prices are largely arbitrary, varying with quality and quantity.

Zanesville, April 6.

204 Walnut St.

THE BUSY BEE MEN.

CINCINNATI, O.

You Should Earn \$25 a Colony from Your Bees This Season

This can be accomplished if you have a young prolific queen and a strong colony when the honey-flow arrives. Many beekeepers fail to secure the greatest possibilities from their bees because their colonies are not strengthened and built up early in the season, making it possible for them to take advantage of the honey-flow when it arrives. This should be a good season for clover honey, as weather conditions last year throughout the country were the best for securing a good strong stand of clover we have had for many years.

We now have a large queen-rearing outfit in Florida for the express purpose of supplying you with **EARLY QUEENS AND BEES IN PACKAGES**. We are breeding from queens that gave a surplus of 300 pounds per colony in a 24-day honey-flow. You should have this strain of bees in your yard, and insure the placing of each of your colonies on a paying basis. We have a large supply of queens at this time, but as orders are coming in rapidly, we recommend that you provide for your requirements early.

DISCONTINUANCES. Notice is given just before expiration. Subscribers are urged, if unable to make payment at once after expiration, to notify us when they can do so. Any one wishing his subscription *discontinued* should so advise us upon receipt of the expiration notice; otherwise it will be assumed that he wishes GLEANINGS continued and will pay for it soon.

HOW TO REMIT. Remittances should be made by draft on New York, express-order or money-order, payable to the order of The A. I. Root Co., Medina, Ohio. Currency should be sent by registered letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

FOREIGN SUBSCRIPTION AGENTS.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents at the prices shown:

PARIS, FRANCE.—E. Bondonneau, 154 Avenue Emile Zola.

Per year, postpaid, 8 francs.

GOODNA, QUEENSLAND.—H. L. Jones. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/7 p.*

DUNEDIN, NEW ZEALAND.—Alliance Box Co., 24 Castle St. *Per year, postpaid, 6/7 p.*

Have You a Garden?

Then these books will interest you. They are up-to-date manuals, interestingly written, thoro, and practical. All 5 x 7½ inches, bound in cloth unless otherwise stated, and all well illustrated.

Asparagus.—By F. M. Hexamer. It is easy to learn how to grow this interesting and delicious vegetable. 166 pages. 35 cents postpaid.

The New Rhubarb Culture.—By J. E. Morse. A complete guide to dark forcing and field culture. 130 pages. 45 cents postpaid.

Celery Culture.—By W. R. Beattie of the Department of Agriculture. 143 pages. 45 cents postpaid.

New Onion Culture.—By T. Greiner. A complete guide in growing onions for profit. 114 pages. 45 cents postpaid.

The Small Fruit Culturist.—By Andrew S. Fuller. An old book frequently revised to bring it up to date. Practical instructions for such fruits as the strawberry. 290 pages. 75 cents postpaid.

The Nut Culturist.—By Andrew S. Fuller. How to cultivate all kinds of edible nut trees. 285 pages. \$1.25 postpaid.

Squashes and How to Grow Them.—By Gregory. Good reading for almost anybody, whether they grow squashes or not. Paper bound. 25 cents postpaid.

Bees and Queens

Three - banded and
Golden Italian

These queens and bees are reared by the most practical and scientific methods known. Large apiaries to draw from which were established in 1884. Deliveries about May 20. We quote the following prices on delivery up to July 1:

1-frame nucleus	\$1.50
2-frame nucleus	2.50
3-frame nucleus	3.00

QUEENS EXTRA:

Untested queens	.1, .75
Untested queens	.6, 4.00
Untested queens	.12, 7.50
Tested queens	.1, 1.00
Tested queens	.6, 5.00
Tested queens	.12, 9.00
Full colonies	.8.00
Bees, per pound.	1.00

Special prices on large quantities on application

Our being centrally located means lowest express rates to you in every direction.
Safe arrival and satisfaction guaranteed on delivery.

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---
30 cts. cash, 32 cts. in trade; wax delivered to Lansing.

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

SWEET - CLOVER SEED

Quick Germination

Get our "Scarified" Sweet-clover Seed, which will germinate from 85 to 95 per cent the first year, and thus insure you a good stand right from the start. By sowing our seed you will save money, as it takes only about half as much scarified to sow an acre as ordinary hulled seed.

PRICES	1 lb.	10 lbs.	30 lbs.	100 lbs.	60 lb. a bu.	5 bu. a bu.	10 bu. a bu.	Lbs. per acre
Unhulled White, re-cleaned	\$0.25	\$2.00	\$5.10	\$16.00		\$4.80	\$4.50	25 to 30
Hulled White, re-cleaned and scarified	0.30	2.75	6.75	22.50	\$13.50	13.00	12.50	6 to 10
Hulled Yellow, re-cleaned and scarified (<i>Melilotus Officinalis</i>)	0.20	1.80	5.10	17.00	10.20	9.50	9.00	8 to 12

When seed is wanted by parcel post, be sure to include postage. Bags will be included in the weight in parcel-post shipments.

Please Note.—All of our seed is thoroly cleaned. The scarifying process usually breaks some of the seeds, and we remove all broken seeds. This is an important saving to you. Samples on application.

Dadant & Sons, Hamilton, Illinois

YELLOW SWEET CLOVER.—Many people fail to recognize the value of the biennial yellow sweet clover as a honey-plant. The fact that it blooms two weeks earlier than the white variety makes it especially valuable to the beekeeper. Be sure, however, to get the biennial variety as quoted above.

NO. 8

EDITORIAL

Our Cover Picture

A STRIKING testimony to the value of bees as pollinators is given by George H. West in his article, page 317. The picture shows a bountiful yield, surely, especially since the crop had been thinned down twice.

Scarcity of Maple Sugar and Syrup

FROM present advices the amount of maple sugar and syrup this year will be very small in comparison with other years. This ought to stimulate the demand for good extracted honey. If the good housewife who has a preference for maple syrup can't get it, and desires a high-grade sweet, she will take honey.

Indiana Beekeepers, Take Notice

IT is not often that GLEANINGS takes a hand in politics; but here is a case where a beekeeper is running for Congress, and we should like to call the attention of the Indiana beekeepers to that fact. S. H. Burton, of Washington, Ind., who is a frequent contributor to these columns, is a candidate for member of Congress on the Progressive ticket, in the 2d Indiana District. He is an extensive fruit-grower and beekeeper, and he stands right on the temperance question. It seems to us that he deserves the support of those interested in good government.

Manufacture of Sugar from Sugar Cane in the United States Decreasing

FROM the Department of Commerce, Bureau of the Census, we learn that in five years the manufacture of sugar from sugar cane has decreased 29.3 per cent. Reports were received from 181 factories, 168 of which were located in Louisiana, 5 in Florida, 4 in Texas, 2 in Mississippi, and 1 each in Arizona and South Carolina. In the season of 1913-14 the total valuation of the sugar produced was \$18,947,683; molasses

and syrup, \$2,631,212; by-products, \$56,477. Total valuation for the season of 1913-14, \$21,635,372.

In 1909 there were 214 factories, and the valuation of the sugar produced was \$26,095,673; molasses and syrup, \$3,211,191. Total valuation in 1909, \$30,620,738. The value of the annual production has therefore decreased nearly \$9,000,000, or 29.3 per cent, as stated above.

No figures in this report were given for 1915. No doubt the effect of the last war has been to increase the manufacture of sugar.

Considering the decrease up to 1914 from the figures of 1909 probably the manufacturers of sugar from the sugar beet and the manufacturers of other syrups are largely responsible. Will the time ever come when honey, so far from being a luxury, will become an article of food that it may influence the manufacture and sale of granulated sugar?

Co-operative Experiments in Apiculture

THE provincial apiarist of Ontario, Mr. Morley Pettit, is now sending out the blanks for the collection of data concerning beekeepers who will assist in performing the prescribed experiments. Such beekeepers in Ontario who have assisted in former years are requested to make formal application for the same experiment as before, as better results are obtained the second year. The following list of experiments, as will be noticed, are those which have to do with swarm control and spring management.

Experiment 1.—Prevention of natural swarming in extracted-honey production by holding the colony together. This is one of the most popular methods. Forty persons tried it last year with good results.

Experiment No. 2.—Prevention of natural swarming in comb-honey production by artificial shaken swarming.

Experiment No. 3.—Prevention of natural swarming by manipulation of hives instead of combs. The instructions will be some-

what changed and improved. This method is especially for advanced beekeepers.

Experiment No. 4.—Method of spring management to get strong colonies for the honey-flow. This includes spring protection and stimulative feeding. Seventy-nine persons tried it last year.

How Much Wages a Helper in a Bee-yard May Expect

IN the course of a year we receive many inquiries from men having one to five years' experience with bees asking how much wages they could expect were they to hire out to some extensive producer. It is impossible to give a definite answer to such inquiries, for the wage to be expected depends largely upon the individual in question, also somewhat upon the average wage for farm help in the locality, and also upon the employer. There are also different bases of figuring—that is, whether board is included, whether the board includes washing and clothing, etc.

A great deal depends upon the references that can be given. But, after all, perhaps the fairest way is for the employee to work a few days in order to permit the employer to judge as to his ability before the wage question is finally decided. We admit that this is not always practical. Very seldom would such a plan be practical, indeed, if the employee lived at a distance. However, as every producer of honey knows, there are veritable greenhorns who, after a couple of weeks, are worth more than some "experts" of a dozen years' experience. Yes, it depends on the man, on his employer, and on the average wage paid in the locality.

Are Certain Animals Immune to the Stings of Bees?

ONE of our queen-breeders, Mr. Arlie Pritchard, who had charge of our apiaries last summer, had some white rats for pets. During the late warm spell when the bees took a flight he took some live bees and gave them to one of the rats. He eagerly grabbed them up (as if he were in the habit of doing it), holding them between his front paws, munching them as if they were one of the most delicate morsels he ever ate. Stings? Yes, the bees planted their stings on his pink nose, but, nothing daunted, he went right on munching his meal as if nothing had happened. Mr. Pritchard later pulled out two stings from the rat's nose, but apparently they did not have the least effect.

He also relates that on another occasion he took some toads and placed them in

front of the entrance of a hive and watched them lap up with their long tongues bee after bee. After a big lunch he would open the mouth of one of these toads and find it literally filled with stings; but neither the aforesaid rats nor the toads seemed to suffer any inconvenience.

Certain birds are fond of lurching on live bees. We have repeatedly seen a king-bird catch them on the wing; but apparently his birdship is careful to crush his victim, and so it is claimed he does not swallow it. Reports, however, have shown that there have been found stings in the crops and throats of the birds, but apparently they do not suffer from them.

Mr. Pritchard once tried a mouse. This was caused to go into the entrance of a hive; but the bees stung him, and he soon came out and died a few feet from the entrance of the hive. There were only five stings, but they were enough to cause the death of the rodent.

The white rats, except for color, seem to be the same as the common gray ones that are such a nuisance on the farm. It is probable that ordinary rats are as immune as white to the effects of beesting poison. Is it not possible that the common rat does a considerable damage in an apiary at a time of night when his work would not be discovered?

A Plea for Warranted Queens

THE following letter came from one of the most prominent queen-breeders in the country—a man who, we know, produces first-class stock; but in view of the fact that some of his fellow-advertisers may feel that we are giving him too big an advantage in an advertising way over all of them we are withholding his name and address. The letter reads as follows:

In reading Mr. Webb's article on mismatched queens it seems he has run into some very careless queen-breeders, surely not representative of the majority of queen-breeders. I was a beginner myself once, and bought lots of queens from different breeders, but never had over one mismatched out of a dozen. I have been a queen-breeder myself for some years in a limited way, and find my mismatings run from 3 to 5 per cent.

For the last two years I have been guaranteeing every queen purely mated, or another queen when returned, and find that very few ever come back; and it gives customers confidence, and increases sales over and above what little loss I may get by returning pure for mismatched queens.

You say in your editorial that guaranteeing queens would open a way for fraud on

the part of customers; but I have never found it so. Most of the small beekeepers are in the game as much for pleasure as profit; and when they feel they have been squarely dealt with and get their money's worth, they have no inclination to take advantage of the queen-breeder.

There is nothing to interfere with any queen-breeder guaranteeing pure mating; but we would recommend that all queens that prove to be mismated be returned, and that the queen in the first place, before being sent out, be marked by a peculiar cut in the wings, so that positive identification will be possible.

While we believe in humanity, and believe that most of the world is honest, we know of an instance that occurred last summer where one party was getting queens right and left of numerous queen-breeders, telling them that the queens were unsatisfactory, and asking for a replacement. As a result he secured a lot of extra queens for nothing.

Where one lives in a locality well Italianized, he can afford to guarantee pure mating at very little expense; and, naturally enough, the public will patronize the person or concern that guarantees its stock, prices being equal. In time this will shut out the irresponsible and careless breeders, and compel all to reach a certain standard or quit the business.

The largest bulk of our complaints concerning advertisers have been against a few that furnish queens—not against those who have advertised queens for many years, but rather against a few of the late comers in the field who do not realize nor perhaps understand the importance of having their mating-yard where there are few or no black drones.

Carrying Bee Legislation Too Far

RECENT discussion in these columns, editorially and otherwise, shows the great possibilities of sending bees in one, two, and three pound lots by express. There is very little likelihood that bees when sent in this way will carry disease if ordinary precaution is taken; and yet there are several states where shipments of bees in pound packages are barred. Already we are getting complaints from these states, to the effect that the beekeepers who are supposed to be protected are being handicapped in that they can get no other bees from outside their own state. The kind of legislation that is too drastic is liable to be overturned, with the result that there will be no protection.

We are informed that European foul brood has made considerable headway in

one state; and yet the beekeepers in that commonwealth propose to bar even queen bees sent by mail. They would thus make it impossible to send vigorous strains of Italians to help combat this terrible disease. Verily, the thing that would safeguard the public becomes a menace. It is time that the beekeepers of the country awake to the folly of carrying things too far.

But perhaps some will object by saying that we have no proof that disease cannot be carried in pound-package form. Some twenty years ago we repeatedly shook out bees from diseased colonies to clear them of American foul brood. We did not call it American foul brood then, because only one kind of foul brood was known. These bees were held in wire packages for twenty-four hours, then given to clean hives on new combs. We never once had a case of bee disease develop in this way. The very essence of the treatment by the Quinby, McEvoy, or Jones plan is to shake the bees from diseased combs and put them into clean quarters. When one receives a shipment of bees without combs the Quinby treatment is automatically put into force.

Objection may be raised that disease might be carried in queen-cage candy, but not more than can be carried by queen-bees in a mailing-cage. While there is danger, the modern queen-breeder today, we believe, is exercising every precaution in that he boils the honey or uses invert sugar in making his candy.

Perhaps it may be said that we are interested in the pound-package business. Admitting this, our interests are infinitesimal as compared with those of the great public at large, who ought to have the privilege of doing an interstate business in the transmission of bees and queens under certain regulations.

The great bulk of bee diseases is carried by broken and smeared-up sections thrown out in the back yard. In the same way extracted-honey packages are sometimes thrown indiscriminately where local bees can get the honey smeared on the inside. The modern glass packages, however, used by the bottling trade, are usually of a type that is useful in the household, and will not, therefore, be thrown away. They will be washed, and the rinsings go into the sewers. The packages can then be used again for the storage of jelly or canned fruit.

After all, the great danger resides in the comb-honey packages. If we are going to debar the shipment of bees in any form, we might better bar the shipment of comb honey from one state to another or in any state.

But such legislation would be a most serious handicap on the industry.

The National Beekeepers' Association would do well to make recommendations thru a resolution sent to all the state and local beekeepers' societies, urging against going too far. It is these local associations that, in some cases, are responsible for putting thru a law that is both a help and a handicap. But why have the handicap?

Our Florida Department and its Genial Editor

WE are glad to introduce Prof. E. G. Baldwin, of Deland University, Deland, Fla. While he is professor of Latin, he is an ardent student of beekeeping. He has something over one hundred colonies of bees with a modern equipment for taking honey. He has traveled quite extensively over Florida, and in *GLEANINGS* for 1911 he wrote a series of articles on Florida beekeeping continuing thru the year. He also furnished some matter for the last edition of the *A B C and X Y Z of Bee Culture*. He is not only one whom it is a pleasure to know, but his geniality shines forth in almost every line of his printed matter.

PROF. E. G. BALDWIN

For some time back there has been a demand for more matter on the subject of Florida beekeeping, and numerous have been the requests for a department. We have finally made arrangements with our friend to edit it, and now the land of sun-

shine and of "eternal youth," balmy climate, oranges, grapefruit, bananas, and last, but not least, honey, will be represented. Prof. Baldwin needs no further introduction, either to the readers of *GLEANINGS* nor to the readers of the *Beekeepers' Review*, of which he is one of the associate editors.

Building up Colonies for the Harvest? To Him that Hath Shall be Given

THERE is no more important matter in beekeeping than having colonies ready for the harvest—not only strong, but bees of the right flying age to secure a crop. Colonies of only half strength, or below par, will come far short of the strongest colonies in honey production. A beginner would naturally suppose that a half or two-thirds strength stock would gather proportionally as much honey as one of full strength. But this is far from being the case. In the production of comb honey, at least, the half and medium sized colonies possibly might not go up into the supers at all, while the full colonies might store 50, 100, or even 200 pounds each. In the production of extracted honey the relative difference between the different sizes of colonies is not so marked, but great enough to make it very important that all colonies should be regular boomers in size, full to overflowing with bees.

The average novice would readily suppose that the proper thing would be to equalize the strength of the various colonies by the interchange of brood a month or six weeks before the main harvest; but if the weak colonies are strengthened at the expense of the strong, the danger is that all the colonies will be below par, and that the yield of honey will be light.

Our best beekeepers of the country are unanimous in the opinion that the process should be reversed. If the colony is strong, it is only necessary to see that it has plenty of stores. Of the two, four, and six frame colonies, the strongest should be selected, and built up by taking brood and bees from the weaker. By this process the nuclei will be absorbed, and all colonies be brought to honey-gathering strength.

In uniting it is best not to take too much brood at a time, as the reinforced colony may have more than it can take care of properly. If that is the case, some of the brood would be chilled or neglected if unsealed. So far as possible it is advisable to use hatching brood, or near hatching brood, in the early part of the season. Later on, when the weather is settled and warm, the

younger brood can be used. Indeed, we advise at that time taking brood, bees, and all, of the weak nuclei, and giving them to the stronger of the sub-normal colonies. In honey production, either comb or extracted, the weakling colony in the spring is usually good for nothing except to use for making increase. But a better rule by far is to unite in the manner here explained, on the principle that "to him that hath shall be given, and he shall have more abundance; but from him that hath not, shall be taken away even that which he seemeth to have."

But the reinforcing with brood, as already explained, will not accomplish much unless the bees have plenty of stores in reserve, and natural pollen in the combs early in the spring. Of course, after the bees can get pollen from the fields there is no danger of a shortage; but before this time there will be bad weather early in the spring when the bees will not breed readily unless provided with combs containing pollen. Without it they will not do much. It should be borne in mind that in the early spring pollen is nearly as important as stores of sugar syrup or honey. Every good beekeeper will see that combs of it are gathered up in the fall and kept in reserve, and then slipped into the hives early in the spring on the first favorable day.* There is no better capital in the beeyard than combs of natural pollen. Artificial substitutes can be given; and while these answer the purpose to a limited extent they by no means take the place of the natural article, for the simple reason that the nitrogenous food element that the bees so urgently need is not supplied in the proper form.

Transferring

At this time of the year we receive many letters inquiring for easy methods of transferring bees from old box hives to hives having movable combs. A great many inquire whether they cannot remove the box hive, put a movable-comb hive in its place, and then put the box hive on top, the idea being to have the bees work down into the lower hive. This plan is usually uncertain. If the queen is caught and put below, and a queen-excluder put between the two, the results are far better. A still better plan, however, is the one in which the box hive is below and the new hive on top. F. Eric Millen, of the Entomological Department of the Michigan Agricultural College, in a special bulletin, No. 76, of the Experiment Station, discusses a number of plans for

transferring, including the Guernsey plan, which has been given in substance in GLEANINGS before, but which will bear repeating here.

At a time when the box hive is crowded with bees, usually in May or early June, the transfer is commenced. The beekeeper provides a hive-body containing one frame of unsealed brood placed midway between a sufficient number of frames of drawn comb or full sheets of foundation to fill the hive-body. The box hive is then opened, and the new hive-body, with brood and combs, or foundation, placed on top. In a few days, usually, the queen will be found laying in the upper (or new) hive-body; but if foundation only is used it may be a week or two before the queen comes up. As soon as the beekeeper is sure the queen is in the upper hive-body a queen-excluder is placed between the box hive and the new hive, and left there for twenty-one days. When examining for the queen it is a good plan to slip the excluder between the two hive-bodies before disturbing the bees very much, as the queen is liable to run below. If, on examination, it is found that the queen has not commenced working in the new hive, the excluder must, of course, be removed and replaced after the queen ascends. Supers may be added to the new hive as required, and work proceeds normally. The success of this plan depends on getting the queen to ascend and commence working in the new hive, and, after that is accomplished, in preventing her return to the box hive. After the queen has been established in the upper new hive, and when the queen-excluder is in position, close up all outside entrances to the old box hive and provide entrance to the new hive by inserting wedges between the two hive-bodies. A sloping alighting-board, extending from the new entrance to the ground, will aid the bees in making a speedy entrance. Twenty-one days after the queen-excluder is placed between the hives, with the queen above, all the worker bees will have emerged from their cells in the box hive.

Prepare an escape-board by tacking a strip of wood just over the edge of the circular hole in the bee-escape. This strip is to aid the bees in climbing up to the Porter bee-escape. Place the board with bee-escape upside down between the hives in place of the queen-excluder. Two days after the escape has been placed between the hive-bodies, all the bees will have gone above, and the old box can be broken up and the combs rendered into wax.

We recommend the Heddon short method of transferring as given in the A B C and X Y Z of Bee Culture. We have so many calls for this that we have printed circulars that we send out on request, giving this plan.

Mr. Millen, in the bulletin above referred

* It is not advisable to have such combs in the hive during mid-winter.

to, gives what he calls the water method of transferring. This plan for transferring from diseased combs was given in GLEANINGS, page 237, March 15, last year. Aside from the inconvenience in providing a tank of water large enough, the plan has much to recommend it. Briefly, the plan consists in providing a wash-tub, or other tank large enough and deep enough to allow the box hive to be entirely submerged in water. Remove the top and bottom of the hive and place the new hive on top. While the two hive-bodies are held in contact, very slowly lower the box hive into the water until the bees have been forced off the old combs up into the combs of the new hive up on top.

Mr. Millen's bulletin is interesting, and is well worth careful reading.

Report of the National Convention in Chicago; Continued from p. 258

ON the afternoon of the last day, after the address by S. G. Snooks, Freight Claim Adjuster of the Erie Railway, the delegates brought in their report, setting forth their recommendation in regard to the matter of reorganizing and naming new officers. This has already been given on page 217, March 15.

Following this, Mr. E. D. Townsend delivered an address on the subject of "Shipping Comb Honey by Parcel Post." He showed several packages that he had been using. For the parcel-post trade he did not deem it practicable to ship it further than the second zone. The postage on a gallon of honey for that zone is 19 cts.; on the third zone, 34 cts. But no one, he thought, would pay this latter price.

Names of prospective customers he secured by advertising. While many would suppose that local papers would be the medium, he had found the women's journals of national circulation much more satisfactory. All the names that he secured he kept in a card index, and then followed these up with circular letters which he wrote from time to time. He was surprised, after he had gone into this kind of advertising, to see how many orders he received for honey to go by freight and express. The general results of advertising showed that about 25 per cent was for honey by parcel post, and the rest for freight or express.

A sixty-pound package is a little large for family use. He had been using the half size, or 28-lb. package for freight or express. He would offer as large a package as a family would take. If he offered only a gallon size, a gallon was all they would

take. Where possible he would sell a 28-lb. size; but of course this would be too large for parcel post.

Postal regulations for liquids (and this, of course, includes honey), he said, require that the container shall be hermetically sealed, and the box surrounding the container must have a double thickness. He did not find it practical to use friction-top pails, as they were not secure enough. He used nothing less than the screw top. The suggestion was made, however, that the friction top might be used providing four drops of solder were used to hold the top in place.

Prof. Francis Jager, in charge of the Apicultural School at the University of Minnesota, then followed with an address on Beekeeping Improvements thru Agricultural School Work. There was a time, he said, when we had to learn nearly everything by ourselves. But the time has now come when we have special schools for every line of work. It takes a great deal of time and work to secure the necessary knowledge and experience by oneself. But now one can get his instruction at a school where oral instruction and demonstrations can be given. Beekeeping at the present is taught in a dozen different colleges in the country. Three years ago there were only three such schools of apiculture. They had at their school 160 pupils, the most of whom were from the homes of beekeepers. The object of the school, he said, was to make better beekeepers, not more of them. We not only need better beekeepers but better beeyards. Too many yards are poor and neglected.

They give every year at their school a short course in apiculture, where instructions as well as demonstrations of how to do the work are given. Many questions are answered; as, for example, how to winter bees in a modern packing-case; how many bees to put into winter quarters in order that they may properly maintain their winter temperature; information is furnished in regard to handling bee diseases; where this and that kind of honey can be secured. In Minnesota they are making a large map showing where the beekeepers are located, where foul brood is, where the best clover areas are situated, etc.

The demand for beekeeping instructions has been increasing. At first Prof. Jager tried to do all the work himself, but since has been obliged to call in an assistant.

As the writer was not present at all the sessions he is unable to report all the addresses or papers that were given. Some of them will, therefore, be conspicuous by their absence.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

LAURENCE A. P. STONE says, p. 275, "If bees get thru the spring months and to the clover flow without contracting European foul brood, it is almost a sure thing that there will not be any until a scarcity of honey again." I know that is claimed, but here it is not likely to put in an appearance until clover begins.

NEW ZEALAND law, which allowed 26 per cent of water in honey, has been changed to 20 per cent, largely thru the influence of I. Hopkins. Analysis of 51 samples of honey gathered from all parts of the country showed the average water content to be 16.46 per cent—*British Bee Journal*, 79. Is the 25 per cent water allowed in this country a bit liberal?

A. I. ROOT, you say you don't entirely agree with me about cross bees, p. 293. I quite agree with you that bees rarely handled may be crosser than those frequently handled. More than that, if continued generations enough it may become a permanent trait. That doesn't bar out heredity. I think you will agree with me that, if you breed from cross stock, cross bees are likely to result. If the temper is not transmitted by the queen, how is it transmitted?

GEORGE H. REA, p. 273, you say shaking is more economical than dequeening for European foul brood. May be, if a single shake will do. But you say, "In order to keep your bees clean it is necessary to have the surrounding territory clean." "Ay, there's the rub." How am I to control the surrounding territory? You speak of a colony, by the dequeening plan, being left without a laying queen for two or three weeks, and then of little value for the rest of that season. Eight or ten days, not two or three weeks; and before I ever had a case of foul brood I had hundreds of cases of big crops from colonies made queenless for ten days, and my bees don't loaf in that ten days. You say, "By the shaking treatment the bees lose practically no time." Don't they lose practically all they've done in the previous three weeks? They do here. If shaking is more economical for you, by all means shake; but it's more expensive for me.

RATHER startling it is to have Doolittle come out flat-footed, p. 236, and say that European foul brood is not conveyed in the honey. I do know that I have fed honey from diseased colonies without conveying the disease, so I know it is not always thus

conveyed. I am pretty well satisfied that it is *continued* in a colony by the nurses eating diseased larvae that have not yet become putrid; but how does it get into the hive in the first place, if not by the honey? Likely robbers, in nosing about among the diseased combs with their millions of spores, get spores on their bodies, and a chance one of these in some way gets into the babies' food. If you insist, it can hardly be denied that there is one chance in a thousand that a stray spore may fall into the honey.

THE 4x5 plain section is gaining in popularity, we are told, p. 248, but the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ is still in the lead—very greatly in the lead, if I am not mistaken, and at the present rate of gaining popularity it will take many a year for the 4x5 to overtake it. It should be remembered that the $4\frac{1}{4} \times 1\frac{7}{8}$ has made and held its way without any boom—never a boom so far as I know—but in spite of heavy booming of other kinds. We were told that we could market some other kind for a cent or two more a section, and probably a good many tried it only to be disappointed and return to their first love. You, Mr. Editor, prefer the 4x5. That helps the 4x5 quite a lot. A beginner, seeing your preference, will at once decide the 4x5 is the thing for him, will adopt it, and use it successfully, and then think no other kind so good, having tried no other kind. But others of us don't like the 4x5, and will none of it. I wonder if we are not considerably more in the majority than you think. Some prefer sizes other than either 4x5 or $4\frac{1}{4} \times 1\frac{7}{8}$; but the majority, including a good many who have tried other sizes, prefer the $4\frac{1}{4} \times 1\frac{7}{8}$. Now if you odd-sizers would sink your personal preferences, and unite to give the $4\frac{1}{4} \times 1\frac{7}{8}$ a fourth of the boosting the other kinds have had, don't you believe that in a short time we could be rid of the nuisance of having more than one kind? [The $4\frac{1}{4} \times 1\frac{7}{8}$ is a long way in the lead, and probably will always hold it. The facts are, the 4x5 is making slight gains if the record of sales means anything. Whether it will continue to do so, of course remains to be seen. It would be almost impossible to make the public confine itself down to one section, one hive, one frame, however desirable uniformity might be. If the shoemaker, for example, could sell only one style of shoes, and all black, and no tan, it might simplify his problems in buying his goods; but the fact is, the human race is fond of variety, and variety is the spice of life.—ED.]

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The sage growth is wonderfully fine, altho the sage weevil gives promise of much injury to the buttons. I am of the opinion, however, that we shall get a good flow from it.

* * *

The orange will be practically gone this season before the sage gets to yielding. This is the first time I have seen this condition in my twelve years in California.

* * *

Mr. T. O. Andrews, inspector of Riverside County, called to see me last week. He informs me that European foul brood is on the decline, while the American type of the disease is increasing rapidly in some localities.

* * *

All correspondents should enclose stamps for reply to any letters asking for information other than mutual business. It costs only two cents to mail a letter; but when 100 is the figure it runs into dollars, to say nothing of the time and stationery used.

* * *

Mr. E. E. Lawrence expects to return to Doniphan, Mo., within a few days. I am sorry business interests have called him away, for I found him to be a man of high ideals, and a noble gentleman. He will probably take up the queen-rearing business again in time.

* * *

Black brood (European foul brood) in this section of the San Bernardino Valley is more prevalent than it has ever been. At least one apiary of which I know is practically out of commission for this season, while there are many cases in other apiaries. Young Italian queens are, without doubt, the strongest battle-line that can be made for the fight. I am sorry this feature has been greatly neglected by most of the beekeepers around Redlands.

* * *

I wish to notify my correspondents that I have many letters remaining unanswered, and can make no promises as to the dates I can get at them. As with all beekeepers, this is a busy time of the year with me. I walk a distance of twelve miles daily, and at night I can be found in my shop busy getting supplies ready to go out to the apiaries. All together, my time is well filled, and I give no promise of immediate answers.

In the March issue I gave my methods of swarm control, which as a rule have worked well for me. This season, however, I was not able to remove my excluders as usual, due to the fact that an exceptionally heavy flow from the orange began before the brood-chambers were filled with brood. At this date (March 29) I am taking full combs of nectar from the brood-chambers and supplying foundation as a means of getting the brood-chambers filled with brood. The queens will lay in the foundation combs as fast as it is drawn out sufficient, while empty combs would be filled with honey within a few days. Out of the orange district, the plan I gave would doubtless work well this season.

* * *

Spring inspection of my Tremont apiary revealed four cases of foul brood—two of American and two of European. One noteworthy feature of the American is that it adjoins the stand where one colony was destroyed last spring, but this time there are two standing in the same row, on stands adjoining where the one was destroyed. One is an immense heavy colony, but has a very bad case. It will be shaken a little later. The others have already gone by the sulphur route.

The two cases of the European are the first of the kind I have ever had, and they were quite a surprise to me. Both colonies are very dark in color, one not being queened last summer. A very peculiar circumstance in connection with the other colony is that there are two colonies being carried over winter in a two-story hive with screen wire as the only division between them, the upper one having a separate entrance. Both were given young queens last summer that were reared from a golden mother. The bees of the lower portion thought they could raise a queen that would suit them better than the one I gave them, so they did. It is this portion that has the disease, while those above the screen are as healthy and strong as one could want a colony at this time of year. Fortunately I have anticipated just such trouble, and have very few colonies that are of low-grade stock. It seems to me that if anything is proven by the double colony it is that good stock is a factor in fighting European foul brood, regardless of the contention of some of our expert authorities that it is not. It appears to me that only one good stock has the vigor necessary.

J. E. Crane

SIFTINGS

Middlebury, Vt.

That Backlot Buzzer, p. 167, is still in trouble — just like some beekeepers I have known.

* * *

Dr. Miller drops a Straw on windbreaks, p. 139, Feb. 15. I believe he is right—quite right. Let us remember.

* * *

Thank you, Mr. Editor, for the suggestion on page 134, Feb. 15, about leaving out entirely that “flimsy following-board.” I am sure many beekeepers as well as inspectors will rise up to bless you.

* * *

Page 147, Feb. 15, Arthur C. Miller tells us that golden Italians are not Italians at all. What a misnomer! I wonder some one had not found that out before. I believe our friend must sit up nights thinking.

* * *

The earth is covered at this time, March 18, with about two feet of snow, with a good deal of zero weather in this vicinity. It looks now as tho it might be a late cold spring, and perhaps a good deal of spring dwindling. At present, however, bees seem to be in good condition.

* * *

Mr. P. C. Chadwick says, page 149. “It was pretty well agreed by inspectors at the state meet that the symptoms of all kinds of brood diseases converge until it is a very difficult matter, in many instances, to tell just what the disease may be.” They are quite correct. Then is the time to send a sample to Washington, Department of Agriculture, to decide.

* * *

The question of the number of hives of bees to the acre in an apple-orchard or orange-grove is discussed by the editor on page 92, Feb. 1, and is one of great importance. It has been proved beyond a doubt in northern Vermont that it pays to place eight or ten colonies of bees to the acre in a cold cloudy time of bloom—a colony for each four or five trees.

* * *

Charles McCulloch, in the market reports for March 1, says, “Lower prices have stimulated the demand for honey, and it looks now as tho the market will be well cleaned up, and no stock to carry over,” while Mr. Byer, Mr. Phillips, and P. C. Chadwick are discussing the question of overproduction, page 184, March 1. Now, it seems to me a case of underconsumption rather than over-

production. Lower prices will usually stimulate the demand, but demand will be small when prices are too high.

* * *

Our friend Doolittle, page 98, Feb. 1, gives us advice as to liquefying granulated honey, which is decidedly sound. The whole subject is one of ever increasing interest. Why should some honey granulate sooner than others? and why should some kinds stand a higher temperature without injury than others? Why has comb honey granulated more readily during the last two years than formerly?

* * *

This time Mr. Frank McNay, of Pasadena, would prophesy, page 175, March 1. “If the ground freezes wet, there will be honey! if it freezes dry, there will be no honey.” I also will prophesy. If the ground freezes wet, if the ground is covered with snow during the winter, if we have no fields of ice on meadow or pasture, if the bees winter well, if April is mild so bees can breed strong early, if apple-bloom and dandelion yield freely, if May and June are wet, if we have no long cold rainstorms during clover bloom, if clover bloom yields nectar freely, and bees do not swarm too much, we shall certainly have a good season; but I believe one of A. I. Root’s speckled buttercup biddies is wise enough not to prophesy until an egg has happened.

* * *

We here in Vermont are in the midst of a lively campaign for state-wide prohibition. I have been astonished at the amount of money expended by the liquor interests for local option as a temperance measure. “When the Devil was sick the Devil a saint would be,” and they would have us believe that untold evil will follow if the forty odd saloons in Vermont should be forced out of business. No alcohol for sickness, no wine for communion purposes! how dreadful! They have not yet learned that unfermented grape juice is used by most churches at the present time. Maine and Kansas are represented as fast going to the dogs in consequence of prohibition laws.

Later.—I am sorry to report that our state has decided by some 13,000 majority to continue local option in preference to state-wide prohibition as the best method of controlling the liquor traffic. We must still be kept in the A B C class until we can better learn our lesson, that the children of this world are wiser in their generation than the children of Ighit.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

A long dry spell has been pretty general thruout the great Southwest. There was very little fall and winter rain, so beneficial for the early honey-yielding vegetation. The winter has been an unusually warm and open one, with little very cold weather. Bees have been reported in good condition. Altho drouthy conditions prevail, and there is but little indication now for any rains, prospects are bright enough. If there are no late freezes some early honey may be obtained. The mesquite is especially promising with an abundance of buds—so far advanced, indeed, that it will come into bloom before the end of March.

But "there's many a slip 'twixt cup and lip," and cold weather might give quite disastrous results. It would do considerable harm to the bees by directly affecting the colonies in their advanced stage of development as well as cutting off the sources of nectar and pollen. With continued warm weather, indications are for much super work thruout the mesquite, huajilla, and catelaw sections.

A visit from Mr. and Mrs. C. P. Dadant, on March 16, was indeed an enjoyable one. The time was only too short. There were numerous apicultural topics for discussion, but many more did not even get out of the "question-box." These good people were accompanied on their visit by Mr. and Mrs. E. G. LeSturgeon, of San Antonio. It is useless for me to begin to enumerate the subjects of most importance that came up at this "beekeepers' meeting" in which the ladies took as much interest as the men folks. It so happens that each one of the better halves is a real partner to her husband, which accounts for their interest in the discussions. Our welcome to such visitors is extended indefinitely. Such discussion usually brings out new ideas and revives many old ones that have been permitted to go into a dormant stage. In other words, "it helps to make better beekeepers out of any of us." That is why I have continually harped on the subject of beekeepers getting together more by visits, beekeepers' meetings, field days, and beekeepers' picnics.

PREPARING OUR COMB-HONEY SUPERS.

It will require about 3000 shallow-frame supers this year in which to harvest our

comb-honey crop besides 1500 or more shallow extracting-supers for extracted honey. While the latter are left on the hives thruout the winter, and the greater part of the year, the comb-honey supers remain on the hives only long enough to become filled and the honey thoroly ripened. After the honey has been cut out of the frames, these scraped clean, and properly replaced in the supers, they are stacked up in huge piles and covered from the weather. In the early spring begins the work of filling them with foundation, work now in progress for the earlier honey-flows.

THIN SUPER FOUNDATION IS USED.

Thin super foundation in full sheets is put in the frames with melted beeswax. Altho this has been mentioned by me a great number of times, questions continue to come from every part of the country on this subject. A frame-rack holding three frames and containing spacing-boards to guide the sheets of foundation to the center of the top-bars is used. Common table-spoons, with usually the lips of the front end of the spoons hammered together slightly to direct better the flowing wax, have been found to be the cheapest and best for the work. The wax is heated in a large stew-pot containing some water, either on a charcoal furnace or gasoline-stove.

IT IS MERE CHILD'S PLAY.

Children do almost all of this work for us now as against grownups of former days. They are better adapted for this kind of work on account of their nimbleness and quickness. The work is light and becomes more difficult for clumsy hands to do. It is especially advisable and essential that this work be done during the earlier and cooler part of the days in the summer on account of the tendency of the thin foundation to become soft and rather difficult to handle. Thus the children can put in good time for several hours in the mornings and earn quite a little amount of pin money. It affords us an opportunity to employ so many more nimbler hands at a time of day when the work can best be done. They enjoy it too, even to our own little four-year-old tot who, by the way, helps every morning, of her own accord entirely, of course, to remove the paper from between the foundation sheets, and lay it within reach of others who put it into the frames.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

BEES AND APPLE-BLOSSOMS.

"I live in a locality where there are many orchards of apple-trees. What relation do these trees bear to our friends the bees, in having them in shape so that they can, by the 'great army of workers' produced thru the stimulation of apple-bloom, gather for us the tons of honey from the white clover and basswood?"

Thus writes a correspondent. In reply I would say that nothing in the line of early honey so stimulates early brood-rearing as does that which comes from the pink and white blossoms of the apple-trees. In fact, it has always been a proverb in this section of the country, "As goes apple-bloom, so goes the season," as to honey. More than half a century ago the hand of that most noted beekeeper, Moses Quinby, of St. Johnsville, New York, penned these words: "In good weather, a gain of 20 pounds is sometimes added to the hive during the period of apple-blossoms. But we are seldom fortunate enough to have continuous good weather, as it is often rainy, cloudy, cool, or windy, all of which are very detrimental. A frost will sometimes destroy all, and the gain of our bees is reversed; that is, their stores are lighter at the end than at the beginning of this season of flowers. Yet this season often decides the prosperity of the bees for the summer. If there is good weather now, we expect our first swarms about June 1. If not, no subsequent yield of honey will make up the deficiency."

Never were truer words uttered, as applied to central New York; and what applies to this locality will apply generally to northern states. Hence we see that the apple-tree bears no mean relation to the beekeeper. In 1877 we had the best yield of honey from apple-bloom that I ever knew; and the results from the apiary that year were the highest ever obtained by the writer, which was an average of 166 $\frac{2}{3}$ lbs. of honey, mostly comb, from each old colony in the spring. I consider the great value from apple-bloom to lie in its stimulating quality, toward plentiful brood-rearing, and in producing stores to tide over the period of scarcity which immediately follows this bloom for a time approximating two weeks. I believe that if we could have the same number of bees in the hives in apple-bloom that we do in basswood time, with equally good weather, the yield from

this source would be nearly or quite as good while the bloom lasted; but since the bloom comes so soon after cold weather, we do not have the bees; and, still worse, the weather is usually such that the bees do not have an opportunity oftener than one year out of three or four to work on the bloom more than enough to encourage brood-rearing; hence I doubt the advisability of trying to work the colonies up to an unusual strength with the hopes of securing a surplus from apple bloom.

So far I have touched only on the practical or dollar-and-cent side of this matter. However, there is still another side which we as beekeepers look after so seldom that we grow poor, and to a certain extent ugly, in our everlasting hustle after that which pours mammon into the home treasury; and we go about continually with a look on our faces which says to every passerby, "Time is money," He who sees in the bees, the apple-blossoms, and the ripened fruit, only that which shall put money into his pocket, lives in a poor half-furnished house. He who obtains from them only what he can sell, gathers but a meager crop. If I can find something besides dollars and cents with my bees or on apple-trees, shall I not take it? Apple-trees, during each year, are like some people we know. In their young and blossoming days they are sweet and pink-hued, and then they grow acid, pale, and hard; but in the ripened experience of later life they may become sweet again, and more enchanting by their ministering to the calls of humanity. So if any of us have become acid, pale, and hard, in our eager grasping after the "almighty dollar" which may come from the bees and apple-trees, let us once more return to the joy and sweetness we had in the springtime of life which may again come into our lives as the deep richness of color comes to the ripened fruit of the apple-trees of autumn. If we have allowed our grasping disposition to get the better of our inner being, something as apples led to the loss of Paradise, is it not about time we begin to reconstruct a bit of Eden by once more listening to that better nature which will, if we will let it, lead us once more under the blossom-laden boughs, made pleasant with their perfume and the joyful hum of the bees? Nature might have contented herself by allowing the apple-trees to bear seeds only; but she accompanied such prosaic action with fragrant flowers and delicious fruit.

FLORIDA SUNSHINE

Deland, Fla.

FOREWORD.

When Editor Root admitted that there might be "room for one more" in the ever-widening columns of GLEANINGS' departmental staff, a new hope was quick to leap in my heart—the hope that fair Florida might be the fortunate one to secure representation among her sister states.

I need not try to tell you, ye editors many and capable, how glad I am to see that hope being fulfilled.

I have felt for several years past that this big southeastern peninsula—the one big peninsula of our Union—deserved more magazine space, possibly, than had heretofore been accorded her. I felt that Editor Root had made a notable advance toward nation-wide apiculture when he reached out hands across the northern border to our brothers and sisters in Canada; when he widened the circle from central to middle West, and then to the great West, until he could see the sun set in the Golden Gate. But my longing eyes missed something. When first I heard the sweet humming of the Dixie Bee I felt like lifting a glad cry. From Medina to Nashville is a long stride; but I felt that this, tho profoundly a step in the right direction, was still only a beginning; for how immense is the territory south of Tennessee and east of the 82d parallel, the line that runs thru eastern Ohio, clips off the eastern tip of Tennessee, and then cuts straight down thru the heart of Florida! Now swing the compass that reaches from Medina to Nashville, "away down south" still further into Dixie, and you barely reach our Jacksonville.

The recent and systematic study of beekeeping conditions in the great Southeast, begun under the direction of Dr. Phillips, only increased my conviction that now was "the psychological moment" to extend still further into the Southland the radii of America's most representative bee-journal—to make it, in this detail at least, more completely representative.

It is in this spirit of glad service, therefore, that I have undertaken the responsibility of special contributor from this particular region of our great Union. Read the telling chapter, "Regional Differences in the United States" in Dr. Phillips' new work, "Beekeeping," and I am sure you all will agree with me that no one contributor can speak authoritatively for all regions.

In the orange-honey belt, which extends from about the 30th parallel of latitude to the Southern Keys, the bloom on all citrus

trees this year seems about the poorest since the "freeze" of '99. A letter from my friend Reynolds, near Fort Myers, on the west coast, says "Orange-bloom a total failure." A like card from Mr. Harry Hewitt, of Apopka, reads, "Only a light bloom." On the east coast it is the same story; and here at Deland on the St. Johns the bloom is the "sorriest" I have known in 16 years. Bees have built up splendidly on it, however, and the hives, light at first, are now heavy with brood, bees, and honey—but little or no surplus. The bees are still working fairly well early and late, but lie off in the heat of the day, showing that the flow is gradually coming to a close. My hive on scales has just about held its own since the first of March, in weight; but it is much stronger in bees than then. It was not a fair representation of the average colony, however. This year only the very cream, the very pick of the prime colonies, stored any surplus from orange.

We cannot complain, however, for of the previous three years one was fair and the other two extra fine for orange honey. It is safe to add that every blossom was visited by many bees this season—no danger of scanty cross-fertilization, for the blossoms were so few and scattering that there would often be two bees trying to get into the same blossom at the same time! Reports so far received from the pennyroyal-honey-section states show that there is a fair crop of that choice article, tho not so good as last year. We have not yet a full report from the tupelo section. The next main source will be the scrub palmetto, then the cabbage palmetto, and mangrove, pennyroyal being the first in point of time.

Best Yields when the Bees are Close to the Source.

P. C. Chadwick thinks the bees are to blame if they do not go over $1\frac{1}{2}$ miles for nectar, page 149, Feb. 15. On page 145 J. E. Crane speaks of scattering bees thru the orchard for better results. If bees go long distances, why is it that they show so much better results close to the bloom? Large orange-growers here in Florida scatter the bees, and they get better fruit close to the bees.

I can show Mr. Chadwick locations here, $1\frac{1}{4}$ miles from mangrove or orange, where bees will starve, altho, close by the bloom, they can get a large yield. I have tried it, and not at one location either.

GENERAL CORRESPONDENCE

HOW TO DO AND HOW NOT TO DO; CLIPPING QUEENS

BY R. F. HOLTERMANN

When a beekeeper has only a few queens to clip, it is not a matter of very great importance when the clipping is done. For instance, if hundreds of queens require to be clipped it may not be advisable to wait until fruit-bloom to do it, because, with probably unfavorable days there may not be sufficient time to clip them all, and in that case I would begin to clip at any time when the bees are gathering pollen and nectar freely. No reason has ever been given, so far as I know, why it is more injurious or risky to clip a queen during the time of, say, maple-bloom in comparison to apple-bloom; and after having clipped thousands of queens any time warm enough for the bees to gather pollen and honey, during a time ranging from early willow to clover and beyond, I have not been able to discover any difference in results. The longer a beginner waits after spring opens to hunt the queen in a normal colony, the stronger the colony will be, and the more difficult it is to detect a queen.

Before a beginner undertakes to clip a queen, or even find her, I take it for granted that he will have studied in literature the appearance of a queen on the comb, and have in his mind's eye just about what a queen will look like. If the operator has never seen a living queen, it is quite an undertaking for him to find her, and I should be disposed to advise setting an empty hive in front of the old hive, with its entrance toward the old hive. Upon this, place a super, with a queen-excluder tacked to the bottom of it. Upon shaking the bees into this super from the combs in the hive in which the queen is to be found, and finally dumping the bees which remain in the old hive into the super, the bees will soon work their way thru the queen-excluder and thru the entrance of the new hive back to their brood and hive. In this they can be gently driven with smoke. The worker bees can go thru the queen-excluder, but the drones (if any) and the queen cannot. In this way a queen should be readily found. I look into this super after shaking each comb, or even glance over the combs before shaking it, and frequently find her before having half shaken the combs; but it is not well to spend much time over this.

Difficult as it may be for a beginner who is not a keen observer to find a queen the

first time, it is still more difficult to catch and clip her. There are generally other bees about her that might sting. Let them sting. Under the finger-nail is a splendid place to be inoculated. But we are also genuinely afraid we might injure the queen. This latter is, I believe, true of every beginner.

I shall take it for granted that the operator knows the difference between the head, thorax, and abdomen of a queen. Some queens are much more disposed to take wing than others. Young queens are also much more likely to fly than older queens. Where a queen appears to be light-footed, and tries to run about the comb and over other bees, even moving her wings, be careful. She has escape in mind; and if one is not careful she may take wing any moment; and if she does I would not give much for the chance of recovering her. If you want to make reasonably sure that she will fly, chase her with your thumb and finger, or blow a little smoke on her. If the queen does take wing, keep yourself and the comb in the position in which you were when she flew, but the chances are she was too excited, when she took wing, to locate herself. After holding a comb ten minutes, looking for the return of the queen, I would not wait any longer.

I have noticed students giving sharp puffs of smoke with the object of separating worker bees and queen. This is bad practice, as it tends to make a queen take wing. The least likely place for a queen to take wing is when she is quiet and her feet are on the comb. That is a place and attitude where she can be picked up by the beekeeper with the least danger.

A queen should never be picked up by the abdomen, as that is the most easily injured part of the body. Many of us have seen dents in the abdomen of a queen, just as we have seen a dent in a tin pail. This was the result of outside pressure, and it never came out. Such a queen is generally superseded. The queen must not, then, be grasped by the abdomen; but a queen can safely be grasped by the thorax.

Some advise practicing clipping by taking drones. If a beginner can first see some one else clipping queens it is quite a help.

Holding the queen between the thumb and finger may be a long way from having her in such a position that one can clip her

wing or wings, without taking some other portion of her body, particularly a leg. Queens are adepts at getting their feet against the finger and trying to pry themselves loose; and if they cannot pry against something under them, which is away from their wings, they will try to do it against something above them, where the wings are to be cut. To be safe when I clip, I like to let the queen rest on my knee, holding her by the thorax from above. When that is done she pries against the knee, and there is no danger of cutting a leg off when clipping. The same can be effected by holding her with one finger under and another above her; but this method is less certain. I like to advise the cautious way. Some beginners chase a queen across a comb with a pair of scissors, making a lunge at her wings—a method of which I never made a success. I clip the wings on both sides; others clip one each year, using the markings as a record.

If a beginner wants to find a queen without shaking and combing the bees thru a queen-excluder the following rules should be observed:

1. Do not jar the hive in which you are about to hunt the queen.

2. Smoke the bees very gently, giving no sharp puffs.

3. Take the combs out as quietly as possible, and look them over intently and fairly rapidly, not forgetting corners or openings between the comb and frame. Set the combs, after examination, outside of the hive until all have been removed or until

the queen has been found. Do not forget to look among the bees left in the hive. With black bees, not Carniolans, she will quite often be found off the combs.

4. If the queen has not been found after trying the above I would recommend looking them over one by one and replacing them in the hive, and, if not found, then leaving the work for another time. My reason for advising the latter is because by that time the bees will have assumed abnormal positions, getting into clusters, etc., in the hive or on the combs, and then it is more difficult to find the queen.

5. When hunting for a queen, do not talk about other things; do not think about other things, but do as a writer somewhere once said—say "Queen, queen, queen," mentally, all the time. In other words, keep your mind on the object of your search, and then you are most likely to find her.

6. Perhaps this should come first of all. If the hive has a honey-board and a beespace above the frames, you can try giving the colony a fairly sharp smoke, say covering about a minute, and you may find the queen on the under side of the honey-board. This is more likely to be the case with black bees.

7. Never try to clip a queen when the bees are likely to rob. Do not try to find her at such a time. Some of us have to do the latter, but it is not work suitable for a novice. If done, do it as nearly at the close of the day as possible, but not after the shades of night are falling.

Brantford, Ont., Can.

AN UNPRECEDENTED SEASON

BY G. C. GREINER

The past season, unquestionably, goes on record as the best honey season beekeepers of the present generation ever experienced in this locality; and, as nearly as I can judge from reports I have received, other parts of the state were favored in a similar manner.

On page 748, Sept. 15, Mr. J. E. Crane refers to Quinby's book, saying, "Clover will sometimes continue to bloom all summer and yield honey." Then he adds, "Such a season was 1865, as I remember. I have been looking for another for the past fifty years, and it has come at last." That is exactly my experience, except that Mr. C. has fifty years to fall back on, while I can call an experience of only forty years my own. If I am not mistaken, the year 1887 was an uncommonly good honey season—

perhaps the best in my recollection; but it was nothing like the one just passed.

With the exception of a few days between the dandelion and alsike-clover flows, honey has been coming in continuously from the time the early spring sources, such as elm, soft maple, the early fruit trees, etc., yielded nectar, until the middle of October. All my summer's honey-house work, including extracting at the close of the white-clover flow, could be done with the doors wide open, and not a bee would offer to molest me. Even as late as the middle of September bees would improve favorable days with such uncommon display that I had occasion at different times to call members of the family to the beeyard to witness the strange spectacle.

It is not strange—yes, it would be only a
