natural consequence—that such an uncommon season would also produce an uncommon honey crop; but the strange part of it is the fact that we had the wettest and seemingly the most unfavorable summer for bees to do field work in many years. Possibly an hour or two in the afternoon, or perhaps a little while in the forenoon, was all the chance they had to go to the field. The fears we entertained during the fore part of the honey-flow, that under these unfavorable conditions the season would turn into a honey failure, were dispelled by our bees. In spite of the many cold stormy days, supers were filling up right along; empty ones had to be given, and finished ones taken at short intervals, so that, by the end of the season, my comb-honey-producing colonies had averaged $6\frac{1}{2}$ supers of finished sections. During the season I have taken from the poorest colonies six, from the better ones seven, and from two (my banner yielders) eight supers of 24 sections each.

All these colonies run for comb honey were divided swarms, or, more correctly speaking, divisions of divided swarms. The parent hives, after two combs of brood with adhering bees and the old queen had been taken, were moved to a new stand, and a young laying queen given at the time the divisions were made. The two combs of brood with the old queen and some empty combs were placed in a new hive and left on the old stand to catch the flying bees. These new swarms were run for extracted honey, and averaged between 140 and 150 lbs. each.

All my white honey brings me 20 cts. per section at retail, and 16 cts. in crate lots at the stores. Weight, to a certain limit, is not taken into consideration, all sections selling at the same price. Of course I am very careful in sorting my honey. Everything below $13\frac{1}{2}$ oz., which I decide by eye and lifting (no scales are used), is not passed as full weight, but sold at a correspondingly low price. Darker grades, such as amber and buckwheat, are also sold for several cents less per section. I do not furnish any crates, but reserve them when sales are made. As I do all my delivering myself I have no expenses for freight or express to meet, neither do I have to let middlemen share my profits. I can not give the exact average price I receive per super; but as the larger part of my crop is white honey, and a good share of it is sold at retail, it is not far from \$4.00 per super, which would be for the average yield of $6\frac{1}{2}$ supers, or \$26 per colony.

The other divisions, those with the old

queen and flying bees, have done nearly as well in number of pounds; but in extracted honey I have no data to compute their average yields in pounds and ounces; but I have some means for ascertaining their yields quite closely. Every super, every comb of honey, and every section taken from my hives, is carefully recorded on the inside cover of the hives, so that, by simply lifting the outside cover, the progress of every colony is revealed. To this my beekeeping friends from different parts of the state who have visited me at different times during my season's campaign, and have inspected my beekeeping outfit and management can testify.

As I have frequently weighed supers before and after extracting, also single combs when I felt especially interested in their weight, I can quite closely estimate the yield of a colony by consulting its record.

By far the largest share of my extracted honey, perhaps nine-tenths of my crop, is sold at retail, and nets me, when put up in pint and quart cans, $14\frac{1}{2}$ cts., and in jelly-glasses 16 cts. The largest package, the quart can, seems to be the favorite of my customers, while the sale of the jelly-glasses is comparatively limited, and takes only a small part of my crop. The average price is, therefore, very little above the price of the larger package. But these prices are for white honey. About one-fourth of my crop is amber and buckwheat, for which I get from one to three cents less per pound. This would reduce the average price of the entire crop to about $13\frac{1}{2}$ cts. As stated above, the yield of my colonies run for extracted honey was from 140 to 150 lbs.; and taking the medium, 145 lbs., as a fair estimate, it brings the income of these colonies to \$19.57 each; and, with the product of the comb-honey divisions added, to \$45.57, spring count.

This yield of the past season has no precedent in my forty years of beekeeping. But it is not all due to the season. It is the result of combining season and management. The method which I have adopted and successfully practiced during the last four or five years gives me, besides unusually heavy yields, other advantages that help to reduce the unpleasant work of the beeyard in a great measure. First in this line stands practically perfect swarm control. Every comb-honey-producing beekeeper knows by experience the deplorable sight that meets one's eyes when a colony sends out a swarm that has two or three supers well under way on their hive. This does not happen to me except in very rare cases. None of my comb-honey-producing colonies

All the supers had been removed from the hives (G. C. Greiner's apiary).

swarmed this summer, and only one of the divisions run for extracted honey swarmed normally during the white-clover flow. Later in the season I had five superseding swarms from the same divisions—those with old queens and flying bees. Two went back of their own accord, and the others I returned to their home by taking their queens away when being clustered on small trees or berry-bushes.

As my method insures me this much-desired swarm control I have no queens to clip; no queen-cells to hunt and destroy, no shaking off or running after young swarms—nothing of the kind; in fact, I have hardly opened a brood-chamber after all colonies had received their full equipment of combs at the beginning of the white-clover flow. Instead, I can spend all my time forcing the production of surplus honey, and my bees are not troubled with swarming notions, but are bent on expending all their energy in the super work.

Another advantage, and one of great importance in producing a heavy yield of surplus, is the breeding-up of a hive full of young vigorous field workers at the right time. My method brings this about.

On page 831, GLEANINGS for Oct. 15, the editor justly cautions the comb-honey producer against the use of bait sections and finishing up sections by feeding back extracted honey. From experience I can endorse every word he says, but with this proviso: "If not properly done." Both fea-

tures are an important part of my method, and are the means of my unusual surplus yields, and, in a certain way, the prevention of swarming. To produce desirable bait sections they must be drawn out and filled, taken from the hive, extracted and cleaned by the bees as soon as possible, and then stored in air and dust proof compartments until wanted. Honey produced on bait sections managed in this way is in no way inferior to any produced in the usual way. It would puzzle the honey-expert as well as the every-day consumer to detect the difference.

It is the same with feeding back to finish sections. It must be done properly. Feeding must begin before the honey-flow entirely ceases. Sections to be finished should not be off the hives any longer than is strictly necessary to prevent them becoming stale at the cell-tops, and feeding must not be allowed to suffer any break from beginning to end. If the honey to be used for this purpose has not been extracted in its green state, when still nectar, it must be diluted to about that consistency. Some of my best fancy honey, exhibited at the fair, was finished by feeding. However, from a honey-producer's standpoint I admit that both features, bait sections and feeding, are detrimental to the quality of comb honey, but not any more so than the use of full sheets of foundation.

The accompanying illustration was taken after all the hives were stripped of their

supers, except one at the lower end that was used for finish work. Supers and feeder are still on the hive. The row in the middle

contains mostly colonies that produced the unusual crop of comb honey described.

La Salle, N. Y.

PARALYSIS AND THE ISLE OF WIGHT DISEASE; ARE THEY THE SAME?

BY F. R. BEUHNE

In the Nov. 15th issue the editor, p. 922, asks for information as to whether the bee-paralysis of Australia and of southern United States is the same as the *Nosema apis* (Isle of Wight disease) of Great Britain. This is exactly what we have been endeavoring to determine ever since the presence of the nosema parasite in Australia became known in 1909. All the evidence up to the present is negative to the proposition that the two diseases are identical.

Shortly after the discovery of the parasite, bees were obtained from 88 apiaries covering five out of the six states of the commonwealth. The parasite was found in the first 20 bees from 86 apiaries. Repeated microscopical examinations of bees from the two remaining apiaries failed to show *Nosema apis*. One of the two clean apiaries was 100 miles inland at Waugaratta. The other was the Departmental apiary at Burnley, close to the city of Melbourne. A visit I paid to the Waugaratta apiary showed that bee-paralysis was present, although nosema could not be found. The Departmental apiary at Burnley was free from both paralysis and nosema. Queens from colonies affected with paralysis were brought from inland apiaries and introduced to several colonies at Burnley. Symptoms of paralysis appeared in from five to six weeks later. Bees from these stocks were then examined, and at intervals later by Mr. W. Laidlaw, B. Sc., Biologist of the Dept. of Agriculture, who also made all previous and subsequent microscopical examinations, but no signs of nosema could be found, even in bees which were in the final death throes of paralysis. Finally the queens were removed, also dissected, and found clean. Queens of a resistant strain were introduced in their places, and in a little over two months all signs of paralysis had disappeared. This experiment was repeated several times in succeeding seasons, and the result was exactly the same. On the other hand, *Nosema apis* was found in bees affected with paralysis when they came from apiaries in which the presence of the parasite had been proved, the degree and percentage of infection being the same, whether the colonies showed symptoms of paralysis or not. Incidentally

I may here mention that I have repeatedly effected a cure of the most pronounced cases of paralysis by exchanging the brood of the affected colony with that of a normal colony, at the same time removing the queen of the former and allowing a queen-cell of a different strain, and raised in a normal colony, to hatch and mother it. The curious thing is that, altho, as might be expected, bees continue to die for some time after the exchange of brood in the affected colony, yet none of the bees hatching from the combs of the affected stock, and given to a normal one, show any symptoms of paralysis, which seems contradictory in the face of the fact that paralysis can be produced in any colony by the introduction of the queen of an affected colony.

Reverting now to *Nosema apis* I must point out that, altho the parasite was found in 86 out of 88 apiaries, the localities from which some badly affected specimens came had never suffered any losses. The colonies showed no symptoms, and were profitable. Further, outside the two apiaries mentioned, it seemed impossible to find bees free from nosema. Even bees from trees in the forest had it, also some of the worst-affected colonies with a little judicious help recovered, and developed into prosperous and profitable stocks.

In view of all this, it did not seem advisable to adopt the drastic treatment of destruction of the bees and combs which is recommended by the British authorities. Quite early in the investigations it became evident that contributing factors were necessary for the parasite to become harmful. Considering the wide distribution revealed by the investigations, it appeared quite hopeless to attempt the total destruction of the parasite, and more advisable to try to find the contributing causes. With this object in view, queens and their escorts from hives proved to be affected with nosema were introduced to a number of colonies at the Burnley apiary. The biologist, at intervals of two and three months, examined bees from the colonies experimented with, and at no time could nosema be discovered in the bees. Becoming bolder, we next transferred 14 badly affected colonies from

inland to the Burnley apiary. These were very small, and could not have recovered without some assistance. A comb of hatching brood was therefore given to each. In three months all of them had completely recovered, and showed no trace of *nosema apis*.

In view of the success obtained, a further and somewhat larger experiment was made. In January, 1915 (which, of course, is summer here), 24 colonies were selected from an apiary 60 miles from Melbourne. Microscopical examination of bees proved all of them to be infected with nosema. Nineteen of these were sent to the Burnley apiary, while five were left behind as controls. In May examinations of all were again made by Dr. Laidlaw, and showed that, of the 19 shifted to Burnley, 16 were now clean, 3 were still affected, but in a lesser degree than in January. The 5 controls still retained the parasite.

Owing to much brood-rearing without an income of nectar it became necessary to feed the 19 colonies in May. Fifteen were given sugar syrup, and four some dark honey of unknown origin obtained in the open market. In spring (September) the examination made showed that three out of the four which had been fed honey were rather badly affected, and only one of the sugar-fed, slightly. Of the controls, two

succumbed during winter, but the remaining three were now clean.

The fact that three out of the four colonies (which were clean at the previous examination) became infected after being fed honey (which possibly came from old brood-combs), that one, altho given exactly the same, remained free, opens up several new issues for further investigation.

The infection of one of the sugar-fed colonies may be accounted for by robbing, of which a little took place at the time.

That the surviving control colonies rid themselves of the parasite may indicate that, under the stimulus of a plentiful supply of good pollen and new nectar, bees are able to throw off the disease in spring. This also applies to the Burnley apiary, where, owing to its location among artificially watered flower-gardens, and the vicinity of the river, there is never a dearth of normal pollen. Nothing is finally proved by the experiments, and I have departed from the rule to publish nothing that is not complete, only with the object of indicating the directions in which a solution of some of our troubles may be looked for, which I take to be the inherited vigor of the strain of bees together with a plentiful supply of good nitrogenous food during the period of their infancy.

Tooborac, Vic., Australia.

THE NEW BEE DISEASE; MORE LIGHT WANTED

BY GEO. W. BULLAMORE

A few years ago I found it necessary to read thru the descriptions of the Isle of Wight disease written by thousands of the beekeepers of this country who had suffered losses. I soon found that, with regard to the symptoms, the definite statements of any one beekeeper were usually at variance with the recorded experience of some other beekeeper, and that the only point on which all writers were in agreement was that there had been a heavy loss of bees. I am reminded of this when reading the accounts in GLEANINGS of "that Western bee-disease." While some are claiming that the disease disappears as the result of the sulphur treatment, another states that the cures are apparent only, and the bees dwindle away and eventually die out. One writer does not think the weather has anything to do with it. To others, weather is the chief or only cause. Some speak of it as a form of paralysis, a disease known to attack the adult bees only, while other accounts mention the rotting brood. A constant feature

of the reports is the crawling bees. This was the case at first in the descriptions of Isle of Wight disease in England; but a careful study of the course of the trouble in districts and apiaries for a year or more convinced us that a symptom of this nature was associated with the dwindling of stocks without sign of dying bees, and also with abnormal winter losses when the bees were found dead in heaps on the floorboard. Whether a sick bee dies inside the hive, in front if it, or away at the pasturage, probably depends on a number of factors of which the organism causing the trouble is but one.

A good account of a trouble which we should diagnose as Isle of Wight disease is given by Critchlow in GLEANINGS for 1904, page 692. The loss of several thousand colonies in Cache Valley and Salt Lake Valley is described. Other accounts are given by Bedell, 1909, page 412, where losses in New York State are recorded, and by Fawell, 1909, page 704, who tells of heavy

losses in Ontario. An interesting statement was also made by James Heddon when discussing the question of wintering at a meeting of Michigan beekeepers on December 1, 1875. He attributed the heavy losses in Michigan to an *intestinal disease*, and said, "In the winter of 1871 two of my neighbors had 65 and 85 stocks respectively. In the following spring they had but one apiece left. All the other bees kept in the vicinity died." We are but too well acquainted with this form of loss in districts where Isle of Wight disease gets a footing.

It should be borne in mind, when comparing the English with the American disease, that our observations in England are made chiefly upon bees in which the native black predominates. On the other hand, many of the American descriptions refer to losses which have taken place in apiaries where the bees are pure Italian, or nearly so. We know, too, that the Isle of Wight disease varies considerably in accordance with weather conditions, so that the double factors of race and climate are bound to affect the American manifestations of nosema disease. In regard to weather, so far as can be traced, epidemics of bee-disease in this country have always been correlated to wet seasons. The epidemics of 1782-'3, and 1860-'3, were associated with wet summers, and an outbreak of paralysis occurred during a long run of wet years which terminated in 1883. Bees do well here at times, owing to the fact that our climate consists of long irregular spells in which dry years predominate, alternating with spells in which wet years predominate. We are now in one of the wet cycles. Rainy springs and autumns aid in the spread of parasites, probably because for breeding purposes the bees carry in so much water from the paths and foliage in the vicinity of the hives. When intestinal disease is present this may be grossly contaminated with infected excrement. Indirectly, too, wet and cold weather may act by influencing the quality and quantity of the food, and by lowering the resistance of the bee to disease.

The American reports often suggest adverse weather conditions as being a factor in outbreaks. The probability is that most bee diseases, and particularly those in which the causal organism is to be found in the intestine of the adult bee, are rendered worse by the occurrence of wet and cold weather.

The nosema organism is reported to be present in the bees of the United States; and as this organism is associated with Isle of Wight disease in this country I have very little doubt that it is at the root of some of

the trouble in America. The newspaper cutting from the *Seattle Times* reads like Isle of Wight disease; but when we read the description of the same trouble as given by M. Y. Calcutt (1915, page 714) we find that rotting brood is a prominent feature of the outbreak. Confirmation of the brood trouble as a symptom is given by P. C. Chadwick in his description of the California outbreak. A. L. Hartl, Texas, page 21, adds the interesting detail that in his case the dead brood was diagnosed as sac brood at Washington. Rotting brood was certainly not a feature of the disease on the Isle of Wight and in other districts that came to my notice. I have handled hundreds of combs of diseased stocks, but have never found any great proportion of them to contain rotting brood, certainly not more than would be affected with foul brood when Isle of Wight disease was not present. In the majority the brood presents a perfectly healthy appearance, and, if transferred in time, will hatch in other hives. In warm weather I have seen brood hatching in a hive from which all the adult bees had disappeared, and on one occasion I took some sealed brood from a moribund hive and hatched it in an incubator for purposes of study. This is the appearance of Isle of Wight brood as I know it, and it is, therefore, difficult for me to reconcile it with the accounts of the western disease.

I am reminded, however, that about 1890 an epidemic which attacked both brood and bees was raging in Italy. Investigations were commenced, and Professor Canestrini isolated a bacillus of the megatherium type. I believe that he failed to establish its pathogenicity, and nothing more seems to have been heard of the disease. Have the West rediscovered it?

If it is correct that Professor Kincaid has discovered spores in the heads of the bees we should expect to find that the glands were diseased. The poisonous products of microbial activity (toxins) might be fed with the gland secretions to the larvæ, and the result would be that the larvæ would die. Under the microscope the dead larvæ would resemble those killed by the filterable virus of sac brood. Personally I have never met with such a condition in any examinations I have made, but have always borne in mind the possibility of its occurrence.

In the present state of our knowledge, or at any rate until it is certain that all the losses in America are accompanied by rotting brood, it is advisable to retain an open mind as to the relationship of the western disease to the English malady, which appear to be directly fatal to the adult bees

only. There can be little doubt, however, that sometimes the heavy losses in America are due to genuine Isle of Wight disease, and therefore some account of the effects of treatment may prove helpful. In the con-

quest of disease every failure narrows the field to be covered, and the lesson gained may direct others to the path which leads to success.

Albury, England.

AN EASILY CONSTRUCTED ELECTRIC WIRE-IMBEDDER

BY E. L. SECHRIST

The electric foundation-imbedder that I am using is easily made from odds and ends, and therefore it costs almost nothing.

For electricity to heat the wires I use the regular lighting current, running it first thru a common electric flatiron, which, after some experimenting, was found to provide just the right amount of "resistance."

To convey the current to the wire I use what I call the goose-neck made of two pieces of heavy insulated copper wire, the ends of which are flattened into wide chisel points at the end where they are to come in contact with the wire of the frame. Pressing on the treadle beneath brings these copper wires down in contact with the wire of the frame long enough to heat the wire to the desired point.

The peculiar form on which the frame is placed to do the imbedding is the result

of considerable experimenting. It is a 3-16-inch board of a size to fit loosely inside a frame. As shown, a 1/4-inch cleat is placed under the center while the ends are nailed to the board beneath. This makes an easy curve. The edges are all rounded off, and the form is blocked up from the table enough to make it convenient.

The sheet of foundation is fastened in the top-bar by any method, and the frame placed on the form with the wires on top of the foundation. The advantage over other imbedders is that both hands, not one only, may be used to adjust things and bring the wires into close contact with the foundation in case of any irregularity. When all is ready, press the treadle until the goosenecks touch the wires on the inside of the frame, just where they go thru to be fastened by the tacks.

As soon as the points are in contact with the wires it is a delight to see that wire sink down to the midrib of the foundation all over the sheet, while the cell walls close up behind it, imbedding it so solidly that it cannot come out.

As soon as the wire is imbedded to suit you, remove pressure from the foot lever. The connection is broken, and both hands remain in place on the frame holding the wire in place until it cools. All this takes only an instant, and the imbedding is done more perfectly than I can do it by using only one hand to hold the frame in place while the other hand operates the electric connections.

Fairoaks, Cal.

HOW THE BEES HELPED TO PRODUCE A RECORD CROP OF APPLES

BY GEORGE H. WEST

I want to tell something about the pollinating of the fruit-bloom in my orchard in the spring of 1911, as the crop I had that year (amounting to over \$11,000) was the greatest the orchard ever yielded.

There are some twenty-eight acres of bearing apples on this forty-acre square, the rest being largely in alfalfa located in the southeast corner. In 1909 and 1910 also I had good crops from the orchard as I had plenty of bees on the alfalfa ground. The winter of 1910 was severe, and the owner of the bees lost most of them. Very early in the spring, having bought land about a mile northeast of the orchards, he removed to his own land the bees he had left.

On going into the orchards about May 1 I was startled by hearing no bees among

night to a location in the northwest corner of my orchard. This location was chosen for two reasons. First, Winesaps, of which there were twenty-two acres, are rather poor pollenizers, but are very receptive to the pollen of other apple-trees; and the Ben Davis, Missouri Pippins, Jonathans, and Ganos in my neighbor's orchards joining my land north and west, are all good pollen-bearers. Second, our prevailing winds are from the northwest and west; and as we have many high winds I believed the bees would work better from that location.

During the blooming period the weather was bright and warm, and two days after moving in the bees when I went over the orchard again I heard the humming of bees everywhere.

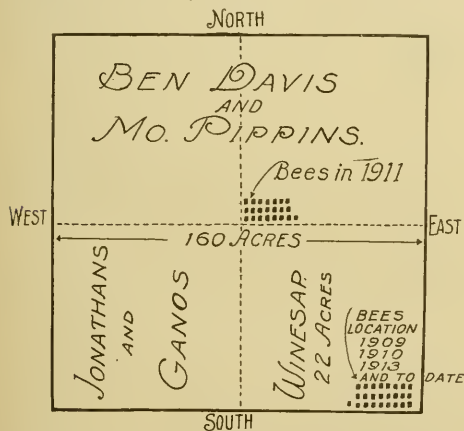

After the blooming period, and when we began spraying, the owner removed the bees. I never had bees as near my Winesaps as I had that year, and have never had as large a crop before nor since. The bees were about the center of the 160 acres, nearly all in apples, and my neighbors also had record crops that year.

The Winesap tree shown in the illustration* is one of 952. In 1910 this tree yielded twenty seven field-boxes (bushels) of apples; and in 1911, the year this photograph was taken, and the year the bees were so close, the tree yielded thirty-six bushels in spite of the fact that the young fruit was thinned down twice. From this tree we packed thirty bushels of apples which sold for \$44.50 cash. The 952 trees averaged over seven packed boxes per tree that year, netting me over \$10 per tree.

In conclusion I wish to say that I have good pollination and plenty of bloom every year; and, except for the hazards of the winter and spring freezes, and damage by hail, I should have good apple crops every year.

Colorado Springs, Col.

* Cover engraving of this issue.—Ed.

the blossoms which were just opening. I went carefully over the whole orchard and some others adjoining it, but there was silence everywhere instead of the usual humming of the bees. I became alarmed, for I knew that, if there were no bees, there would be no apples. Altho the loss in bees the winter before had been serious, as I have said, by some effort I secured twenty vigorous colonies and had them moved that

SUBURBAN BEEKEEPING

BY J. H. DONAHEY

[Mr. Donahey, as our readers know, is the cartoonist of the Cleveland Plain Dealer, whose clever work attracts attention from all parts of the country. He was a beekeeper before we became acquainted with him, and it was the occasional beehive in his cartoons that made us suspect that he knew something about bees. He is the originator, of course, of the Backlot Buzzer.—Ed.]

I am sending you a few snapshots taken in my small suburban beeyard. It overlooks a ravine, and is on a timbered hill sloping

to the east, and was utilized as the only available place where the hives could be located. Running thru the valley is a small

The hives are located on a hillside, the only available spot in the lot. The scaffold keeps the hives from the wash of the hill, and permits easy handling from the rear.

stream where the bees go in the springtime to get their first drink.

The hives rest on platforms built on the side of the hill, and are two or three feet high and operated comfortably from the rear, where steps are arranged to get up

The beehouse with a root cellar underneath is a fine place for a city man to spend a rainy day.

and down the hill. The high scaffolds prevent the wash from the rain from damaging the hive.

Walks lead to the beehouse where the material is kept, and many pleasant hours of education and amusement are spent there every year. Underneath the building is a

root-cellar, a luxury for a city-dweller; and between the whiffs of pippins in the winter and the delightful half-hours sitting in the shade on the porch watching the bees scurry in and out during a honey-flow, the man who spends his working hours in a great city finds it a rare pleasure indeed.

The children who come to learn of the bees have been told that the building is a "grouch" house. They have sought high and low, from roof to root-cellar, and under the porch, but never a "grouch" can they find. I always tell

Below the beehouse there is a stream where the workers gather for water in the springtime. To sit on this porch and watch them rush in and out of their homes during a honey-flow is a privilege that few city men can enjoy.

them that it is there when I am there, which leads to questions, and sometimes I almost have to confess.

"Tony," who works around the yard and the garden, slept for a time in the "grouch" house. His cot was directly under a skylight and near an observation hive, which we had arranged inside the building, permitting the bees to enter thru a small box from the outside. For some reason or other, probably from the settling of the building, the box slipped loose from the wall, and

many of the bees flew up and tried to get out thru the skylight, and, failing, dropped down on Tony's bed. It was dark when he came in that night, and, being tired, he did not light the lamp; and, undressing, he hopped right into bed, and straightway he hopped right out again. It was three miles to the place where his people lived, but he was back at seven in the morning, ready to go to work, but in appearance he was not quite the same Tony.

Cleveland, Ohio.

THE GOLDENS VS. THE LEATHER-COLORED ITALIANS

Have the Criticisms of the Golden been Too Severe?

BY M. E. BALLARD

[In the following few pages we are presenting the discussion promised in the editorial, page 217, March 15. Since some have felt that GLEANINGS has not given the golden a fair chance, we are publishing here practically all the letters we have received favoring the golden. Furthermore, and because the experience was limited to only a few colonies, we have thought best to withhold several letters supporting Arthur C. Miller's condemnation of the golden. In order to be fair to all, we are not publishing the names of the breeders who have contributed the four articles marked "By Breeder." We believe that all the breeders of golden Italians who advertise in GLEANINGS are thoroughly reliable. Our own view of the whole question is fully set forth in the editorial above mentioned.—ED.]

Mr. A. C. Miller, p. 116, Feb. 15, cites a series of cases of improper acts which are credited to the golden. In case 1 the bees failed to select larvæ of the proper age to raise a queen. Will not black bees or leather-colored Italians do the same thing?

Case 2. This combination is wholly unnatural. Mr. Miller had, in that nucleus, bees from two different colonies. The bees which were on the frame of brood with the two queen-cells were in need of a queen, or otherwise there would have been no queen-cells on the comb; and as these bees were united with the nucleus they failed to unite properly—at least failed to recognize this strange virgin queen—and continued to build and draw out the cells on their original comb. That is strictly in accordance with nature; and who would expect bees to do otherwise?

Case 3, while rather peculiar, I think needs some correction, for at that stage it would be difficult to determine just when those laying workers began laying. Nevertheless, since the hive was for a time queenless, and working bees had thrust upon their organs the task of producing eggs, what should we expect those laying workers to do with those eggs when developed? Perhaps Mr. Miller will say they should have gone out on the alighting-board and dropped them in the grass.

Case 4 illustrates their "bad temper," and this I consider too unreasonable to comment on; but I should like to ask if there was any robbing going on.

Mr. Miller also states that "true pure leather Italians" are extinct, so far as he can find. I am wondering if they ever existed. Did any one ever see a colony of "pure Italians" without a yellow trace in their makeup?

Mr. S. H. Burton also condemns the golden. He does not explain why; but from what he writes we take it for granted that the reason is because his bees came near starving to death. This throws no light on the subject unless Mr. Burton had a percentage of leather-colored Italians, and made comparisons which he fails to state. There were bees that did actually starve to death in this locality under similar conditions in June, blacks as well as Italians; so is that any reason to condemn golden? As the Caucasians excel Italians as honey-gatherers, a cross between these two should make an improvement over Italians so far as honey-gathering is concerned. Will Mr. Burton kindly inform us what breed of bees those were that went into winter quarters in the best condition?

In discussing the qualities of the golden, will some one with experience, who is inclined to condemn them, tell us "why and what for," and not condemn them for something that is just as common among leather-colored bees and blacks?

The only doubt I have as to the efficiency of the golden is their wintering qualities, and at present I am not prepared to say whether that is below the standard.

Roscoe, N. Y.

IF AT FIRST YOU DON'T SUCCEED (WITH GOLDENS) TRY, TRY AGAIN

BY A. T. RODMAN

The bees of my first colony of goldens were so cross that I could do nothing with them. I killed the queen and thought I would try again some time. At this time I had a strain of bees that had the reputation of being as good as any three-banded bees in the United States.

The next spring I tried two golden queens from Arkansas. They were fine queens, and were the first to go into the supers. But about this time my neighbor put out a washing and they ran her in the house; also some little chickens were badly stung; in fact, everything that came in reach got stung. I decided to exterminate them; but how was the question. I waited till night, and then put a weak colony in their place, and put them in a secluded place. The next day the field bees returned to the old stand and were peaceable. As there were only young bees left in the hive with the golden queen I had no trouble in getting hold of her. Was I discouraged? Not at all. I still believed these were good goldens, and I ordered another queen from the East. She was not so cross, but she was not as golden as she should be, and was inclined to produce lazy bees. She was also removed in due time.

Still I was not discouraged, and commenced to look around for more goldens. I drew two more failures, but I finally secured a golden queen the equal of any queen I ever owned. Being a little afraid on account of my former experience I introduced her to a weak colony some twenty miles away. She came thru the winter stronger than any other colony. Her bees were gentle, and seemed to be fairly crazy to get into the hive with their loads of honey. I brought her home on four frames of bees and brood, and she beat everything on the place that season. I raised queens from her for two years, and am still requeening from the same stock, and expect to continue to keep on doing so long as I have bees.

Now, I don't expect to have any queens for sale this season, so this is not a ruse to get free advertising.

These bees suit me better in many ways than the three-banded. They are better hustlers, are more gentle, and keep the moths out better than the three-banded. They never produce a lot of bees that shine like a stovepipe, and seem to be deformed, having large heads and small abdomens.

Kansas City, Mo.

IN FIVE YEARS THERE WILL BE MORE GOLDENS THAN EVER

BY H. M. MOYER

We have more golden Italians at present than we had five years ago. Why? Because they are good bees. I tested almost all the bees, including the Cyprians and Holy Lands. The Cyprians are extra good in every respect, except they are cross. I tested blacks, dark Italians, and golden Italians side by side.

I have been a practical beekeeper for some 35 years. Goldens are gentle and

fast breeders. The queens are large as well as the bees, and are good honey-gatherers. They winter well in spite of what is said against them.

Five years after this we shall have more goldens than we have today. The Feb. 15th number was too hard on them. I have no queens nor bees for sale, and hence am not interested.

Boyetown, Pa.

GOLDENS ARE BRED BY COLOR SELECTION FROM ITALIANS

BY A BREEDER

Beyond doubt there are some strains of goldens which are practically worthless. To say about all, "they are no more Italians than an Ethiopian is a Caucasian," is simply to tell what is not true of the best strains. If Mr. Miller denies that one can breed goldens by color selection from Italians he is crazy. That is just what is the matter with many strains of goldens. They

are bred for color until that is all they are good for. There would be no cause for such criticism as Mr. Miller's if the papers prohibited advertisers making extravagant claims about their stock.

Now don't get the idea that I am a golden breeder, peevied in what I say, for I sell about six three-band queens to one of the golden.

GOLDENS THAT ARE WORLD-BEATERS

BY A BREEDER

On page 63, Jan. 15, A. C. Miller speaks of killing 20 old queens in full colonies and smoking in a like number, all in 45 minutes. Now, I have no doubt caught and caged more queens than Mr. Miller ever saw—from one or two to one hundred a day during the queen season for the past 15 to 18 years—and I'll say right here the man who catches and cages 25 queens an hour from *nuclei* is going some; and it is an altogether different proposition finding queens in full colonies. It *might* be done once, but I have my doubts.

As to the "curse of the goldens," I have before me a letter from a man in Idaho who seems to take kindly to the "curse of the industry," as he orders 200 of them and reports 250 pounds of comb honey from a colony headed by one of these "curses." Don't you think it would be well for the industry if there were more of the "accursed" kind?

I realize that there are, no doubt, goldens that may not be all they should be; but did you ever think of the great number of three-banded bees that are in the same boat? Why don't we hear from them? For a number of years I have had goldens and three-banded bees in the same outyard, and these three-banders were as good as any in the world; and if there was any difference in the production or disposition I failed to find it.

You find some people who have a twisted conception of life and what it means, and are inclined to get out their little tack-hammer and knock everything in sight that they may have taken a childish dislike to. Now, this does them no good, and might do others harm. Personally I do not care for Caucasians, for they are not the bees for this location; but I do know they are hard to beat where you have several good flows during the season. I never knock them, because, for certain sections, they are *the* bee.

If we are to believe Mr. G. M. Doolittle (and I know of no more truthful man), goldens have been bred up from the three-banded bees, and not by crossing with Eastern races—at least his have; and you will find, by writing to breeders of golden queens in the United States that at least half of such breeders have founded their stock on the rock of Doolittle. There are breeders of golden queens who are giving their best efforts to producing a strain of bees that will be world-beaters; and I'll tell you right now that they have about reached the desired goal. It takes a greater intelligence to rear goldens than some other strains. The more difficult it is to reach a desired result, the harder you must work and think and plan; but if you keep at it long enough you will succeed.

THOUSANDS OF BEEKEEPERS PREFER GOLDENS

BY A BREEDER

I have been in the bee industry over 20 years, and have tried and tested all kinds of bees side by side. Taking everything into consideration, the goldens have proven the best and most gentle. They will gather more honey than any other strains with double the quantity of bees. I have only goldens now; but I will not try to run down any race. There are some very good bees of the dark races. The best and oldest beemen in this country praise the goldens, and

recommend them. The editor says that one who buys goldens or extra-yellow bees is likely to receive bad and good stock. I would ask if it would not be the same in case of the three-banded. I think it is getting time for those who have goldens to stand up for the superiority of these (the disease-resisting strain). I know there are thousands of beemen who would not have any bees except goldens, no matter what any one says.

THE BRIGHTEST GOLDENS ARE THE GENTLEST

BY A BREEDER

Mr. Miller is very evidently biased on the subject, and in support of this I cite his assertion that goldens were the cause of laying workers. Why blame the poor bees

just because they were yellow? One would infer from his assertion that laying workers are found only in golden colonies.

It is not color that influences me in decid-

ing on goldens. I know that a great many prefer the so-called leather-colored or three-banded Italian; but it has been my observation that my brightest yellow bees are the ones easiest to manipulate, and they are better workers. I use no veil or smoker on my yellowest ones, but the ones showing a tendency to three bands or leather color I have to subdue before manipulating.

I do something in the way of demonstrating at fairs, and I always use my brightest yellow goldens to work with, frequently demonstrating on cool cloudy days, when, to open a hive of dark bees, would be to invite serious consequences. Among my favorite stunts is to shake a whole derby hatful of bees on top of my head (and there is not much protection left there any more).

Now as to Mr. Miller's query regarding behavior of the six hives of goldens that were previously gentle, a possible explanation is that, as long as they were *pure golden*, they were gentle (which he admits). On superseding the old queen her daughter would still show the racial characteristics, even if she should mate with a hybrid or black drone, and would still produce apparently golden bees.

Another reason is that the source of nectar, or, rather, the lack of a source of nectar, was the cause. He also states that the bees were in the hands of beginners. Ah! Any race of bees if handled in a careless timid manner is apt to resent it. If the bees were tinkered with six days of the week by a novice Mr. Miller could not expect to find them the acme of gentleness.

A HUNDRED DOLLARS TO GET RID OF THE GOLDENS

BY D. E. LHOMMEDIÉ

Mr. Miller is right. A number of years ago I was desirous of getting some new blood into my stock. At this time the late Mr. Alley was advertising a dozen golden queens, every one a breeder, for \$10 per dozen. I received a dozen by mail. They were so bright, and they came thru so well, that I ordered three dozen more, and introduced them into four different apiaries.

The next spring about cured me of goldens. To make sure, however, I got some queens of another breeder, but they were very little if any better. They are not like honeybees. It cost me over \$100 to get them cleaned out of the yards. But the goldens have one good quality—they are handsome.

Colo., Iowa.

A CALIFORNIA YANKEE'S METHOD OF WIRING FRAMES

BY S. A. NIVER

Perhaps my wiring-clamp will interest some beekeepers who have found the wiring of brood or extracting frames very puzzling. It is a slow tedious job at best. I have taken several ideas from the bee-jour-

nals, and combined them into a simple device for holding the frame rigidly and squarely. It is easy to fasten the frame in position and release it, and the wires are strung tighter than by any other plan I know of.

It is a double-decked affair. Fig. 1 shows the lower deck with the lever arranged to pull the iron lugs against the end-bars, bending them in toward each other, while the wire is threaded. No. 2 shows the upper deck with a frame in position pushed to the left, and held in place by the "button." The clamp is fastened to the bench by means of a

couple of screws so you can yank the wire as hard as you wish. After stringing the wire in the frame and releasing it from the clamp the end-bars spring back and draw the wires very tight.

In this locality, where the sun is hot and honey thick, I have found the cross-wiring scheme an excellent plan, worth all the trouble and more too. Fig. 3 makes it plain. I buy the wire

in the coil, and make a spool to fit it that revolves on a spindle attached to a frame fastened at the end of the bench. After

threading the end of the wire thru holes 1, 2, 3, 4, I tack it fast, then cut the wire at the spool and thread the other end thru Nos. 5, 6, 7, 8. One can avoid kinks in the wire that way.

A magnetic tack-hammer to pick the tacks up from the upper deck and start them in the proper places is handy.

We extract in the upper story of our honey-house, run the honey thru pipes immersed in hot water, into six-ton tanks below. It gets thin enough to strain thru fine cloth. This was illustrated in GLEANINGS some time ago.

Greenfield, Cal.

MY WIRE-REEL AND WIRING-BOARD

BY J. E. JORDAN

The illustration shows my wire-winding device. By using this device, all the wires will be of the right length to wire fully the frames, and all will be cut at one stroke.

To make this, bore a hole in a block and nail the block to the corner of your honey-house. This will serve as a bearing for one side of the reel. Put up the framework for

the other side of the reel as shown. Select a board $\frac{1}{2} \times 7 \times 39\frac{1}{2}$ inches, and exactly in the center nail the axle, a square piece of wood, rounded at the ends as in the illustration. Nail a small strip, $\frac{1}{2} \times \frac{1}{2} \times 7$, across the board 3 inches from the end. This is to raise the wire for cutting.

Wind on all the wire that the spool holds, then with clamps hold the wire tight about 6 or 7 inches from each end of the board. Now with a pair of tinner's snips cut the wire at the half-inch strip,

and nail the board to a table within reach. By using the wiring-board shown in the second illustration I can easily wire 60

frames an hour, and all will be tight. After placing the frame on the board, force the

wedge between the brace and the end-bar of the frame, springing the latter in. After the frame is wired and this wedge taken out the end-bar will spring back in place and tighten the wires.

Morgan, Ky.

[We use practically this plan for cutting the wires the proper length; but instead of using clamps we merely tie coarse strings around the wires, board and all.

An important advantage of this plan which Mr. Jordan does not mention is that the wires drawn from the board are much less likely to kink than if pulled directly from a spool.—Ed.]

AS GLIMPSED THROUGH THE CAMERA: THE BARTLETT-MILLER CAPPING-MELTER

BY H. H. ROOT

Since the publication of the article by H. Bartlett-Miller, page 164, Feb. 15, a number of beekeepers have written, asking for further particulars regarding the making of this capping-melter, because the sectional view shown was not entirely clear.

Believing that this particular form of melter has much to recommend it, we built one to test the coming season. The illustration shows two views of the melter. The first one was taken before the end was soldered on, in order to make plain the

construction of the inside part. The steam generated in the lower part rises and heats the curved false bottom, passes around the ends of this, and circulates thru the triangular tubes. The outer end, when soldered on as shown in the second illustration, confines the steam so that it circulates only thru the tubes. Both ends are exactly alike in this respect. There is no exit from the water or steam compartment except at the filler lip on the end opposite from the honey and wax outlet. In case the steam

Bartlett-Miller capping-melter described on page 164, Feb. 15. In the first view the end is not yet soldered on, so that the interior construction may show.

Half-pound cage for shipping bees. The triangular construction adds to the strength and insures abundant ventilation.

pressure becomes too great it can escape thru this opening.

When the cappings fall into the melter they strike the nearly vertical sides of the steam-heated tubes, and begin to slide down immediately toward the narrow 5/16-inch spaces between the tubes at the bottom. By the time the honey drips down on to the false bottom beneath, the wax is melted, and the honey and wax both run out of the opening at the end of the gutter. The honey is not subject to the heat any longer

than is absolutely necessary, and there is no possible chance for it to dam up or be confined.

Mr. Miller, since the publication of his article, has been using a capping-melter on some rather strenuous work. On one occasion he reduced 267 pounds of cappings and a few combs of non-extractable honey in just thirty minutes.

In the melter which we constructed we reduced the height of the hopper over the tube to only 2 inches, as we knew that this would take care of the cappings under all ordinary circumstances. If two are uncapping, or if we wish to melt up a large amount of granulated honey, we shall build an extended hopper made of thin boards. This can be taken off out of the way when not needed.

At the present time there is one drawback to this design of capping-melter, and that is the question of material. Sheet copper is nearly three times its normal price; and that means that if copper were used the material alone would cost in the neighborhood of eight or nine dollars. It requires close to two days' time for labor in constructing. We finally decided on galvanized iron as the most practical material available. After considerable experimenting we succeeded in seaming the joints so that the solder would hold it securely. We do not think the plan of soldering the tube mentioned by Mr. Miller is practical when galvanized iron is used,

The one-pound cage.

for the alternate changes in temperature would be likely in time to cause a leak. With proper care, the galvanized metal ought to last a number of seasons.

A NEW STYLE OF COMBLESS PACKAGE FOR SHIPPING BEES.

Since our experiment with the Achord combless package as recorded on page 89, Nov. 1, we have been doing considerable further experimenting with a view of finding a more compact cage that could be more cheaply constructed than the one sent us by Mr. Achord and that would take a little less room as well. The cleats extending out beyond the sides of the cage are not especially liked by the express companies.

Our Mr. Arlie Pritchard has suggested the construction shown in the accompanying illustration. Notice that the ends of the cage are triangular, and that there is no vertical surface. It is impossible to crowd the cage so tightly to the wall as to shut off the ventilation, hence no projecting cleats are needed. This construction is light and strong, and it furnishes far more room for the bees than the old-style cages.

One extensive shipper to whom we sent one of the cages wrote that it looked like the best thing out; but he thought the cross-sticks should be arranged a little nearer the center to give more space between them and the wire cloth.

A BEGINNER'S EXPERIENCE IN MANITOBA

BY MRS. FLORENCE WESTGATE

During the winter of 1914, owing to poor stores and too much heat and smoke in the cellar, out of sixteen colonies put in I took out only two which were of any use.

Seeing bees advertised in pound packages I ordered a pound from the South just for an experiment. They came the first of May, in the very best condition, with only about one dozen dead bees. I put them on two drawn combs filled partly with sugar syrup. They were beautiful bees. The weather was very cold, so I covered them with quilts and stuffed a feather pillow in the open space at the side of the hive and left them alone, except to visit them and sit and watch them hustle. They were the greatest little workers—out first in the morning and in last at night.

I determined to have more of them, and wired for five more packages which arrived

May 26 in even better condition than the others—not a spoonful of dead bees. How proud I was of them!

I followed the directions as nearly as possible, giving them drawn combs of sugar syrup. I tried putting a tomato-can of syrup inverted, on a saucer in the open space at the side of the hive, and it must have worked all right from the way those little duffers worked and built up.

I shook one of my old colonies June 17, and gave frames of brood to the new ones. They had their hives full of brood and bees in the middle of July. On the 19th the first one cast a fine swarm, and from then on I had a swarm every day until all but one of the new colonies had swarmed.

The bees I received May 1 filled two supers of sections and one half-depth super of extracted. I got 20 cts. per section and

A good retreat from the summer's heat—in Manitoba.

about 30 lbs. of extracted, which I sold at 15 cts. a pound. I did not give these bees any brood either, as they were almost a month ahead of the other five.

I now have 16 good strong colonies and two not so strong if they winter successfully. From the remaining colonies I sold 193 sections and 196 pounds of extracted.

I am enclosing a picture of part of my

new colonies. I am standing by the hive, with my daughter and two young friends who had been helping me extract. My little apiary is on the north side of the lawn, with about 20 acres of natural shelter to the west, and with a hedge on the east. The bush is oak and wild fruit-trees—plum, cherry, and saskatoon.

Portage la Prairie, Manitoba.

WASHINGTON BEEKEEPERS' CONVENTION

BY H. T. SKINNER

The 22d annual convention of the Washington State Beekeepers' Association was held in the Commercial Club rooms at North Yakima, on February 9 and 10.

Weather conditions were unusually bad, and the attendance was not as large as expected; but those who braved the elements were well repaid, for the program was an excellent one.

The officers' reports showed the association to be in a healthy condition.

There were papers and addresses by some of the best-known beekeepers of the state on subjects of interest to beekeepers, one by Mr. Sauter, of College Place, Washington, on queen-rearing, being of particular interest. Mr. Sauter is the only large commercial queen-breeder in the state.

There was a paper by Professor Wilson, Entomologist of the University of Wisconsin, entitled "Better Queens, better Bees; better Bees, less Disease."

Professor Thornber, of the Washington State College, told of the college extension work.

On the evening of the 9th Professor Melander, Entomologist of the Washington State College, gave an illustrated lecture entitled "Ants, Bees, and Wasps," which was a revelation to many of those present.

Auson S. White, the only surviving one of the charter members of the association, read an interesting paper on the original membership and the early days.

The members were so well pleased in buying containers in carload lots in 1915 that they decided to order the same way this year, and may add some other articles to the list.

During the year four members have passed away, viz., L. R. Freeman, a charter member, and first secretary of the association; D. B. Greenwalt, at one time president; J. D. McIntosh, and Mrs. Pressey, all well and favorably known.

Ten new members were added during the year.

A committee was appointed to draft a foul-brood law, and also one to arrange for the purchase of containers for the coming year's product.

The officers elected for the ensuing year were: President, J. B. Ramage, North Yakima; vice presidents, C. W. Higgins, Wapato; E. Sauter, College Place; W. H. Tucker, Prosser; J. J. Peters, Arlington; secretary, H. T. Skinner, North Yakima; treasurer, Gus Sipp, Selah.

North Yakima, Wash.

[The program of the Washington State Beekeepers' Association for this convention is a pleasing departure from the conventional type. It is a really creditable 24-page booklet giving the program, interesting facts regarding the association, lists of members, etc. Enough advertising was secured to offset the cost of the printing and probably more.—ED.]

A BEE-PROOF SUIT

BY "BEGINNER"

I have followed the discussion on the above subject in GLEANINGS, but all the suggestions developed weak points in practice. Here is one, however, that is *quite* bee-proof. It is the helmet of mild steel, built on the sealed-cover system, and fitted with a pair of magnifying rectilinear lenses. These enable the most timid student to make

accurate observations of the annoying bee oscillating flight in perfect security. The visor is of cold-drawn heavy-gauge steel wire. GP is a new-pattern glass periscope for viewing all cowardly rear attacks, and, incidentally, the important gauge glass on the oxygen-tank. S (beneath the OT) is the new type of cold-smoke battery. SD,

An improved bee-proof suit.

smoke discharge, shows the modern powerful sixteen-inch howitzer pattern. Hanging conveniently is the combined hive and

trenching tool. In case of onslaught by *overwhelming* numbers the apiarist may fearlessly dig himself in. Later the entrenchments should be lined with straw; and the bees wintered therein, thus turning apparent defeat into conclusive victory. On the front of the helmet is H.A., hot-air vent. This is very conveniently situated, as are also the aural apertures; but since the latter are covered with Porter bee-escapes the merest tyro will see that safety is the first consideration. (Unthinking critics have suggested this is to allow the "bee in the bonnet" to escape.) The smoke control is adjusted on that popular spot the knee, while shock-absorbers on the toes will minimize the difficulties should a hive be kicked by accident or diabolical intention. (Vide modern methods of handling hives instead of frames). R.H. is rubber heels to prevent hive-jar when walking about the apiary. The body of the suit is made of vulcanized sail canvas covering two inches of absorbent packing, preferably chaff; arctic moss is splendid, tho rather scarce. The whole is lined with the finest silk—not bee silk—for very few other clothes are worn with this dress. It will be noticed that the vital part of the head is reinforced with a metal jacket. In summer, water or ice may be inserted to keep everything comfortable. This point may be readily ascertained by the thermometer, T.

N. B.—Take care that the escape be fitted right side out.

SOME CURIOUS ADVENTURES IN QUEEN INTRODUCTION

BY J. H. TODD

"The Dixie Bee" asks Mr. Todd or some other advocate of the Simmins method of introduction to explain "the advantage of the darkness," and she mentions how queens were introduced by the fasting method in broad daylight.

The advantage of the darkness in introducing a queen is that the bees are quiet, there are no robbers on the prowl, and the bees are not expecting or looking for intruders. They are, therefore, less likely to be suspicious of the queen than they would be, perhaps, if the operation were done in the day with possibly several robbers following the apiarist from hive to hive, and making a dart for the combs whenever a mat is raised.

Of course, I dare say that, during a honey-flow, the plan will work well in daylight; but we can take many liberties in such happy times that would cause no end of trouble in a time of dearth.

WERE CELLS STARTED IN SPITE OF THE PRESENCE OF A VIRGIN?

Since my article, p. 581, July 15, two rather strange things have occurred. On September 17 a hive with a very prolific queen was so crowded with brood and honey that the bees started loafing. The queen had been raised the previous autumn, and was in her prime. Brood was placed in a super above the excluder; below were drawn combs, one frame of brood and queen, the intention being to divide on the Alexander plan.

I was unable to attend to this hive at the proper time, and on October 2 I found virgins hatching in the super. I destroyed as many as I could find. The queen was mismated, and I did not want her young as mothers. One or two, however, were at large. I found and killed one.

On October 3 I found my poor laying queen outside the hive, just dying. Why?

Had one of these newly hatched virgins managed to get into the lower box the day previous when I was looking for them in the super?

Well, that same day I moved the super to a new stand. Now please remember these facts, because it is *just possible* that each box might contain a virgin.

On October 15 I gave each of these two hives a frame of brood to see whether they had a virgin. Both commenced queen-cells, and the evening following I gave each a young laying queen by the Simmins method. Next morning, and the morning after, I examined the ground outside these hives. There were no dead queens, and, as usual, I said to myself, "Accepted."

On the fourth day after introducing I examined these hives to see if the queens were laying, and found both of them being balled. One looked as tho she had been persistently ill treated ever since being introduced, and in neither case were any eggs laid. There was no honey coming in, and both hives had been queenless a long time. Well, I caged both queens on the push-in-comb plan, and twelve hours later I liberated them (yesterday). One appeared to be accepted, but the other was attacked at once. So I shook all the bees on to a board in front of the hive after making them fill up well with honey, and let the queen go among them again; but they went at her, even on the board. So she was caged again; and if they attack her again, as they have no brood, I shall confine them all in a swarm-box and see if that modifies their views at all. Is it possible they had a virgin, and started queen-cells on the brood I gave them in spite of this?

I know some one will say, "That fellow ought to feed those bees, and then perhaps the queens would be accepted, as there is no honey coming in." So may I give another strange experience along this line?

A STRANGE MIX-UP.

I have two hives of blacks only, standing side by side. They have old queens. The willows had yielded well, and they both prepared to swarm; but before the event came off the willow flow ceased, and dearth and windy weather came on. In one hive the cells were not far advanced, and I destroyed them, raising the brood Alexander plan. The other hive had sealed cells, and they had destroyed a few, evidently on account of the failure of the willow-flow. However, the day was hot, so I watched them, and at 11 A. M. out they came, leaving the old queen with her clipped wing. I moved the brood, substituting a hive of foundation to which they returned. Then I

knew that foolish swarm would starve. So two days later I went to give them some frames of honey, and was just in time to see the tail end of the procession entering the adjoining black hive and the old queen hopping around on the alighting-board.

"Well," I thought, "you have made real fools of yourselves. Now do you think that neighboring hive will admit a half-starved crowd such as you are?" To my surprise, however, they did without any hesitation. This event just coincided with the commencement of my young queens laying in twelve baby nuclei (*i. e.*, 24 compartments). Now, of these 24, six queens were lost in windy weather, mainly thru getting into the wrong side of the box. This left 18 which got mated; and just as they were due to lay, six of them swarmed out, even tho they had plenty of food. One lot repented and came back with their queen, and she settled down to lay the same day. Two more united, and came back with one queen and settled on a bush. I put them into an empty box and the queen went ahead laying at once.

I found another of these six queens dead outside one of the big hives, and still another dead outside the black hive which accepted the starving swarm mentioned above. I could see the yellow bees of the nucleus mixed with the black bees, and so many of them that I thought they must be at least two little swarms joined together. Curiosity caused me to pull the hive apart and see if, by a stroke of luck, one of my yellow queens had supplanted the old black tho I thought such far too good to be true.

Well, it is the unexpected that happens, and there she was, a fine yellow queen at the head of affairs. How is that for a mix-up of bees and queens with no honey-flow? Bees were all in a bad temper, but there was no fighting. Why should this black hive let in all sorts of swarms and queens without trouble, while this other hive and its increase are so set against accepting a laying queen?

THE NUCLEI THAT SWARMED.

These baby nuclei that I referred to swarmed out just as the queen should have commenced laying, but before she actually did commence, so I could not shut her in. I don't think the bees went with her on her mating-flight, as they went in the forenoon earlier than the queens generally fly. I saw most of the queens had been mated 48 hours previous. Those which I recovered were laying queens. They had plenty of food but little or no brood. The day was hot, but the nuclei shaded. No queenless nuclei or those with virgins swarmed—only those where the queen was due to commence

laying just as the swarm left. I have in mind Mr. Miller's article on the subject, p. 363, May 1, and I am trying with those which swarmed, leaving them in possession of the whole box as he says—three combs, one feeder, and the empty space remote

from the entrance. Of course this just halves the mating capacity of the twin boxes. Again, the editor says in the A B C that these boxes do not do so well with one compartment empty.

Renwick, N. Z.

THE MIRACLE OF LIFE

BY GRACE ALLEN

Within a beehive in the spring
There lies a very wondrous thing—
So frail an egg, it almost seems
A mote to float thru fairy dreams
In dews at night when silver light
Comes dancing down in streams.

Yet life is in this tiny thing,
And growth, and future eye and wing,
Sure instinct, and the love of light,
And treasured heritage of flight.
(O wing of bees! And eye that sees
With such a different sight!)

Wee egg, what miracle befell
To couch you in this fragile cell?
What miracle shall yet befall
When wingéd life thru waxen wall
Shall break its way some summer day
To follow life's far call?

How vain my questions, egg in cell!
You cannot understand nor tell.
I cannot understand nor know
How life can come and life can grow.
All wonder seems to end in dreams.
Perhaps we worship so.

These photos are interesting, mainly as showing the Alexander bee-hat in use; a method of opening a hive by which any rush of bees is directed away from the operator, a little smoke sufficing; the operator working barehanded, but having the smoker (held between the knees) handy for quick use; a hive-tool in the right hand; hive tilted slightly forward to shed water better; extended and sloped alighting-boards; simple hive-stand which has been previously described and illustrated in GLEANINGS. The hives are located among young fruit-trees, and bees are plainly shown on the wing before the hive.

B. KEEP, New Jersey.

Heads of Grain From Different Fields

The Backlot Buzzer

Our neighbor who moved out from the city says there was a hive of pesky blacks on the farm when he bought it, and they were living in an old cracker-box back of the wagon-shed. He read in the papers that bees were good for fruit bloom, but he's afraid to move them. He wants to know whether it would be all right to move his apple-trees.

Illinois State Civil-service Commission Inspector of Apiaries May 6, 1916.

On May 6, 1916, the Illinois State Civil Service Commission will hold competitive examinations at Anna, Carbondale, Charleston, Chicago, DeKalb, East St. Louis, Elgin, Jacksonville, Kankakee, Lincoln, Macomb, Mt. Vernon, Normal, Olney, Peoria, Pontiac, Rockford, Springfield, Urbana, and Watertown for the position of Inspector of Apiaries.

This examination is open to men over 21 years of age who are residents of Illinois. The salary is \$4.00 a day and traveling expenses while working.

The duties of the position are defined by statute, and may be briefly described as involving the inspection of bee-farms thru-out the state in order to prevent the spread of foul brood and other contagious diseases found among bees. It is the duty of the inspector, when such foul brood or other contagious diseases are found, to serve notice on the bee-farm and to have such infected apiaries, hives, and bees destroyed or do it himself, making a report of pecuniary damage done to the owner. The position, therefore, demands a thoro knowledge of diseases

peculiar to bees and considerable experience in breeding and caring for them.

Successful applicants will not be employed continuously, but will be notified as occasion demands it, to inspect certain bee-farms in their neighborhood. Accordingly, liability to notification will be restricted to the six or seven warmer months of the year.

The examination will consist of the following parts weighted as indicated:

Training and experience, 4; special subjects, covering treatment of foul brood, the habits and general care of bees, 6.

The candidates must make a grade of 65 or more on special subjects.

Applications will be received at Springfield until 5 p. m., Saturday, April 29, 1916. Address requests for application blanks to the State Civil Service Commission at Springfield, Illinois, or at Room 904, 130 N. Fifth Ave., Chicago.

Persons receiving a copy of this notice are requested to bring it to the attention of those qualified.

This circular contains all the information which the Commission has to give out concerning the above examination.

A New Use for the Hot-water Bottle

The other day, the weather having turned mild, I was taking a walk thru the beeyard, and noticed before one of the hives an unusual number of dead bees—an almost sure indication that something was wrong—starving, I suspected. I hastily removed the packing and found the bees just quivering—quite past taking honey unless something was done for them. It suddenly occurred to me that the hot-water bottle would be the most convenient thing to apply. Returning to the house I filled the bottle, took it out, and placed it over the almost dead cluster, and drew the packing over it. The effect was magical. The gentle heat revived every bee that had any life in it, and they were soon filling themselves with honey from the card I had slipped in. The hot-water bottle warmed up the bees with no loss whatever; and a day or two later, when the sun was shining brightly, they were flying as freely here as at any of the other hives.

Ethel Robson.

100 Colonies from Nothing to Start with

I have 100 colonies, all in eight-frame hives, which I made myself. Five years ago my brother and I were pumping an oil-well; and so, having considerable extra time, we began catching wild bees. The result was a nice yard of 100 colonies, all hybrids, but workers.

I have never had a cell of foul brood so far, and I have never fed one pound of anything. The lateness of the tarweed bloom

accounts for that, as all colonies are heavy with stores now, Jan. 19.

I will extract before the main honey-flow starts, getting possibly 1200 or 1500 pounds of farweed honey, which is almost a total loss, as there is no sale for it here.

I am a great admirer of the Dixie Bee, and wish it had more space.

On page 17, Jan. 1, appears an article by Frank C. Pellett, on the habits of skunks. If I had my bees in one yard and my chickens in another, and had to turn Mr. Skunk loose in one, I would put him in the backyard. There are lots of skunks here, especially the small spotted variety, and I have seen them near my bees many times, and see their tracks in the wet sand; but I can't say that I ever lost any bees by them. But, on the other hand, in this country the skunk is a natural-born chicken-killer.

Rain! say, isn't it great? It's been raining for almost three weeks now, and the sage is beginning to leaf out.

Orcutt, Cal.

W. P. Worsham.

Frames with a Double Top-bar

Herewith is a sketch of the style of frame I have been using for the past ten years. It is far ahead of the solid top-bar, I think. Before I used them I used to put in sticks or a Hill device; but these were a poor substitute. I have frames that I used when I first adopted these, and they have never been filled up by the bees. They are very easily made.

I have found that laying a piece of burlap over frames and then a board right down on burlap tight will winter bees better than any cushions over bees. I have kept bees, or they have helped keep me, for about 30 years. I use large hives—nothing less than 15 to 24 L. frames, side by side. I had only one swarm from 40 last year. Large hives did it. I use two queens below, and let the bees all work together above. It's fun to see such colonies at work carrying in honey.

East Claridon, O.

E. C. Miller.

[The double top-bar as here illustrated was exploited some twenty years ago. They are all right, and we do not quite understand why they did not receive more recognition than they have. The claim was made at the time, that they would provide bee-passages so that the bees would go back and forth from one comb to the other during the winter. The claim was also made that they would eliminate to a great extent burr and brace combs, and that is true.

This is an instance of one of the good things that were introduced some years ago, but which dropped out of sight. About the time this double top-bar was suggested, the thick top-bar was also brought to the front. As this was a little better for eliminating brace-combs, it seems to have crowded the double top-bar into the background where it was forgotten.—Ed.]

Know the Men with Whom You are Dealing

On page 74, Jan. 15, L. E. Webb asks, "Are breeders of untested queens guilty of sending out a majority of their stock mated?"

The dishonest queen-breeders, if there are any, can positively answer this question, but they won't. The purchaser who has had the misfortune to get even 25 per cent of untested queens is not in position to say positively that he is being made the dumping-ground for hybrid queens; but his suspicion is aroused, to say the least. But what can be the opinion of one who receives eleven untested queens, and a mismatch in each case? It would seem that there is but one of two conclusions—namely, that the queen-breeder is dishonest or he is surrounded with black and hybrid bees.

In either case he should not be patronized. But why will one risk his money where there may be a doubt as to fair treatment when there are so many whose reputation is above question? I believe one should always buy his queens from the nearest reputable breeder, in order to insure quick and safe delivery. "Safety first."

I have been buying untested queens for many years, but from only two breeders—one in Ohio, the other in Kentucky, and have never had a mismatch yet. I had one drone-layer, which was made good at once. So it seems that the best advice to Mr. Webb's question would be, "Know the men with whom you are dealing."

Indianapolis, Ind.

J. F. Kight.

Some Bee-tree

We have had a very interesting time here the past week, as we stopped here and went bee-hunting. We found four trees on the railroad company's right of way, and proceeded to cut them; and I am frank to say that in 45 years of bee-raising I never saw the like. Two of the colonies had evidently been in the trees for some time, as they inhabited twenty feet of the main trunk of a tree, the hollow part being 13 inches in diameter. I never saw as many bees in one swarm in my life. There were bushels of them, nearly black, and the honey was the finest I have tasted in years. I have not weighed what we took out, but presume it will run about a thousand pounds, comb and all. To be sure, some of it is dark comb, but a large amount of it is new comb.

OUR HOMES

Editor

What then shall I do with Jesus, that is called Christ?—MAT. 27:22.

Thou art the Christ, the Son of the living God.—MAT. 16:16.

And whosoever liveth and believeth on me shall never die. Believest thou this?—JOHN 11:26.

While I write an evangelist by the name of Stough is stirring the city of Tampa by a series of sermons; and, as a result, hundreds are coming forward and accepting Christ as the "Son of the Living God."* From the Tampa *Morning Tribune*, March 24, I clip as follows:

Comparing some of the politicians of Hillsborough County to Pontius Pilate, Evangelist Stough preached a strong sermon on the words of Pontius Pilate, "What then shall I do with Jesus?"

As he neared the close of his sermon Dr. Stough said that every man left the tabernacle after having either made a decision for or against Christ.

"The question of this text is not that of a Christian, but of a non-Christian, and is asked of a non-Christian crowd. Today no question is more vital, no question is asked more than the one of this text. Gladstone was visited at one time by an American just at the time of Armenian atrocities. The Premier was walking with the American when the latter asked as to what was the greatest need of the day for England, and Gladstone, without any hesitancy whatever, replied, 'You know there is but one question, it is that of Christianity, and, when my nation becomes convinced that that question is right she will answer every other question before her.'

"He was right; and remember that he who was the greatest statesman of his time was so keen of perception that all questions were gathered up in the one and exclusive question of Christianity.

QUESTION WOULD SETTLE WAR.

"If the question what we shall do with Jesus were settled tonight the war in Europe would be settled instantan. The main issue in Tampa, in Hillsborough County, is what we are going to do with Jesus. While here I shall arraign the men who are responsible for having this city wide open, and having held open, the sluice gates of vice and corruption. I shall not hesitate to strike wrong in high or low places or wherever it exists; but the chief question after all is, what are we going to do with Jesus?

"I want all to understand that I am not here as a reformer by any means or as a political propagandist. There is a question that is far greater than the one of who is going to be the next mayor of Tampa or who will represent this district at Tallahassee or at Washington. Reduce all the issues to the last analysis if you will, and the question is, what is Tampa, what is Hillsborough County, going to do with Jesus, who is called the Christ? What are you citizens, what are you heads of families, what are you individuals going to do tonight with Jesus, who is called the Christ?

"Don't let the little politicians dust your eyes. I am not here, as they claim, as an agent of the Anti-saloon League or any party, altho I am interested in anything that will work for the betterment of the nation. I am an evangelist of the cross of Jesus Christ.

* We clip the following from the *Christian Herald*:

"Evangelist Henry W. Stough and party closed a six-weeks' campaign in Atlantic City early in February, and 1000 conversions are reported. The Stough party went from Atlantic City to Tampa, Fla.

LET OFFICIALS ANSWER.

"I want to ask the mayor of your city what he is going to do with Jesus, who is called Christ? I want to ask the sheriff, the chief of police, and every policeman and every candidate for office what he proposes to do with Jesus; and if he answers this one question correctly he will answer all the rest in the right manner.

"Jesus Christ is on trial these days. These are no common hours for Tampa. These are God's particular hours. The heart of God is concerned. This appeal for an answer to this question is made to the individual as well as to the community at large. No man can dodge or sidestep this most momentous question. Acceptance or rejection of God depends upon the answer to this question.

"Dr. Torry, while preaching in the Moody church in Chicago, one Sunday morning, said that if the wickedest woman in Chicago were to come to Christ he would be ready and willing to accept her. Torry little knew when he spoke these words that there was such a woman, or one of the lowest class, seated under the balcony in the church. She had not been within a church in years. She heard what the preacher said and said to herself, 'I wonder if he means me.' After the service she slipped up the aisle and found Christ while kneeling with the great preacher.

"There are people who pride themselves on the fact that they have been living decent and respectable lives. After the gospel of Christ has been preached 1900 years they still say that, since they live decent and respectable lives, it won't go so hard for them in the hereafter.

"That was spawned and spewed in hell; and if it were true that the living of a moral life would get a person into heaven, then Christ would have been an imposter and the church would be simply a teacher and a publisher of lies. No man ever gained heaven and eternal life without first answering this question and answering it right.

"Morality is not Christianity. Neither is Christianity morality alone. Morality is only one of the fruits of Christianity. God does not damn people because they are bad, nor does he save them because they are good. All of us have sinned and come short of the glory of God. If there is any damning done at all, man does it himself in not giving the right answer to this text.

ONLY WAY TO SECURE PEACE.

"Don't be deceived. You will never find peace until you come to the foot of Calvary's cross. It is a momentous question.

"I have the profoundest respect and pity for Pontius Pilate. He is one of the wonderful characters in the pages of this book. Did you ever study him? He is one of the keenest, clearest, and brainiest men of the crowd that stood against Jesus. He is a man who spoke little, but what he did say has come down to us thru the centuries.

"Oh what a chance Pilate had! If he only would have done so, his name might have come down thru the ages synonymous with those of Jesus. He could have championed his cause. Pilate had a wonderful chance and lost it. He knew of Jesus; and yet, if you never knew of Jesus before you came in this tabernacle tonight, I have said enough tonight to send you either to heaven or to hell.

"Pilate had a conscience that warned him three times, and you have a conscience. Then Pilate had a wife who warned him, and you have friends that have warned you and who have been praying for you.

"There are three things that kept Pilate from answering the question aright: He was a vacillator. He was a typical Hillsborough County politician.

Pilate wasn't so bad, but he had no backbone or convictions. Where the vertebrae should have been there was only gristle. Like the grain in the field, he swayed every direction. He was looking for the vote. He wanted prestige, the favor of the crowd. Do you know any like him about here? The town is full of them—side-steppers, men who lack conviction and courage, and are always apologetic, men who always train with the big crowd.

AFRAID OF PUBLIC OPINION.

"Pilate was afraid of his friends. He could not stand ridicule. How sorry I am for many people of Tampa, many of them church members, who are of this class. While this campaign is talked up and down the streets they are cravenly and cowardly, and can't stand the criticism, so they don't speak up. They apologize for the campaign, and side in. Next thing you know they lose an opportunity.

"Within the next ten days I hope to see the issues drawn closely, and you will be on one side or on the other. If you are a mere church member, Almighty God will put you on the side where you belong.

First, they knock me because I am the handiest thing to knock. Next they knock the tabernacle, and next the church, and then the question becomes deeper—it becomes one of righteousness or unrighteousness. Then it becomes one of enforcing or breaking of law, and before this campaign is much older it will be a line between Jesus Christ or the devil.

"Pilate tried to side-step, and he chased Jesus to Herod, but Herod drove him back. He could not get rid of the question, and neither can you.

"Pilate was afraid of his sins. He was crooked, and therefore a crook. He has lots of relations in Tampa. He had a record that he was ashamed of. There are men in this town who are opposing this campaign because they know that, if their record is shown up, state's prison is their desert.

"Tissot's famous painting shows Jesus and Pilate face to face, and underneath the painter has written, 'Christ before Pilate;' but he has painted better than he has written, for it really is *Pilate* before *Christ*."

A few days ago a visitor called who said his father took GLEANINGS years ago, when he was a boy, and A. I. Root's Home papers were his especial delight, etc.; yet this man, the father of a family, had never united with any band of Christian people. If I am right about it, he seemed to think, as above, that "living a decent and respectable life" was enough. I said, "Surely, my good friend, your sympathies and feelings are with Christian people and what they are trying to do to save the world." He replied something like this:

"Oh, yes! of course," etc.

I should have said (but I did not get around to it) in the language of our text, "What are you doing with Jesus? Do you accept *him* as Peter did, as the Son of the living God?"

My good friend, whose eyes are resting on these pages, how is it with you? Do you accept Christ as you know him, as the Son of God? Your answer settles the whole question. Will you not write and tell me you *do*, that there may be more "joy in heaven," as we read about in God's holy word?

When the world accepts Christ or even a *majority* of the world, war will end in an instant as the evangelist has said. I hardly need add that the one who makes this acceptance must stand up before the world and live in accordance with it; and I am glad to note that the thousands who are coming forward in answer to Billy Sunday's earnest appeals, and other evangelists like him, are living out their profession nobly, with *very few exceptions*. Remember the voice from heaven that proclaimed to a sinful world, "This is my beloved Son in whom I am well pleased."

FOR OF SUCH IS THE KINGDOM OF GOD.—
LUKE 18:16.

The following from the *Christian Herald* of March 15 is an excellent supplement to the Home paper of Feb. 1:

SHALL WE LET THESE BABIES DIE!

Judge Ben B. Lindsay recently addressed a meeting held at New York under the auspices of the Citizens Committee for Food Shipment, on the question of sending shipments of milk to save the lives of the starving babies of Germany. Judge Lindsay said:

"One of the most gripping scenes I ever witnessed, and one that I shall carry with me to my dying day, was the sight of a long line of mothers with tiny babies in their arms, waiting to be supplied with milk. I saw the splendid sanitary equipment and other arrangements for handling the milk-bottles and caring for the milk, but I saw no milk. The supply for the day had given out, and still there were hundreds of mothers left in the line who must pray for milk on the morrow, for milk to keep their babies alive. I saw the tear-stained faces of those mothers as they turned away, not knowing whether the little bit of life in their babies could be sustained until tomorrow.

"In many cities of 30,000 or 40,000 in Poland there is not a baby alive under three years, and in many places not a child under ten years, so terrible has been the demand for milk."

There seems to be plenty of other sorts of food in Germany; but the one thing that the babies cannot live without, the country is short of. Germany has never been a grazing country. Much of the food for its cows has been imported. Now these imports are cut off, and the babies are dying.

England and France say the United States must not allow the shipment of condensed milk to Germany to save the lives of these babies. What does the United States think about it?

One plan suggested by the committee is to arrange for shipments of milk to the Netherlands, to be reconsigned to Germany.

The *Christian Herald* would stop, if we could, the air raids on England, in which babies have been killed. We would stop, if we could, the submarine warfare in which children have perished. But the fact that these dozens of babies have been slain is no reason why America should acquiesce in the killing of millions of babies in Germany by taking away the milk they cannot live without.

You know the cry of the hungry child. You hear your own baby cry in the night. You know the sweet little sounds of content, as it finds the milk nature demands for it. Can you hear these other cries that do not cease, night or day? Can you see the little forms wasting, the cries growing fainter, the little eyes, their brightness long since gone, being drained at length of their tears, growing more

and more dim, and closing at last to open no more! Not dozens, nor scores, nor hundreds, but many thousands dying like this!

We send shells to kill men. May we not send milk to save babies!

AEROPLANE DEVELOPMENT.

The war has revolutionized the aeroplane. We no longer hear about the dangers of mere flying; mechanical ingenuity has apparently overcome them. In almost any kind of weather except the severest gales, the fliers now sweep along at over a hundred miles an hour, under 150 horsepower. Waldemar Kampffert, in a recent article, writes that there are over 5000 planes of various models in use in the different armies, and that the perils from armed aerial enemies and from aeroplane guns on the field below are such that the average flying life of a plane is not longer than two weeks! Very few of the machines used at the beginning of the war are now in service, and to repair the waste it may be necessary to build 50,000 aeroplanes a year while the war lasts. There have been no radical departures from the early models of Orville and Wilbur Wright, altho there are many varied arrangements of the wings. Types may vary, but the original principle persists. No longer is the aeroplane the toy of sport and adventure. It has become a surprisingly dependable machine.

THE "SUNSHINE CURE," GOD'S MEDICINE.

Mr. A. I. Root:—Do you remember the sick boy who came to Brantetown with his mother in the spring of 1914? Well, this is he, and I am not dead yet.

I read in your Home talks about the baby that is allowed to enjoy the sun every day (p. 1001, Dec. 15), and I am going to tell you about my experience with the sun cure.

The doctor advocated rich food, such as cream, raw eggs, buttermilk, etc., which, of course, I found agreeable enough. I sleep on the porch winter and summer, and never expect to quit. But the most remarkable part of the treatment, and the part that brought me up like a soap-bubble, was the sun cure. Fortunately I live on a farm with no near neighbors, so I had no hindrance from that quarter. The treatment consists of going as nearly naked as possible in the hot sun. From May 1 to Sept. 1, 1914, we had practically no rain in this section of the country. The sun beat down with a fury. Crops were ruined, and it looked like bankruptcy to most of the farmers, but it was just the thing for me. I made use of it too. That was one summer I did not "sit in the shade." I was in the broiling sun all summer with nothing on except a narrow pair of bathing-trunks. Of course I had to get myself accustomed to the sun before I could stand the continual glare all day. That is a tedious job, and must be gone about with caution. One would think that the heat of the sun would be very disagreeable; but I enjoyed it. It puts a snap and vigor into the body, and at night I slept like a baby, which was indeed a treat to me after the many nights I had suffered from insomnia and cold sweats. I am perfectly well now; but I wore my "sunning" clothes last summer, and intend to again this summer, just for the life it puts into me. LYMAN L. DULEY.

Smithland, Ky., Feb. 17.

In the above, nothing is said about exercise while out in the sun; but I take it our friend was all the time busy at work of some kind. Many times when I felt "too sick to do anything," by getting out in the sun, in scant attire, with my light hoe, I would soon be feeling fine.

The following from the *Plain Dealer* comes in nicely right here:

LIGHT THE BEST DISEASE CURE; EXPERT SAYS IT'S SUPERIOR TO WATER-BAG OR POULTICE.

Prof. E. C. Titus, in an address, stated that light is a much better cure for disease than hot-water bag or poultice. He says that when rays of light fall on the skin some are arrested by one layer of skin and some by another, while some are not stopped until they have penetrated the subcutaneous tissues.

When the light is thus arrested it produces radiant heat, which has a higher penetrating power than convection heat, such as generated by poultices, etc. Radiant heat penetrates two inches or more, while convection heat is excited principally on the surface.

MEDINA 45 YEARS AGO, OR 3 YEARS BEFORE GLEANINGS WAS STARTED.

My attention was recently called to a clipping from the *Medina Gazette* of July 8, 1870. This was about five years after I bought my twenty-dollar queen, and about three years before GLEANINGS was started. Below is the clipping:

The statement made by A. I. Root in his communication on the fourth page of the *Gazette*, of the amount of honey made by his bees within the past two months, seems incredible; but it is a solid fact. Five thousand pounds in sixty days by fifty hives! Has it ever been beaten in the United States?

After I got the Italian queen from Mr. Langstroth I began studying bees and bee culture almost day and night, in my desire to find out everything known about bees on the face of the earth. I commenced hunting up bee-books and subscribing for farm papers that contained articles on bee culture. The above report of 100 lbs. per colony for an apiary of 50 colonies was at that time considered a feat; but when the news became spread of what was possible with bee culture, reports came thick and fast from Florida, California, New York, Michigan, and all over our land. If I recall correctly, the largest number of pounds per colony from a fair-sized apiary was produced in the vicinity of New Smyrna, Fla. Perhaps some of the veterans can give me the figures. So far as I can recall, an apiary of somewhere toward 100 colonies made an average of between 200 and 300 lbs. per colony. This was just before the disastrous freeze of 1895.

"CHURNLESS BUTTER!" HOW THEY MAKE IT IN CHINA.

It might interest A. I. Root to know how we make churnless butter here. Not being able to get more than four to six large bottles from a cow per day we have very little to spare for butter. After going through the process of getting the cream to the top we put it into a wide-mouthed bottle, say Mason jar; and after a few minutes of jerky shaking, which slops the cream against the side of the bottle, we have a nice solid piece of butter. A steady shake is not so good. It wants to hit the glass sharply. J. F. MOORE.

Shau Tai Kuran, China.

WATER-WITCHING AND THE DIVINING-ROD.

From away off in New Zealand, at the close of a kind letter, we find the following:

I enclose an article on water-divining to convince A. I. R. that his sweeping statement recently made is not *always* correct. I know personally the Church of England parson referred to.

H. BARTLETT-MILLER.

Kihikihi, N. Z., Sept. 13.

Our friend incloses three pages of an article in the *New Zealand Farmer*. This article gives several illustrations and over two large pages of reading-matter. The man who has acquired a widespread reputation, as I take it, for his skill in finding water, is pictured; and as he is a reverend gentleman there is no question but that he is honest and sincere. If he studies his Bible, however, he will probably learn that "God is no respecter of persons," and he should also be aware that *science* is no respecter of persons. In the scientific world, what one man has discovered and learned in the way of controlling the forces of nature, other men can be taught, and I believe our most scientific and learned people recognize this. Yet he writes:

My theory is this: Flowing water generates a force which is at present unknown. This force, which is generated by internal friction, radiates upward, widening out, fanlike.

Electricity, wireless telegraphy, and all these wonderful things, work with everybody alike. I quote from the Rev. Mr. Mason as follows:

"I have tried hundreds of people and found that only three per cent have the power with the rod—but, as I have said, the rod is not reliable."

I quote again:

"I can quite understand people scoffing at such an idea as the divining-rod," said Mr. Mason, "and I can the more easily excuse it because the rod is not accurate in divination. With me, if I take the rod across a paddock it may move very vigorously; but in perhaps 25 per cent of the places where the rod responds so freely not a trace of water may be found upon sinking. With such a percentage of failures as that, people naturally say that the use of the rod is no good. In those cases I do not know what causes the rod to move; but the fact remains that it does. As I have said, I do not use the rod now, but simply move along with my arms in the position I have described."

"And do you think it possible for you to be mistaken now?" asked the writer.

Mr. Mason turned the question over in his mind. "No," he said, with quiet deliberation, "I really don't think so. Out of about 500 times in which I have located water, on only three occasions were the boring efforts unsuccessful. And even in those cases I feel perfectly convinced that if they had gone deep enough the water would have been got."

First he admits that only about three per cent of people generally can get any result at all with a divining-rod. Then, again, as you will notice in the above, he makes the

astounding admission that, even in his hands, the failures are about 25 per cent. I am very glad that he has made that acknowledgment; and I am glad, too, that he has thrown away the senseless stick or branch of a tree. He gets the impulse from his hands alone. I think he has helped the whole wide world, perhaps, to get along a *little* out of this old-fashioned superstition. In his concluding sentence quoted above he thinks the few failures would have been successes had they gone *deep* enough. But is it not probable that we might get water almost anywhere, sooner or later, if we only go "deep enough"? You see the explanation of this whole thing is like buying medicine at a drugstore. You take the medicine, and you get better. How can anybody tell if he would not get better just the same without it? Now for the divining-rod:

The water-witch tells you where to dig, and you find water. Would you not have found water, even if you had not employed him to locate it? Of course, one who has given the matter much study can judge pretty well by the growth of the trees, if there are any trees, or vegetation smaller than trees, such as weeds and grass. Our good friend owns up that it is not done through electricity or any other known force in nature. He gives it as his opinion that the water (perhaps a hundred feet or more below the surface) will manifest itself to the water-witch by some new force at present unknown and unrecognized by science. These old superstitions, like the moon's influence on animals and vegetation, predicting what the weather will be in certain localities months ahead, etc., die hard.

We clip the following from the *Scientific American*:

G. E. S. asks: I have heard of a method of finding a spring of water. Take a limbo of a plum-tree which has a crotch in it. Take the two prongs of the crotch in the hands and hold the limb horizontally. Walk along, and when you walk over a spring of water the stick will be attracted to the ground. Please let me know through your valuable paper what condition of the wood (dry or green) gives best results. What size of limb should be used? Can any other kind of wood be used? To what depth can a spring be detected? Is this method successful when the ground is covered with snow? What causes the branch to dip? One person told me that, when he heard of it, the branch was attracted so that it broke. *Ans.*—We must say that we do not know anything about the finding of water by means of a crotched stick, nor do we believe it can be done. As a boy we lived in the country, where wells were depended upon for water, and we saw not a few men use the witch-hazel stick. It was said then that the stick must be of witch hazel. You say it should be plum. One is doubtless as good as the other. We have seen many failures with the sticks, and have known men to dig deep where the stick had turned down vigorously,

without any water being found. Sometimes water was found; but if there is a divining-rod of any value, water should always be found when it indicates water with any force. We cannot be of any help to you in explaining the divining-rod. The rods used were usually green, freshly cut.

SELLING HONEY; EDUCATING THE PEOPLE; SOMETHING ABOUT FETERITA.

In GLEANINGS for Aug. 15 I see an account of successful honey peddling. I am glad some one has been successful. As honey brings only 4½ cents a pound for the best grade, we thought we would try selling it from house to house. We fixed up an outfit and started out. We certainly learned some lessons. We found that 99 out of 100 families right here in the up-to-date little city of Riverside never taste honey. They hardly know what it is.

We stopped at one home, and my husband got out and took a quart jar of fine orange honey with him. He asked the ladies on the lawn if they would like some orange honey, and then went on to explain that we had also some buckwheat honey as well as orange comb honey and buckwheat comb honey. One woman looked up and said, "Have you any *bce* honey?"

My husband gravely informed her that it was all *bce* honey; and even then she didn't buy any.

The trouble with the honey business is that people are not educated on the subject. They think it strange that I let my little boy eat all he wants of it, and that it never makes him sick. He used to cry for candy every day until I let him have his fill of honey. He scarcely ever asks for candy now.

When the new shortening, "crisco," was put on the market, no one knew much about it. Now it is in nearly every house. How was it accomplished? Answer—advertising. The manufacturers knew they had a good article, but they didn't wait for it to sell itself in the face of keen competition. They didn't set it back in the corner of a grocery and wait to see what would happen. No; they started out to educate the people as to the peculiar merits of this particular article. They gave valuable recipes in the advertisements, telling how to use this fine new shortening. Now, in the short space of three years, the people have been educated on this subject. Why can't the same thing be done with honey?

Karo is advertised on every corner, for every purpose the manufacturers can possibly invent. Why can't the same be done with honey?

My father, W. E. Little, has been a close reader of GLEANINGS for 20 years. I read it, too. I am much interested in what Mr. Root writes about *feterita*. Milo maize grows well here; but the birds will harvest a five-acre piece with ease with no charge for labor. How do they like *feterita*?

Riverside, Cal., Aug. 29. MRS. MAUDE THOMAS.

My good friend, I guess you are pretty nearly right about educating the people; and our company are now spending thousands of dollars just to let people know what honey is *good for*.

In regard to *feterita*, I think you have struck one of the main troubles—it is so handy for the birds. The seed does not come in a husk like corn and wheat. It just stands right out in plain sight, ready to be appropriated. We have had that trouble in Florida already to some extent. If we do not cut it and give it to the chickens just as soon as it is fit to eat, the birds are after it.

ALLEGHENY CO., PA., FOR SUFFRAGE.

We clip as follows from the *Union Signal*:

Thirty-one of the sixty-seven counties of Pennsylvania voted "yes" for woman suffrage! Chief among these was Allegheny County (with the city of Pittsburgh and its population of over half a million)—a county exceeded in population only by California among the suffrage states, and now facetiously called "the state of Allegheny." Allegheny County enjoys the distinction of being the first county of a million or more population to give a majority for suffrage. Two of the big anthracite counties, Luzerne and Lackawanna, including the cities of Wilkes-Barre and Scranton, were carried for suffrage.

HIGH-PRESSURE GARDENING

SWEET CLOVER; SEVEN BUSHELS OF SEED SECURED FROM THE ROADSIDE.

Sweet clover is taking a large place in the cropping of the little land I have to farm.

Last spring I sowed about twenty acres. Some of it has done well, and other parts not so well. This fall I am sowing eleven or twelve acres. About two acres were sown some ten days ago, and it is coming up nicely, as a rain came on while we were seeding the ground. On Monday of this week we finished sowing the clover, and then made a test of some four acres of the Grimm alfalfa. A good rain has just come, one day after seeding, and the prospect seems good for a fine start this fall.

Many people, our agricultural-college people included, claim that it will winter-kill. However, I am going to make the experiment, and know for myself. Do you know whether successful fall seeding is possible?

This fall I cut about an acre of roadside sweet clover, and secured seven bushels of seed from the same, which I count a very good yield.

Emporia, Kan., Sept. 15. CHAS. A. BOYLE.

In regard to sowing sweet clover in the fall, we sometimes have succeeded, and then we have failed. It depends a good deal on locality and on the amount of rain in order to have the young plants get root enough to avoid being thrown out by the frosts.

HANDLING SWEET-CLOVER SEED.

The following, from Chas. B. Wing, which we clip from the *Rural New-Yorker*, will, I am sure, be read with much interest by our readers.

There is no secret at all about the proper method for handling sweet clover for seed. I let mine get pretty ripe—ripe enough so that about three-fourths of the seed-pods have turned somewhat brown. Then I use a self-rake for harvesting, and I harvest only when wet with rain or dew. If it is a dry time this means getting up about two o'clock in the morn-

ing, harvesting until half an hour after sunrise, and then quitting. Handled in this way there need not be any loss from shattering, or at least not enough to amount to anything. If you have a very large acreage it would pay you to rig up some form of automobile lamp, and to cut all night.

I drop the bunches off just moderate sized, and do not touch them at all until just before time to thrash. I like to have at least one shower on them before thrashing, and count on the plants lying from three to six weeks before attempting to hull. The day before hulling, if the bunches seem tough underneath, we get out before daybreak and just tip them over, being careful while doing so not to jar, thereby preventing shattering.

This seed must be handled with extreme care from beginning to end, or else it will all be wasted. When ready to thrash I use tight-bottomed wagonbeds or sleds, and usually spread a canvas over these beds. We load on just what will ride comfortably, without having a man on the load at all, simply piling up what we can from the ground without any loading or tramping, and we hull with a clover-huller.

SWEET CLOVER AND MILK.

It is reported that the plant will sometimes taint cows' milk. It may be that it will; but I have fed this crop for several years, and am as particular about the milk as I very well could be, and have never as yet noticed any such result.

Ohio.

CHARLES B. WING.

OUR FLORIDA ALLIGATORS; A GLIMPSE OF THE "VARMINT."

The pictures below are from a "gator" that our good friend A. E. Ault and his boys captured near his place. On one occasion when the animal had sunk his teeth in a heavy stick Mr. Ault had in his hands, he commenced to roll over so rapidly the stick was either broken or twisted out of Mr. Ault's hands; and this reminds me that years ago Mr. Irving Keck told me of a couple of darkies who planned to capture a 'gator almost as big as a horse. They threw a rope over his head, and for safety (?) one of them tied the other end about his waist. As soon as the great reptile saw he was caught he commenced, like this one, to roll

over and over toward the lake. Had it not been for a sharp knife in the hands of his comrade the captor would soon have been drowned in the lake, and this is probably one of their regular "stunts" when in trouble.

"GATHER UP THE FRAGMENTS, THAT NOTHING BE LOST."

As there may be other localities like Florida, we give place to the below, clipped from the *Bradentown Evening Journal*:

SAVE THE WASTE PAPERS.

For the past seven or eight years that we have been spending our winters in Bradentown, it has pained me to see waste papers, magazines, paper boxes, etc., burned up as if they were of no value, while in the North every scrap of paper and strawboard is bought up and worked over by the paper-mills. Altho I have been unable to find a market down here, I have been saving up our papers until Mrs. Root declares I shall have to build a barn to hold them, but finally relief is in sight. See the following item, just clipped from the *Cleveland Plain Dealer*:

"Shortage of paper stock in the United States was discussed at a conference today (March 18) between Secretary Redfield and Charles A. Holder of the foreign trade adviser's office. France's embargo on the export of rags has caused many American manufacturers to fear that they may have to curtail production of their mills.

"The Department of Commerce recently appealed to housewives to save old papers and rags. Today the department began sending out 1,000,000 circulars to be posted in postoffices and elsewhere thruout the country, urging that papers and rags be saved. The commerce department promises to put those who save papers and rags in touch with manufacturers. Chambers of Commerce and trade associations have been asked to cooperate."

In Ohio the W. C. T. U. has for some time been gathering waste books and papers, and shipping them to the paper-mills, and some time ago I was told a similar movement was on foot in Florida. When I first came here I was also told there was no market for empty grain-sacks; but I kept on saving them up, and just recently I received several dollars for them from the Tampa Bay Company; but they said they then knew of no market for books and papers. "Waste not, want not." A. I. Root.

The animal stretched out on the smooth stone road in front of Mr. Ault's house.

MYERS Giant and Stayon DOOR-HANGERS

It is a satisfaction to have MYERS EASY-OPERATING DOOR-HANGERS on your barn, garage, and similar outbuildings, for they end all door troubles.

The HERCULES STEEL-GIRDER TUBULAR TRACK, illustrated on the right, has a protective covering that completely shields the track and tops of the doors from the rain and weather.

Ask your dealer about Myers Door Hangers or write for our descriptive booklet which shows twelve styles.

NEW KEROSENE LIGHT

BEATS Electric or Gasoline

10 DAYS FREE

SEND NO MONEY CHARGES PREPAID

We don't ask you to pay a cent until you have used this wonderful modern light in your own home ten days—we even pay transportation charges. You may return it at our expense if not perfectly satisfied after putting it to every possible test for 10 nights. You can't possibly lose a cent. We want to prove to you that it makes an ordinary oil lamp look like a candle; heats electric, gasoline or acetylene. Lights and is put out like old oil lamp. Tests by Government and 33 leading Universities show it Burns 50 Hours on One Gallon common coal oil, and gives more than twice as much light as the best round wick open flame lamps. No odor, smoke or noise; simple, clean, no pressure, won't explode. Several million people already enjoying this powerful, white, steady light, nearest to sunlight. It's GUARANTEED.

Men Make \$50 to \$300 Per Month with Rigs or Autos

delivering the ALADDIN on our easy trial plan. No previous experience necessary. Practically every farm home and small town home will buy after trying. One farmer who had never sold anything in his life before writes: "I sold 51 lamps the first seven days. Another says: "I disposed of 37 lamps out of 51 calls." Thousands who are coining money endorse the Aladdin just as strongly. NO MONEY REQUIRED. We furnish capital to reliable men to get started. Ask for our distributor's plan, and learn how to make big money in unoccupied territory. Sample sent for 10 DAYS' FREE TRIAL. We want one user in each locality to whom we can refer customers. Be the first and get our special introductory offer under which you get your own lamp FREE for showing it to a few neighbors and sending in their orders. Write quick for 10 DAY ABSOLUTELY FREE TRIAL. Address nearest office.

Add price of queen to bees by the pound if queens are wanted. Safe arrival guaranteed on bees by the pound within six days of Mathis. Orders booked now, and queens shipped when wanted.

B. M. CARAWAY, MATHIS, TEXAS

Dr. Miller's Strain of Italians

We have made arrangements with Dr. C. C. Miller to furnish us breeders, and therefore offer you the finest queens reared from the best stock on earth, as Dr. Miller holds the world's record for an apiary of more than 70 colonies having averaged 266 sections weighing 244 pounds. These are not queens bred from a mother that has produced one good yield, but it has been bred in them for generations until their honey-gathering is a fixed quality. In GLEANINGS, p. 788, Editor Root says, "Those queens (DR. MILLER'S) ought to be worth \$10 to \$25 each."

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.

Virgins, 50 cts.; untested, \$1.50; tested, June, \$2.50. Breeders, August \$5 to \$10. Bees, our strain, 1 lb., \$1.50; 2 lbs., \$2.50; nuclei, 1-frame, \$1.25; 2-frame, \$2.25; 3-frame, \$3.25; 8-frame, colony, \$6.00; 10-frame colony, \$7.00. Prices do not include queens. Queens, our strain, Untested, 75 cts.; Tested, \$1.25; Select Tested, \$1.75. Satisfaction guaranteed as well as safe arrival. 200 colonies in 10-frame hives at \$6 each. Orders filled in rotation; deliveries will be made as promptly as possible after about April 15. One thousand mating nuclei.

THE STOVER APIARIES, MAYHEW, MISSISSIPPI

Archdekin's

Fine Italian Queens---3-banded

Proflig, Hardy, Gentle. They are Persistent, Profitable. Producers. None better.

Prices	Before July 1			After July 1

Talking Queens

Laws' queens speak for themselves, as "actions speak louder than words," while pleased customers everywhere have been boosting Laws queens many years.

Twenty-seven years' continuous advertising in this journal as queen-breeder, with continuous careful breeding from the very best Italians, places Laws queens and Laws methods far above the average.

If quick service and reliable dealings count with you, place your orders with me. My capacity is from five to six thousand queens in the next five months. Five hundred young laying queens ready now April 3, and many more before this reaches your eyes.

Prices: Tested, each, \$1; 12 for \$10; 100 for \$80. Untested, 90 cts.; 12 for \$9; 100 for \$70. Breeding queens, extra select, \$5 to \$10.

There is not a known case of bee disease in this or adjoining counties.

W. H. Laws, Beeville, Texas

Inspector for Bee County

Three-band Italian Queens

They are bred from imported mothers. They are the best for honey-producing purpose; very gentle, and not inclined to swarm. If you buy once you will buy always.

GUARANTEE that all queens will reach you in good condition, to be purely mated, and to give perfect satisfaction.

All orders filled at once.

J. B. BROCKWELL, Barnetts, Va.

A daughter of one of *Dr. Miller's best honey queens*, and the *Beekeepers' Review* for 1916 for only \$2.00. A daughter of one of the very best honey-getting queens selected from 1100 colonies worked for extracted honey, from the yards of E. D. Townsend & Sons, and the *Review* for 1916 for only \$1.75. The queens will be mailed in June direct from our breeders in the South. A rare buy.

THE BEEKEEPERS' REVIEW, Northstar, Mich.

If you want a queen for that queenless colony, we can send it to you by return mail. Young tested queens, \$1.00, \$12.00 per dozen. Untested, \$1.00; \$9.00 per dozen. We breed the three-band Italians only, and we breed for the best. Our thirty years of queen-rearing proves this. We never had a case of foul brood in our apiaries, and we guarantee every queen sent out by us.

J. W. K. SHAW & Co., Loreauville, La.

Carniolan, Golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, box 135, Buffalo, Tex.

Three-banded queens and bees by the pound, ready now. One untested queen, 90 cts.; \$9.00 per doz.; \$17.50 for 2 doz.; \$65.00 for 100. Tested, \$1.50 each; fine breeders, \$5.00 each; 1-lb. swarm with fine queen, \$2.25 each; without queen, \$1.50 each; 50 for \$70.00; 100 for \$135. Add queens at above prices. I can furnish you in any quantity from one to 1000 queens or swarms of bees at above prices from April 15, thruout the season. Write to Curd Walker, the Queen-breeder, your wants. He will give you a square deal. Box 18, Rt. 1, Jellico, Tenn.

FOR SALE.—Swarms of Italian bees in packages, 1 lb. of bees, \$1.50; 2 lbs. of bees, \$2.50; for 50 or more they are 12½ cts. less. Untested Italian queens, 75 cts. each; tested Italian queens, \$1.25 each. No reduction on quantity of queens for April and May. Quality, service, safe delivery, and no disease, I guarantee. We spare no labor nor money to produce the best for you is why we cannot make a lower price. Early swarms get the honey. We can deliver the goods with pleasure to both of us.

W. D. ACHORD, Fitzpatrick, Ala.

The successful package-shipper and queen-breeder.

BEES AND QUEENS.—Doolittle's Italian stock speaks for itself. They are gentle, resist disease, and are fine honey-gatherers. We breed this stock only, and guarantee delivery only to points west of the Rocky Mountains. Untested queens, 75 cts. each; \$8.00 per dozen; \$60 per 100; tested queens, \$1.25 each; \$12 per dozen; \$85 per 100. Three-frame nuclei, \$2.25 each; \$200 per 100. Bees, ½-lb. packages, 75 cts. each; \$6.00 per 100; 1-lb. packages, \$1.00 each; \$85 per 100. Add price of queens to above packages. Complete catalog free on application. SPENCER APIARIES, Nordhoff, Cal.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei, with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can, therefore, supply you with the biggest and strongest nuclei you will be able to find anywhere. Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier, if necessary. Bees are all on standard Hoffmann frames, and combs are all built on full sheets of foundation and wired frames. We guarantee bees to be free from disease.

THE HYDE BEE CO., Floresville, Tex.

QUEENS.—Italians exclusively; golden or leather-colored. One select, untested, \$1.00; 6, \$4.25; 12, \$8.00. Tested, \$1.25. Best breeder, \$5.00. Early swarms of young bees in light screen cage a specialty. One 1-lb. package, \$1.25; one 2-lb., \$2.25; queen extra. For ten or more, write for price. Also nuclei and full colonies. I am booking orders now, with ten per cent deposit for delivery March 15 and after. Safe arrival, prompt service, and satisfaction guaranteed. Circular free.

J. E. WING, 155 Schiele Ave., San Jose, Cal.

H. C. OLEMONS, Boyd, Ky.

TRADE NOTES

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

HIVE-HANDLES.

We have a surplus stock of handhole cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of both 8 and 10 frame packed single and 5 in a package, which we offer, to close out, as follows: YW 5/8, one story, with frames, eight frame; 8 packages, one hive each, at \$1.75, and 12 packages,

HIGHEST CASH PRICES

The A. I. Root Company, Medina, Ohio

five hives each, at \$8.00. The same in 10-frame size, 2 packages, one hive each, at \$1.85, and 3 packages, five hives each, at \$8.50.

NO. 2 OR B GRADE HOFFMAN FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

METAL SPACERS SLIGHTLY DEFECTIVE.

In making the metal spacers for the metal-spaced frames there are a percentage which come out either sheared a little scant on one side, or with slight breakings in the tin where it is drawn up into the spacing-boss. These are hardly passable as perfect stock, but in actual use they will answer every purpose as a spacer. Rather than throw these into the scrap we will offer them while they last, including nails to nail them on, at 20 cts. per 100; \$1.80 per 1000. Transportation charges extra.

1½ H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or, including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1½-inch tire, and solid cast hub holding spokes and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

SUPERS FOR EXTRACTED OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. b. Medina.

200 D9/10, nailed and painted, with top and bottom starters, nine frames in each, new. Sell new for \$1.20; offered at \$6.00 for 10; \$55.00 per 100.

410 D8/10, nailed, and some painted two coats, some one coat; 273 not painted. Sell new for 90 cts.; offered at \$5.00 for 10; \$45.00 per 100.

180 D8/10, nailed supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first two lots are the 5½-inch supers with hanger cleats and shallow Danz. frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

TOBACCO DUST FOR KILLING INSECTS.

Fine tobacco dust is used for dusting on lettuce and other plants for killing the insects, as well as for fertilizer. We have two kinds of dust—the very fine, from ground stems, which we offer at 20 cts. for 10 lbs.; \$1.50 per 100 lbs., or a case of about 400 lbs. at \$1.00 per 100 lbs. We can supply, also, a much coarser dust from leaves, which is much stronger, at 50 cts. per 10 lbs., \$3.50 per 100 lbs.

ALSIKE CLOVER SEED.

We still have a number of bushels of alsike clover seed, which we offer, subject to previous sale, at \$10.00 per bushel, with 25 cts. extra for bag to ship in. Any quantity from a peck up at this rate. Lot of two bushels or over, no extra for bags. It will not last long at this price. If you want some, better order promptly.

SWEET-CLOVER SEED.

We have a good supply of very choice hulled white-sweet-clover seed scarified for quick germination, requiring only 10 lbs. per acre for a good stand. We offer this for a short time to reduce stock at \$18.00 per 100 lbs. Now is the right time for sowing with a nurse crop to produce hay or bloom with seed next year. We have also choice hulled yellow which we will sell at \$15.00 per 100 lbs. A thousand pounds of hulled white for shipment direct from Little Sioux, Iowa, not scarified, offered at \$15.00 per 100 for prompt acceptance.

BEEHIVE PAINT ADVANCED.

The prices of all ingredients used in making paint has gone so high that we can no longer maintain prices on paint which have been in force. We quote till further notice, \$2.75 per gallon; \$1.40 per half-gallon; 75 cts. per quart; 40 cts. per pint, with a corresponding advance in the wholesale and jobbing price.

SPECIAL SASH FOR COLD-FRAMES.

We have several dozen sash made for Root brooders with four lights, 10 x 14, and measuring outside 24x34. We offer them open at 30 cts. each; 6 for \$1.50; with glass at 55 cts. each; 4 for \$2.00. These might be used on small cold-frames for starting plants and are much cheaper for size than the regular hot-bed sash.

IMPROVED CAPPING-MELTER.

The capping-melter illustrated elsewhere in this issue is covered by Beuhne's patent issued several years ago, under which we secured license to manufacture. We will furnish these machines made of galvanized iron at an introductory price of \$15.00; or, made of sheet copper, at \$25.00. If these give the satisfactory service we have every reason to believe they will we expect to catalog them in the next edition as "Beuhne's Improved Capping-melter." It would make too long a name to include in it the names of those instrumental in so improving the original Beuhne as to make it so much more satisfactory in operation.

THE A. I. ROOT COMPANY, Medina, Ohio.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

HONEY - CANS

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

A New Complete Book for Every Ford Owner, Dealer, Salesman, Repairman

The Model T Ford Car

Price \$1.00 Postpaid

Its Construction, Operation, and Repair

By Victor W. Page

Author of "The Modern Gasoline Automobile," etc.

300 (5x7) Pages; Over 100 Specially Made Engravings, and Two
Large Folding Plates

This is the MOST COMPLETE and PRACTICAL instruction book ever published on the FORD CAR. A high-grade cloth-bound book printed on the best paper, illustrated by specially made drawings and photographs. All parts of the Ford Model T Car are described and illustrated in a comprehensive manner—nothing is left for the reader to guess at. The construction is fully treated and OPERATING PRINCIPLES MADE CLEAR TO EVERY ONE. Complete instructions for driving and repairing are given. Every detail is treated in a non-technical yet thorough manner.

This book is written specially for FORD DRIVERS AND OWNERS, by a recognized automobile engineering authority and an expert on the FORD, who has driven and repaired Ford Cars for a number of years. He writes for the average man in a practical way from actual knowledge. All parts of the Ford Model T Car are described.

The illustrated chapter on repairing and overhauling alone is worth many times the price of this book.

Special description of book sent on request.

EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A post card will bring it to your address free.

Red Catalog, postpaid.

HONEY GRADING RULES

GRADING RULES OF THE A. I. ROOT CO., MEDINA, O.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

CULL COMB HONEY.

Cull honey shall consist of the following:

Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uni-

form color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells altogether, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.
Honey in badly stained or mildewed sections.
Honey showing signs of granulation.
Leaking, injured, or patched-up sections.
Sections containing honey-dew.
Sections with more than 50 uncapped cells, or a less number of empty cells.
Sections weighing less than the minimum weight.
All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon: It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.
Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.
Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES

Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

INDIANAPOLIS.—Comb honey at this time is moving very well; however, extracted is going rather slow. Honey is selling about the same: Choice No. 1 white comb is selling at \$3.75 to \$4.00 per case; No. 2 at \$3.50. Extracted of good quality is bringing 9 to 11. We are paying 28 cts. cash or 30 in trade for beeswax.

Indianapolis, April 19. WALTER S. POWDER.

DENVER.—Local demand for comb honey light, with ample supply. We are selling in a jobbing way as follows: No. 1, per case of 24 sections, \$2.93; No. 2, \$2.70 per case; white extracted, 8½ to 8¾; light amber, 8, 8¾; amber, 7 to 8. We pay 25 cts. per lb. in cash and 27 in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY PRODUCERS' ASS'N.
Denver, April 20. F. RAUCHFUSS, Mgr.

KANSAS CITY.—Our market is overstocked with extracted honey, with a very light demand. The receipts of comb are light, and the demand just as light. We quote No. 1 white comb, 24-section cases, at \$3.00; No. 2 ditto, \$2.50 to \$2.75; No. 1 amber ditto, \$2.75 to \$3.00; No. 2 ditto, \$2.50 to \$2.75; white extracted, per lb., 7 to 7½; amber ditto, 5½ to 7. Beeswax, No. 1, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.
Kansas City, April 15.

NEW YORK.—There is no demand for comb honey to speak of; and while No. 1 and fancy white are cleaned up, there is quite a stock of off grades still on the market, for which there is practically no demand, and hard to dispose of. The market on extracted honey is in a little better shape, and prices now show an upward tendency, especially on fancy West India honey. Supplies are sufficient to meet all demands. Beeswax is steady at from 29 to 31, according to quality.

New York, April 19. HILDRETH & SEGELKEN.

CHICAGO.—Trading is of a very limited nature in both comb and extracted honey; and especially is this true of the comb situation. Our stocks are not heavy, but there is a great deal of it offered on the market, and prices are uncertain, ranging for best grades of white comb from 12 to 15 cts., but sales are made mostly at 13 for No. 1 to fancy; extracted white, 7 to 8; amber grades 6 to 7. Beeswax, 30 to 32.

R. A. BURNETT & CO.
Chicago, April 18.

ST. LOUIS.—Our honey market is very quiet, and the demand limited. Quote southern extracted and strained, bright amber, in barrels, 5 to 5½; in cans, 6 to 6½; dark, ½ to 1 ct. per lb. less. Comb, amber, 10 to 12; dark and inferior, 9 to 11; broken and leaking, 7 to 8; fancy clover, 14 to 17. Comb honey in neat clean cases of fancy clover, from \$3.25 to \$3.50, and light amber from \$2.50 to \$3.00; undergrades less. Beeswax, prime, 29½; impure and inferior, less.

R. HARTMANN PRODUCE CO.
St. Louis, April 22.

MATANZAS.—Honey is selling here at the present time at 45 cents a gallon, in barrels.

Matanzas, Cuba, April 4. ADOLFO MARZOL.

ASSETS OVER ONE MILLION DOLLARS

ZANESVILLE.—At a season when the honey business is usually light, we are having a fair and normal demand. There has been no marked revision of prices. As heretofore, best grades of white comb bring around \$4.00 in single-case lots. Some lots of Western are offered at \$3.75. On quantity orders some concession is allowed, and of course jobbers are given the usual 12 per cent discount from list prices. Extracted in cans is quoted at 9 to 11 for best grades of white, there being little demand for amber. Twenty-nine cents cash, 31 in trade, are ruling prices paid producers for beeswax. Selling prices are largely arbitrary, varying with quality and quantity.

Zanesville, April 20.

Woodman's Section-fixer Gold Medal

for the finest comb honey at the recent Michigan fiftieth anniversary convention was won by Floyd Markham, of Ypsilanti, Michigan. He says:

"We have several kinds of machines for folding sections and putting in the starters, but since we got one of your Section Fixers, about two years ago, no other machines for the purpose are used in our shop. It pays to use bottom starters, and your Section Fixer is the only machine that I know of that will do the job at any rate of speed and do it right."

DO YOU KNOW that with this machine you always handle large pieces of foundation, which makes the putting in of bottom starters easy! Special circulars will tell you all about it. Price \$2.75 with lamp and one form block, shipping weight 5 pounds, postage extra.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powderpaint. It comes in the form of a dry powder, and all that is required is cold water to make a paint weather-proof, fire-proof, and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone, or brick, spreads and looks like oil paint, and costs about one-fourth as much.

DESTROYS DISEASE GERMS.

This paint is a strong disinfectant and effectually destroys disease germs and vermin. On this account it is especially valuable for the interiors (as well as exteriors) of dairy barns, poultry houses, basements, stables, etc.

Write to Mr. A. L. Rice, Manufacturer, 17 Wardwell St., Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

Best by test. Prices on request.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---
30 cts. cash, 32 cts. in trade; wax delivered to Lansing.

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

NO. 9

EDITORIAL

THERE are several very strong articles in this issue for the expert honey-producer. Particular mention should be made of the one by J. A. Green on page 351 for a new-old plan for freeing supers of bees without any bee-escapes, brushing, or smoking, inside of 15 minutes. Do not forget to read this and the other articles.

Over-supply of Comb Honey

THE market is still well supplied with comb honey, and, as we have stated before, considerable will be carried over, and, of course, that means that some of it will be granulated. Extracted honey of good table quality seems to be pretty well cleaned up, and beekeepers, where they can do so, might do well to change over to extracted. The prospects for a crop of clover honey, alfalfa in the West, and mountain sage in California, are excellent. If there should be another big crop of comb honey the same as last year, there will be a slump in prices.

Advertising, like the Hertzian Waves of the Wireless, Radiate in all Directions

ELSEWHERE mention of the fact is made that extracted honey is being fairly well cleaned up. Said an advertising man of large experience, "Mr. Root, your large campaign of advertising honey has not only helped you, but it has boosted all of your competitors who have honey for sale. Such competitors should be exceedingly grateful to you for opening up the market to them," and several of them are. While, probably, more comb honey has been sold this year than any previous one, the production was away beyond the demand.

Death of Chas. H. Lake

MR. C. H. LAKE, of Baltimore, formerly an occasional correspondent for GLEANINGS, passed away on Feb. 20 last. He was, at the time of his death, a member of the

Maryland Horticultural Society, of the Luther Burbank Society, and in 1896 he was appointed to a chair in the Maryland Agricultural College, which he held for about five years, during which he conducted a course in bee culture at the College.

Our Cover Picture

A BEEKEEPER owning several out-apiaries, who does not have at least a light roadster for quick trips and light hauling is the exception rather than the rule. Our cover engraving shows Mr. J. W. Schlenker (whose article appears on page 354), standing by his machine just ready for the out-apiary. The light detachable box on the back of the runabout furnishes plenty of space for all the load that is required for quick trips.

We are very sorry that we are unable to use more of the interesting articles on out-apiary management in this special number. Our readers responded so nobly to our request for material that we could have published two or three special numbers on this subject. We have reserved quite a number of these splendid articles for use later on in the season.

We still have room for a few more good articles on the subject of wax production and wax-rendering for our June 1st issue. Such material should reach us, however, not later than May 10.

Drifting in Quadruple Winter Cases

WHILE our bees have come out in excellent condition in the big winter cases, four hives to the case, we are having considerable trouble from drifting—that is, flying bees going into the wrong entrance.

Of course there is more or less drifting in the early spring in any yard; that is, the younger bees, and older ones as well, are quite inclined to fly into the entrance of the strongest flyers during their playspells; but the trouble from drifting is considerably greater with the big winter cases.

Each case looks like every other one, and, moreover, the entrances are side by side.

Not only the home yard but at the out-yards we have discovered that some colonies that were strong a week ago are now very weak, while the colonies with entrances alongside of them are abnormally strong. In some cases one hive in a pair will be so strong there is hardly room to get in another bee, while in the next hive in the pair there are but very few bees left.

Our winter cases were placed last fall with the entrances facing all points of the compass, for the express purpose of avoiding this drifting; but apparently it failed to some extent. We hope to overcome the difficulty another year by placing each case near some shrub or bush, and at the same time paint the sides of the case over the entrance a different color from the other side. Otherwise these big cases seem to be a success.

Cherry-growers Want More Bees

WHAT beekeepers may say in regard to the value of bees as pollinators is sometimes considered biased, even tho the beekeeper is also a fruit-grower himself. When fruit-growers, however, who have no interest at all in the bees aside from their value to the fruit crop, demand bees, and more bees, it is pretty convincing evidence. We clip the following from the March 11th issue of *The Packer*, a California paper.

BEES TO AID IN POLLINATION.

Hood River, Ore., March 10.—Growers of the Mosier district have reached the conclusion that the district needs more bees to aid in the pollenization of tracts at the blooming season. The Mosier cherry crop was very light last year because of rain during the blossom period. Growers say that the crop would have been made much heavier if bees had carried the pollen, which was too moist to have been transported by winds. The Mosier growers are adding apiaries to their orchards.

Concerning Queens Mailed from States Having No Inspection Laws

SEVERAL breeders living in states having no foul-brood law or bee-inspection law of any kind are asking for particulars as to shipping bees into other states.

There need be no difficulty along this line provided the honey used in making queen-cage candy is diluted and boiled at least twenty minutes. A statement signed by a notary should be secured, and a copy of this in the form of a printed certificate put on the mailing-cage. This conforms to the postal regulations. Unfortunately, how-

ever, as pointed out elsewhere in *Stray Straws*, boiled honey is not as good for the purpose as the unboiled. Where possible, an inspector's certificate should be used to comply with the ruling, and an unboiled honey from a source where there is no bee disease. A honey of unknown source should not be used.

Some New Automatic Folding Machines

WE explained that our last issue was late, owing to the fact that we were unable to get the paper for *GLEANINGS*, notwithstanding that our order for a carload of paper had been placed months before. It has been very difficult to get print paper, and some of the smaller magazines and papers have been compelled to suspend publication. Paper has gone up two or three times its ordinary price; and the worst of it is, it is very difficult to get. We finally secured a couple of carloads on contract, and hoped we should be able to get *GLEANINGS* out promptly; but the installation of some new automatic folding machinery delayed us again on our issues for April 15 and May 1. We will soon catch up now.

By the way, one of these folders will pick up and fold 64 pages at a time. The other machine does smaller work, including the cover of *GLEANINGS*. *GLEANINGS* office now has the latest there is in printing machinery, and it needs it.

How the Bees have Wintered

LATER reports show that bees have wintered remarkably well all over the country with one or two exceptions. Severe losses are reported in Montana, Wyoming, and Idaho. How general these losses may be thruout the territory named we are unable to say. The spring is, perhaps, a little late, but the conditions for the growth of clover have been remarkably favorable.

How the bees have wintered in Ontario is thus summarized in a report of the Provincial Apiarist, Morley Pettit, Guelph, Ontario, Canada.

Up to the present date, April 20, about 700 persons keeping 20,000 colonies of bees have reported a winter loss of about 13 per cent. The loss was largely due to starving, owing partly to an insufficient supply of stores on account of the high price of sugar, and partly to a mild spell in January, which caused the bees to rear brood and draw heavily on their stores. The few warm days early in April gave the bees a splendid cleansing flight, and their general condition now is reported as very good. Few really heavy losses have been reported from extensive beekeepers. More report-forms than

ever have been returned marked "Not a beekeeper." These are mostly from the smaller beekeepers, who are finding that specialization pays best. It is an indication that the industry is getting on a better business basis from year to year.

Clover prospects seem very good thruout the Province. The latter part of the season of 1915 being wet gave the new seeding an excellent start, and the scarcity of farm labor has increased the acreage seeded down. On the whole, present indications are for a good season, and beekeepers are even more optimistic than usual.

The Combles-package Business has Come to Stay

GLEANINGS was the first to start the business of selling bees in combless packages. Away back in the early '80's A. I. Root did a thriving business; but owing to some difficulties encountered it was dropped for the time being. Later on we took it up again, and succeeded, and our success has been duplicated by a good many others. Bees in pound packages are now being offered at very low prices, and what is shipped in this way is being guaranteed.* And this fact makes it possible for the honey-producer to bring his weak colonies up to the proper strength for building up in time for the harvest. A pound or two of bees in a colony in the spring will make a money-maker, whereas without the boost it will be only an expense and a drag on the business that season.

There is probably no danger in transmitting bee disease when bees are sent without combs. Bees by the pound by express are much cheaper than nuclei or colonies by express or by freight in carload shipments. In time, legislation may prevent the shipment of bees in any other way, or except under certain restrictions. The business has come to stay.

More Milk from Sweet-clover Hay than from Timothy; the Hay Not Injured by being Wet down

ON page 519 of July 1st of last year we referred to that patch of yellow sweet clover from which we took two cuttings that we had on our place. It will be remembered that it furnished a great deal of honey, so that the bees of our home yard were going back and forth to that patch in a perfect roar.

We cut this sweet clover, and fed it to

* The prospective buyer should first ascertain whether safe arrival is guaranteed; if not, buy of one who does. There is no use in paying express on dead or half-dead bees.

our stock. It looked as if the stumps left would never grow. But they did, and we took off a second cutting. Just about as we were taking it into the barn it rained every day for two or three weeks. It looked as if the hay were ruined; but we gave it to the stock, and they ate it readily. It was so wet when put in the barn that it mildewed and turned white; and yet, remarkable to relate, our cows are eating it in preference to timothy or any other hay; and what is more, says our teamster, the cows are giving more milk than he had been getting from any other fodder the cows have.

Ordinary timothy, red clover, or alsike, if it has been left out in the wet for two or three weeks, as this has been, would have been ruined, not only for milk but for fertilizer as a top dressing; and yet the facts are that, with all this wetting and mildew, the cows prefer this sweet-clover hay and give more milk. The proof of the pudding is in the eating. What would the cows have said of it, if they could talk, if they could have had it without this wetting and if it had not been mildewed?

It is a well-known fact that sweet clover is not injured much by rain after it is cut, and this one thing is a great point in its favor. The farm papers are beginning to advocate it; and the time is not far distant when sweet clover will be grown from the Atlantic to the Pacific, and from the Great Lakes to the Gulf. When that day comes, the old proverb about "milk and honey shall he eat" will come true if it ever did in all the world's history.

Beekeeping in Wisconsin

A PIECE of work managed by N. E. France, Platteville, Wis., is sure to be managed well. H. F. Wilson, Chief of the Wisconsin Department of Economic Entomology, says of him:

It is now about 18 years since N. E. France began his work as State Apiary Inspector; and no greater tribute can be given him than to record the fact that thousands of the beekeepers of the state believe in him, and depend upon him for guidance. All these years he has worked steadily and unselfishly in the interests of Wisconsin beekeeping and beekeepers.

It is not surprising, therefore, that Bulletin No. 264, of the Agricultural Experiment Station of the University of Wisconsin, by N. E. France, ably assisted by his son, L. V. France, should be an interesting and valuable report, well worth the careful reading of any beekeeper.

In the first part, statistics are given concerning the general business of beekeeping, showing that about 90 per cent of those who start in bee culture fail because of a lack of knowledge of bees and of modern methods of honey production. A striking lesson is taught by two pictures. The first shows a rundown apiary of 75 colonies kept by a man who never reads nor studies. His average crop from the whole 75 colonies is less than 500 pounds of honey per year. The picture on the next page shows an up-to-date apiary of eight colonies that produced, in addition to honey used at home, 1240 pounds, while an increase to 32 colonies was made.

The number of colonies in Wisconsin is estimated at 150,000, and the annual honey crop as exceeding three million pounds.

The following principal honey-plants are named: Dandelion, May 1 to June 1; white and alsike clover, furnishing most of the surplus honey, June 1 to August 1; basswood, or linden, July 1 to July 20; sweet clover, July 1 to August 1; willowherb, or fireweed; buckwheat, goldenrod, Spanish needle, asters, and many fall flowers in late summer and fall.

The state is divided into six bee regions, and on page 9 a map is given showing the distribution of the principal beekeeping regions. The entire northern part of the state, so far as beekeeping is concerned, is practically undeveloped, altho fairly well adapted to beekeeping.

Italian bees are given the credit of being much less liable to have European foul brood. As might be expected from a man who has had so much to do with the control of bee diseases in his state, Mr. France has devoted several pages of the bulletin to a history of American and European foul brood. There is no question but that the diseases of bees in Wisconsin, as in other states, are forcing the slipshod beekeeper out of business. In time, of course, this will be of untold benefit to the industry. An illustration is given which proves this conclusively. In an old log house were stored the remains of about 300 colonies of bees that died of American foul brood eight years ago. The hives and combs, containing about 1000 pounds of honey, were piled one above the other in this open building where bees, both domesticated and wild, were robbing the honeycombs, carrying the honey to the beeyards of nearby beekeepers. How much better it would have been for the industry if such a beekeeper should never have started! It is fortunate, as Mr. France says, that the number of such beekeepers is rapidly decreasing. Better con-

trol and more immediate prospects of eradication of bee diseases exist in the state than ever before, partly due to the increased appropriation for apiary inspection made by the laws of 1913. Practically all the diseased localities are under control.

The Country Gentleman on Sweet Clover; How Beekeepers may Increase their Pasturage

IN the issue of the *Country Gentleman* for April 8 appears a valuable article by Mr. E. Bowers on sweet clover for pasturage. As that magnificent paper has a very large circulation, and as this article speaks very highly of the legume, it will have a tremendous influence in breaking down the silly prejudice that exists in the minds of many farmers today, who regard it as a weed.

Among other things, Mr. Bowers says sweet clover makes a very fine pasturage for cows, horses, sheep, and swine; and while these animals will not eat it at first, they will soon learn to like it, and many times will eat it in preference to other fodders. As many as twenty medium-sized hogs will fatten on an acre of sweet clover; and some farmers claim that stock makes better growth.

Sweet clover has an advantage over alfalfa and red clover, he says, in that it will not cause animals to bloat, and bloating causes serious losses to the farmer and stockman.

It not only produces early pasturage, but extends over a longer period of time—long after other plants have ceased to grow. It defies a mid-summer drouth, and frequently is used to supplement other pasturage.

If sown in the spring it will furnish grazing by the middle of May, and it can be pastured thru the season. The second year it comes out early, and makes a very rapid growth.

The plant is gaining popularity in the corn belt; and one farmer states he has found one acre of sweet clover will pasture from two to three times as many cattle as any other plant of which he has any knowledge.

Finally, Mr. Bowers answers the complaint that sweet clover taints the milk. Careful investigation, however, shows that this is not true. In cases where it has done so, the cows were allowed to eat it while being milked.

This article in the *Country Gentleman* is an unusually strong one; and if our readers do not take the paper, they are advised to

get a copy (or, better, several of them) of the issue for April 8 and show it to their farmer friends. In this way sweet clover can be introduced in their locality, and make it much more valuable for their bees.

Sweet clover mixed with white clover or any other clover makes a very fine table honey; and the probabilities are that, as sweet clover becomes more and more popular among the farmers, white clover and sweet clover honey will be mixed by the bees, and thus most of our clover honey will be a combination of the two. Speed the day!

But that day will come sooner if our subscribers will take these articles that appear in the agricultural papers and bring them to the attention of their farmer friends within flying range of their bees.

Missouri Bulletin on Farm Beekeeping

SOME bulletins put out by State Experiment Stations, while valuable to a beginner, are copied quite largely from other bulletins or from standard works in apiculture, hence are less interesting to the advanced beekeeper. Bulletin No. 138 issued in November by the State Experiment Station of College of Agriculture (University of Missouri), is not of this kind. The writers, E. E. Tyler and L. Haseman, have done a considerable amount of original work in the preparation of this bulletin, which, as stated in the introduction, is not intended for experienced beekeepers.

A discussion of the queen, drone, and worker, with something of the natural history of bees, is given in the fore part. On page 7, under "Races of Bees," the term "Goldens" and "Italians" are used synonymously. We do not believe that the authors intended this, for, obviously, while all goldens are supposed to be Italians, not all Italians are goldens.

For an uncapping-can a five-gallon or larger stone jar or crock is recommended, with a notched board across the top for a frame-rack. If a cracker-barrel supported over a galvanized-iron washtub had been recommended instead, it would have been a more practical outfit, in our opinion. No would have to be used. A stone jar would mention is made of a screen, altho one be a rather unwieldy affair to handle when filled with honey or cappings.

A very good frame-nailing guard or rack is illustrated; and to make the handling of frames somewhat more convenient and to lessen the danger of killing bees, the authors advise the use of a bottom-bar $\frac{1}{4}$ of an inch shorter than the top-bar. This "draws

in" each end-bar $\frac{1}{8}$ of an inch inside of the perpendicular. This is a good, practical idea, altho if full sheets of foundation are put in, the sheets will have to be cut a little shorter than usual, or better still, the ends of the sheet should be clipped off to fit the shape of the frame.

Practical instructions are given on handling bees, hunting bees, transferring, etc. For weak colonies in the spring a modification of the Alexander plan is given, consisting of placing the weak colony over a strong one, with the entrance in the opposite direction and a screen between the two colonies.

Methods of making increase are discussed, and for beginners natural swarming is recommended.

On pages 30 and 31 some selected recipes are given, then follow some uses of beeswax. In this connection it may be well to point out an error in the illustration of the top and bottom starter. The lower starter is shown to be perhaps an inch and a half wide. It should not be over $\frac{5}{8}$ of an inch. A wider starter will almost surely topple over when the bees cluster on it.

General instructions are given for the different seasons, which, with a brief paragraph on honey-plants, robbing, etc., completes the bulletin.

A Cheap Cold-water Paint for Beehives

It is not often that we make an editorial mention of any article advertised in our columns; but when we believe that by so doing we can do a real favor to our subscribers we are glad to do so. But this is not because the advertiser requests it. Many of them, doubtless, would be willing to pay a good round price for an editorial space. But this is not for sale at any price.

In the case of the cold-water paint advertised by A. L. Rice, Adams, N. Y., we feel like saying a favorable word. A few days ago one of our subscribers complained bitterly, saying that this "powdrpaint" was not "good," and that we ought to take it out of our advertising columns. As we had seen quite a number of favorable reports concerning it we wrote our correspondent to that effect, and in the mean time sent a copy of our letter to Mr. Rice, the manufacturer. In reply he sent us a large number of letters from his files that he had recently received, speaking in the highest terms of his cold-water paint—how, in some cases, it had outlasted lead-and-oil paint, how that it had been used for several years, and was still looking bright. The fact that these testimonials were unsolicited, and all of them

autograph letters from the writers themselves from all parts of the United States, leads us to believe that our correspondent who made the complaint either must have extraordinary conditions or did not use it right. As it was, Mr. Rice sent him an equal quantity of pure linseed-oil paint, as he wants all of his customers to feel satisfied. But in spite of this our correspondent complained.

There are a good many beekeepers living in hot climates who feel that perhaps they cannot afford to use lead-and-oil paint. Some among them, like Dr. Miller, believe that the moisture in the hives cannot pass thru the walls when the hive is covered with an oil paint. It occurred to us that we might be doing our subscribers a real favor all over the country by telling them of a water paint that has none of the objections referred to by Dr. Miller.

There is nothing that will improve the value of a farm or residence like bright white fences and buildings; and if Mr. Rice has an article that is cheap and good, we feel like giving him a boost. We have carried his advertising for some time, and this is the first complaint we have ever had.

Years ago A. I. Root used on his old original American hives a sort of cement or sour-milk paint. As we remember, it gave good service, was cheaper than lead and oil, and the hives gave good service until he abandoned them in favor of the Langstroth dimensions; for in these days he was experimenting with different hives and frames, and after carefully testing out these hives he came back to the Langstroth.

Our Foreign Exchanges; What the Great War has Done to Beekeeping in Europe

If anything were needed to cause us to realize that things are out of joint in Europe it is the almost complete cessation of the bee-journals of Germany, Belgium, and France, which for so many years have graced our table. We find none here dated later than January, 1916.* *The British Bee Journal* (England) comes to us regularly as before. *The Irish Bee Guide* has been coming also. Several of the friends have asked us lately for the address of the "best German" or "best French" bee-journal; but in each instance we have felt that any journal we could refer to might be out of print by that time. The demoralization of the beekeeping fraternity of all Europe seems to be complete. If that continent

were to be compared to a strong colony of bees knocked over by accident it would give one a fair idea of the horrors now taking place in

"—thy cornfields green, and sunny vines,
O pleasant land of France!"

The thunder of cannon and the hiss of shell have silenced the peaceful hum of the bee, and, in many cases, the coo of the babe in its mother's arms.

As indicative of the state of things in France even a year ago, we quote the following from our valued exchange *L'Apiculteur* for March, 1915; but in doing so we do not wish to plead the cause of one side as against the other, for it is a battle of the giants—diamond cut diamond, and a lot of them at that.

"Wherever they have passed, the German armies have left nothing behind but ruins. The bees have not escaped the common fate. It even seems that, in the invaded regions, the apiaries have been destroyed systematically in conformity with orders from superiors."

The last copy we have had of that journal was dated November, 1915, and we fear it has at least temporarily suspended.

Even in Switzerland, a neutral country, the people feel the stamp of red Battle's foot. *L'Apiculteur* says, Jan. 1, 1916:

"What a sad New Year's Day! For nineteen centuries it has been sung from our churches, 'Peace on earth, good will to man'; and yet, oh bloody wrong! the Christian people of Europe have been massacring each other. The flower of these nations are cut down by hundreds of thousands; and, as if the slaughter did not go on fast enough, the Turks and pagans are called in to help. What opinion will these heathens form of Christianity when they see these things?"

The writer of the above was the celebrated Ulrich Gubler, whose death we noted last year with his picture.

More than a year has passed since the above extracts were written; and, sad as is their tone, the condition there has steadily grown worse till the bees seem to be left to their own resources while the entire nation has gone to war.

The bee-journal in question speaks of a former Paris manager of the A. I. Root Company's branch office in that city as serving as an officer in the front; and his wife lately wrote us of her experience in trying to carry on his business alone. Thomas Wm. Cowan, at the age of 70, is even reported as serving as a railroad guard. Truly the time has come when "nation shall rise against nation."

* Most of them suspended early last year.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

PROF. BALDWIN, I like your looks, p. 300. Come on in.

ADVICE is given, p. 301, to put the queen below the excluder when transferring. All right; but it needs watching unless a brood is put with the queen. I knew a man to lose his best queen by leaving her below an excluder with no brood. Two cold days came; the bees deserted the queen and left her to perish. The man was no greenhorn either, for I'd been keeping bees some 50 years.

THE water method of transferring, p. 302. "While the two hive-bodies are held in contact, very slowly lower the box hive into the water until the bees have been forced off the old combs." That will take some time; and won't it be pretty hard on the arms? Wouldn't it be just as well to put the hive in the dry tub, and then "very slowly" pour in water?

R. F. HOLTERMANN, you say, p. 310, "I clip the wings on both sides." I wonder why. It's less trouble to clip only one side, and it's handy to have a wing to catch the queen by. The only thing I can think of in favor of clipping both sides is that you can more surely distinguish the clipping when you get a fleeting glimpse of the queen, and I'm not sure of that. Please tell why. [Clipping a queen on both sides would make her more conspicuous, perhaps, but it would be rather difficult to pick her up when it is desired to transfer her to another colony. But after all, does not the one-side clipping make the queen conspicuous enough? She certainly cannot fly, and it is up to Holtermann to explain the reason why.—ED.]

Now comes Penn G. Snyder, and says: "Sugar $2\frac{1}{2}$ + 1 water equals $3\frac{1}{2}$ bulk (your figure). Honey, $3\frac{1}{2}$ bulk, holds 1-5 water, or 2.8 sugar and .7 water. So your recipe, $2\frac{1}{2}$ sugar to 1 water will contain more water than the same bulk of honey." Your arithmetic is off color a bit, friend Snyder, in the present case; for if you add a pint of water to $2\frac{1}{2}$ pints of sugar you will find in your vessel, not $3\frac{1}{2}$, but somewhere about $2\frac{1}{2}$ pints. So in the present case $2\frac{1}{2}$ plus 1 equals $2\frac{1}{2}$. But if you say "weight" instead of "bulk" you've got me, and I acknowledge the corn.

"A pint's a pound the world around" is true of dry sugar and a good many other things, but not of honey nor of any mixture

of sugar and water. I took 8 parts (by bulk) of sugar, and as I added water to it, little by little, it gradually shrank in bulk—the more water added the less the mixture—until I had added one part water, and there were then 5 parts of the combined sugar and water. That was the limit of the shrinkage. After that each part of water added made one part more of the mixture.

WHEN I said I had found in sealed queen-cells grubs not half grown, it did not occur to me that I was butting my head against orthodox teachings. Now comes that heterodox chap, Arthur C. Miller, and says: "Don't you know that all the orthodox teaching is that the queen-grubs do receive and must receive a *constant* and abundant supply of the same rich food as is given to worker-grubs during their first three days?" Well, it's the bees that are heterodox, and neither of us Millers. I told only what I saw. Arthur C. goes on to say, "The fact is, the little sealed-up grub is as well or better off than her unsealed sister," and explains that it's the enzymes that keep the baby's mess from going stale, even if it gets nothing fresh for two or three days.

DR. N. E. MCINDOO, one of Dr. Phillips' fellow-conspirators at Washington, it will be remembered, not long ago gave as the result of his investigations that the smell-organs of the bee were to be found almost anywhere except in the antennæ, where we had been taught they were. He has not by any means given up his upsetting investigations. In his latest work, while saying that he has found some organs of smell in the antennæ, he ruthlessly shatters all our ideas about the delicate and discriminating taste of the bee by saying and proving—that it has *no taste at all*—only smell. It happened that, soon after reading his work, I saw a dog after a rabbit. The rabbit was not in sight, but the dog at a full trot was following the trail by the scent. The rabbit had gone over the ground at a lively gait; and if you or I had held our noses to the ground perfectly still, it is not likely we should have discovered any odor of the rabbit by the most careful sniffing; yet that dog kept track of it while on the run. Now, how much stronger is that dog's sense of smell than ours? Probably a hundred times as great. If so, is it at all impossible that the bee may go the dog a hundred better? So it doesn't look at all impossible that a bee may scent a basswood tree or a field of clover two miles or more away.

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Some of us are treasuring those articles by Mr. Orel Hershiser on European and American foul brood, over against a day we hope may never come—another case of preparedness.

Brood-rearing seems to be coming on pretty well, tho probably not so fast as tho there had been fruit-bloom. There is a little sealed drone brood.

"Cut it out!" Mr. Scholl insists, page 223, March 15, referring to drone comb. It sounds a bit personal to some of us who realize that we may not have cut it out so closely as we ought, but we do know what excellent advice it is.

Most of the reports show bees thruout middle Tennessee to have wintered well, tho we have heard of some that starved out because of failure to feed in the fall. ("Lack of sense or cents?" queries our correspondent reporting it.)

"Feeding fourteen dollars' worth of sugar every three days, with rain between spells," as recorded by S. H. Burton, Feb. 15, page 153, is certainly persistence in the face of obstacles. Sticking-to-it is one of the qualities that make for ultimate success. Here's hoping Mr. Burton's bees more than repay him this year.

We lost one colony—queenless. Perhaps it served me right, for my last record of last fall says, "Did not see queen." Other-wise colonies were in fairly good condition, tho I was sorry to observe the last one or two combs to the north in many hives moldy—in some of them, very moldy. Why? And why the one to the north, I wonder? Super covers seemed looser than usual this spring, not sealed down so tight as other years. Perhaps we fed a little late.

Just to the end of one alighting-board I was puzzled, one day in the early spring, to find quite an accumulation of pollen balls. There were none around any other hive, or elsewhere by that hive. After watching a bit I saw a little bee with great generous loads of bright yellow pollen drop on that end of the board, and squeeze into the hive thru a tiny opening where the entrance-contractor, a trifle short, failed to

reach the end of the entrance. And as she squeezed in, the pollen was scraped off and dropped to the ground, wasted.

Please, everybody, hold your breath. It looks excitingly as tho we might have a stunningly good year, if something just doesn't go wrong. The weatherman was not considerate during fruit bloom—indeed, in our immediate neighborhood there was practically no fruit-bloom this spring, which you will admit was a grievous disappointment. Of course there are no orchards around here, anyway, but usually there is considerable bloom, all told, in the yards round about. But this year the peach-buds, which had been swelled since early February, were held back thru freezing weather till nearly April, whereupon the trees with a bit of a pout threw out leaves instead of blossoms. So, too, with the early plum. Then it rained almost constantly during the blossom time of the later plums, and there are no apple-trees around here. So we have had to feed part of our little yard to tide over till clover. Out in the country, where there are apple-orchards, things are decidedly better. "This bloom," writes one bee-keeper, speaking of apple, "laps over into crimson clover, which in turn laps over into white clover," which certainly sounds good to a city backlotter. But the prospects for white clover are fine, and we are willing to risk a little sugar in the hopes of being ready for it.

The Bee Larva.

Larva that lies so still,
Wonderful worm so white,
Guarded from ill of hunger or chill
In dusk like a mid-summer night,
How did you come to be?
How did you break the egg?
E'er yet we can see, has the mystery
Encircled a thorax and leg,
Groped for a brain and an eye,
Dreamed of a gossamer wing
And how it will fly when some early June
sky
Makes summer a marvelous thing?

Peacefully you lie curled,
Sheltered from struggle and strife,
Tho wings, when unfurled, become part of a
world
Of measureless labor and life.
Pray that some elf a choice brings
Of lying summer—long so,
Or wearing out wings doing fair, brave
things—
Which would you choose? I know!

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

With sugar selling at seven dollars and sixty-five cents per hundred pounds bee feed will cost heavily this year, and the bees are going to require a lot of feeding too. Sweet clover and alfalfa are in fine condition, dandelions are in bloom, and breeding is going along in fine shape. It ought to be easy to have all colonies in excellent shape; and if judgment is used much increase can be made at no expense of honey crop. All that the beekeeper needs now is enthusiasm, good judgment, and hard work to have the colonies in prime condition.

A few weeks ago it looked as if we should have a very early spring, and that there was great danger of the fruit bloom freezing; but it turned cold soon enough to hold back the fruit bloom. Apricots, cherries, and a few apples have suffered; but the great majority of the orchards are safe at this writing. Dandelions have been kept back by the cold weather, and look a little the worse for the freezes. We may not have so many of them this year. Bees that have had protection have wintered well in Idaho, and colonies with good queens and honey have come thru well in Colorado.

Prospects are favorable generally. The prospects are poor in the Arkansas Valley, according to reports I have received. Bees are not in good condition there, on account of the poor season last year. Several cars of bees are to be shipped out of the valley this year. The older irrigated sections are not the honey locations they used to be. Cultivation is too intensive, and sweet clover gets little chance to grow.

THE NATIONAL ASSOCIATION.

In letters that I received from members and non-members, while secretary of the National Association, the thought was expressed that the National ought to do something for the beekeeper. Instead of asking what shall I benefit if I join? it would be better to say, what will the association ask me to do if I join? If the beekeepers want anything it is up to them to get it. There has been too much waiting for the railroads, the legislatures, the government, the honey-buyers, the commission men, and the National Association to do something for the beekeepers. If the beekeepers want

anything individually or collectively they had better go after it. Let us not complain of these agencies. Let's quit expecting charity, and let's dig down and pay for what we want. And do not expect a dollar fee in any association to solve all our beekeeping troubles.

If the beekeepers expect the marketing problem solved it will have to be handled in a business way, and the building will have to be done from the bottom up. The producers who have the surplus must get together and work with the beekeepers who have no surplus, but are nevertheless vitally interested in seeing prices kept up. The beekeeper is just like any other individual. He will sacrifice future profit for present advantage, not so much because he does not look into the future as because he has the present to contend with. Members of associations will sell honey for cash at ten per cent below what could be secured by holding thirty days, and they will sell to competitors of their own associations. A little more capital would enable them to stick by the associations, and on the average they would do better and would be contributing to the life and success of the association.

The National Association has elected officers who will push the association along educational lines only, leaving the commercial interests to others. This, it is hoped, will limit the activities to lines that can be successfully pursued. We cannot lose sight of the fact that too much education cannot be carried on covering foul brood, wintering, and overstocking, and as much, if not more, is lost from overstocking than from the other two, speaking of the inter-mountain region.

It is a pleasure to see that such an amiable and enthusiastic man as Prof. Jager has been elected president of The National Beekeepers' Association, and Dr. Copenhaver, of Helena, Mont., as the new vice-president. Dr. Copenhaver was elected president of the Montana State Beekeepers' Association a year ago at the time of its organization. He is an efficient enthusiast, and will well represent the interests of the Northwest. My best wishes go to all the new officers of the National. Serving as an officer of that association will give one an opportunity to do a great deal of work that may be of much value to American beekeeping. The writer is glad to be relieved of the duties of secretary, as his work is such that the office could not be well carried on.

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Clover apparently has wintered well. With abundance of moisture in ground prospects should be fair for a crop of honey. Markets are well cleaned up, so any crop obtained should move off readily.

How the war will affect prices is an uncertain proposition. Practically all food products are going up in price all the time, and honey should hold present prices at least, even if it does not go up in proportion with other staples.

At this date (April 10th) it is possible to form a fair idea as to how the bees in Ontario have wintered. I have received no reports from cellar winterers; but, judging from letters at hand, I think that outdoor bees have wintered well wherever colonies were very heavy with good stores last fall.

Owing to the unusually warm January, many colonies with young queens and lots of empty comb available, reared brood extensively, with the result that stores were used up fast and the vitality of the bees was used up as well. What little loss we had in our own yards can all be traced to that cause, and this winter has once more demonstrated that while the so-called "winter nest" does no harm in more southern localities, and may even be an advantage (alho I much doubt it) here in Ontario it is never a necessity and is often a decided disadvantage to a colony. Proof abundant along this line is furnished by the fact that every colony contracted and made practically solid last fall by feeding is in simply perfect condition this spring.

Good advice is given on page 263 as to how to clip a queen's wings. Women are proverbially more handy than men, and I wish Mrs. Allen would try clipping the queen's wings without even catching the queen at all. I am as clumsy as the ordinary man at least, yet in common with a number of others that I know, I annually clip nearly all my queens while on the combs, without catching them and leaving any odor that quite often causes balling even with the most careful management.

Get a pair of small curved surgical shears—buttonhole scissors may do for a lady, but the finger holes are too small for a man's fingers. Find the queen and rest one end of comb she is on, on edge of hive and so manipulate it that the queen is heading up-

ward—many Italian or Carniolan queens will often remain quiet on the comb. Gently and deftly slip the thin-pointed shears under the wings and *clip*—that is all there is to it. If at all nervous, practice on a few drones first and you will be surprised how easily the trick is done. How much you take of the wings is a secondary matter. I like to clip all wings off so that the queen is well marked for future finding. Nothing in the idea that a queen closely clipped is apt to be superseded.

March was unusually cold here in Ontario this year. During the first 24 days of the month we had a temperature of 14 degrees below zero. Our bees had no flight till the last three days of the month when conditions were ideal for the bees to have a perfect cleansing flight. After having not seen the north apiary of 250 colonies since last October, I took the train on April 5th and found they had wintered perfectly again. They were covered with snow from early February till March 24th, so is it any wonder I am quite strongly of the opinion that snow rarely hurts bees? Here in York Co. we had a heavy wet snow with wind from southeast that sent snow right into entrances of hives. Two days after it turned very cold, and remained that way for three weeks. I shoveled this wet snow away from the hives in three of the apiaries and left the other one as it was. Parties in Ontario wrote me after the storm in question saying that this snow if left would do harm as it was so wet that, when freezing came, entrances would be frozen and trouble caused. However, when I went to shovel the snow away from this one yard about the last of the month, I found them none the worse as every colony had a space around the entrance where snow had melted. In fact, the bees were better by being shut in, as, during the two weeks previous to the time they were opened, we had bright cold days and large numbers of the bees came out daily in the yards that had clear entrances. Such bees were of course lost in the snow. While the great majority of these bees were no doubt old and about ready to die anyway, the fact I wish to make clear was that under such extreme conditions snow did no harm. With warm weather following the snowstorm, so late as the month of March, then I would not want to leave snow over hives any length of time.

Mention is made on page 1040 of the plant called "Devil's paint-brush," or "orange hawkweed." Judging by what I have seen of this pest when we had an apiary near Brockville, Ont., I do not wonder that they have coupled the ordinary title of his Satanic majesty to this plant. Out there the soil is of a thin limestone formation with much of the land being left for pasture; in fact, much of it is good for nothing else. Well, this "paint-brush" is rapidly crowding out all other vegetation on hundreds of acres, and it is literally good for nothing, as stock will not touch it, and the bees seldom touch it at all—only a very few being noticed on bloom, and they were after pollen. If it yields honey in the locality mentioned by C. L. Williams, I am very much surprised.

* * *

As to clipping queens, page 90, Jan. 15, personally I either want both wings off at one side or else all wings quite closely cropped straight across. The reason? Just because such a queen is more conspicuous, and a single glance, even in a hurry, no matter where the queen is, will tell you that she is clipped. The old argument about clipping one wing first year, another the second, and so on, is out of date, because we do not want to keep queens that long if we can help it. In clipping this spring, if a young queen is found she will be clipped and the hive thus marked. Should I find the queen is already clipped, the colony is marked "old queen," and if things go as I desire during the season, an effort will be made to requeen that colony before fall. That's all the record I need of a queen's age.

* * *

"If you were starting an outyard of 100 colonies how close would you go to a neighbor who had about the same number of bees, and still expect him to be your neighbor?" This is the query asked in the *March Canadian Beekeeper*, and answered by J. A. McKinnon as follows: "If I were starting an outyard I should not want to have that number of colonies any closer than three miles. I think five miles would be better." There may be some exceptional cases to which the above advice might not apply; but in the main most of us will, from a common-sense standpoint, and a common-justice standpoint, most sincerely agree with Mr. McKinnon. Please note that he is considering himself primarily in so advising, and the other fellow simply as a secondary matter. But see here, friend McKinnon; I warn you that you are stepping on a number of people's toes pretty firmly by saying what you have. To the

best of my knowledge, I am not personally hit; but that may be solely because of selfish views; for I well know that, if I put a large apiary right up near another large apiary, I shall suffer just as much as the man already established. There is not now, nor do I expect there ever will be, a law on this continent defining just where a man may put an apiary; and so it is one thing to be thankful for in this matter under discussion that one cannot injure another without at same time suffering loss himself.

* * *

Undoubtedly sweet clover yields some honey; in fact, we secured some last year at our Markham yard. But, enthusiastic as I am on bee matters, I have not yet got where I can conscientiously recommend farmers to grow the plant, especially on strong rich clay soils where other hay is grown. Mr. Linton, of Aurora, Ont., gave an instructive paper on sweet-clover growing at one of our conventions, and he has unquestionably made a success of it. But his farm, I understand, is hilly, and soil rather light—in fact, not adapted to growing timothy and clover. He admitted, in the discussion that followed his paper, that growing timothy hay and sweet clover on the same farm would not work.

From an experience on our own place—at least the place we formerly owned—I can well understand the reason. Probably forty years ago my grandfather, who was an enthusiastic beekeeper, sowed a field of white sweet clover and allowed it to go to seed. Every time that field has been seeded to timothy or red clover since then, we have been reminded of the fact. The soil is a very strong clay loam with clay subsoil, and, no matter how well it has been looked after, some seed seems to survive and show up from year to year. Sweet clover is all right for hay; but mixed in with timothy it is worse than useless, as the timothy has to be left so long that, by the time it is ready to cut, the sweet clover is about as good as sticks so far as hay is concerned, and some of it is ripe, leaving seed in the ground.

Another matter that has made Ontario beekeepers slow to boom the plant for honey production is that the honey from this source is undoubtedly very much inferior to that from alsike or white clover. In some cases, especially in Kent and other western counties, well-known producers have told me that they wished there was not a stalk of it within their reach. This is no knock on sweet clover, for I believe it has a future on the farms, especially on light, hilly, or worn-out locations; but it is well to look at these questions from different view-points.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

DRAWN COMBS IN SECTIONS.

"As the season of 1915 was not the best for honey, I have many sections with combs in them left over from that year. What had I better do with these sections—cut out the combs and clean up the sections, melting the combs for wax, or would you use the whole thing for fire-kindlers as does a beekeeper near me?"

Well, now! that is ahead of any wastefulness I ever heard of except letting the larvæ of the wax-moth destroy the combs. Sections filled with combs are equal to money in the bank. Money is put in the bank for safe keeping, but more especially for the interest it will bring. If these sections of combs are given to the bees at the opening of the clover or basswood harvest, they are not only preserved and filled with honey, but they will give big interest by drawing the bees into the supers before they would otherwise enter them. The very first honey is thus secured from these sources at the very start, which practically insures a good yield to the very end.

I have had years of experience in this matter, and know that when the flow from either clover or basswood opens very suddenly, or, at least, becomes very profuse soon after it opens, neither starters nor full sheets of foundation can begin to compare with sections filled with comb. There is no time in which drawn combs can be used to such good effect as at the rush that comes at the opening of the basswood harvest.

Then these combs are of equal value in getting the bees started at work in the sections at the beginning of the clover harvest, at which time the commencement of the nectar flow is not such as it is with basswood. When honey comes in slowly, the bees have to be coaxed into the sections or else they are very slow in starting, and these sections of comb are the greatest "coaxers" in bee life of anything which can be used. When honey comes with a rush, there is no time for deliberation; the honey must go somewhere, and work will at once be commenced in the sections full of inviting combs.

Then drawn combs are ahead of foundation—at least so far as the amount of honey to be secured is concerned—at any stage of the flow. If we could have all sections filled with nice white combs there is no reason why we cannot get just as much comb honey as extracted. If I could have my choice I should be glad to have all the sections in the first super filled with drawn or partly

drawn combs. I have seen seasons in which I was satisfied that a super of partly drawn sections of comb to give a colony at first meant just one more super of finished honey. A colony given a super of combs would have those combs filled, and be started upon a second super of sections filled with foundation by the time a colony given a super filled with only foundation had barely made a start. Where only foundation is used in the first super put on, the bees are slow to make a start, seeming rather to store in the brood-combs below. If a bee emerges from a cell, and the queen doesn't stand ready to put in an egg, it is quite likely to be filled with honey. Give such a colony a super of sections filled with partly drawn combs, and the bees will store honey in these combs just about as readily as in the combs below—a long time before they will draw out foundation in the sections. Combs in the sections relieve the pressure upon the brood-nest. More brood is the result. Yes, and it starts the bees to storing above the brood-nest, and, having made a start, they are sure to continue it unless the flow of nectar nearly or quite stops altogether.

Considering the value of drawn combs, I do not try, to any great extent, to restrict the number of unfinished sections at the end of the season. Supers entirely filled with drawn combs are not only just the thing at the beginning of the white-honey flow, but they are equally good near the close, for I have many times given colonies supers half filled with drawn combs and half filled with foundation near the end of the basswood flow, in which the drawn combs were filled and nicely capped; and the foundation, altho in the center of the super, was left entirely untouched. If I had sufficient drawn combs I would use them exclusively during the white-honey season, at the beginning, middle, and end; and by giving the colonies, after the basswood season is ended, supers of sections filled with foundation at the beginning of the buckwheat flow, the bees will draw out thousands of them during that and the fall flow. This can be extracted, and the combs used the following season. The extracted dark honey may be used for feeding, or it may be sold to those who prefer dark honey. In uncapping, it is well to cut quite deeply, thus reducing the depth of the cells, as when combs are nearly completed and used over again they will not have the smooth new look of those just built, nor of those that were not more than half completed the previous season.

GENERAL CORRESPONDENCE

FREEING SUPERS OF BEES IN OUT-APIARIES

A Quick Plan that does not Require Shaking, Brushing, nor the Use of Bee-escapes

BY J. A. GREEN

One of the most important operations to the beekeeper under any circumstances, but more especially to the one who keeps his bees in out-apiaries, is getting the bees off the honey. The time-honored method of smoking and brushing is still followed by many, especially among producers of extracted honey. Comb honey is likely to be injured by this method, especially when honey is not coming in plentifully, or with some strains of bees which begin to uncap the honey as soon as the hive is disturbed. Most beekeepers now use the bee-escape, which has been one of the most useful inventions ever presented to the beekeeping world. Especially to the keeper of bees in out-apiaries has the bee-escape been invaluable. Except to the one who takes an extracting-outfit to the outyard and shakes or brushes the bees off the combs, the bee-escape has been all but indispensable.

The escape has its drawbacks at all times, particularly for use away from home. First there is the danger that it may become clogged with dead bees, fragments of comb or other refuse, so that the bees cannot leave the super. This may result in nothing worse than having the work to do over again, though I have known bees to be suffocated and honey injured in a super over such an escape. A board containing more than one escape is, of course, much less dangerous.

Then there is the danger of robbers getting into the super and carrying off or damaging the honey. There are few hives or supers which have been in use a number of years (some of mine are thirty years old) that are not liable to have openings or cracks when they are piled one on another. Danger from this source may be avoided to some extent by plastering over all suspicious places with mud after the escape is in place. But even this cannot be depended on long in Colorado, where the continued presence of bees in a hive is necessary to keep joints tight. If we place an escape under a super, being careful not to lift the cover or disturb the sealing, that cover will often begin to crack loose and warp as soon as the bees are out of the super, and in a

day or two there will be a crack thru which bees can enter.

One of the worst faults of the bee-escape method for out-apiary use is that two trips are often necessary to take off a lot of honey, as it usually requires from 24 to 48 hours to get all the bees out in this way. Another bad fault for the extracted-honey producer is that the honey above an escape-board becomes too cold to extract well soon after the bees have left it. In Colorado, with our cool nights and very thick honey, bee-escapes are not very practicable for honey to be extracted, unless the honey is to be warmed up after taking home. The wire-cloth escape-boards that have been recommended for this do not suffice to keep the honey warm here.

Lastly, there is the danger that thieves who have learned what a bee-escape is for may carry off the honey over escapes before the owner gets back to it.

I am going to tell you of a better plan than using bee-escapes; but first I want to recite a little ancient history. When John Reese first made public in GLEANINGS, some years ago, his invention of the bee-escape, it attracted little attention. I think it was a year or more afterward when, noticing that no further mention of it had been made, I wrote an article for GLEANINGS, calling the attention of beekeepers to the fact that they were overlooking an invention that I had found practical and valuable. A short time after this was published, I met, in Chicago, James Heddon, whom old-timers will remember as one of the brightest men who ever kept bees. Said he to me, "Green, you ought never to have written that article. Reese's description of his bee-escape fell perfectly flat. I don't suppose there were a dozen men in the United States who ever tried it, and none of them said anything about it. It is a big thing; but such things ought to be kept in the hands of the specialists, who can appreciate their value. You have stirred it up again, and it will likely come into common use, which will be bad for the professional."

I will not discuss now his position in regard to new ideas, which is not altogether

uncommon. I have always been ready to share anything I knew with any one it would help, though I have sometimes been slow in making public a thing that has not been thoroly tested or perfected.

His prediction in regard to my article was apparently correct, for it renewed interest in the bee-escapes. Various improvements were made, and the original inventor was soon lost sight of. I know of no work on bees that gives him credit for his important invention. A letter from him appeared in GLEANINGS a year or two ago, in which he gave a hint of a better method of getting bees off the combs than the bee-escape; but this hint, like the original description of the bee-escape, seems to have fallen on stony ground. So I am going to "do it again," and try to wake some of you up to an appreciation of the better way, for there is a better way, for many of you at least.

I keep all, or nearly all, of my bees in out-apiaries, producing both comb and extracted honey and hauling the honey home to extract. For the last three years the bee-escape with me has been a discarded implement, an antiquated device that is used only occasionally. I drive into an outyard with my auto truck, and in ten or fifteen minutes can begin loading into the truck supers of honey perfectly freed from bees, without shaking, brushing, or any previous preparation. I do this by using the carbolized-cloth method. This was frequently mentioned in the bee-journals several years ago, and appears to have had considerable vogue in England, tho if it has ever been used to any great extent in this country, we have never heard of it. Properly used, I find it one of the greatest time and labor savers for the beekeeper who runs out-apiaries.

Tear any ordinary cotton cloth into pieces a little larger each way than the top of the hive. To work to advantage you will need four or five of these, and will probably find more unnecessary. Put these into a two-quart Mason fruit-jar, which makes a good thing in which to keep them. Pour over them a ten-per-cent solution of carbolic acid, one part of pure acid to nine parts of water, just enough of the solution to keep them about as wet as they can be without dripping. Any surplus can be squeezed back into the jar. The exact proportions of acid and water are not very material, and some other proportions may be better under some circumstances; but this is what I have generally used and found satisfactory.

Go to the hive from which you wish to take honey. Remove the cover, lay the carbolized cloth over the frames, and replace the cover or throw something else over the

cloth to prevent drying and waste of material. This is all that is necessary, tho I find it advantageous in practice to use smoke in connection, puffing a good volume of it into the top of the super, to get the bees to running before the carbolized cloth is laid on. Go to another hive and repeat the operation. By the time you have four or five thus prepared, the first super should be ready to come off. Put the cloth from this hive on another, and take off super number two, using its cloth as before. This makes a continuous operation, taking off supers as fast as you can prepare the hives and handle the supers. If you have to spend much time in hunting for supers that are ready to come off, you will not need as many cloths, as it takes only a few minutes ordinarily for the combined smoke and odor to drive the bees down, and the cloths should not be left on longer than necessary. Too strong a solution or a cloth left on too long may taint the honey somewhat. The odor passes off soon when the combs are exposed to the air, so that it does no harm to comb honey. You must be very careful with extracted honey that you expect to extract soon. When extracted soon after removal from the hives I have sometimes noticed the carbolic flavor in the honey drained from the cappings. I never take off honey before it is sealed. Probably unsealed honey would more readily acquire a taint that might be permanent if the honey was not exposed to the air.

Use nothing but the best refined acid. I tried crude acid, thinking that the stronger flavor would be more effective. It was, but the disagreeable tarry odor remained on the combs much longer. Carbolic acid is very high now, on account of the war; but, even so, I think it pays well to use it. Keep your cloths away from the air as much as possible. Put them into the jar as soon as you are through using them. Add a little more solution; seal them up and they are ready for use the next time you want them.

The method works much better with comb-honey supers and shallow extracting-supers than on deeper ones, tho I have used it with many of Langstroth depth. If you have more than one super to remove from a hive it is better to take off the top one as soon as the bees are out of it, leaving the cloth for a short time on the one below. Do not loosen the super from the hive before the bees are out. The draft of air from the crevices thus made interferes with the action of the carbolized air from above.

The method does not work well when the bees are sluggish from cool weather. There is one great objection to the plan, and it is

this that has made me hesitate so long about saying anything about it. This is, that the knowledge of it puts a very effective tool into the hands of those who might be dishonestly inclined. A thief who understands his business could get away with a great deal of honey in a short time, and could re-

move the honey from the hives by night almost as well as by day. So if you use this plan, let me advise you to keep it strictly to yourself. Do not use it when visitors are around. The outfit needed is small. Keep it out of sight when not in use.

Grand Junction, Colo.

CARING FOR 1000 COLONIES OF BEES IN IMPERIAL VALLEY

BY JOSEPH GRAY

To see four carloads of honey piled up in one lot, the product of one 1000-colony bee-keeper, speaks well for the system here outlined. Here in the Imperial Valley our flora is chiefly alfalfa bloom. The desert and banks of the canal system yield less every year from the cottonwood, willows, wild hollyhock, greasewood, arrow-weed, etc. Bermuda grass, price of hay, the reluctance of ranchers to irrigate and harvest in July and August when the thermometer is 110 in the shade; the putting in of barley along old alfalfa pastures for barley hay in the spring; the changing of crops to cotton, milo maize, feterita, melons, canteloupes, all tend to cut down the long honey harvest for which this valley has been noted.

Eight apiaries of over 100 colonies each, stretching away over ten to twelve miles, means considerable figuring for simplicity of handling. Two men in a Ford or other small car can do all the work of the apiaries early in the season, weeding out the dead, caring for the combs, and equalizing stores. It does not pay here to buy sugar to feed. The feeding is all done by exchange of combs. Only one size of frame is used—the standard Langstroth. It matters little if it is plain or spaced, thick or thin top-bar, wide or narrow. The same applies to hives 8, 9, or 10 frame. All are in use in 1000 colonies. Later in the season two teams of two men each are needed, and a boss to follow the work, requeening, drawing honey, getting it hauled, cans and cases, besides the wax question. A market-wagon carries what is needed for the day. One man operates the yard while the lesser experienced man uncaps and extracts. The combs of honey are collected in a long five-foot box mounted on a skeleton wheelbarrow covered with four wet sacks. When it is run into the extracting-house the two men lift the box on two upturned supers and place an empty box of combs on the wheelbarrow. One of the easiest methods to handle cappings is a wet sack on the bottom of the uncapping-tank. The cappings after draining are lifted out bodily and carried to the solar extractor.

Many are the devices used to make each hive an open book. Fig. 1 shows a hive-cover with three columns—a “wanted” column on the left; spare column on the right; center column, queen. A little reflection will give you the positions. *Right* is abundance; *left* is want; *center* is queen life; a small blue nail driven into any of these positions gives the index to the colony. For instance, a nail is shown in Figure 1 at “watch.” The boss finds the notation “26-4, drone-layer,” hence the index at “watch.” Another may be indexed “Requeen.” This calls attention to a possible record—“26-4, queenless.” Again, the index at “Queen” may reveal, in date column, “26-4, saw queen XXX.” That gives the apiarist’s opinion of the queen as seen at that date. The list of terms covers nearly every phase of beework.

Wanted Bees	Queen	Spare Bees
weak	Watch	strong
Stores	Virgin	Stores
Combs	Requeen	sections
Cell	Cell	Cell

A location here costs about \$25.00 per year rent. The bees must be put 100 feet from the fence line, and 300 feet from the roadway. One must consider the possibility of the bees getting irrigated as well as the land. As we have no rain, the roadway for the wheelbarrow will need to be irrigated for a barrow will not run in loose sand. We secured a location for one year, or may be two. A longer time is not advisable, because next year, instead of alfalfa we might see a mile of cantaloupes, or a couple of miles of corn or cotton; and, though it will cost you \$50.00 to move, it pays to shift

such an apiary. If as the editor suggests a new Imperial Valley opens out by way of Mexico, then the old-time alfalfa crops without Bermuda grass will prevail once more.

Having selected our site we proceed to plow and then "V" two banks on which to set the hives. These are run east and west, with the extracting-house at the east end.

Around the whole a border is plowed and "V'd" to keep out the water when the land is irrigated.

Next comes the building of the "ramada," the necessary shed or shelter. For this, 14 bents will be required, as shown in Fig. 2. Ramadas for stock are built with flat roofs; but for bees the roof should come low down at the sides with a six-inch streak of light down the center. With the ramada set east to west, and the west end covered in, no hive can get the full force of the sun. The bents are made of 2 x 3 lumber, and 1 x 3 lumber for the roof. To get an accurate

gauge to cut your lumber by, use a temporary card gauge. Mark with your square three inches along one side and six inches along the right angle. The result will be a measure that will answer for every cut.

Having our bents made and up we proceed to stretch six wires anchored to the deadmen. At each end arrow-weed is cut and the roof thatched. Light wires run along and are fastened to the under wires. This completes a very cool shade for so hot a country.

Heber, Cal.

A SUMMARY OF THE SEASON'S TRIPS TO OUT-APIARIES

BY J. W. SCHLENKER

I use the eight-frame dovetailed hive, and think it is best for comb-honey production. I make my first visit as soon as bees can fly well in the spring, and at this visit determine which colonies, if any, are short of stores. These I feed with full combs of honey saved over from last season for this purpose.

The next visit is made during fruit-bloom, at which time I remove paper coverings and clip all queens not previously clipped. Colonies showing so strong that they are likely to be crowded before May 1 are given another hive-body containing drawn combs, which are usually on hand at this time, from hives that have been fed, and from those that have died. These are set on top, and the queen given liberty to lay as much as she pleases.

About May 1 I make another visit, start-

ing to haul supers to the yard, and putting them on colonies showing sufficient strength. This is very important, because, if bees become crowded at this season, they will get the swarming fever and be much harder to handle.

After the honey begins to come in freely I aim to visit each yard once a week to put on supers, and determine whether any colonies contemplate swarming. This is done by tipping the hives back and blowing smoke over the bottoms of the frames. If any queen-cells are found these colonies are treated by shaking bees off all but the two outside frames, and filling the vacant space with frames of foundation, then returning supers and adding others as needed. From time to time I remove those that are filled. Colonies so treated rarely attempt to swarm again that season. The six brood-frames

thus taken may be used to build up weak colonies, if any are present, or to make increase. I usually pile them up on the new stand with contracted entrance about three stories high, and give a ripe queen-cell. This cell hatches before the young bees get to storing honey, and the young queen will destroy all other queen-cells, thereby eliminating all danger of swarming. The weather at this time of year is warm enough so that there is no danger of chilling brood, and young bees hatch fast enough, together with those few not shaken off, to care for the young larvæ. These three-story hives are usually so crowded with honey by fall that both the brood and queen will be found in the lower story. The upper stories can then be removed and used for feeding next spring.

Colonies that were given upper stories during fruit-bloom are divided as soon as super work gets well started. Most of the honey and capped brood will be found upstairs in these hives. I shake most of the bees off in front of the lower story, to which I have added two supers in place of the upper story; and after making sure that the queen is in the lower story I treat the upper story the same as other shaken frames.

When I think the honey-flow is half over I stop shaking bees, because those colonies that go half way through the honey-flow

without attempting to swarm can be kept in the supers by destroying queen-cells once a week if any appear. A great many colonies will not attempt to swarm at all if properly handled, and those are the ones that usually make the best yields. Great care must be taken along the latter part of the honey-flow in order to get as many sections completed as possible; and to avoid being caught with a lot of unfinished supers, this is entirely a matter of judgment of the beekeeper, and applied to the home yard as well as the outyard.

After the white-honey flow is over I remove the filled supers and give at least one empty super to each hive to catch any unexpected surplus. If there is a fall flow, supers are added as needed. There isn't often much swarming at this time; and as I do my requeening in the fall I can control what there is without trouble.

About Nov. 1 I remove all supers, and prepare bees for winter by contracting entrances to keep out mice, and by placing about a dozen sheets of newspaper over hives, and covering all with waterproof building-paper folded to shed water, tying with stout string to hold all in place. This has proven better than cellar wintering for me, to say nothing of the labor saved.

Ankeny, Iowa.

[Mr. Schlenker and his auto are shown on the cover of this number.—ED.]

A NON-SWARMING SYSTEM THAT GETS RESULTS

BY J. M. BUCHANAN

For several years I have been testing out a plan for preventing swarming at out-yards; and as I have had such uniform success with it I feel that I can recommend the plan to others who are situated in a similar location, or working under like conditions. Our main honey-flows are from locust and white and alsike clover, and usually begin about May 1, clover closely following the locust, and continuing about two months. There is generally a light aster flow in the fall. My bees are run principally for extracted honey, but with some slight modifications this plan will give good results in comb-honey yards.

Most of the spring work is done in the fall—that is, we see that the colonies breed up strong during September and October so as to go into winter with a large force of young bees. If there is not a flow sufficient to cause such breeding, the bees should be fed thin syrup or diluted honey every few days for a month or so. This is a very im-

portant factor in the next season's honey crop. A colony that will not breed up at all had better be broken up, and the combs and stores used elsewhere, as it will hardly pay to winter such a colony.

In October the excluders are removed, and all supers are taken off, except one, leaving the bees the run of two full-depth stories. (I am using both eight and ten frame hives.) There should be at least 25 pounds of sealed honey in the combs, some of which may be in both stories. They are now ready for winter.

No other protection is given, except that in a very cold winter the entrances are reduced with blocks. They should now be left entirely alone until April, when they are looked through hurriedly to see that all hives have stores and queens. No stimulative feeding or spreading of the brood is done.

A few days before the main flow begins, we go through the hives and put the queen

One of J. M. Buchanan's out-apiaries in winter, each colony being in a two-story hive.

and most of the unsealed brood into the lower story of the hive, with two or three empty combs. From three to five frames of the oldest brood are placed in the center of the upper story, over a queen-excluder, and the rest of the combs placed on each side of the brood. At this time we generally find fifteen to twenty frames fairly well filled with brood. Should we find eggs in queen-cells, most of the brood is placed in the upper story, and what brood is left in the lower story is alternated with empty combs or foundation, all queen-cells being removed.

A week or ten days later we look thru the upper stories and destroy any queen-cells that are found—no use to look for cells below the excluder, as there won't be any there if a good job was done when the queen was "put down." Some of the brood in the upper stories is used in nuclei for increase. At this time all colonies that are storing well are given another super of empty combs next to the excluder. We go over the yards about once a week and give supers to those in need, as it is important that they do not feel crowded.

The hives are tiered up, and the honey allowed to ripen well before it is removed. In taking off the honey, which is usually done about the end of the flow, bee-escapes

are used. Before these are put on we drive down most of the bees with a cloth wet with crude carbolic acid, which is laid over the frames for a minute or two. The extracting is done at the outyards, in a honey-house or in a tent, and the wet combs put back on the hives after sunset.

From two hundred colonies worked on this system we have had less than one per cent of swarming for two years, while our neighbors report fifty to a hundred per cent. I find the bees winter better, and build up faster and stronger in two stories than in one, and require much less attention in the spring, and they will get the honey if there is any to be had.

My bees are a good strain of Italians, mostly three-band, and only the poorest colonies are requeened each season. The rest supersede as they see fit. One factor that may have an important bearing on the swarming problem is the rearing of a large number of drones. I keep this down by allowing only worker comb in the brood-chambers, and using full sheets of foundation.

The illustration shows one of my out-apiaries in winter, with the bees in two-story hives. The trees in the picture are locust.

Franklin, Tenn.

IT TAKES NO MORE TRIPS TO OPERATE OUTYARDS FROM A CENTRAL EXTRACTING-PLANT

BY A. B. MANN

I believe in the central extracting-plant system, for I think it is by far the safest and most economical plan. Forget the portable or the separate plant at each yard, and put up a central extracting-plant, and install a friction-drive power extractor, and be happy. I care not whether you use team or auto truck, it pays just the same. Of course, an auto truck is much to be preferred; but you can get along with horses. Leave your wagon a few rods from the hives and out of the bees' line of flight, and keep all honey well covered after it is taken from the hives, and you are not liable to have trouble.

It takes no more trips to operate your outyard from a central plant than it does to extract at the yard; but it does take a few more supers. Load on the wagon your extra supers, as many as you will need, and go to your outyard toward evening. Take off the hives the full supers, and in their places put supers with empty combs or full sheets of foundation, as the case may be, on these the bee-escapes, and finally the supers of honey which you wish to take off. In the morning go back and get your honey. You will find the bees all out of the supers providing you use a good, clean, double Porter escapes. (I have used them all, and the Porter double escape is the only one that has given entire satisfaction and cleared the supers of bees.) Load your supers, together with the escapes, and haul them home and extract where everything is handy. The work can be done in less time, and in a more satisfactory manner, than is possible at an outyard without too great a cost for equipment; and as soon as honey is extracted you are ready for another yard.

The interior of the honey-house you arrange to suit yourself. I use an eight-frame extractor and a tank 1 foot deep, 2 feet wide, and 6 feet long, standing on a lower level so honey runs from the extractor thru the strainer and into the tank, and then a hole cut in the floor, and boxed off underneath to hold the scale. So you see the honey goes directly from the extractor to the can, where it is weighed without any effort of mine, and then it is labeled and packed ready for shipment. If your time is worth anything, and you have enough bees to warrant it, by all means get a power extractor. It will pay you, as one man can accomplish as much as two with a small extractor turned by hand, and do a cleaner job of it.

I also believe that the foul-brood situation is more easily controlled by the use of a central plant than the portable or separate plant. Where there is American foul brood it is necessary that the extracting-room be absolutely bee-tight, thus preventing robbing, as it is an established fact that the honey from a diseased colony is contaminated, and thus it may easily be seen what disastrous results may follow carelessness and robbing. After the bees leave your honey-house, and even assuming they did not get any contaminated honey there, their robbing instinct has been stirred up and they will look around for more of the precious sweet; and if you have any weak colonies they are pretty apt to find it; and if you have foul brood you are sure to have weak colonies. By operating a central plant you are in better position to keep it up in shape, neat and tidy, and free from robbers. One thing I would suggest to those unfortunate enough to have American foul brood is to have a small extractor for extracting the honey from combs of diseased colonies only, and never place those combs over healthy colonies. If you extract them in the same extractor with the rest, even tho you keep the combs separate, more or less of the good combs are sure to become contaminated by coming in contact with the baskets of the extractor after the diseased combs have been extracted. If you are careless about handling the honey when you have American foul brood you can hardly expect to be able to eradicate the disease. Shake and work all you have a mind to, and be careless about extracting and putting combs back, and you will still have the disease. Better still is it to run every diseased colony for comb honey and take no chance with extracted. I believe you will all find that it is a great deal easier to get rid of the disease while running for comb honey than extracted, and that is one of the reasons why some succeed in stamping out the disease while others meet with flat failures.

With European foul brood we have a different proposition. The bacilli are found in the brood and bees themselves, also the queen, not in the honey, and therefore this disease requires different care and treatment; but in both cases the prevention of robbing is of paramount importance—yes, an absolute necessity. Therefore contract the entrances to weak colonies and do all in your power to prevent robbing.

Regarding prevention of swarming before

the queen has the brood-nest full, and before she begins to feel cramped for room—while the weather is favorable, and the bees are finding nectar enough to keep the queen laying—remove from the brood-chamber one or two combs, according to the strength of the colony, and pick those containing the most sealed brood, and, after cutting out all queen-cells, place them in the center of the super of empty combs and then set them back on the hive over an excluder. Care must be taken to see that the queen is not on the combs removed; and in place of the combs removed give frames with drawn-out comb or full sheets of foundation, as the case may be. This gives the queen room for laying, and the brood in the upper story will soon hatch, and the bees will begin storing in them. In about eight or ten days go thru the super and remove queen-cells if any have been started; and if the queen has things pretty well filled up again, then repeat the operation. Give the queen plenty of room, also the bees an abundance of room for storing, but don't go

to extremes. Watch them and use judgment. Also give them plenty of ventilation, especially those in the sun and those in close places where the air has not a chance to circulate freely. The hive raised up on to $\frac{7}{8}$ -in. blocks in front, and a small entrance at top, suits me best. With the metal top and inner cover this can be accomplished easily. Slide the inner cover back a bee-space, and place two small blocks in front of it on the corners of the super for the outer cover to rest on. This will hold it up at the forward end, and give a bee-space, besides sheltering the opening from rain and sun; but you must weight the cover down or it may blow off. Placing $\frac{7}{8}$ -inch blocks under the four corners may be all right, but it does not suit me. I don't like to work around a hive that is open right in front of where I always stand when working with them. The scuffling around of my feet seems to irritate them. I prefer to have the rear of a hive on the bottom-board.

Fillmore Co., Minn.

FORTY YEARS OF COMB-HONEY PRODUCTION IN OUT-APIARIES

BY J. E. CRANE

I have been running out-apiaries for comb honey for nearly forty years, and most of this time I have had several such yards.

Much of one's success will depend on doing everything when it should be done. Supers must be filled with sections with starters in place. All hives should be put in readiness during cold weather, or at least before it is time to work with bees. As soon as warm weather comes so it is safe to open hives, every yard should be looked over, and all put in shape for brood-rearing. If one colony is found short of honey, honey should be given it—a solid comb from a hive that can spare it, or from those that have been kept over in our storerooms. Weak colonies should be shoved up on to three or four combs with a tight division-board; or, if none is at hand, a solid comb of honey next to them.

Next will come the clipping of the queen's wings. Apple-blossom time is the best for this work, as the fewest bees are then in the hive, and there is little danger from robbing at this time. Two men should go thru a yard of eighty or one hundred hives in a day, besides doing any other work necessary. Clipping queens is very necessary when running outyards for comb honey, as such yards are much more liable to swarm than when run for extracted honey. When

I first began I thought it necessary to hire a man for each yard during swarming time; but I have found it much more economical to clip our queens and look after all the yards myself.

Where many bees are kept in one place, some swarms are likely to issue during our absence; but with queens' wings clipped they will return to their own or some other hive—sometimes two or more to the same hive. When we find them we divide them, giving the bees to those hives most needing them, or use them for making new colonies with brood we have taken from other hives to discourage swarming.

A small building, if not absolutely necessary, is a great convenience for storing supers, combs, and honey, and we have at all our yards a building eight by ten, or usually ten by thirteen feet, for this purpose.

At the approach of clover bloom we give all colonies supers with sections filled with full sheets of thin foundation, or all colonies strong enough to begin work in them promptly. During the spring we do not aim to visit outyards more than once in two weeks; but with the blooming of white and alsike clover we may expect preparations for swarming, and each yard should be visited once in eight or nine days, not only to control swarming but to put on or take

off supers of honey. At each visit we aim to give each colony all the super room it will require until the next visit. We go over the yard by course, examine each hive, and usually remove every super from hives that have not swarmed, and open them that we may know their exact condition as to whether they are preparing to swarm or not. If we find larvæ in queen-cells it is time to begin by removing part or all of their brood, or, instead, their queen. There appear to be two main causes for bees swarming—old or failing queens, and a surplus of brood. If the queen is old it is better to remove her at once and cut out all sealed queen-cells, and, eight days later, again cut queen-cells, and, eight days later, give a virgin queen. It is better to discover such queens before any preparation is made for swarming, and remove them, giving a young queen in place of them; but we cannot always do this.

In regard to the removal of brood, it is much more effective when first preparations are made by a colony for swarming; for the longer it goes after they begin to prepare to swarm, the harder to get it out of their little heads, until sometimes they will swarm any way, even if you rob them of all their brood.

It is time more than wasted to try to prevent a colony that has an old queen from swarming by removing brood; for you may remove all of it and give dry combs in their place, and it is more than probable she will lay a few eggs in a patch as large as the palm of your hand, and queen-cells will be promptly started, and swarming results.

Bees as a rule work in supers much better when no preparation is being made for swarming, and we should forestall any desire on the part of the bees by giving plenty of super room and abundant ventilation as well as shade. There is doubtless a great difference in different strains of bees

as well as in seasons. Some years bees are much more given to swarming than in other years. Much will also depend on the skill of the apiarist. I believe I have had quite as good success by spending one day in eight to a yard, with one man to assist me, as when I employed a man for every yard. Taking off honey or supers at an outyard is a very simple matter since we have used bee-escape boards.

We have sometimes run one or two yards for extracted honey, but have thought the work quite as hard as when run for comb honey. Perhaps we did not understand how as well. It might seem like pretty hard work to lift supers and open 75 or more hives in a day, but we have seemed to get along fairly well.

For four or five outyards we have got along with one horse and an express wagon, altho an auto truck would be better in some ways. One experienced active beeman with a good assistant can take care of a yard of eighty to one hundred colonies in a day, leaving the other six or seven days for other yards.

There is, doubtless, a difference of opinion as to whether we should work with bees on Sunday; but I don't believe it pays when it can be avoided. There is a lot of sound sense in the statement by that old Hebrew preacher that "They that wait upon the Lord shall renew their strength; they shall mount up with wings as eagles; they shall run and not be weary, they shall walk and not faint." How many times during the swarming season have I felt completely worn out by Saturday night, when the rest of the following day, with church services, and mingling with pleasant people, with all thought of bees removed from me, I have gone to my work on Monday morning with strength renewed and the whole world smiling for me.

Middlebury, Vt.

A HUNDRED COLONIES TO THE APIARY

BY D. L. WOODWARD

It is some years since my father, A. E. Woodward, and I started our first out-apiary. It is also some years since my father retired from the bee business on account of ill health, and, like some other veteran beekeepers, took up his winter residence in Bradentown, Florida.

Since then I have been conducting the business alone. I aim to keep about three hundred colonies, which are temporarily located in two outyards and the home yard. Before the time of the automobile I extract-

ed my honey for several years at the outyards, but decided that it was less work to move the honey home to extract than it was to do it at the outyards. Another thing to take into consideration is the fact that we can be at home more, and can enjoy a warm dinner in place of a cold lunch at noon.

I still have a honey-house at one outyard which I would not know how to dispense with as it is very convenient to have a place to store supplies, etc.; then, too, we always have a shelter from storms.

I have been using an auto in my business for the past five years, and would not be without one again. Five years ago I purchased a large seven-passenger car, second-hand, and converted it into a truck for hauling my bees and honey to and from the outyards, and for marketing my honey. I found it unsatisfactory, as it was not geared right for a truck, and was too expensive to operate for my light running about to outyards, etc., so I sold it and bought a smaller car for my outyard work and marketing, and went back to the old reliable horse for my heavy hauling.

This year I have ordered a Stewart truck of 1500 pounds capacity, and will again try my luck, but this time with a car built for the business. Touring cars are not built for trucks, and any one who invests his money in a second-hand car of this type expecting to do trucking with it might as well save his money. I shall keep my small car for the light work the same as before.

if the combs are well capped over; if not, it may take a longer time.

All honey is hauled home from the outyards and tiered up in the honey-house before a comb is extracted. The honey-house is built on a slight sidehill. The upper end of the house is raised about three feet, and supported by piers, while the other end is two stories high. The roof is nearly flat, and covered with a composition roofing which draws the sun's rays and makes the temperature very warm in the honey-house.

In front we have a bridge level with the honey-house door, and about the height of the auto platform from the ground. This makes it very handy for unloading and loading.

In the room below we have a stove, waxpress, scales, etc., and a 3000-pound-capacity honey-tank. This tank was made for us by Sears, Roebuck & Co., at the small cost of \$7.10. It is made of galvanized iron,

At the outyards as well as the home yard we always leave the honey on the hive until the close of the flow, raising the supers as they become filled and two-thirds capped, and placing the super of empty combs underneath; then when we are ready to start extracting we can make a business of it. Going thru the yard and sorting out the filled combs once a week or so, as some recommend, takes too much time for outyards.

When the honey is ready to come off we go to the yard; and while one man raises the super the other inserts the escape underneath. If there is more than one super to come off we generally place the escape under one at a time. In this way we go thru the whole yard at one time. In twenty-four hours the bees will have left the super

and is three feet in diameter and six feet high. It extends about six inches thru the ceiling into the room above. The extractor is arranged near by, and the honey is run by gravity thru a galvanized tube into an Alexander strainer hung over the tank.

I have read that galvanized iron would darken white honey, but have yet to discover that it does so. We use several smaller tanks, all made of galvanized iron, and a bottling outfit made of the same material. Of course we never leave the honey in the large tank for any length of time unless it is the last extracting, which is sometimes left for several days. Ordinarily as soon as the tank is full we stop extracting for half a day or long enough to draw off the honey from the tank. Understand, this honey is all well ripened on the hive, and can be put

up for market at once with safety. All combs that are not capped are sorted out, and kept until last, to be extracted by themselves. This unripe honey is put into our smaller galvanized tanks and left to ripen.

My bees are all moved home from the outyards in the fall, and wintered in our house cellar. In the spring they are all set out in the home yard, where they remain until about the middle of May, when two hundred or thereabout are moved to the outyards. All weak or diseased colonies are left at the home yard, where they can be watched and taken care of much better than at the outyard.

About July 20 or just as the buckwheat is coming into bloom, we again move all our bees, including the home yard, to the mountains for the buckwheat flow, there being no buckwheat to speak of raised in the valleys below.

It is a beautiful sight to stand upon some peak in the Helderberg Mountains where you can look from three to eight miles in every direction upon hundreds of acres of buckwheat in full bloom. I have inspected fields of buckwheat located less than a mile from my 300 colonies, and found only now and then a bee, showing that, when there is plenty of pasture, they do not go far from home in pursuit of nectar.

Last season I had one freak colony that would not work on buckwheat, but stored all their honey from late sweet clover. When we took this honey off we were surprised to see all nicely capped combs of white honey with occasionally a cell of buckwheat near the outside. This colony was given all empty combs after being moved to the buckwheat location, just the same as the rest.

In locating an out-apiary there are several things to take into consideration. There should be a stream or pond of water near by—the closer the better, as it will save the bees valuable time. I try to keep my bees busy every minute that it is possible for them to work, by locating them close to the flora and water. A southern exposure and protection from high winds is advisable on the north and west if possible; and the yard should be located where the bees will not be a nuisance to neighbors who may be work-

ing on land adjacent to the apiary. I have always tried to locate my outyards near a house, as I do not think the bees are as likely to be molested as when they are off in some out-of-the-way place. Then, too, it is very nice if you can locate this apiary close to the highway; but this can seldom be done.

One of my yards is located within twenty yards of the highway, but is separated from it by a hedge of brush ten feet high, and the road is five or six feet below the ground where the bees stand. On the north there is a bank twenty feet high, and on the west there is a wood; on the south a creek with large trees on either side. Taking everything into consideration, it is an ideal spot for an outyard.

I believe that most beekeepers set their hives too close together, and in too systematic rows. It all looks very pretty, but it causes a lot of drifting and mixing, and I fully believe that it is the main reason why it is so difficult to exterminate bee diseases, mainly foul brood. On account of lack of space I set my bees in rows and in pairs generally; and for several years I have noticed that, where a colony had foul brood, and was not treated at once, generally the next colony to it on one side or both would develop the disease some time during the season. Last season I had one colony that was slightly affected with foul brood, on the end of the last row in my home yard. I thought they would clean up of their own accord when the honey-flow started, so I did not treat them until I found that the five colonies next in the row were infected. I have found that the surest way to exterminate foul brood is to shake the bees as soon as the disease is discovered.

About one hundred colonies is all that can be successfully operated in one location in this locality. I am acquainted with beekeepers who insist on overstocking their locality by keeping several hundred colonies in one apiary, and consequently get a very small average per colony; whereas if they would divide them into several yards of about one hundred each they would realize a handsome profit for the extra work that would be required to manipulate them.

Clarksville, N. Y.

PREVENTING SWARMING BY PUTTING BROOD ABOVE AN EXCLUDER

BY DANIEL DANIELSEN

I run five outyards for extracted honey, and I prevent swarming by raising brood over queen-excluders and leaving the queen below on empty combs as often as she gets

the hive full of brood. Of course the bees raise cells above the excluders; but that seems to make no difference so far as swarming is concerned.

One of Daniel Danielson's outyards showing protection of roofing paper.

Sometimes I make an entrance in the back part between the stories for ventilation, and they thus get a laying queen in the upper story. If so, I put the old queen on the new stand and put the young queen down, and that ends all swarming.

I don't see how any one can run outyards for comb honey unless he visits and overhauls them at least once a week. To keep bees from swarming, plenty of room is needed in the brood-nest and super, and that is a hard problem in comb honey.

Brush, Col.

PRODUCING COMB HONEY IN OUT-APIARIES

Disease Broke up the Celebrated Let-alone System

BY ALLEN LATHAM

The statement on page 218, that "Allen Latham holds the imaginary cup for operating bees on the let-alone plan" needs a correction in tense. Put *held* for *holds* and the truth will be better observed. Before foul brood struck this locality this plan of keeping bees was carried on for several years with marked success. One year in particular I produced a honey crop which netted me over \$60 per day for time actually on the job. This was done with bees having a strong admixture of black blood. European foul brood came, and at once difficulties piled up. Italians will swarm where the blacks will work contentedly; but the blacks succumb to the disease. It was absolutely essential that yellow blood be put into the place of the black, but this was done at great expense in the economy of the let-alone system.

Formerly only about one-fifth of swarming took place, and one could well afford to run bees on the plan, allowing in advance

a loss of one-fifth the crop. With the Italians the swarming jumped right up to ninety or more per cent. To prevent this the apiaries had to be visited several times prior to and during the honey-flow. Even with much added labor the crop was cut down and the cost of operation tremendously run up.

It begins to look here as if the disease had spent its force. If I can again go on with black blood I may regain the lost imaginary cup. In the mean time I am at work upon the problem of succeeding with yellow stock. If I ever solve the problem I will announce the fact.

The foregoing paragraphs concern the production of chunk and strained honey. During the last two years, seeing that I had to make visits to my out-apiaries frequently, I thought I would try section-honey production. My efforts have been fairly successful, and I will give some suggestions as to swarm control. There is nothing new in

my methods, but a résumé may be of service to those interested in this subject.

One can control swarming to the extent of having no swarms run away by cell-cutting and wing-clipping. This means a weekly visit and a general overhauling of practically every colony in the apiary. There is a lot of labor in this, but it is labor well paid for if one can find no better way. The chief objection, aside from the labor, to this method is that colonies which get the swarming fever badly will not finish up sections. They will continue to store honey, but will not do a finished job. This can be offset in part by placing their partly filled supers upon a colony which is doing finished work, and giving the unruly colony fresh supers. Careful manipulation in a reasonably good season will result in a fair percentage of completed sections, but one has to look out or he will have too large a percentage of cull sections.

Another plan which gives much better results is to prevent the swarming fever from starting in. Now don't get excited! I have no infallible plan. Early in the season, before the colonies are too crowded, cage queen or remove her. Substitute a ripe queen-cell, either immediately in a protecting-cage, or, three days later, unprotected. Colonies thus treated will sometimes later acquire the swarming fever, but most of them will not; and if the operation is well timed the crop is but little affected thru the temporary absence of a queen.

If one does not care to carry out this plan in wholesale (and who does not find

queens that he cannot bring himself to displace?) then put the plan into operation only with such colonies as start cells. It will work pretty well here; but once in a while the young queen will lead out a rousing swarm just as soon as she has laid a few eggs.

If the last-mentioned plan is adopted let the apiarist forestall a lot of the queen-displacing by requeening the previous season. It has been the experience of the writer that queens reared in September rarely lead out swarms the following season. (I use this expression, "lead out swarms," entirely aware that the queen leads only in the sense that she is a controlling influence.) For many years I was able to state that I had never had a swarm issue which was headed by a September queen. But this last season broke down all precedents. September queens, young queens, old queens which had already been out once, etc., were embroiled in a fever of swarming that rivaled the war-fever in Europe.

Whatever plan one follows, therefore, in the production of section honey in out-apiaries, he is sure to encounter difficulties. He cannot, as in the production of extracted honey, give unlimited room, for if he does he will get an unmarketable crop. But he must give room or he will not get any crop. Aside from the problem of the swarming he has this other great problem, and in his wise discretion in the matter of supplying supers rests his success in getting a good profitable crop to market.

Norwichtown, Ct.

DON'T TRY TO MANAGE OUTYARDS WITHOUT AN AUTOMOBILE

BY R. F. WIXON

I am producing comb honey in outyards as a main crop, and extracted honey more as a by-product. Comb honey appeals to me because it has a ready sale. Until three years ago I did not use an extractor, and thus did not see the possibilities open to the producer of good ripe extracted honey.

Last spring 56 colonies of bees, spring count, were increased to 110 colonies during the season. These were in three yards—two outyards and one home yard of about 25 colonies. This season (1916) I wish to increase the total number to winter to 200. These colonies will be away from home, and will be run exclusively for fancy comb honey. The ten-frame standard hive, factory-built, with the $4\frac{1}{4} \times 1\frac{7}{8}$ -inch sections, split on three sides (Hand method) makes a hive and super combination that gives excellent satisfaction and good results. As I have

used the split sections only one season it is not quite fair to say whether they are exactly ideal or not; but so far as last season was concerned they gave good satisfaction and stood a large amount of rough handling, both before and after being filled by the bees.

As soon as it is safe to open hives in the spring, the colonies are examined to determine if there are enough stores, and to learn the exact strength, so as to be prepared to deal with each colony wisely. When settled weather comes, sometimes between April 20 and May 1, the queens are clipped, and the smallest frame of brood in the brood-nest is transferred so it comes between two larger frames, or, in other words, one of the outside frames of brood becomes an inside one. The second week the same operation is repeated; but on the following

or third week an empty comb is placed in the center of the brood-nest, as this happens now in more settled weather; and as the cluster of bees is larger, a little spreading does not seem to hurt the prosperity of the colony. This method of spreading is used until the hives become full of brood, and then some combs are raised into an upper story over an excluder. All colonies are given upper stories as soon as their strength will permit, even if their brood has not reached the number of ten frames (I sometimes have colonies make 30 to 40 pounds of extracted honey before June 1). As the main flow from clover does not come on until the first week in June, or later, I find that this extra room keeps the colonies from getting the swarming fever, and I am also the gainer, often by many pounds of extracted honey that perhaps otherwise would never have been gathered. The colonies in the yard that have an upper story are shaken on clean empty combs or foundation with one frame of capped brood, and the proper amount of super room given at once. Two or three supers, one fitted with four to eight baits, are given to each shaken colony. By this method one has a large amount of brood on hand. This is saved by placing it over weak colonies till it is capped; then it can be used for increase, or left on the weak hives until the combs are filled with honey.

In the Altay yard there were 23 hives of brood from 35 colonies. Six weak hives cared for the brood. In ten days these hives became so strong that extra entrances had to be provided in order to prevent the bees from hanging on the outside of the hive. During the white-honey flow the combs were filled with honey, and also an extra set for each six hives. As soon as the brood had all hatched, these bees were shaken from the combs into one hive-body, and four to eight supers given to each hive. I cannot remember exactly, but I know one made 336 sections before the buckwheat flow, and the other five filled between four and six supers each.

Colonies worked in this way produce

fancy comb, the finest that can be made. They do not even offer to swarm as long as plenty of super room is given. Every colony is inspected once a week to determine if honey is fit to remove, if plenty of extra room is ahead of bees, and last, but not least, to see if any colony contracts the swarming impulse. If one should, the cells are broken down, room and more ventilation provided; and by the following week, if they still insist on swarming (as they did in 1915), all brood is removed, which in most cases cures.

The empty supers are placed under the partly filled ones at the beginning of the flow, and on top of all the supers as the flow nears the end. Bee-escapes are used exclusively, paying well for the extra trip required.

Increase is made by the Alexander plan in some seasons; but the three-frame nuclei, made and transferred by auto to another yard, have the advantage in that all the bees stay.

Hardly any attempt is made at queen-rearing. Good queens can be bought in large lots at reasonable rates from experienced men. If one gives his colonies extra good care, there is not much time left to rear queens. Men who have reared queens for years can send out better queens than persons of only a few years' experience. Colonies are requeened every two years unless queens prove poor.

Colonies are numbered, and a record of each colony kept. The records help to control the swarming. They give the age of queens, but do not give yield of honey per colony except where colonies prove poor and the queens require changing. The sales for the season give the average of honey per colony.

The crop last season was, in round figures, 5000 sections of comb and 3000 pounds of extracted honey from 56 hives, spring count, and an increase to 110 colonies. I believe that these bees could have been made to average an even 200 lbs. per colony if I had known then what I know now.

Don't try to manage outyards without an automobile.

Dundee, N. Y.

OUT-APIARIES IN RHODE ISLAND

BY ARTHUR C. MILLER

Out-apiaries are not a joy to the "bee fusser," nor are they a royal road to wealth for him. "Let-alone" systems must be used for best results, all things considered.

All of my apiaries are now "out-apiaries," and are from eight to twenty-five

miles from home. The nearest thing to a home yard is the one eight miles away, and it is where I raise my queens and do most of my experimenting. I have three yards all together totaling about two hundred colonies, and I have an oversight of two

other yards of a score of colonies each; and during any spare time I have I act as bee inspector for the state. Those are my side lines, my vocation being banking. So far I have had sufficient time to eat, sleep, and be merry.

Early in my attempts at "wholesome neglect" of the bees I ran into the swarming trouble, and it overshadowed all the others. I tried all the orthodox remedies—found most of them "patent medicines" in which the cure was worse than the disease, so "threw physic to the dogs," and worked out a treatment of my own. Now I have almost forgotten how a swarm looks or sounds, and my eyesight remains good and my ear keen.

The formula is a simple one, and can be compounded by any beekeeper who will take the necessary pains. The ingredients are good combs with room enough for them, young queens, ample entrance, and a shaded hive.

To elucidate: *Good combs.* Do you know what they are? In my yards they are all built on foundation in wired frames, and every inch of them is available for brood—except when the workers get there first and put in pollen or honey; but there are no stretched or distorted cells, and drone comb only in the lower half of the frame next to the entrance. (Entrance is at long side of the hive.)

There are ten combs in each hive, and hives all have $14\frac{3}{4}$ inches clear, inside width. Combs are kept away from the sides of the hive by three good bee-spaces, and that insures brood in outer surfaces of outer combs when the queen needs the room. The half-comb of drone at the outside means a minimum number of drones commensurate with wants of the bees and the labor of the beekeeper. The bees are bound to have some drones; and if you fail to allow them room for raising them they will cut down worker-cells and put in drone anywhere that suits their fancy. Personally I dislike their fancies, so I allow them the minimum space for the purpose and put it where I want it, and that is at the front where the queen occupies it late and leaves it early. Drones may not be a direct cause of the swarming fever; in fact, they may be only a symptom (choose for yourself), but certainly there is more swarming where there is an excess of drones, and less where there are few; wherefore I choose to assume that they are more or less direct disturbers of the peace, and permit as few as the bees will acquiesce in.

Room enough! Hump! If you don't know what that is you had better give up the business and leave your room for a

better man. But perhaps you are a well-meaning youngster, and anxious to know, so I'll tell you that room enough means a little more than the hive manufacturers have usually deemed necessary (I almost said *thought* necessary). It means enough room so that you can offset the combs from the hive sides sufficiently for one layer of bees to be on the comb, one layer on the hive side, and another layer promenading between. The promenaders keep the others from becoming too somnolent.

Young queens—not so young as to be frivolous, but young enough to be vigorous hustlers. Mine are raised and introduced in August and September. Why? Well, 'tis a rather long story, and it took me a whole lot longer to find out that queens reared and used then were best suited for the ends sought; but they seem to be so. In some other localities some other time might be better, but not here. Such queens, in the first place, put the colonies in bang-up shape for winter, and follow it up by presenting me with a fine score for the honey-flow, and make wholly good by sticking to business till after the flow and the season for all swarming foolishness is past. My queens are not only all of the same age, but daughters of the same mother, so all colonies are very closely alike, and a look at one or two tells the story of all. If any one in the yard is out of condition, entrance appearances tell it. With such queens there is no spring stimulating, no transposing of brood, no fussing nonsense of any kind. Annual requeening *pays*. Be the reasons what they may, I find I cannot omit the young-queen factor from my reckoning.

Ample entrance. For me, I find an entrance one inch high by eighteen long is ample. You see it is six inches longer than the standard entrance to a ten-frame hive, and also six inches nearer to the most remote part of the hive. Use has proved it good.

Shade. Something to prevent the sun from frying the brood—double covers, telescope covers, trees, any old thing to keep the sun off during the hottest part of the day—that is, during the honey-flow. At other seasons I prefer a goodly amount of hotness.

The conditions under which the foregoing combination has made good are these: The ordinary northeastern United States climate, so far as heat and wind and "weather" are concerned, but tempered, and often abused, by cool to cold nights, often with fog and sometimes high winds. The main flow comes in July; but sometimes we get three or even four "surplus flows," as locust

the last of May, sumac early to mid-July; clethra, buttonbush, and elematis the last of July and early August, and goldenrod in August and September. This makes a noise like a bee paradise, but 'tisn't. We have a little something coming in much of the time, except when a drouth butts in now and then, and we almost never have a "flood" of honey. Bees seldom get such "a load on" that they have to be helped into the hive. They are more temperate hereabout.

The other problems are transportation of supplies and crop, and getting to and from the yards. Trolley express goes right by one yard, while freights plus farm teams cover the others. Trolley or train carries me to one yard and train and auto to the others. All yards are run for both comb and extracted honey.

Comb honey is cased at the yard, and generally shipped in by auto. Extracted honey is put into cans, and goes to town by the farm team. A little money, a little honey, and a little jollity is all that is needed.

A room in some one of the buildings at each place serves all purposes of preparation, extracting, etc.

Supers are put on when it suits my convenience. To be sure, the bees now and then gnaw the foundation if there chances to be a dearth before the flow starts; but what's the odds when they make it all good again as soon as there is something coming in?

Most of the honey is removed by use of escapes. When I cannot go down the night

before, I have some one at each of the more remote yards whom I can usually get to do it for me.

And it all sounds so simple and so easy! Well, it is; but every step is planned out ahead, every kind of short cut is used, and no operation is followed which can be omitted. In other words, the whole thing is a machine with every wheel doing its duty in its turn, and not a useless cog in it.

Pardon me. I must hedge a little. I do do quite a bit of experimenting, but it is all in attempts to find other short cuts.

Did you ask which factor I considered most important in swarm prevention? All of them. The young queen comes first, perhaps; combs second, and the other things bunched. You see those good combs properly spaced give the queen all needed room, and the supers on ahead of time give the bees loafing room before the flow and storage room during it. If honey happens to pour in before any comb is ready in the sections, and brood combs are pretty well filled by the queen, the bees just pop it into every empty cell having only eggs (I have never seen them submerge larvæ). This is removed and ripened during the night, and then goes above (where combs by then are growing fast), for they are pretty careful not to hamper the work of that young queen, and the temporary honey bath never harms the eggs.

The secret of success in handling out-aptaries here or anywhere is preparation, material and mental. If you cannot work out the second, never mind the first.

Providence, R. I.

CONTROL BUT DO NOT PREVENT SWARMS IN OUTYARDS

Hive Swarms on Starters and Put Full Sheets of Foundation in the Supers

BY F. W. LESSER

It is easy enough to prevent swarming in outyards run for comb honey if we do not consider the work or loss of honey involved; but after trying all sorts of non-swarmling schemes for years I have come to the conclusion that it pays much better to direct the swarming impulse into proper channels than to try to prevent it entirely.

The dequeening or caging method will prevent swarming, but it requires a lot of expert labor, and the results in storing are far from satisfactory.

The plan of allowing the bees to fill an upper story full of honey, and, when the flow is well on, shaking the bees on to it and putting boxes on is not to be recommended, as Italian bees will not carry up the honey satisfactorily, and what is car-

ried up will be of poor quality. Also, this plan requires good judgment as to the proper time to put on the boxes, and makes a lot of work at a critical time.

Any plan which requires an extra set of brood-combs is bad, as it increases the investment, risk of disease, and makes a lot of work to keep the combs the rest of the year. I know of no greater nuisance to the comb-honey man than a lot of empty combs to keep from moth, disease, robbers, mice, etc., for eight or ten months of the year when not needed under the sections.

After trying about everything the plan I like best is "shook" swarming, which I learned in Colorado fifteen years ago. I believe it is the best plan to use wherever there is foul brood. Those Colorado fellows

not only know how to produce fine comb honey, but they know how to produce it at the lowest possible cost. That prince of comb-honey producers, Mr. M. A. Gill, his wife, and one helper have managed as many as 1000 colonies, producing 70,000 lbs. of comb honey in one season by the shook-swarm method, and the plan works as well here as there.

Every one knows the plan, but I will give a few details which we have found good. Clip the queens early. Equalize the brood in fruit-bloom to keep early swarming down. Put supers with a few baits in them on before the white flow begins. Better be ten days ahead of time than one day late. Put a shade-board on all colonies in the sun, and raise the hive up an inch from the bottom-board a little before the swarming season. Make a date, before swarming begins, for visiting each yard once a week to examine all colonies for cells. If in a hurry, we tip the hive back and look between the frames for cells. We may miss one occasionally; but as the queens are clipped they will not get away before the next trip, when we shall probably discover the cells.

We have tried to discourage swarming by destroying cells; but as a rule we have found that it does not pay at this regular swarming period. When the bees of a colony once get eggs and larvæ in queen-cells they have gone too far to change their mind in a hurry, and the best thing to do is to satisfy their desire. The queen has eased up on egg-production; the workers have begun to secrete an abundance of wax; there is honey in the fields, and everything is as nature intended for the making of a new home. Don't spoil all this preparation by compelling them to forget it by cutting cells, caging queens, dequeening, etc. Take advantage of this natural impulse and let them get the fever out of their system by working it out, which they will do if given an empty brood-chamber. We might as well try to get eggs from a sitting hen as to try to get good work from bees with the swarming fever. Give them an empty home, and they will work like beavers.

Don't make the mistake of hiving on combs or full sheets of foundation if you desire to get as much fancy comb honey as possible. With starters in the frames and full sheets in the sections, the inducement to store is practically all in the sections. With full sheets of foundation in the frames the inducement is largely in the brood-chamber. With combs in the frames the inducement is about all in the brood-chamber, with a consequent crowding of the queen, and poor work in the sections.

When eggs and larvæ are found in queen-

cells, shake on starters on the old stand, and set the old hive at one side or corner of the new. Don't shake too many bees at the first shake. In two or three days contract the swarm to the capacity of six L. frames, and put on the sections from the old colony. In six or seven days after shaking, shake one-half or one-third of the remaining bees from the old hive in front of the swarm, and move the old hive to another part of the yard to build up for winter. There will be no after-swarming, as the first queen out will destroy all remaining cells. This colony will usually build up in fine shape for winter, and, having a young queen, will be one of the best the next spring. Before the fall flow, the swarm's brood-nest should be increased to eight L. frames capacity to allow them to build up for winter, and to prevent late swarming which might happen if left on six frames. But use full sheets of foundation in the frames at this time.

There will not be much drone comb built in the six frames of starters if the queen is good and plenty of room is given in the boxes. A little sorting and patching in the fall or the next spring will make everything all right. Combs built from starters are much superior to many of the combs built from full sheets of foundation, as there is no sagging of cells, and brood will be reared up to the top-bar, which is quite an item in comb-honey production.

As European foul brood is now pretty well scattered, most of us must keep Italians; and as they dislike to leave the brood-chamber we must plan to force them into the supers by using small hives and hiving on a contracted brood-chamber.

I know beekeepers who have had fair success in producing comb honey with black bees; but after they Italianized, they made miserable failures by the same methods. The cause is large brood-chambers and hiving in full-sized hives on full sheets of foundation in the frames.

DOES THE CENTRAL EXTRACTING-PLANT SPREAD FOUL BROOD?

From my experience I would say that the danger is great. There is always more or less drip on the wagon or auto, and robbers are always around when loading or unloading; and with ordinary help the combs from different yards are sure to get mixed.

Some of the worst scrapes I have been in with horses have been in hauling full combs home to extract.

We have also used a tent for extracting; but hereafter we want a bee-tight house at each yard.

East Syracuse, N. Y.

Motor cycle for outyard work.

THE MOTOR CYCLE FOR THE BEE BUSINESS

BY A. H. BOWEN.

The picture shows the machine I have been running this summer for the conveyance of bees, hives, and supplies to and from the out-apiaries.

The machine is a single-cylinder, 1913, 3½ h.-p. Triumph, to which is attached a

roomy Canoelet side car. It is fitted with a free engine-clutch and three-speed gear, which obviates the necessity of stopping the engine in traffic, and gives greater power on hills.

Four eight-frame colonies in traveling crates can be hauled at one trip in the side car, or 150 lbs. of honey in 28-lb. tins may be easily carried.

Fragile articles such as skeps of bees with young tender combs, or crates of full sections can be conveyed with very little jar; and, indeed, the machine is now indispensable to out-apiary management. By the speedometer the machine has been run 5500 miles this season, and it was driven every day thru the finest weather. The greater part of this

Part of a Cotswold apiary with a natural windbreak.

milage was done with the side car loaded.

I have had no punctures, and only two stoppages worth recording—once with a choked petrol pipe, and once by a faulty plug. Economically driven at speeds averaging 12 to 16 miles an hour, the expenditure for fuel and wear and tear are reduced to a minimum. The total cost of maintenance, including two new tires and a belt was a fraction over half a shilling per mile, or 14 cents.

A Canoelet side car offers several advantages over the bare side-carrier I have often seen illustrated. No tying on of goods is necessary; and when starting out on a bee-tour one can load up with small articles

such as smoker, carbolic cloth, knives, some frames of foundation, a super or two, a roll of sections, and a package of booklets and pamphlets to be distributed at each stopping-place. All can be easily found when wanted, and there is no risk of the articles being shaken off when traveling along a rough country road. Outfits of this kind are very popular in England among people who can not afford to own a car. The first expense and cost of maintenance is not so heavy; and with care it will give long and lasting service. It is particularly well suited to the needs of the present-day business beekeeper, and my own machine has stood the test far better than I first anticipated.

Cheltenham, England.

SOME EXPERIENCES WITH A MOTORCYCLE

BY RAY C. WILCOX

In the spring of 1914 I was engaged as helper by a large apiarist of Tompkins County, some 35 miles from my home, where I had an apiary of 30 colonies. The bees were in good condition, and it was my desire to work them to the best of my ability, both for extracted honey and increase. Owing to the fact that the railroad connections between my home town and that of my employer were indirect, and that my bees were nearly two miles from the railroad station, I realized that the expense of working my bees would be high in time and ear fare.

I had been interested in motor cycles, and, after some consideration, I decided that one was just what was needed to work my little apiary to the best advantage and give me maximum amount of time for my employer. I finally bought a twin-cylinder machine of a popular make. It was a second-hand affair, but was in fine order, and, as motor cycles go, I believe I got my money's worth. Indeed, while I had the machine the more important parts of the motor never troubled me.

But from the first I was disappointed with my purchase. Even after learning to handle the motor, which I did with comparative ease, I found that it greatly preferred smooth roads. To be sure, one could ride over rough roads, but it was a most shaky experience, and very hard on all concerned—except the road, perhaps. I have often wondered at the durability of motor cycles. On the whole these machines are certainly well made to stand up under the usage they receive. However, I soon found that there is a knack about picking one's way; and after six months' experience I could ride

with comparative comfort and at fair speed over roads which, at first, would have well nigh unseated me.

But while rough roads were unpleasant they were passed over with ease as compared with muddy ones. Indeed, it was the helplessness of the machine in the mud that was most disappointing, for I found it almost impossible to get my heavy machine over wet slippery roads. It not unfrequently happened that a rain came up while I was at my apiary with the motor, and the road would become so slippery as to be practically impassable for a motor cycle. That meant loss of time, or returning to work by rail, which meant that I must make the next visit to the beeyard in the same way. The same conditions often necessitated a trip to my yard by train. Of course these were not the usual conditions, but they were often enough so to be very annoying. At the close of the season I figured that I had saved \$19.00 in ear fare, and possibly as much more in time, at a cost of \$16.00 maintenance on machine, to say nothing of depreciation, which, when figured in, left me considerably behind on my investment. Some of the wear and tear, however, was due to pleasure riding, for which the machine was used a good deal.

During the season of 1915 I lived some 10 miles from my apiary. The motor cycle proved a great help during the whole summer, but was especially convenient because of the excessive swarming, so common last season. Muddy roads were often bothersome as in the previous season, but the distance was easily within driving range for my horse, altho the time required was fully four times that needed to make a trip with

the machine. It was often necessary to use the horse any way, because I had to take quite a load. In fact, the incapacity of the motor cycle to carry a load is really the greatest objection to the machine for the beekeeper's use. If one has only a single conveyance it is important that he be able to haul considerable load.

Motor cycles with side car attached have been recommended; but even then the capacity is small and the outfit is impracticable for bad roads. Besides, unless in a level country it needs a very high-powered and expensive machine to handle a side car. In a hilly country a one-speed motor cycle with two cylinders cannot manage a side car

efficiently except under the most favorable conditions. To be sure, two and three speed high-powered machines may be had, but the price rivals that of a Ford automobile, while their efficiency is scarcely to be compared with such a staunch little car as the Ford.

As a pleasure machine the motor cycle stands in a class by itself, and, tho it may scarcely sound businesslike, I am free to say that I do not begrudge what mine has cost me for pleasure. As an investment I am sure it has not paid; but if one can afford one as a luxury it will often be found convenient for making quick trips.

West Danby, N. Y.

ONE WHO SUCCEEDS WITH A HOME YARD NOT ALWAYS SUCCESSFUL WITH OUTYARDS

BY F. P. QUINBY

My experience in California, Nevada, and Illinois, has taught me that the following points cannot be ignored if the maximum results are desired from outyards.

One of the first items to be considered in establishing an out-apiary is this: Have you knowledge of the conditions that surround the locality? and do you realize that your outyard may differ to a wide extent from your home yard, and as such require different management? The foregoing is but one of a large number of questions that might be put to the "small" beekeeper who is desirous of establishing an outyard, but it is an item of vital importance.

The same rule applies to the management of outyards as to the man who, having been successful in business on a small scale, desires to branch out into a larger field, in which undertaking he often meets with failure on account of the lack of training or inability to cope with larger situations.

One of the more difficult problems which the beginner must solve after he has established an outyard or two is how to control the swarming with as few visits to the outyard as possible. The system which I have followed for the past four years in Illinois is as follows: I introduce a strong young laying queen into each colony just before the fall flow begins, on account of which my colonies go into winter quarters well provided for; i. e., with a young queen, young bees, plenty of good stores, and the fall honey is all removed from the hives.

As soon as I find there is plenty of bloom I confine the colonies, which are wintered in two-story chaff hives, down to the first story, taking out all the surplus honey by lifting

the brood-nest, which is by this time well started, and is usually in the top story, and putting it into the lower part of the hive. I put only those combs below that have brood or honey in them, always placing a card of honey next to the brood-nest proper. The rest of the hive is filled with empty combs, and the frames are well covered up. An ideal condition is thus created; i. e., I have a young vigorous queen, a brood-nest that is not clogged up with candied honey or old pollen, and the season is advanced so that, with the pollen plentiful, and enough new honey coming in, the queen will do her best with the force she has at this time, and good results cannot help being obtained.

I utilize the rest of the honey which is found in the hives as follows: I place one of the combs over the cluster after a piece as large as the size of my hand has been uncapped with the knife, and every other day repeat this until the comb is used up, at which time I start another comb in the same manner. By so doing, my old honey is entirely consumed by the time of the main flow, and has been turned into brood, which is the result most desired by beekeepers at this time of the year. I am well aware that a good many beekeepers find their bees are without stores a good while before the flow begins, but I consider it poor management. With a good young queen at the head of a colony at the opening of the season, keeping the colony compact and warm, and using the old honey as stated above, it is not long before I can start with my second brood-nest. I consider this the secret of swarm control and strong colonies.

When I have accomplished the results as outlined, it is necessary to make only one visit every ten days to my outyards, and all I do at such time until the flow is on is to shift the brood-nest, which is at the bottom, to the top, and *vice versa*. As soon as the flow is well started I put my queen-excluders on the colonies running for extracted honey, the same being placed between the two brood-nests, making sure that the queen is below. I also change the brood-nests, putting all brood about to hatch into the lower hives, so as to give the queen room to lay more, in this way keeping the colony in shape for the sweet-clover flow.

I put all my first supers for comb honey

with top and bottom starters between the two brood-nests of the same colony—this with the intention of keeping on for forty-eight hours. In this way my sections are started nicely, and they are not discolored. At the end of the time stated I remove the upper brood-nest with brood; also two frames from below. I also add my second comb-honey supers at this time, for the reason that my colonies are invariably strong enough for this to be done. I now make only one visit during the week to my outyards, and this for the purpose of putting on supers and shipping honey until the close of the season.

Western Springs, Ill.

AN AUTO TRAILER FOR THE OUT-APIARY

BY J. P. MOORE

Unlike most out-apiaries, mine answers three purposes. First, I form about 200 nuclei from it; second, it takes care of my new swarms at home, and prevents my home yard from being overstocked; third, it produces a good supply of honey each year. For many years I have dreaded the long nine-mile trip to this out-apiary, not only for the ride in a heavy farm wagon, but the danger which I underwent with two powerful horses which I drove; for had a bee stung either, I should have been kicked to death or dragged by this high-spirited team if I had been caught un-awares. No horse, no matter how gentle, likes to have bees alight on his back and sink their sting into him. From four to six of these trips had to be made each year for forming nuclei, and two for bringing home the honey, and each trip was like a beating for me.

In 1914 I purchased a Hupmobile touring-car, and, with the aid of the running-gear of an old carriage, I fashioned an auto-trailer, the sides and bottom of which were slatted to allow the circulation of

plenty of air. An iron Y brace was then put in place of the shafts, which in turn was clamped to the axle of the machine, and I was then ready for my experiment. My son-in-law and assistant, Mr. J. E. Jordan, acted as brakeman on the trailer to save the brakes on the machine in descending long grades. One blast from the auto horn was the signal to apply brakes, and two to release them. The result was, we were able to drive down between the rows of hives without the slightest fear from stings to our steel horse, and the trip was made in less than half the time than with the team.

Our trip is now a pleasure, and very few hills are so steep that I have to resort to low, even with 48 nuclei in the trailer. Bees stand the trip better, and I have experienced no broken-down combs. The automobile has now really replaced the horse in my business. Mr. Jordan sometimes makes the trip up to introduce queens on his Indian motor cycle which has a side car attached. The side car, being pretty large, will accommodate all kinds of supplies and tools.

Morgan, Ky.

VISITING AN OUT-APIARY ONLY FOUR TIMES A YEAR

BY S. G. CROCKER, JR.

One year I ran an outyard with but four visits, and did not have a swarm. The first and greatest swarm preventive is young queens, so all my hives were requeened late in the fall. Another great help is drawn combs, of which I had a good supply the year referred to.

I am not going to give a set rule by which we can have an outyard run on four

visits with no swarming. In the first place, the kind of season, the weather, the honey-flow, and the breeding of queens from non-swarming colonies, control swarming to a great extent. If we have a rainy spell at the beginning of the honey-flow when the sun does come out I have noticed swarming will invariably follow.

I think we all agree that the greatest

cause of swarming is a congested brood-chamber. When the queen lays in every available cell she feels she has done all she can for the colony, and goes out to start a new colony. That is why putting on comb-supers will not prevent swarming. I have had colonies in the spring whose queen had 16 Hoffman frames of brood and eggs in all stages of development. Now, how could we expect to hold a queen like that in an eight-frame hive? We must expand the brood-chamber to keep down swarming, either by removing the capped brood, shake swarming, or putting capped brood in an upper story away from the brood-nest.

To describe my visits: I made my first trip when my bees at home showed they needed super room by the clustering-out of the strongest colonies. On visiting the out-yard I equalized my colonies by exchanging capped brood for eggs or empty comb, leaving the bees on the capped brood, and using a little smoke. I have no trouble from fighting. I then got a full-depth body for each colony, and, removing five empty combs, exchanged them with five combs of

capped brood, putting the capped brood in the upper story and giving the queen access to both stories; then put a shallow super on top as a kind of safety-valve in case the flow proves heavy before the next visit.

On the second visit I followed the same plan as at first, raising capped brood and honey, and inserting empty body or bodies below, according to needs of each individual colony. One can find the queens at this time, put them on new combs in the lower body, and keep them there with queen-excluders; but I have never thought it paid for time required to find the queens.

The third visit I made about ten days after the spring flow was over, removing all honey on each hive, putting all brood in one or two bodies according to the amount, and hauled honey home to extract.

The fourth visit was after the fall flow, which is not heavy in this locality, and rarely affords any surplus. If a few colonies had surplus I removed it and put it on colonies short of stores; if not, I fed sugar. I then reduced the entrances, and packed the bees for winter.

Baltimore, Md.

WITH SHEEP AND BEES AND HONEY BOB SURELY MADE SOME MONEY

BY REV. J. M. LEWIS

Bob was a shepherd who pastured twenty sheep. They browsed around the meadow where the grass was long and deep; but when the leaves had fallen and November winds were chill, out in the open meadow they could not get their fill. So Bob he kindly put them in a well-protected shed, with hay enough to feed them in the mow

up overhead. But the seed kept sifting down, and it lodged amidst their wool, and there it safely stayed till the April moon was full.

And then went those muttons out in the rain, you know, and in less than twenty days the seed began to grow; and it grew and kept on growing like the bean in fairy song, till the grass upon their backs was at least two inches long. And Bob, he expected that, later in the year, the fragrant clover blossoms would certainly appear.

The moral of this tale is clear to every eye—that by judicious management (if a person cares to try), he may with little trouble when the days are warm and sunny, have the sheep supply the nectar for the bees to make the honey. North Westport, Mass.

Heads of Grain from Different Fields

THE BACK-LOT BUZZER.

A pound of honey is better than a pound of beef-steak. Sammy Cucumber says he doesn't care if it is. Sam's a vegetarian.

The Winter in Montana.

I went into the winter with eleven colonies, two of which were second swarms, and none too strong. They were all wintered out of doors; and as we had the severest winter ever known in this section of the state—not the coldest weather, but the longest continuous spell of cold weather, getting as low as 40 degrees—I was very anxious about the bees, as my experience covers only a few years.

About the 10th of February the weather broke, and the bees came out for their first flight since before Christmas. Every colony showed signs of life and considerable activity, and all but one were strong. Of this cold spell I may say that, for three weeks or more, the temperature was away below zero every night, and for much of the time did not get above zero during the twenty-four hours. Another thing about this spell of weather, which I feared might have a bad effect upon the bees, was that, after about ten days of extreme cold, the weather moderated one day, and the next day the temperature was 53 above zero in the afternoon, and within twelve hours thereafter it again fell to 20 below, and the extreme cold continued for another ten days or more; but all of this severe weather seems to have had little effect upon the bees.

I winter in double hives, patterned after

the Root hive—one of them is a Root; but the outer casing is considerably larger than the Root double hive—large enough for four inches of filling around the brood-nest. In this space I put three thicknesses of thick cellular box material next to the outer walls and bottom of the outer ease, and the rest of the space is filled with chopped alfalfa, and over the top about six inches of leaves.

Last summer was a poor honey season here, and my bees were wintered mostly upon syrup. I gave them all that they would store. The system is not what might be called "beekeeping for profit," but I keep the bees mainly for the pleasure they afford, and, incidentally, to have my own honey.

The experiences of the past winter have convinced me that a bee-cellar is not a necessity in this climate, however it may be within the arctic circle or some other cold section of the earth.

Lewistown, Mont., March 10.

Massachusetts Society of Beekeepers

The fifth of the six regular meetings of the years 1915 and 1916 was held in the Williams room in the Ford Building, Boston, Saturday evening, March 18. Miss Dorothy Q. Wright, of Lowell, was the speaker. Being a practical beekeeper she was very interesting, and held the attention of the large gathering for about two hours. She had a display at an exhibition in Lowell recently. There were miniature hives in an apple-orchard, dolls with hoods of net tending them. The trees were made of bayberry shrubs with the berries painted red. Above was a sign "An Apiary," and a large number of visitors stepped up to ask her what sort of animal an apiary was.

Miss Wright believes that all beekeepers should raise their own queens, as queens sent by mail are more or less injured.

Henry W. Britton.

Stoughton, Mass., March 20.

An Inexpensive Way to Bind Gleanings

The following is the most satisfactory way of binding copies of Gleanings that I have yet found: Punch four holes with a leather-punch, one pair near each end and about $\frac{1}{4}$ -inch from the back edge. Then get two pieces of tough cardboard for corners and punch corresponding holes in them. The holes should all be punched with the same pattern. Strong cord is used to tie them together. I put six issues in a volume, as this is the handiest size. The word Gleanings and the date of the first and last issues are written on the corner, and the volume is complete. These volumes can be opened and handled as easily as a book, and any article can be quickly referred to.

Jennings, Kan.

Taxes on Bees in Wisconsin

Can bees be taxed by law in Wisconsin? If so, what is a colony valued at?

Cylon, Wis., Jan. 18. Almond Kohn.

[This was referred to Mr. France, who replies:]

Bees are assessed and taxed in Wisconsin (five colonies exempt). The valuation is left with each assessor, which varies from nothing in many cases to \$5.00 per colony; but generally \$1.00 to \$2.50 is the valuation given.

I suppose if true law were called to bear in the case, bees by law would be called wild by nature. The beekeeper owns said wild insects by virtue of good management, liable, however, to "skip" any warm day. But the hives and attending fixtures are personal property, subject to assessment and taxes. Some of my apiaries were never taxed, and others have been part of the time, depending on who the assessor is.

Platteville, Wis., March 13.

The Drouth Broken in New Zealand at Last.

The Acting Secretary of the National Beekeepers' Association of New Zealand, Mr. R. W. Brickell, writes under date of March 15, 1916, that "New Zealand has just passed thru the worst honey season it is possible to imagine. Scores of our largest beekeepers, men whose bees are their sole means of livelihood, are in many instances just at the present moment, when the honey-flow should be closing, still feeding their bees. Hundreds of square miles of our best clover country have been in drouth since May, 1914; but I heard this morning that the drouth broke on Sunday last."

Amherst, Mass. Burton N. Gates.

Who Has Built up a Parcel-post Honey Business?

If any one has made a success of selling extracted honey by parcel post I wish he would tell about it. I should like to know how he got his customers; what class of people they were; what he got for the honey. It looks as if I shall have to take up that line of business, and I should like to know how others have succeeded.

John A. Van Deman.

Benzonia, Mich., March 4.

A Correction.

On page 228, March 15, in my description of the outdoor wax-melter (you call it capping-melter), the word "budge" is used instead of bridge. This is, of course, due to the difficulty of deciphering my hieroglyphics. My 'r' looks like the first half of a 'u.' The word 'budge,' as printed, has no meaning, and renders the description of the melter unintelligible. It's my fault for not writing plainer, and I'll try to do better hereafter.

Salem, Ida. Joseph J. Anderson.

A Clergyman's Out-apiary.

My work as pastor of a charge does not give me the time one should have if he were to keep many colonies in an outyard; but with the 20 colonies three miles northeast of town the colonies were stronger and made more honey than my 25 colonies at home, where there are perhaps 50 colonies in the town.

First, I built my colonies up strong with bees early in the season, putting on the supers with bait-combs as fast as the bees would occupy them, always being sure they had plenty of room. At the first sign of swarming I set off the supers and looked for queen-cells. When they are about ready to cap over I take away the queen, killing her if I find her undesirable, leaving only one queen-cell. If she is a good queen I use her in making my increase. I had only three natural swarms in this yard, two being found hanging in a tree near by, and these were where I had overlooked the queen-cells. I had no natural swarms in the yard at home. These colonies averaged 100 pounds of honey each, besides making a 40-per-cent increase.

My bees are almost all of the golden Italian strain, and I find that these, with a possible cross of the leather-colored Italian, are the best all-purpose bee for this part of Iowa.

Stockport, Ia.

J. W. Stine.

Two Tons of Comb Honey from 75 Colonies.

I am running for comb honey only. Last summer, 1915, I got nearly two tons of honey per 75 colonies. I prevent swarming by giving the bees their supers the last week in March, and give them plenty of room in front of the entrance so that they have plenty of room for air. A small entrance will make bees swarm, it matters not how many supers you have on. During the honey-flow bees want a large entrance. Give them the full front entrance open, about 1 inch high, 12 to 14 inches long. This is a good cure for swarming.

But the best remedy I ever discovered is to cut queen-cells every seven days for two months. This means the months of May and June; and be sure to keep the hives shaded by using a special cover or roof for shade. Shade is a big swarm preventer; but be sure to give your bees plenty of room during the honey harvest.

Wrightsville, Pa.

E. E. Sterner.

Meadows White with Bloom in March.

I have been looking at my bees this morning. They are in fine condition, and they will have all they can do very soon now. Some white clover is in bloom, and the blackberries are almost ready to bloom too. When they come out the meadows will be white with blossoms for miles in every direction.

OUR HOMES

Editor

Eye hath not seen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him.—I. COR. 2:9.
Thou shalt love thy neighbor as thyself.—MATT. 22:39.

Thou God seest me.—GEN. 16:13.

I suppose most of our readers have noticed an item in the papers concerning a remarkable hen named Lady Eglantine, that laid 314 eggs in the year ending Oct. 31 at the Delaware Experiment Station. Not only the agricultural papers but the daily and religious papers have been free to comment on the performance. The thing that particularly got hold of me was the statement that this hen was "manufactured to order," if I may so use the term. For some years past, Mr. Tom Barron, of England, has been furnishing the laying hens that broke the record in America. I have for some time been urging that we wanted hens to lay eggs, or at least a part of us do. We did not care how they looked, or whether they conformed to the standard or not. We want them (to furnish humanity food—good and wholesome food—at a reasonable price) not only for men, but for women and children who love chickens. George A. Cosgrove, in the *Rural New-Yorker*, says in regard to Mr. Barron:

I frankly admit that Mr. Barron has not paid as much attention to beauty as I wish he had; but the great body of American poultrymen are far more interested in having their hens lay an extra couple of dozen eggs per year than in having their cockerels "carry their tails low." If he had so done, his birds would not have been able to make a record for egg-laying year after year in all the egg-laying countries, that no man in the world has been able to equal.

It was the *Rural New-Yorker*, also, I think, that said that Tom Barron and a poultry expert in Maryland had been working together for some time past along the line of the Mendel theory concerning the laws of heredity; and as a result of their experiments they sent five hens to the Delaware College. There are two points here that will be of interest. The test was made by the college, and was, therefore, of course, unbiased. Secondly, she was one of five furnished, and the other four made a record well up toward the 300 mark. If the results were from a single hen we might consider it a freak or an accident; but if four of the sisters proved also to be tremendous layers, it begins to look as if the poultry world had finally got hold of something. I said to Mrs. Root one day that I would give a dollar apiece for a setting of eggs from Lady Eglantine; but pretty soon the papers said the eggs were bringing five

dollars apiece; later, ten dollars; and finally the *Christian Herald*, in writing up Lady Eglantine, said, "It is said that her eggs sell for sixty dollars each." I soon ascertained that this was a mistake; and, by the way, I wish our periodicals, all of them, when they begin to write up things out of their regular line, would be a little more sure that they are right. Submit the matter, for instance, to somebody who ought to know, or some one who is posted along the line in question. Well, I finally wrote to the owners of Lady Eglantine, and found I could get one of her eggs, with fourteen others thrown in, these latter being eggs from her sisters, for \$20.00; and, furthermore, they offer eggs from her sisters, or hens nearly related to her, at only \$2.50 per 15. In due time the eggs came by express on a long trip away down to Florida; but I was greatly disappointed to find, after the seventh day, only three eggs that showed clearly fertile, and I succeeded in hatching the three chicks. They came out about the first of April. I wrote, explaining the matter, and the company very courteously expressed to me at once another setting. From this setting I secured six lively chicks, making nine in all. On Monday, April 17, I put the nine chicks, three of them three weeks old, and six about one week old, into a market-basket, and sent them by express to Medina. By the way, I was greatly pleased to find it cost only 69 cents. I suppose the express company was figuring down close because of the inroads that parcel post has made on their trade. The chicks were on the route four days; but they came to hand bright and lively, and ravenously hungry for water and bread and milk. I supposed I put sufficient wheat, rolled oats, and grit in their basket to last them; but it seems it did not hold out. Just now they are out in the bright April sunshine here in Medina, making explorations in every direction, and even over on to the neighbors' premises. After their long hours of being shut up, and especially the last day without food or water, they appreciated the Ohio angleworm in a way that I never saw chickens do before: and I am about as happy as they are to see them scamper about, helping them out of their troubles when they get into them. For instance, a door was left open, and they got in on the clean cement floor of our basement. Mrs. Root not only had a time in getting them out, but also in sweeping up after them.

Some of you may inquire what the above has to do with my usual Home papers, and particularly what it has to do with the texts I have mentioned. Well, my first text was taken to remind us of a great and precious promise. In years past, in some way I had taken this text to refer to beautiful things after this life is over; but of late I have been thinking it refers also to this present life. If we look about us and see the progress that is being made in everything pertaining to human life and happiness, I think we might recognize the fact that the promise is coming. The boys' and girls' clubs along the line of agriculture are not only surpassing their fathers and mothers but the world at large. The developments of science—just think of it! My father, with a good-sized family of girls and boys, came from Connecticut to Ohio with an ox team. Those of you who have lived for sixty or seventy years have witnessed the wonderful strides. Sometimes we think we have got pretty near the limit. Here is a clipping from the *Sunday-school Times*, with a moral to it:

One who has gone deepest into "the deep things of God" has but scratched the surface of the depths of the riches of Christ. Bible study and interpretation is only in its beginning. The most mature Christian has scarcely begun to lay hold on that for which Christ has laid hold on him. A country lad with a mechanical talent some years ago left home to take his first position in a large machine shop. After his first sight of the great room filled with its wonderful machinery the boy wrote home sadly to his father that there was no chance for him. The work had all been done, and, no matter how good a machinist he might become, there was no improvement that he could make. "Before I finished my four years' apprenticeship," he said, in telling the story afterward, "I saw every single piece of machinery in that great shop thrown on the scrap-heap and replaced by new and improved models. And," he added with pride, "my own hands had left their touch upon that new product." The country boy is now himself a leading manufacturer, and is constantly telling young men to remember that it has not "all been done," that electricity, like every other science, is just in its infancy, and is waiting for some boy to dig deeper into the marvelous hidden secrets.

It looks to me as if four years is a rather brief time in which to dispense with expensive machinery in a great shop; but we have the same thing here in our own shop. Machines that we thought a few years ago were about the best thing that could be made, in a brief time have become entirely out of date. And this is true of the farming business as well as of the machine-shops. We are making progress in improving domestic stock; and it seems this is true of the lady cows as well as the lady laying hens. See the following from the *Plain Dealer*:

UPSETS BUTTER RECORDS; \$20,000 COW ECLIPSES FORMER PRODUCTION MARK.

BUFFALO, Dec. 10.—Lady Pontiac Johanna, a cow valued at \$20,000, has just broken the world's record for butter production by yielding 658 pounds of milk in one week, from which was made 41 81-100 pounds of butter. This eclipses the former butter record by five and one-fourth pounds.

The record cow was milked four times daily under supervision of a representative of the New York State Agricultural Department. Lady Pontiac Johanna is owned by Oliver Cabana, Jr., of Buffalo.

In Our Homes for March 1 I told about that little tract from Charles Gallaudet Trumbull, "The Life that Wins," and I told you in closing that paper that I had at last made a little start along that line, and that is proving true. Where I saw only one wrong thing in my daily habits before, there are now scores; and the above chicken story gives me an excellent chance to illustrate how these things creep in. After I received a postal card from the Eglantine Farm, saying they would send me another setting, free of charge, in thanking them I said something like this: "My good friends, I do not like to be outdone in generosity. If half or more of the eggs turn out fertile I will send you half price for those of the second lot."

When the time came for testing I went into my darkened room and counted out seven of the eggs that showed clearly fertile. Seven is half of fourteen, but not quite half of fifteen. But there was one egg left that I could not fully decide whether it was fertile or not. A germ had started, but there was a faint black line that looked very much as if the germ had died. As I sat there in my darkened room rolling the egg around so as to let the rays of sunlight strike it in different directions I said to myself, "I am really under no obligation to send them \$1.25 more, for there are only seven eggs that are clearly fertile." A better spirit, however, whispered that the eighth egg *might* hatch a good chicken after all; and then came the question, if I am working and striving for that "life that wins," that higher life, I must learn to love my neighbor as myself. I must give *him* the benefit of the doubt just as readily as I would decide in favor of myself when in doubt. And then I said, "Get thee behind me, Satan;" and, for fear I might change my mind, I went straightway and put a dollar and some stamps in a letter and addressed it to the Eglantine Farm, and felt very much happier than if I had decided to "save" the amount sent. My good friends, I realize that it is a little humiliating to confess here in this Home paper that I still have defeats along the line of self, and temptations to be selfish. Oh, what a world this would be if every

human being were just as anxious and just as ready to decide all questions without *self* biasing the judgment! Where one is truly "hungering and *thirsting* after righteousness" it ought not to take him very long to settle all such questions as the one I have illustrated above: and such a course, as I understand it, is "the life that wins."*

I believe that just now our best authorities recognize two important elements in figuring on better vegetables or better domestic animals. 1. Heredity and then environment. With these nine precious chickens I have heredity—at least I suppose I have—from the Eglantine Farm by paying for it. And now it is my great pleasure to furnish the best possible environment for these high-pressure chicks. It seems to me they fly and scratch and tear around at a bigger rate than I have ever had chickens of a like age do before. By the way, I forgot to note in the proper place some newspaper reports this remarkable hen produced eggs in one year that weighed *twelve times* as much as she herself did. It is said that she eats about a half more food than an ordinary hen, and that, while it requires about 100 days for the ordinary moult, it took her only *50 days*, and then she commenced laying again. Her weight is 3 lbs. 14 ounces.

Before closing, let me go back a little to this matter of improvement in farm stock. From the little pamphlet sent out by the Eglantine Farm, Greensboro, Md., I clip the following:

And we desire to give full credit to Mr. Tom Barron, whose personal help and professional interest have followed our work. We have made every female bird on the farm. We follow the Mendel laws of heredity.

Notice the expression, "We have made every female bird on the farm." That is, they laid the plan, selected a path, and went to work to build up a superior strain of egg-producing White Leghorns. They went to work as a carpenter starts out to build a house or a machinist to make a new machine; and then they let the Delaware College take the product and report the result to the world.

* Under circumstances like these we are often inclined to think it is entirely an affair of our own; nobody knows anything about it. We can decide one way or the other, and the great wide world will never be any the wiser or know anything about it. At such times as these it is well to keep in mind that other brief little text, "Thou God seest me." Instead of thinking that we alone are to decide, let us think rather of that beautiful poem that we gave the readers of GLEANING: some time ago—"Alone with God." And may we not strive, in our effort for that "victorious life," to feel always and under all circumstances, that God is with us—that there is no *possibility* of escaping the fact expressed in the brief text, "Thou God seest me?"

HAVING SUNDAY ON SATURDAY.

I have been reading your Homes for the last ten years. I don't believe I have missed one paper, and I have enjoyed them and profited by them. I am told by some of my friends that Sunday is the first day of the week, and that God blessed the seventh day, or Saturday, and made it the sabbath. It is not convenient for me to keep the seventh day, and I wish you would point me to the time and place where God gave authority for the change. I should like to think as you do in this matter: and certainly a man of your position and influence would not teach anything without first looking into the matter for good reasons for his position. So I look to you for enlightenment, and I am sure you can help me.
Fennville, Mich., Oct. 16. E. H. JACKSON.

My good friend, if you have been reading my department of GLEANINGS for ten years past it seems to me you must have noticed what I have said about having Sunday on Saturday. Suggest to the good friends who insist that mankind would be better, and that God would be better pleased by such an arrangement that they call *Monday* the first day of the week, for it really is the first business day, and then we'll have peace and harmony. But one of the Advent friends replied when I suggested the above, "We won't have it so." Once more, on the opposite side of the earth they could not have Sunday on the same day we do, because it's midnight; and there is an island in the sea where there is a dispute about which day is Sunday. Part of the inhabitants came in from the east and part from the west, and the matter isn't settled and cannot be settled unless the people agree to call a certain day Sunday. As I see it, there is nothing in the Bible that does tell or *can* tell which day is Sunday; and it behooves us as Christian people and followers of the Lord Jesus Christ to agree about Sunday as well as about other things and turn in and work together.

If we could agree on voting so as to do away with the liquor business, and in the same way do away with wars and bloodshed, it seems to me it would be a *thousand times* more important than wasting our time about which day should be Sunday.

CAN A CHRISTIAN GO TO WAR?

In reply to my footnote on p. 1084, Dec. 15, A. F. Foster replies as below:

Let me say that desperadoes and criminals might be treated as we treat the dangerously insane—restrain, confine, restore, and reform if possible, as we would a member of our own family. Let *none* be set at liberty until judged safe. For us who have learned the *perfect law*, it seems easy and safest and a method God has promised to bless.
Nampa, Ida., Jan. 8. A. F. FOSTER.

But, my dear brother, it often takes a *deal of fighting* to "restrain, confine," etc. As I pen these lines, April 6, our nation is spending untold thousands in the effort to

"restrain, confine" Villa that he may cease murdering Americans. Shall our nation cease trying to protect its peaceful citizens?

"GOD'S KINGDOM COMING."

The *Christian Herald* for April 5, after recording the startling progress prohibition is making in *Canada* and neighboring provinces, closes with these words:

The nation-wide, the race-wide war on the liquor traffic which is being waged by Christ's followers is one of the signs of the establishment of his kingdom in accordance with this prophecy: "They shall not hurt nor destroy in all my holy mountain; for the earth shall be full of the knowledge of the Lord, as the waters cover the sea.—ISA. 11:9.

Notice the words, "The establishment of his kingdom."

REDBUGS, "JIGGERS," FLEAS, AND OTHER "VARMINTS."

Friend A. I. Root:—I suppose you are right in the flush of the redbug season. The little pests are just beginning to crawl out from their winter hiding-places here. I have read with much interest all you have had to say regarding that insect. For more than thirty years I have been battling with them every season, and have learned how to diminish, somewhat, the annoyance they create. I wrote to Dr. Riley, Chief of the Division of Entomology, Department of Agriculture, Washington, a good many years ago, for information regarding the jigger, or redbug. He said there were two varieties, belonging to the flea family—the *Penetrans* and the *Imitans*. They are found everywhere south of the Potomac and Ohio rivers, but more numerous in the gulf states. They are white and invisible until filled with blood, when they can be seen by some persons with the naked eye. Grease or strong essential oils rubbed on the parts exposed to them will keep them away.

I have tried many methods and substances, and have settled down to the following plan: After being exposed to them by being out in the bushes or weeds, bathe with carbolic soap or a few drops of carbolic acid in the bath water in a wash-dish. To stop the itching and burning, I moisten the places with strong ammonia water into which I have mixed enough oil of citronella to make the mixture pleasantly aromatic (I use the same for bee-stings); then rub about the ankles and other parts troubled a mixture of kerosene with moth-balls dissolved in it, and enough oil of citronella to make a pleasantly fragrant lotion. Before going out into jiggery places rub some of the moth-ball-coal-oil liniment about the ankles and wrists, etc. They hop on to our clothing and crawl into the meshes of the cloth, and many remain there for days or weeks ready to devour us when we put them on.

To head them off, last year for the first time I cut the top out of a five-gallon honey-can, pounding down the rough edges smoothly, placed my jiggery garments loosely in the can, poured about a teaspoonful of bisulphide of carbon on a rag, quickly laid it on the garments, and covered the can with, first, a piece of soft towel paper, then with a piece of board weighted down. In half an hour or longer there were no live redbugs in my clothes. I could put them on and feel sure of getting no more bites. Fleas, seed-ticks, bedbugs, chicken-mites, nor any other insect, can live long in the bisulphide fumes. But be very careful not to have any fire near the bisulphide.

Mentone, Ala.

DR. C. F. PARKER.

Thanks for suggestions, doctor. I am glad to say redbugs have given us very little trouble here during the past winter. Our remedy is a strong solution of sal-soda. As soon as you feel the itching, give the place a good scratching and then apply the solution. It will, doubtless, make it smart at first, but it is soon over, and the insect is killed. It should be applied, however, just as soon as you discover you have been bitten.

MITES, CRUDE OIL AS REMEDY.

Mr. A. I. Root:—I just read your article in Nov. 15th GLEANINGS on sticktight fleas and mites. I was bothered with mites for two years after buying some roosters. I let them get quite a start before I noticed them. I cleaned my hen-house every morning, so I thought there was little danger of insects, but I have found by experience that, with several hundred hens, it is necessary to spray often and keep close watch. I tried moth-balls and coal oil in the nests. Of course I burned all straw, etc., in the boxes and charred the boxes as soon as I discovered the mites, and sprayed with coal oil, soapuds, and crude carbolic acid; but still I had mites under the roosts, and places where spray didn't reach. So I got crude oil, nasty black stuff, and painted roosts and sides of walls. Of course I did that several times in all coops; but it did the work. I have no more mites, and have had none this season. Of course hens get daubed; but it soon wears off.

I have found spraying with strong bluestone water to be effective with fleas. I think they must be short-lived, as they disappeared, so I don't think they breed on the fowls. Of course a person can grease chickens' heads, which will kill the fleas; but that would be some work with several hundred hens.

Manteca, Cal., Dec. 12. ERNEST E. WARREN.

As long as the crude oil remains "dauby" and sticky, mites are pretty sure to stay away. I am glad to add we have not found a mite on our premises here during the past winter, and it is several years since I have seen a "sticktight" flea. As the country becomes settled up, I think these *usually* disappear. Even "redbugs" now trouble very little.

REDBUGS, PINE-NEEDES FOR MULCHING.

Mr. A. I. Root:—I have before me your reply to my letter of Feb. 25, in GLEANINGS for Nov. 15. After reading it I asked my sister-in-law, who has lived in Florida some time, if the redbugs there were the same that we have here, and she said that they are the very same. Now, you may never have seen a redbug; but I am sure I have seen a great many of them. They have to stay on long enough to get full of blood, however, before they can be seen. At that stage they appear as a very tiny red speck that is hard to see. We have also the chicken-mite here, and it is a very bad customer. As to the mulched potatoes, I don't know why the bugs did not bother them; but I think the pine needles kept the ground so moist that the tip-burn, which is said to be caused by drouth, did not get a chance at them. I don't think the odor had anything to do with it. We use dead pine needles here for mulching, bedding stables, and for some other things. They make fine bedding for stock.

Arcola, N. C., Dec. 1.

J. F. HUNTER.

HIGH-PRESSURE GARDENING

SWEET CLOVER; A QUESTION, ETC.

Mr. A. I. Root:—I should like a little information in regard to a piece of ground that I raised a crop of sweet clover on two years ago. I let it go to seed and plowed it under in the fall. I put corn on last summer, and got a good crop. I want to plow it this spring and put oats on it. I turned all the seed down. Would it be safe to turn that seed up again and sow oats and get a good stand of sweet clover, or must I sow more seed? If so, how much to the acre? This piece of land lies on a hill hard to haul manure to, so I have put sweet clover on as a fertilizer, and intend to sow oats this coming summer, mow the sweet clover, and the next season put corn on the same piece, using the clover as my fertilizer, and put on about 8 bushels of lime to the acre every third year. This is my plan, and I have come to the conclusion that I can reap a crop every year by sowing other clovers and vetch in the corn. This has been a very poor field, but I got two loads of soil of a lady about a mile from here, who had a patch of sweet clover in her yard for a flower-bed. The seed she gathered in the Wyoming Valley along the Susquehanna River, so she wanted me to rid her of the clover by taking the soil. I didn't quite rid her of the clover, but I got a good stand, and my bees worked it all summer. The clover grew as high as seven feet in some places. Some of my neighbors laughed at me when I told them about sweet clover; but I am getting the clover, and corn twice and even three times over what they are getting, so I will still stick to sweet clover. One of my neighbors likes to hunt. He said that clover was the largest crop he ever saw on that field, and he wanted to know what I put on that corn to make such a good crop. I told him sweet clover and a handful of hen manure and ashes to every four hills. He said that was the biggest crop he ever saw growing on that field. I wish to show this section that sweet clover is their best friend if they get acquainted with it right, and give it only half a chance.

Dallas, Pa.

H. HEADMAN.

My good friend, I cannot answer positively, but my impression is you will get plenty of clover without sowing any seed if you let all the seed fall on the ground before plowing.

SPINELESS CACTUS; MISLEADING ADVERTISING

We clip the following from the *Florida Grower* of April 1:

Some time ago we were threatened with a lawsuit because we refused to accept the advertisement of a man who wanted to sell spineless-cactus slabs. We refused this business because we believe that the only man who will make money from spineless cactus in Florida is the man who sells the slab seed at \$1.00 each. I had been thru the spineless-cactus furore out in California ten or twelve years before, at which time the promoters claimed that its production would revolutionize the cattle business. If there was any part of the United States where cactus would grow it would be in the dry valleys and on the desert, and it did indeed seem as tho it could be grown without expense and in prodigious quantities there, and that if it was all its promoters claimed for it that cattle could be fed for almost nothing. However, we noticed that the agitation soon died down, and at the time we were offered the spineless-cactus advertising we wrote to Prof. Cook, Horticultural Commissioner of California, asking him what the results had been. His answer determined us

that we were right in refusing to endorse spineless cactus, and this attitude on the part of Prof. Cook was also the attitude of the heads of our own State College and Experiment Station. The suit was never brought. A recent ruling of the Postoffice Department is that papers have a right to refuse to publish advertisements when, in the judgment of the editor, it would not be for the best interests of the paper or the community it represents.

I have never doubted that a publisher had this right, but it is just as well that this ruling settles the question for all time. We have consistently refused to accept advertisements offering liquor, patent medicines, fake employment agencies, and the like, and the land company that gets a permit to use our columns had been closely scrutinized, tho we have inadvertently carried advertising of this kind that we would not carry again. Occasionally we are fooled by parties who seem to be all right.

We commend the *Grower* in the stand it has taken, and devoutly wish there were more such editors. The wild cactus is certainly a boon to cattlemen (see letter below), but it may not pay to grow spineless cactus.

THAT GASOLINE-TORCH (SEE P. 253), AND SOMETHING ELSE.

We saw in GLEANINGS of March 15 where you wanted to know about the gasoline-torch and where made. I would say they are sold in Pearsall, Texas, by Beever & Hinds. The "pear-burners" are used quite extensively in southwest Texas to burn the thorns off the pear so the stock can eat it. The prolonged drouth lately has brought many of them into use. The stockmen employ Mexicans to run them, and you can see a hundred head of cattle following the Mexican as he sings the spines off. We would send you a picture of one as the Mexican burns the pear if we had the time to get it, but we are busy with the bees now. The bees are gathering honey from the mesquite; and if the rain came now it would spoil the bloom, so the beekeepers are not wishing for rain while the stockmen are; and those that have both cattle and bees are betwixt the devil and deep sea.

If it were not for the prickly pear in southwest Texas the stock would die by the hundreds in drouthy times, unless fed cottonseed and cottonmeal. Before the pear-burner was invented, the people used a stick or fork, and with a brush fire would burn for cattle. The gasoline-torch is quite an advantage over the old way.

Nueces County, a stronghold of the antis, went dry. The Texas "pros" are gradually making Texas a dry state. Some of the strongest "antis" are coming over to the pros on account of the brewery frauds that were exposed in Texas.

We are somewhat apprehensive over the war situation between the United States and Mexico. We live below our town about fifteen miles, and now get the mail but once a week. We are about sixty miles from the border, and feel somewhat uneasy. I don't think a Mexican could catch us in some of this brush; and if you could see it you would think we could never be found except by a dog.

I think the gasoline torch costs \$18.00, but since all kinds of metals have advanced in price it may be much more now.

We look forward to the semi-monthly visits of GLEANINGS, and turn to the Home Talks the first thing. May you be spared to us and all the readers of GLEANINGS many years.

My good friend, when I got to the end of your very valuable letter and saw "not publish," I was vexed, and I have taken the

liberty of disobeying, omitting your name. God grant the troubles with Mexico may be peaceably ended.

TEMPERANCE

REFORM (?) LITERATURE SENT OUT BY THE
BREWERS' ASSOCIATION.

We clip the following from *Christian Work*:

The U. S. Brewers' Association is very active nowadays in distributing literature. "Beer Good for Ball-players," and other leaflets of similar caliber. Among the rest is a flyer entitled "Saloon Closer to Christ than Churches," which describes an alleged debate under the superintendency of Mr. E. J. Ward, a former Presbyterian minister, now employed by the University of Wisconsin, to awaken interest in community centers. At this debate it was decided by a vote of ten to five that "the saloon of today follows the general ideas of Jesus Christ better than the church." It was suggested that the good-fellowship of the saloon must be combined with the spiritual ideas of the church, if the latter is to fulfill its mission, and wound up with "Were Jesus to come back to earth, the church would be his first object of attack and not the saloon!"

We are told that drowning men grasp at straws, and the above seems to be a pretty good illustration of it; but when they try to make out that beer is good for baseball players it seems they have got hold of a very flimsy bit of straw. While we have no particular desire to see the brewers of the United States suffer death literally, we are very glad indeed to see indications that their entire business is fast going to the bottom of the sea.

KANSAS AND PROHIBITION: STILL MORE ABOUT IT.

So long as the "wets" keep scattering their misleading and false statements we propose to keep on giving the truth. We clip below from the *Christian Herald*:

PROSPER IN PROHIBITION KANSAS.

Despite the expression of deep distress upon the part of the liquor dealers at the failure of prohibition in Kansas to prohibit, it does prohibit marvelously well, according to the most reliable testimony. The attention of the whole nation was attracted by the report for 1915 of a mortality of only 9.8 to the 1000 of population, being the lowest of any state in the Union. Samuel L. Rogers, director of the United States Bureau of the Census, wrote to W. J. Deacon, Registrar of Kansas Vital Statistics, asking why the death rate was so low. Mr. Deacon in his reply gave prohibition credit for a full share of the public health in these words: "Kansas is a prohibition state, and in Kansas prohibition really prohibits." He said also that there was general education, the people had money enough to make them comfortable, and were wise enough to avoid the things that impair health and shorten life. Kansas began the new year without a dollar of indebtedness, having burned up the last mortgage for \$159,000, and claiming the enviable notoriety of being about the

only state in the Union free of debt. Prohibition Kansas holds in one hand the cleanest bill of health, in the other the completest financial exhibit, while in the mind it has truth and in its heart love. The violent denunciations of the failure of prohibition in Kansas by those whose pockets have been affected by it, and by those who have been deceived by their false statements concerning it, do not change the fact that prohibition in that state does prohibit, bringing with it the reward of health, intelligence, thrift, and virtue. Kansas with eighteen sister states is by its law saying: *Look not thou upon the wine when it is red, when it giveth its color in the cup, when it moveth itself aright. At the last it lieth like a serpent and stingeth like an adder.*"

SAVING THE COST OF DOCTOR'S BILLS.

If you are not already taking *Farm and Fireside*, you had better send for the issue of April 8 and read the article entitled "How a Kansas County Decreases its Number of Deaths a Third." It may be worth a good many dollars to you. I clip from it as follows:

The death rate to the thousand for Kansas is 9.8, which, according to a recent federal census statement, is the lowest death rate of any state that is conducting a state-wide health work.

Such a record as Riley County has made is possible only because the work has been in charge of a competent, progressive, and efficient man. Dr. J. C. Montgomery has been the county health officer, and has directed the health work of the county since it was started six years ago. He has taken the public-school children and their parents into his confidence. Now after six years' work the school children as well as their parents are well informed about disease. They know the causes of disease and how to prevent sickness.

Since the health work was started the death rate for the county has not only been decreased greatly, but the people have been saved thousands of dollars in doctor and medicine bills, and every one has been able to do better and more work because they have been enjoying health.

The cost of conducting the health work a year has been slightly more than 6½ cents a person. And this isn't really an expense; it is an investment, because the saving in death losses, doctor and medicine bills alone is many times more than the actual money spent.

Many persons who some time ago ridiculed the health department and complained bitterly every time a few dollars of the public money was used to prevent disease now indicate not only a willingness but a keen desire to co-operate with the department.

I did not find any mention in the article in regard to prohibition in Kansas; but the fact that Kansas stands almost if not quite at the head of our nation as a healthy place to live is doubtless largely owing to the absence of saloons.

WHY NOT BUY THE VERY BEST QUEENS?

when you can get them for no more than others are asking for queens that do not have as good a record? We have made arrangements with Dr. C. C. Miller to furnish us breeders from his best stock, which means the best stock in the world, as his stock has produced more honey than any other strain in the world, or 266 sections weighing 244 pounds (how is that for filling the sections full?). In extracted honey this would mean about 488 pounds. Just think of it—an average of nearly 500 pounds per colony. The breeders Dr. Miller sent us are as fine as can be, besides the record they have, being pure three-banded Italians, very gentle, and produce fine large daughters. These are not queens from a mother that has produced one good crop, but it has been bred in them for generations until their honey-gathering is a fixed quality. Editor Root says in GLEANINGS, page 788, "Those queens (Dr. Miller's) ought to be worth \$10.00 to \$25.00 each." Others have sent him \$10.00 to \$25.00 for a single queen. Few people ever have a chance at the best in the world; so, grasp the opportunity while it is offered you.

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.

H. D. MURRY, MATHIS, TEXAS

Talking Queens

Laws' queens speak for themselves, as "actions speak louder than words," while pleased customers everywhere have been boosting Laws queens many years.

Twenty-seven years' continuous advertising in this journal as queen-breeder, with continuous careful breeding from the very best Italians, places Laws queens and Laws methods far above the average.

If quick service and reliable dealings count with you, place your orders with me. My capacity is from five to six thousand queens in the next five months. Five hundred young laying queens ready now April 3, and many more before this reaches your eyes.

Prices: Tested, each, \$1; 12 for \$10; 100 for \$80. Untested, 90 cts.; 12 for \$9; 100 for \$70. Breeding queens, extra select, \$5 to \$10.

There is not a known case of bee disease in this or adjoining counties.

W. H. Laws, Beeville, Texas
Inspector for Bee County

Archdekin's

E. A. SIMMONS, Greenville, Ala.

If you want a queen for that queenless colony, we can send it to you by return mail. Young tested queens, \$1.00, \$12.00 per dozen. Untested, \$1.00; \$9.00 per dozen. We breed the three-band Italians only, and we breed for the best. Our thirty years of queen-rearing proves this. We never had a case of foul brood in our apiaries, and we guarantee every queen sent out by us.
J. W. K. SHAW & CO., Loreauville, La.

This is the combination you have been waiting for: Your *Dr. Miller queen* introduced to a 2-lb. swarm; listen: Two pounds of bees, \$2.50; 1 *Dr. Miller queen*, \$1.50; the *Beekeepers' Review* for 1916 (we have the back numbers), \$1.00. Total amount, \$5.00. Send us only \$3.75, and your *Review* will begin coming immediately, and the two pounds of bees with a *Dr. Miller queen* introduced will be shipped by express in June. The reason we make this extraordinary offer is, we want to put the *Review* in the hands of every subscriber of GLEANINGS, and we take this way of introducing it to you. Address, with remittance, *The Beekeepers' Review*, Northstar, Mich.

GRAY CAUCASIANS.—Early breeders, great honey-gatherers; cap beautifully white; great comb-builders; very prolific; gentle; hardy; good winterers. Untested, \$1; select untested, \$1.25; tested, \$1.50; select tested, \$2.00. H. W. FULMER, Andalusia, Pa.

ITALIAN QUEENS, Northern-bred, Three-banded, Highest Grade, Select Tested, Guaranteed. Queen and drone mothers are chosen from more than 600 colonies noted for honey production, hardiness, prolificness, gentleness, and perfect markings. Price, one, 80 cts.; 12, \$8.00; 100, \$55.00. Also bees by the pound. Send for circular.

J. H. HAUGHEY, Berrien Springs, Mich.

Carniolan, Golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, Box 315, Buffalo, Tex.

A daughter of one of *Dr. Miller's best honey queens*, and the *Beekeepers' Review* for 1916 for only \$2.00. A daughter of one of the very best honey-getting queens selected from 1100 colonies worked for extracted honey, from the yards of E. D. Townsend & Sons, and the *Review* for 1916 for only \$1.75. The queens will be mated in June direct from our breeders in the South. A rare buy.

THE BEEKEEPERS' REVIEW, Northstar, Mich.

Three-banded queens and bees by the pound, ready now. One untested queen, 90 cts.; \$9.00 per doz.; \$17.50 for 2 doz.; \$65.00 for 100. Tested, \$1.50 each; fine breeders, \$5.00 each; 1-lb. swarm with fine queen, \$2.25 each; without queen, \$1.50 each; 50 for \$70.00; 100 for \$135. Add queens at above prices. I can furnish you in any quantity from one to 1000 queens or swarms of bees at above prices from April 15, thruout the season. Write to Curd Walker, the Queen-breeder, your wants. He will give you a square deal. Box 18, Rt. 1, Jellico, Tenn.

Special for May, express prepaid on 10 or more swarms of bees in packages, at my regular price of 1 to 49, 1-lb. at \$1.50 each, and 2-lb. at \$2.50 each, and 50 to 500 of the above at 12½ cts. less each. Untested Italian queens, 75 cts. each; tested Italian queens, \$1.25 each. No reduction on quantity of queens for April and May. Quality, service, safe delivery, and no disease, I guarantee. We spare no labor nor money to produce the best for you is why we cannot make a lower price. Early swarms get the honey. We can deliver the goods with pleasure to both of us. W. D. ACHORD, Fitzpatrick, Ala., the successful package-shipper and queen-breeder.

BEEES AND QUEENS.—Doolittle's Italian stock speaks for itself. They are gentle, resist disease, and are fine honey-gatherers. We breed this stock only, and guarantee delivery only to points west of the Rocky Mountains. Untested queens, 75 cts. each; \$8.00 per dozen; \$60 per 100; tested queens, \$1.25 each; \$12 per dozen; \$85 per 100. Three-frame nuclei, \$2.25 each; \$200 per 100. Bees, ½-lb. packages, 75 cts. each; \$6.00 per 100; 1-lb. packages, \$1.00 each; \$85 per 100. Add price of queens to above packages. Complete catalog free on application. SPENCER APIARIES, Nordhoff, Cal.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei, with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can, therefore, supply you with the biggest and strongest nuclei you will be able to find anywhere. Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier, if necessary. Bees are all on standard Hoffman frames, and combs are all built on full sheets of foundation and wired frames. We guarantee bees to be free from disease.

THE HYDE BEE CO., Floresville, Tex.

HELP WANTED

WANTED.—Helper in apiaries. State experience, \$50 month and board.

(GEORGE A. BALDERSTON, Kennett, Cal.)

WANTED.—At once, young man to work with bees. Give age, and wages expected, in first letter.

M. C. SILSBEE, Rt. 3, Cohocton, N. Y.

WANTED.—Helper in apiaries. State experience, age, and wages wanted in first letter.

MATHILDE CANDLER, Cassville, Wis.

WANTED.—Industrious young man, fast worker, and of clean mental and body habits, as a student helper in our large bee business for 1916 season. Will give results of long experience, and board and small wages. Give age, weight, experience, and wages in first letter.

W. A. LATSHAW CO., Clarion, Mich.

ON THE BOOKSHELF

It is surprising to note the various uses to which Portland cement can be put. There is no building permanently constructed that does not require the use of concrete for one part or another. Beekeepers have been quick to see the advantages of this material, not only for hive foundations but for beecellars, honey-houses, fence-posts, walks, etc. Reinforced concrete — that is, concrete strengthened by wire or rods—makes a construction that cannot be matched for strength and durability.

In concrete work especially, a lack of intelligent handling and the use of improper materials and mixing, accounts for many a poor job. One of the best books that we have ever seen on the subject is "Concrete on the Farm and in the Shop," by H. Colin Campbell. This book is amply illustrated with halftone engravings from photographs of work actually under construction, and should appeal to a beekeeper desiring to make anything, from a concrete slab for a hive to rest on, to an elaborate bee-cellar. Price 75 cts. Published by the Norman W. Henley Pub. Co., 132 Nassau St., New York.

Convention Notices

SPRING BEEKEEPING SCHOOL AT THE MASSACHUSETTS AGRICULTURAL COLLEGE, AMHERST, MAY 31—JUNE 14, 1916.

The most ideal time in the year to study bees is in May or June, when the colonies are at their maximum in strength and activities. The bees are easily handled. The student quickly gains a full acquaintance with the majority of the manipulations necessary to beekeeping. At this time of the year, once in three years an intensive course in beekeeping is offered at the Massachusetts Agricultural College, primarily for a limited number of practical beekeepers. This year particularly the course is to be conducted by an especially strong staff of the College faculty, and will occupy seven hours daily for two weeks, Saturdays being devoted to excursions. The course comprises lectures, laboratory practicums, work in the beeyard, and field excursions. It is under the direction of Dr. Burton N. Gates.

The College maintains a practical beeyard of about fifty colonies as well as outyards and a well-appointed beehouse and laboratories, besides a wax-working laboratory, library, and beekeeping museum. These exceptional facilities are offered the student in this subject.

APPLICATION.—It is desirable to apply for this course early, as it has been found necessary to limit the school to fifteen students. Students will be accepted in the order of application as shown by date of their letters. Application should be made by letter to Prof. W. D. Hurd, Director Extension Service, Massachusetts Agricultural College, Amherst.

FEE.—A fee of two dollars is charged to cover all laboratory expenses.

EQUIPMENT.—Such equipment as is made by the students in their course may be purchased at cost.

COURSES.

1. **PRACTICAL BEEKEEPING.**—Lectures: laboratory practice in the general work of the beekeeper; beekeeping equipment, practices in the preparation of materials, location of the apiary; commencing with bees, handling of bees, practice in beeyard procedure; spring manipulation; fall preparation, wintering; comb and extracted honey production; bee diseases and their treatment; apiary sanitation; making increase; elements of queen-rearing, etc.—Burton N. Gates, Associate Professor of Beekeeping; John L. Byard, Superintendent of the Apiary; Gladstone H. Cale, Laboratory and Apiary Assistant.

2. **LIFE OF THE HONEYBEE.**—Lectures.—Henry T. Fernald, Professor of Entomology.

3. **SPECIAL PROBLEMS OF THE BEEKEEPER.**—Lectures: Demonstrations in requeening, the races of bees, the introduction of queens; swarming and handling swarms; comb-honey production; enemies of bees.—James B. Paige, Professor Veterinary Science.

4. **CROPS FORAGED BY BEES.**—Lectures: field excursions.—William P. Brooks, Director of the Experiment Station.

5. **THE RELATION OF BEES TO THE POLLINATION OF PLANTS, INCLUDING COLORATION, ODOR, NECTAR SECRETION.**—Lectures: Laboratory work in blossom structure and dissection.—A. Vincent Osmun, Associate Professor of Botany.

6. **BEES IN HORTICULTURAL PRACTICES.**—Lectures: field work in the utilization of bees in fruit production, market gardening, cranberry culture, and greenhouse cucumber-growing; beekeeping as affected by spraying practices.—Walter W. Chenoweth, Associate Professor of Pomology.

GENERAL INFORMATION.

Amherst is desirably situated in the Connecticut Valley. In May or June the scenery is at its height in beauty, hence this season offers a pleasant opportunity for the course at the Agricultural College. Besides the work in beekeeping, ample opportunities will be afforded to visit the other parts of the Massachusetts Agricultural College as well as to visit Amherst College. Excursions will be taken as opportunity and the work may demand. It is usually customary to make a trip to some practical beeyard and queen-rearing establishment. Students returning from this course should be well equipped to handle bees on their own account.

SPECIAL NOTICES

BY A. I. ROOT

"THE DEFEAT OF INJUSTICE."

Here in my Medina home that little tract, "The Defeat of Injustice, or how to be Happy when People Abuse You," has, in consequence of the rush of business, been out of print for a time. Those of you who ordered them and did not get them can have them now if they will kindly repeat their request.

BACK IN MY OLD HOME ONCE MORE.

From now on, the many kind friends will find me here at my old Medina home (the Home of the Honeybees) at their service, with one or more stenographers to give you a helping hand whenever the benefit of my years of experience is called for. Perhaps I had better remind you, however, that of late I have had so little to do with the bee business and the factory that I am not as well posted as some of the younger ones. My one-hive apiary in Florida gave no surplus whatever in 1915, altho it has its upper story well filled most of the time; but it made no surplus in the third story. During the orange bloom this spring they did quite well for a time, and made a little start in the third story; but on account of the most severe frost of the winter, along in March, and a rather severe drouth following, the orange-bloom gave no surplus in our neighborhood. I mention this because so many of the good friends in the North seem to have gotten the idea that *down in Florida* there is *always* honey coming, year in and year out. But the truth is that, while we occasionally have good success, with abundant honey-flows, Florida has its ups and downs, at least in some localities, like almost all the rest of the universe.

We left our Florida home—chickens, garden, and all—on the morning of April 17, and in just about 48 hours from the time of starting we were once more back in Ohio in time to see the apple-trees bloom; but in place of the apple-bloom and the "May flowers," we have been having a series of April showers for about a week.

I have just read my letter (adv. page 21, March 15), and it places me in an embarrassing position. In line 10 you make me say "my grandmother." I don't remember using that word. If I did, it was truly a slip of the pen. I certainly did not intend to use the word, for "grandma" Lincoln Bowman is my nephew's grandmother, my brother having married her daughter. We all call her grandmother—almost everybody—and in that sense I meant it. I very much regret that my syntax was so faulty that it gave a different meaning to my letter than I had intended.

But Anglo-Saxon is not my mother tongue, so there you have it. J. C. SCHAUFLE, M.D.
Colchester, Ill., March 19.

A TRUE STORY OF HOMESTEAD LIFE

How wife and I left our school work and homesteaded 1280 acres of land under the Kinkaid Act. How we bought Government land for \$2.50 per acre when land joining our place sold for \$9.50 per acre. This tells how horses, cattle, and sheep are raised in this vicinity; how to build sod-houses and sand-bucket wells; how we raised 1000 bushels of clover seed. Has eleven illustrations including a township plot giving the number of people, horses, and cattle on each claim; also number of acres of plowed land, etc. The following is the last paragraph from an article in the *Breeders' Gazette*, page 337, of September 2, 1915:

"In the last Congress the grazing homestead bill passed the house by an almost unanimous

vote, and that it will be taken up and passed by the next Congress with little delay and few or no changes, is the general opinion of every man conversant with the situation. With the passage of such a measure the western public land states will undoubtedly see one of the greatest scrambles for land since the memorable opening of Oklahoma. It will positively be the 'last call,' the final offer of free homes, the winding up of the nation's land business, a remnant sale of what is left of our stock of free land. It will be a bargain day for settlers and a case of 'First come, first served.'

A True Story of Homestead Life sent post-paid for 30 cts. in stamps or personal check. If any one is dissatisfied after reading it he can return it, and we will refund his money.

R. A. Klover, Ellsworth, Nebraska

SPECIAL BARGAINS

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

HIVE HANDLES.

We have a surplus stock of handle cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of both 8 and 10 frame packed single and 5 in a package, which we offer, to close out, as follows: YW 5/8, one hive each, with frames, eight frame; 8 packages, one hive each, at \$1.75, and 12 packages, five hives each, at \$8.00. The same in 10-frame size, 2 packages, one hive each, at \$1.85, and 3 packages, five hives each, at \$8.50.

NO. 2 OR B GRADE HOFFMAN FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

METAL SPACERS SLIGHTLY DEFECTIVE.

In making the metal spacers for the metal-spaced frames there are a percentage which come out either sheared a little scant on one side, or with slight breaks in the tin where it is drawn up into the spacing-boss. These are hardly passable as perfect stock, but in actual use they will answer every purpose as a spacer. Rather than throw these into the scrap we will offer them while they last, including nails to nail them on, at 20 cts. per 100; \$1.80 per 1000. Transportation charges extra.

1 3/4 H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or, including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1 1/2-inch tire, and solid cast hub holding spokes and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

SUPERS FOR EXTRACTING OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. b. Medina.

200 D9/10, nailed and painted, with top and bottom starters, nine frames in each, new. Sell new for \$1.20; offered at \$6.90 for 10; \$55.00 per 100.

410 D8/10, nailed, and some painted two coats, some one coat; 273 not painted. Sell new for 90 cts.; offered at \$5.00 for 10; \$45.00 per 100.

180 8/10 supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first two lots are the 5 1/2-inch supers with hanger cleats and shallow Danz. frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

ALEXANDER FEEDERS FOR EIGHT-FRAME HIVES.

The Alexander feeder as we now make it is adapted to either eight or ten frame hives. Formerly we

made a shorter length for the eight-frame than for the ten-frame hive. In cleaning up old stock we find 300 of these eight-frame feeders which we offer, to close out, at half regular prices—viz., 15 cts. each; \$1.35 for 10; \$11.00 per 100; \$30.00 for the lot.

TIN COMB-BUCKETS.

While these are listed in the catalog in one line at \$1.50 each, their convenience in carrying combs to the extractor shut up from robbers is not set forth. We have a surplus stock, and offer them, to reduce the number on hand, at \$1.25 each. You can place four Hoffman frames or five non-spaced frames of Langstroth size in each bucket.

JONES HONEY-KNIVES.

This is a form of honey-knife used largely in Canada, and preferred to the Bingham by those who have tried it. The blade is 1 1/2 inches wide, and a flat V or triangular shape. We had a lot made to supply a call we had, and still have in stock 28 of them. We offer them at 75 cts. each. Mailed as a pound parcel when packed.

SHIPPING-CASES FOR 12 AND 24 SECTIONS.

When we discontinued listing shipping-cases to hold 12 sections we still had quite a stock of various styles on hand, many of which are still in stock. We have also some of the older styles of cases for 24 sections of various sizes. We offer these various cases to close out at the following bargain prices. Here is an opportunity to lay in a stock of cases preparatory to the honey crop near at hand at very low prices. None of these cases, except as noted, are large enough to take sections with cartons or corrugated liners, except the bottom sheet. 12-lb. 2 or 3 row cases with 2 and 3 inch glass for the 4 1/4 x 1 1/2, 4 1/4 x 1 1/2, 4x5 1/2 sections, packed 50 in a crate at \$4.00 a crate; packed 10 in a crate at 85 cts. a crate. A few crates of cases for 16 sections 4 1/4 x 1 1/2 at \$4.50 per crate of 50 or 95c per crate of 10. A few crates of cases for 24 sections, 4 1/4 x 1 1/2, 4 1/4 x 1 1/2, and 4x5 1/2 at \$8.00 per crate of 50; \$4.00 per crate of 25, or \$1.70 per crate of 10. The 12-lb. safety cases, which we no longer list with safety cartons, and 2-inch glass for 4 1/4 x 1 1/2, and 4x5 1/2 sections, per crate of 10, \$1.20; per crate of 25, \$3.00. Without cartons, but including corrugated liners and glass, \$4.50 per crate of 50.

IMPROVED CAPPING-MELTER.

The capping-melter illustrated in the April 15th issue is covered by Beuhne's patent issued several years ago, under which we secured license to manufacture. We will furnish these machines made of galvanized iron at an introductory price of \$15.00; or, made of sheet copper, at \$25.00. If these give the satisfactory service we have every reason to believe they will we expect to catalog them in the next edition as "Beuhne's Improved Capping-melter." It would make too long a name to include in it the names of those instrumental in so improving the original Beuhne as to make it so much more satisfactory in operation.

ALSIKE CLOVER SEED.

We still have a number of bushels of alsike clover seed, which we offer, subject to previous sale, at \$10.00 per bushel, with 25 cts. extra for bag to ship in. Any quantity from a peck up at this rate. Lot of two bushels or over, no extra for bags. It will not last long at this price. If you want some, better order promptly.

SWEET CLOVER SEED.

We have a good supply of very choice hulled white-sweet-clover seed scarified for quick germination, requiring only 10 lbs. per acre for a good stand. We offer this for a short time to reduce stock at \$18.00 per 100 lbs. Now is the right time for sowing with a nurse crop to produce hay or bloom with seed next year. We have also choice hulled yellow which we will sell at \$15.00 per 100 lbs. A thousand pounds of hulled white for shipment direct from Little Sioux, Iowa, not scarified, offered at \$15.00 per 100 for prompt acceptance.

THE A. I. ROOT COMPANY, MEDINA, OHIO.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

HONEY - CANS

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

Bee book free

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

BLANKE MFG. & SUPPLY CO., Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST. LOUIS, MO.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out—and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hand. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

17 CENTS A DAY! Remember this grand-new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features. Yet we have decided to sell it to every one everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY--Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

Cleanings in Bee Culture

MYERS

COG-GEAR PUMPS

Did you ever wish for a pump that would throw more water than your old one which slowly fills the water-pail? MYERS COG-GEAR PUMPS will do it, for they save one-third of the operating power. You can use a larger cylinder and pump three gallons while you were pumping two with the old pump and with no more effort.

MYERS PUMPS are made in the force and lift styles for shallow and deep wells, and for hand and windmill operation. The Siphon Spout, Large Air-chambers, Long Set Length, Adjustable Base, and Non-corrosive Glass Valve-seat are some of the other improvements.

If you use a pump of any kind, write for our Pump Booklet.

F. E. MYERS & BRO.
351 Orange St., Ashland, Ohio
Ashland Pump and Hay Tool Works

Do it before it ruins your crop prospects. Timely spraying will kill off the destructive insects—banish the blights. Spraying pays. Save money on your spraying outfit, too. We can save you one-quarter to one-half on any kind of sprayer, hand or power. Look at this one, for instance—

Newcomer Barrel Spray

Can Be Used \$6.45
With Any Barrel

If you bought it in the ordinary way it would cost you between \$10.00 and \$12.00

For various kinds of spraying—orchards, vineyards, shrubbery or for whitewashing dairies, poultry houses, etc. Double acting—brass nozzles—brass cylinder—brass valves—brass valve seat—paddle agitator. Furnished with 6-foot hose. Built to last for years—guaranteed to give satisfaction.

Send for Valuable FREE Book—our Special Farm Book, every page filled with hundreds of BARGAINS in all kinds of Spraying Outfits and Supplies—as well as farm tools and materials. New—just off the press. Send for a FREE copy today.

A New Complete Book for Every Ford Owner, Dealer, Salesman, Repairman

The Model T Ford Car

Price \$1.00 Postpaid

Its Construction, Operation, and Repair

By Victor W. Page

Author of "The Modern Gasoline Automobile," etc.

300 (5x7) Pages; Over 100 Specially Made Engravings, and Two Large Folding Plates

This is the MOST COMPLETE and PRACTICAL instruction book ever published on the FORD CAR. A high-grade cloth-bound book printed on the best paper, illustrated by specially made drawings and photographs. All parts of the Ford Model T Car are described and illustrated in a comprehensive manner—nothing is left for the reader to guess at. The construction is fully treated and OPERATING PRINCIPLES MADE CLEAR TO EVERY ONE. Complete instructions for driving and repairing are given. Every detail is treated in a non-technical yet thorough manner.

This book is written specially for FORD DRIVERS AND OWNERS, by a recognized automobile engineering authority and an expert on the FORD, who has driven and repaired Ford Cars for a number of years. He writes for the average man in a practical way from actual knowledge. All parts of the Ford Model T Car are described.

The illustrated chapter on repairing and overhauling alone is worth many times the price of this book. Special description of book sent on request.

EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A post card will bring it to your address free.

Red Catalog, postpaid.

HONEY GRADING RULES

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each

five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING RULES

Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in lady stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

MATANZAS.—Honey is now selling at 45 cents per gallon in this city.

Matanzas, April 24.

ADOLFO MARZOL.

St. LOUIS.—Our local demand for honey is very light, with ample supplies. Altho quotations remain unchanged since our last letter, they are only nominal. We quote southern strained bright amber in barrels, 5 to 5½; in cans, 6 to 6½; dark, ½ to 1 ct. per lb. less; comb honey, amber, 10 to 12; dark and inferior, 9 to 11; broken and leaky, 7 to 8; fancy clover from 14 to 17; western comb honey in neat clean cases, fancy clover, \$3.25 to \$3.50; bright amber, \$2.50 to \$3.00; under grades less. Prime beeswax, 29½ cts.; impure and inferior, less.

St. Louis, May 6. R. HARTMANN PRODUCE CO.

CHICAGO.—There is very little movement in honey of any kind at the present time. Comb honey drags, and prices are quite uncertain. Extracted remains steady without any change in price from our recent quotations. Beeswax sells at 30 to 32 upon arrival, if yellow and free from sediment.

Chicago, May 3.

R. A. BURNETT & CO.

BUFFALO.—There is some improvement in the demand for white-clover honey. Other grades and extracted are selling slow. Stocks are not heavy, and we think white comb will clean up soon. No. 1 to fancy white clover in sections is selling at 15 to 17; white extracted, 8 to 10; amber, 5 to 6; dark, 5 to 6 if good and pure. Buckwheat, about 7 to 7½. Beeswax, 28 to 30.

Buffalo, May 9.

W. C. TOWNSEND.

KANSAS CITY.—The honey market seems a trifle better on extracted honey, but there is no change in prices. We quote No. 1 white comb, 24-section cases, \$3.00; No. 2 ditto, \$2.50 to \$2.75; No. 1 amber ditto, \$2.75 to \$3.00; No. 2 ditto, \$2.50 to \$2.75; white extracted, per lb., 7 to 7½; amber ditto, 5½ to 7; No. 1 beeswax, 28; No. 2, 25.

C. C. CLEMONS PRODUCE CO.

Kansas City, May 5.

NEW YORK.—There is no demand for comb honey to speak of; and while No. 1 and fancy white are cleaned up, there is quite a stock of off grades still on the market, for which there is practically no demand, and hard to dispose of. The market on extracted honey is in a little better shape, and prices now show an upward tendency, especially on fancy West India honey. Supplies are sufficient to meet all demands. Beeswax is steady at from 29 to 31, according to quality.

New York, May 8.

HILDRETH & SEGELKEN.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: No. 1 per case of 24 sections, \$2.93; No. 2, \$2.70. White extracted, 8½ to 8¾; light amber, 8 to 8¼; amber, 7 to 8. We pay 26 cts. per lb. in cash and 28 cts. in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.
Denver, May 6.

F. Rauchfuss, Mgr.

ZANESVILLE.—There is no particular change in the honey situation here, the demand being about normal for the season, and prices practically unaltered. In a small way best white comb brings around \$4.00 a case. Some western sells for \$3.75. Jobbers are allowed usual trade discount. Extracted is in limited demand at prices as heretofore, 9 to 10 cts. for best white; darker grades correspondingly less. For good clean beeswax we pay producers 29 cts. cash, 31 trade, and invite shipments on this basis.

Zanesville, May 6.

CINCINNATI, O.

STOP! LOOK! READ!

MARCHANT'S FAMOUS 300-POUND BREEDERS are now being bred in Florida during our honey harvest, and every beekeeper knows the best queens are reared during the honey harvest. Our 300-pound breeders are still holding their own.

When you order Bees and Queens from us you get **QUALITY, PURITY, AND HONEY-GATHERERS.** We can fill your orders from the above famous strain for Queens, Bees, Nuclei, and Full Colonies promptly, or at such time as the purchaser may desire, and guarantee safe delivery and entire satisfaction to you in every respect. Our aim is to give you the best stock on the market at the time you want it. We ask you to give us a trial and let us prove to you that everything we claim for our bees is true. We will ship from Florida until May 20; after that date from Canton, Ohio. Prices as follows:

ISLAND-BRED ITALIAN QUEENS.
Shipments begin March 1.

	1	6	12
Untested	\$1.50	\$ 7.50	12.00

PROTECTION HIVES

Price: \$14.75 for five hives, delivered to any station in the U. S. east of the Mississippi and north of the Ohio Rivers.

Air spaces or packing as you prefer. Seven-eighths material in the outer wall, which means that they will last a lifetime. Used and endorsed as the best hive on the market by many prominent beekeepers of this and other countries.

Norwichtown, Conn., May 24, 1915. (Extract from letter and order): Our State Agricultural College has just been voted a sum of money to be used in the construction of an apiarian building and outfit. They are negotiating with me for some colonies, and I will furnish them in your Protection Hives, for I believe them to be the best on the market.

ALLEN LATHAM.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---
30 cts. cash, 32 cts. in trade; wax delivered to Lansing.

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

NO. 10

EDITORIAL

Our Cover Picture

OUR cover this issue, also the picture p. 396 show Mrs. Susan E. Howard, a Massachusetts woman who has demonstrated that a woman can make beekeeping pay. Besides writing for GLEANINGS, she contributes to some of the popular magazines.

Thru a misunderstanding, we omitted to credit the picture of J. W. Sehlenker and his auto, that appeared on our cover last issue, to *Productive Beekeeping*, by Frank C. Pellet. When we received the picture we overlooked the fact that it had already been used by Mr. Pellet. This breach of editorial etiquette was, of course, unintentional, and our apologies are due Mr. Pellet and the publishers, J. B. Lippincott Co.

A Correction

THRU an error we inadvertently made J. L. Byer say in his department in the May 1st issue, that, during the first twenty-four days of March, the temperature in his locality was fourteen degrees below zero. What he really did say was that during the first twenty-four days of the month there were fourteen days when the temperature was below zero. The mistake is our own, and Mr. Byer is in no way to blame for the exaggeration.

Honey-crop Prospects; the Need of Preparedness

THERE has been a heavy flow of honey in Texas, but the season has been a "little off" for sage in California. Prospects in Colorado and other alfalfa districts are good. Clover prospects in this locality, and in most places from which we have had reports, were never better. The indications are the best we have had for years for a favorable season thruout the United States

with the exception as noted. But we have had these "good indications" before. While "there's many a slip 'twixt cup and lip," it behooves every beekeeper to be prepared. There never was a time in all our history when preparedness seemed to be more important than right now in the beekeeping world. Many a crop has been lost because the beekeeper was not ready.

Bees Profitable in Canada

IN an interesting article entitled, "One Man Who Found His Answer in the Soil," which has been running in the February and March numbers of the *Countryside Magazine*, Mr. Justus Miller tells of the experiences of Mr. F. W. Krouse, of Guelph, Ontario, in getting a start in beekeeping. Says Mr. Krouse, "It was with bees that I had the time of my life! With them I have finally been most successful." The net receipts from Mr. Krouse's farm for last season were as follows:

Honey	\$3530.00
Poultry	100.00
Asparagus	500.00
Cherries	200.00
Berries and Currants	75.00
Potatoes	500.00
Total.....	\$4905.00

The bees, as this table shows, produced 72 per cent of the entire earnings of the farm.

Yellow Annual Sweet Clover

ALL the sweet-clovers are honey-plants. Two of them, white biennial and yellow biennial, are common in the greater part of the country; but the small yellow annual variety, *Melilotus indica*, is seldom considered of much value except in southern California where it is grown in orchards as a

cover erop and is used as a green manure to be plowed under before spring sowings.

A short bulletin entitled *Melilotus indica* (Circular No. 126), summarizing facts about sweet clover, and giving directions for inoculation and preparing the seed-bed, has been published by the Agricultural Experiment Station, Berkeley, Cal. It may be obtained free of charge by those interested.

Lots of Reading on Bees

"READ the books on beekeeping" is a frequent word of advice to men taking up the work. Very good; but it should not be carried out literally, of course. The simple fact is that if a man were to read all the books he can read on this absorbing subject he would have no time to do anything else for the rest of his life.

The experts of the apicultural laboratory of the Department of Agriculture, Washington, have compiled a bibliography of all known works on bee culture. The number of books listed up to date is 2295. It would take an entire issue of GLEANINGS to print this list once, assuming that each title took two lines of print.

Besides this list of books the laboratory also has a bibliography of articles and other contributions to the science, much greater in extent. Together with the list of books this numbers 22,440 titles, approximately.

Photographs for Reproduction

SCARCELY a week passes that we do not receive photographs submitted for publication in GLEANINGS that are so poor that one can hardly distinguish the details in the photograph itself. Of course, in the process of making an engraving some of the detail is lost, and in printing there is a still further loss. Consequently, a photograph suitable for reproduction must be very good indeed.

As we have stated before, we receive far more photographs than we can possibly use. Ordinarily, we prefer those which are instructive, or which are necessary to illustrate some point in an article.

Lately we have received several photographs from different parties that were almost ruined by pencil-marks made on the back with a hard pencil, the indentation of which showed on the face of the picture. We always like to have the name and address written on the back of the photograph; but in doing this one should use a pen or soft pencil, and lay the picture on something hard. If a hard pencil is used, and the photograph lies on a blotter, for

instance, every mark shows thru. No writing of any kind, either with pencil or pen, should be done on the face of the picture.

Bee Inspection in Connecticut

IN a small state the problem of eradicating bee diseases is just as important as in the larger states, altho the smaller area to be covered reduces traveling expense so that the cost of inspection can be kept low.

In Connecticut there are two inspectors—H. W. Coley, of Westport, who has the four southern counties, Fairfield, New Haven, Middlesex, and New London, and A. W. Yates, of Hartford, who has the four northern counties, Litchfield, Hartford, Tolland, and Windham. The inspectors have the situation well in hand, according to the report of the Connecticut Agricultural Experiment Station for 1915. European foul brood is the disease found most frequently, altho there is some American foul brood as well as sacbrood. In 1915 a larger proportion of apiaries and colonies were found free from disease than ever before.

A summary of the inspection is as follows:

	Apr.	Col.
Number inspected.....	424	1494
Infested European foul brood....	129	441
Per cent infested.....	26.1	10.3
Infested American foul brood... 4	8	
Per cent infested.....	.8	.18
Pickled or sacbrood.....	10	20
Average No. colonies per apiary.		8.58
Cost of inspection.....		\$746.31
Average cost per apiary.....		1.51
Average cost per colony.....		.175

Favorable Spring for Bees

WHILE the spring is a little late, and fruit-bloom has been delayed, the conditions were never better for bees. With the exceptions noted in our last issue, bees have wintered unusually well. While the spring has been backward it has not been such as to cause serious spring dwindling. In fact, none has been reported. The very fact that fruit-bloom has been delayed by the inelement weather makes it apparent that the bees will have a good chance to get at the blossoms without spells of bad weather shutting them off. When trees come into bloom in April in our locality, it means that the bees may not have more than a couple of hours' work on the blossoms. But here it is May 8. Cherry-trees have just opened, and fruit-trees are just starting. One of our colonies, according to one of the bee-inspectors, Mr. A. C. Ames, has already 15 lbs. of new honey; and others have quite a sprinkling all

thru the hives. This will mean a tremendous boost to brood-rearing, and, in the case of the stronger colonies, swarming.

Short Course for Beekeeping at the Massachusetts Agricultural College

WE desire to call especial attention to the photograph on page 398 of the class in beekeeping at the Massachusetts Agricultural College, while on an excursion to the historic apiary where Langstroth carried on his experiments. This class has proven very popular; and with so good a man as Dr. Gates in charge, it is no wonder. Those who are able to profit by this opportunity should be congratulated on being able to take advantage of such instruction.

A general announcement of this Short Course appeared on advertising page 18 of our last issue. Those desiring to enroll in this class must register early, since the number that can be accommodated is limited. If there is a large attendance the work has to be divided up, making it difficult to handle the students. Fifteen is the preferred number.

"Near" Honey

SOME time ago our attention was called to an advertisement of a recipe for a honey substitute. With our antieipations running high, we sent our five two-cent stamps and received the following, written in pencil:

"A good recipe for an article resembling honey, but not honey, is made by taking glucose and reducing it to the consistency of strained honey. When cool, add one dram of pot. alum to the gal., first dissolved in a small portion of the dilute glucose. Add a small portion at a time of rose flavoring extract until the mixture has the right flavor."

We wonder what the "right flavor" would be in this case. Probably the first small portion would give a flavor about right for clover or sage honey, the second for basswood, third for aster, and so on up to buckwheat. We wonder how many more small portions would have to be added to make chincapin honey!

Beekeeping in the South Atlantic States, Again—a Correction

A CORRESPONDENT, referring to our report of Dr. Phillips' address in our April 1st issue, page 259, regarding box-hive beekeeping in the south Atlantic states, complains that not all the beekeepers in this portion of the country are in the box-hive

class—that there are many progressive and up-to-date beekeepers there.

It is but fair to say that Dr. Phillips in his address at the Chicago convention went on to state that some of the best beekeepers in the country were located in that portion of the Southland, and that what he was about to say represented only those beekeepers up in the mountain districts and other portions of the state remote from towns and cities. The omission, therefore, was no fault of Dr. Phillips, but, rather, our own. Our apologies are due, therefore, to our correspondent, and to Dr. Phillips in particular.

Locating Outyards; the Importance of Shrubbery or Trees

AT this time of the year many outyards will be located; and it is important to place them where the individual hives will be screened from each other. When all the hives are placed out in the open, every hive is in plain view of every other one, cross-bees are more inclined to follow their owner all over the yard. Experience has shown over and over again that an outyard of bees located in the midst of shrubbery will be comparatively tractable, while the same yard of bees, when put into an open yard may become cross.* The reason of this is very plain. When the operator or the hives are screened from general view these stray angry bees lose sight of the operator as he moves about, with the result that he can work all day in quiet without a veil, and with very little smoke. It is probable that the vision of bees at close range outdoors is not very good; at all events, it is very easy to dodge them. We have frequently, when followed by angry bees, merely stepped behind a bush or a tree, and then gone on to another portion of the lot unmolested.

Of course, it is not always practicable to locate apiaries in favorable spots, and one is compelled to take what he can get rather than what he would like.

In locating one or two hives in a back lot in town, it is important to place these hives where the bees do not get a general view of the entire premises except as they fly up to go to the field. When out in quest of stores they are usually very quiet and gentle. Trouble between neighbors can very often be averted by so placing the hives that the surroundings will be of the character we have described.

* Over and over again we have discovered that the same bees that were gentle at the home yard, where each hive is behind a trellis of grapevines, would often be mean to handle at outyards placed out in the open, where every hive is in view of the other.

Self-Sterility of Sweet Cherries; the Value of Bees as Pollinators

THE following from the *Fruit Grower* of St. Joseph, Mo., April 1, 1916, is both interesting and valuable. Statements of this kind are not prejudiced in favor of the bees, hence are of all the more value.

It has become more and more apparent during the past few years that a number of varieties of sweet cherries grown commercially in Oregon failed to bear, from no apparent reason. This seeming mystery has attracted so much attention that finally it was decided by the state experiment station authorities to make some experiments to determine the cause, if possible. The first of these experiments was undertaken primarily for purposes of breeding tests, and the results obtained pointed so clearly to self-sterility that they were continued with the idea of testing the latter condition, rather than as a further breeding trial.

The experiments were conducted, both at The Dalles and Corvallis, with quite similar results in each case. It was found that for all practical purposes Bing, Lambert, and Napoleon (Royal Ann) were self-sterile. Cross-pollination was then tried, and they were found to be also inter-sterile. The fact which at first seemed to be somewhat mysterious, that this lack of fertility in the blossoms was apparently only of recent occurrence, was finally explained by noting that practically all the solid blocks of any size had been planted within recent years, and that the older orchards contained a greater number of varieties, including a few seedlings in most cases.

The most careful tests were made during three years, and the following conclusions were reached: It is necessary to set a number of varieties together in order to insure pollination that will produce a profitable setting of fruit. If there are a few trees of Black Republican, Black Tartarian, or even seedlings near the Bings, Lamberts, or Napoleons, they should be allowed to remain, and if necessary a few trees may be top-worked to these varieties in order to provide pollinators. If nothing better can be done until these latter can be secured, a number of large branches of these known pollinators may be cut and placed thruout the orchard in pails or kegs of water, just before the blossoms open. While this will not be likely to give a maximum crop of fruit, yet the results will probably be such as to make it profitable.

Probably about one tree in every six or eight, scattered thru the blocks of Bing, Lambert, or Napoleon, will be sufficient for the purpose of pollination. It should be remembered that the three varieties named are inter-sterile, as well as self-sterile. This means that they will neither pollinate themselves nor each other. Their pollen is not of itself sterile, for it will fertilize a num-

ber of other varieties, but is neutral when applied to any of the three named.

The method of fertilizing by means of seedling branches cut off and placed upright in receptacles of water thru the orchard, was tried by one grower in 1914, and the yield of his trees was increased to three times what it had been previously.

The importance of bees as agents for the dissemination of pollen cannot be over-emphasized. In the case mentioned a number of swarms of bees were placed thruout the orchard along with the seedling branches at blooming time. No matter what other favorable conditions are present for cross-pollination, it will not be effected unless bees or other insects are present to carry the pollen from tree to tree. There is no doubt that many cherry orchards that are now shy bearers could be greatly improved by the introduction of a number of swarms of bees.

As pollinators for the Bing, Lambert, and Napoleon, the Black Republican, Black Tartarian, and Waterhouse take first rank, but Elton, Wood, Coe, Major Francis, and Early Purple were also found to be good, altho somewhat variable in their results.

At least some of the sour varieties of cherries are capable of pollinating the sweet cherries. The ability of a variety of cherry to set fruit is not altogether dependent upon pollination. Soil and climatic conditions are also factors in the case. While, so far as we know, no experiments of this character have been made in the Middle West, it may be worth while to investigate along the lines mapped out by the Oregon station.

An Unfortunate Theory; More Proof Needed

PROF. H. A. GOSSARD, Entomologist of our Agricultural Experiment Station, Wooster, Ohio, and one for whom we have a regard, has just issued a bulletin entitled "The Role of Insects as Carriers of Fire-blight." Since he attempts to prove that the honeybee is eminently injurious in spreading this disease, we desire to examine his arguments. In doing this the editor admits, of course, his prejudice in favor of the bee; but it is obvious that any attempt to incriminate the bee should be backed by proof; and in our opinion Professor Gossard has come short in furnishing such proof.

He begins by quoting extensively from a paper by Prof. M. C. Waite, of the Department of Agriculture, read before the National Beekeepers' Association (32d annual meeting, Buffalo, New York, September, 1901), in which this author gave his evidence that the honeybee can and does carry blight. The editor remembers this paper well, because he had the pleasure of

presiding at the National when this was read. The evidence presented by Professor Waite has been accepted by the beekeepers as conclusive because of its thoroughness. He called attention to the fact that flies, wasps, and other insects swarm over the exuding sap on hold-over cankers, and fly to the opening blossoms. So far we have seen no evidence that bees do this, the only previous claim of their part in carrying the disease being in conveying the blight organism from blossom to blossom.

Professor Gossard admits that weather conditions of the past few seasons in Ohio have encouraged the multiplication of aphids in early spring, and that these must play a large part in starting off the infection early in the season. He does not indicate why he thinks them instrumental simply in "starting off" the infection. Prof. J. H. Merrill, of the Kansas Agricultural Experiment Station, showed in a paper published in the *Journal of Economic Entomology*, August, 1915, Vol. VIII, p. 402, that a control of aphids by spraying with "Black-leaf 40" practically eliminated blight in Doniphan County, Kansas. Similar results have been obtained elsewhere. While other entomologists are rapidly vindicating the bee, our Ohio entomologist seems to be working on another line.

Professor Gossard also quotes from an article which he intends to publish in the *Journal of Economic Entomology*. In this he has proven the following points: The bacillus which causes fireblight has not been found in old honey in early spring nor in fresh apple honey, altho in one hive the bees were certainly working on blighted blossoms. When the bacteria were artificially placed either in sterilized or unsterilized honey, they lived for nearly two days, and it would seem that they are finally killed in honey, altho this is not clear in the paper. There is no reason to believe that they grow in honey, altho he thinks this might be possible.

These facts should satisfy any prejudiced defender of the bee, to whom Professor Gossard jokingly gives the name "bee monomaniac." Unfortunately the rest of the paper contains "inferences," "presumptions," and phrases like "it stands a good chance," "inferential evidence," and similar expressions which might lead one to believe that he is anxious to prove something on the bee. He even says, "In an attempt to connect definitely the hive," and in another place, "the direct evidence we are seeking, i. e., to prove the hive an infection center," are expressions which do not indicate the right scientific spirit. Bee-

keepers will not deny proven facts derogatory to bees, but we candidly are not in sympathy with attempts to secure proof to bolster up a preconceived idea.

Professor Gossard evidently thinks that the reason blight spreads so rapidly is that the bacteria are carried to the hive, accidentally distributed among the bees, and then carried out to thousands of blossoms. Evidently, if this is true the bee is more harmful than any other insect. Since he has no proof that this is the case, and since he never found the bacteria in the hive, the theory is as yet pure speculation.

The nature of the inferences will be evident from the following quotation: "We believe we have proved that if one bee carries 100,000 bacilli into the hive one day, that on the following one or two days each of 1000 bees has the possibility of carrying a considerable fraction of 100 virulent bacilli out to fruit-blossoms, because practically all the bees in the hive are at work during the night curing the honey." In reply to such speculation, let us speculate also that by the next day over nine-tenths of the contaminated honey is already eaten and digested, and surely Professor Gossard will not assume that the bacilli are filtered out. The rest is stored so that, while a bee may be contaminated, a "considerable fraction" of the organisms will have ceased to trouble the fruit-grower. It is very seldom that any fruit-bloom honey is stored. At that time of the year brood-rearing is nearly at its height, and practically all of the nectar gathered is used immediately. So far Prof. Gossard has not found the organism in the stored honey; and even when he introduced it artificially it did not live. His evidence is negative so far.

It would be possible to go thru the paper and point out many unproven suppositions and what appear to us to be unscientific conclusions—even in the face of the facts which are actually helpful to the beekeeper's estimate of his bees. The author says, "My purpose in investigating the hive has been solely with the object of emphasizing the need of cutting off the supply of blight organisms before they reach the hive." We could wish that his object had been solely to find out what part the bee and other insects play in carrying fireblight, and that he had carried out his investigations with a more open mind, and let the truth come where it may instead of putting himself in the position of "an attempt to connect definitely the hive." We hope, however, that he will not drop the problem until he has found out how much truth there is in his theory.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

J. L. BYER, p. 349, says sweet-clover honey is very much inferior to alsike or white clover. May be, if pure. Here it gives a vanilla flavor to clover honey that is delightful. Too much of that-flavor might be objectionable.

R. F. WIXON, p. 363, when settled weather comes, swaps an outside brood for an inside one, repeats it a week later, and in another week puts an empty comb in the center of the brood-nest. Now, I wonder what makes the difference; is it locality, bees, or what? If I should do that it would give a bad set-back. For the bees of themselves have all the brood they can cover, and spreading can cause only delay, unless it be chilled brood. Are there some bees that fail to have all the brood they can cover unless their combs are spread?

WHEN J. E. Crane finds a colony with larvæ in queen-cells, and the queen is old, he removes her and kills cells, kills them again 8 days later, and 8 days later still gives a virgin, p. 359. That leaves the colony 24 days or longer without egg-laying. I wonder if that time might not be safely shortened. How would it do to give a laying queen instead of a virgin? That makes only 16 days without eggs. Allen Latham, p. 363, gives a ripe cell at removal of queen. But he does that before cells are started, and sometimes the colony swarms later. I have generally had success by caging or removing the queen, killing cells at the same time, killing them again ten days later, and freeing or returning the queen. If a *young* queen were given in place of the old one at the end of the ten days, not one in a hundred swarmed.

I've always said that beekeeping could never be on a stable footing so long as there is no law against planting another apiary right beside you. In some of the states of Australia you can make sure that no one shall have an apiary within two miles of yours by paying annually about \$20.00. Worth it, too, isn't it?

Later.—Since writing the foregoing, comes GLEANINGS, May 1, in which J. L. Byer says, p. 349, he never expects there will be on this continent a law defining where a man can plant an apiary. Why not? Aren't there just as good brains here as in Australia? And if satisfactory restrictive laws can be made there, they can be made here. All that is needed is for beekeepers to say they want such laws.

Some day they will; for it is not for the interests of either producer or consumer to have beekeeping such an insecure business. I'm satisfied that there are now three times—may be ten times—as many beekeepers as there were forty years ago, who would like to see beekeeping on a solid basis.

GARDNER B. WILLIS, p. 156, describes what is undoubtedly the work of the larvæ of a bee-moth, a much smaller affair than the common bee-moth, *Galleria mellonella*. A cluster of three or four bees, fully matured and fully colored, will be seen constantly wriggling in their cells, unable to get out. Dig down to the bottom of the cells and you will find the small larvæ of what Cook calls the "Wee" bee-moth, *Ephesta interpunctella*, and Sidney Olliff, in A B C and X Y Z, calls the lesser beeswax-moth, *Achroca Grissella*. I've seen it but a few times in my life, and I think it amounts to little in this region, altho it may be worse elsewhere.

AN Illinois correspondent had a strong colony in a two-story ten-frame hive (20 frames in all) which went into winter with 78 to 80 pounds of good honey by actual weight. March 14, flew strongly; April 1, all dead. No honey in upper story; 45 pounds in lower story; combs clean; all bees (about 10 quarts clinging closely to combs, even to those in lower story which had honey in them. Query: What was the trouble? A plain case of starvation. The cluster was in the upper story, and when the honey in that was consumed it was too cold to leave the cluster, and the honey in the lower story might as well have been a mile away. But how about those bees that were on the combs of honey below? When a colony starves, some of the bees in their death-struggle crawl away from the cluster, apparently only desiring to die elsewhere, and may be seen hanging in peculiar fashion to the entrance and front of the hive. In this case they had strength only to get down to the sealed honey, but no strength to get the honey. Likely enough the disaster might not have happened if in the fall the two stories had exchanged places. [We do not know why this is true; but bees when starving will separate themselves from the main bunch in small clusters. We have observed this time and time again in bees that have come in combless packages from the South. If the candy has run short there will be little bunches of bees detached from the main cluster.—Ed.]

SIFTINGS

Middlebury, Vt.

HOW THE BEES HAVE WINTERED.

Bees have generally wintered well here in western Vermont, altho March was the coldest known for thirty years. I notice that bees almost invariably winter well after a good season.

* * *

I am greatly interested in Mr. Byer's whopper colony of bees he mentions on page 267, April 1. We hope we may hear from it again, and that the capacity of the bees to gather honey will be as great as the fecundity of the queen.

* * *

I am glad Prof. E. G. Baldwin, of Deland, Florida, is to test thoroly the question of bees in fertilizing the flowers of the orange about Deland, and settle, if possible, the value of bees in orange-groves in Florida. I believe that, as we study this whole subject, we shall meet with many surprises.

* * *

Mr. Doolittle gives his opinion on page 268, April 1, as to the best bees. He says that queens of one or two generations from imported leather-colored queens crossed or mated to drones in no way related are the best for extracted honey; while for white comb honey there is nothing better than the golden Italians. How about the wonderful improvements some breeders claim to have made?

* * *

One is reminded of the size of our country and variety of climate from Mr. Scholl's statements on page 223, March 15, when he informs us that in Texas it is the proper time to clean up beeyards as well as beehives, while here in Vermont the snow was two feet deep on a level, and many of our hives were entirely out of sight under snow-drifts and the mercury playing about zero.

* * *

Mr. P. C. Chadwick's notes on the navel-orange blossoms, page 264, April 1, are of special value in the discussion of the value of bees in the fertilization of fruit-blossoms. It shows very conclusively that bees are quite unnecessary, and cannot in any way be helpful. The surprising thing about the navel orange is that it should grow so large and be so perfectly developed without producing seeds. There are several varieties of seedless grapes, but so far as I know they are, without exception, all small.

Mr. Doolittle's experience and experiments as given on page 226, March 15, add to our evidence that European foul brood is not transmitted from hive to hive thru honey. This is a most important matter as bearing on the necessary treatment of diseased colonies. What we want to know further is whether this is *always* true, or does honey from a colony having European foul brood sometimes transmit disease? What we want is facts, not opinions or theories.

* * *

Don't forget the postage-stamps, says the editor, page 218, March 15. Of course it is forgetfulness; but it seems sometimes almost inexcusable when a stranger asks you to take time and paper to answer his questions, and then forgets to pay the postage. I received a letter from a gentleman a few days ago asking for some information, and he enclosed two stamps, and then wrote me a note thanking me for what I had done for him. We all love to be appreciated.

* * *

On opening hives this spring in early April we found an unusual amount of brood, notwithstanding an unusually cold March, and we almost instinctively ask how this can be. One reason is that most colonies went into winter quarters strong in bees. Another is that the excessive cold of March was favorable to brood-rearing. Dr. Phillips tells us that, when the temperature outside of a cluster of bees gets below 57 degrees, the temperature inside of the cluster rises. I have found a summer temperature inside a cluster with mercury below zero outside the hive. So it would seem that bees have bred freely during the cold month of March.

* * *

That picture of Mr. Chadwick's yard, page 184, March 1, took my eye. I have often wished I might visit him, and now I can look on one of his yards. How true and level the hives stand! and those great hills or mountains in the rear! How easy to wheel the honey to the house! And then that class of beekeepers at the Ontario Agricultural College! How we wish we could have been among them, for we are never too old to learn! Again, I see the home and workshop of H. B. Phillips, page 204, of Auburn, Me., with whom we have transacted business for many years. He does a large business in selling comb and extracted honey, altho he is totally deaf.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

A very practical and successful beekeeper recently made the remark that old black combs are breeders of disease, and that it is next to impossible to eradicate disease when using them. With new combs he claims the work is half accomplished before beginning.

A California beekeeper of some prominence once said: "The bee business is the most hopeful business of any and all businesses." He was right. Honey cannot be measured on prospects of the season. But hopes remain when reason seems to have fled.

I have just extracted nearly two tons of the finest orange honey I have ever been able to secure. Had this immense flow, with the unprecedented good weather during the orange-blooming season, been one month later, it would have been an easy matter to secure five or six tons.

In a recent letter from Mr. Doolittle I am informed of his severe illness with heart trouble. It is to be hoped that his condition may improve, and that we may yet enjoy reading many pages of his work in the columns of GLEANINGS. Mr. Doolittle, to my notion, is one of the few *very able* writers of his day.

At this writing the season appears to me as one that is to be full of disappointments as to final results. The hoped-for late rains have failed to appear, with the result that the button sage is not yielding as was expected, and the chances for the flow from the later-blooming plants diminishing as the bright sunshine daily takes its toll of moisture from the soil.

In viewing the list of officers of the United Honey-producers of America, one is led to wonder if it is not really an Indiana concern, and inclined to favor Indiana producers. It seems to the writer that it is a poor policy to expect a heavy following with an organization so centralized. That has been tried in our state. It is impossible to amalgamate the interests of beekeepers even in a state like our own, with all of the officers in one end of the state. With a national organization the task is even great-

er. [We believe the plan is to have a vice-president from each state.—Ed.]

After thirty years among the bees I have experienced what I call a disastrous honey-flow. How can a honey-flow be disastrous? A few months ago I could not have believed that such a condition would in any likelihood arise, but with me it did. In my notes I have pointed out from time to time the winter conditions in this state. Our winter, as will be remembered, was one of extremely heavy rains, and more than the usual amount of cold, at times with snow. The rains stopped abruptly, and gave way to an unusually early and warm spring. On March 1 I think I never saw my bees in a more promising condition, and the work of my young queens was all that could be asked for. Two weeks later the orange began blooming in earnest, and the flow of nectar was never greater. The results were that, within a period of ten days, my queens were blocked with honey and nectar, and relieving the situation seemed to be an impossible task. There were few colonies at that date that were ready for storing nectar in the supers; for, indeed, the bee force was lacking to perform the work. The nights were cold, as is always the case at this time of the year, and the nectar was placed close into the brood-nest. In this manner the work of the queens was stopped abruptly. To place dry combs in the brood-nest was of no avail, for it was immediately used to hold the onrush of nectar. To place foundation in the brood-nest gave very little aid, for in the greater number of cases there was not a sufficient number of bees at that time to draw it readily; or if it was drawn it was in most cases filled with nectar before the cells were half drawn. The disastrous feature of the situation was in the fact that brood-rearing seemed to have been forgotten in the mad rush to the orange, and even the cells where brood was hatching were promptly filled with honey. A more exasperating situation could hardly be imagined. Here was a wonderful flow of nectar, with too few bees to store it in the extracting-supers, so it was literally drowning the life out of the colonies. Had the flow come a month later it would have been one of immense value, and the results could have been only for the best; but as it was, the bee force for later work became so curtailed that the results of the season for me have become doubtful.

E. G. Baldwin

FLORIDA SUNSHINE

Deland, Fla.

THE BEE FLORA OF FLORIDA.

I venture the assertion that no other query is so often propounded to me, by letter and by word of mouth, as this, "What do my bees gather mostly in Florida? and how shall I get them in best condition for the honey-flow?" With the hope of being of real service to the inexperienced, in our own state and possibly answering the unspoken inquiries of some outside of our state who may be looking with longing eyes to our borders, and who wish to know the sources and methods best adapted for those honey-flows, I purpose to give soon a short series of suggestions on the bee flora of Florida, with a practical end in view. I shall try to follow, chronologically, the order of blooming of the various sources of honeys, and detail, not too fully, methods that have been found practicable, and mainly successful for each source of honey in the various sections of the state. I might add right here that by reference to p. 175, March 15, 1911, a map will be seen showing the state to possess six main sources of honey—that is, surplus honey—honey in sufficient quantities to find its way into the markets of the country. These will be seen to include the region of tupelo, the partridge pea, and chanquapin, the orange section, the palmetto (saw and cabbage), and the black mangrove, with the very limited area of the manchineel in the southeast. I ought, probably, to include pennyroyal, tho it has not been important, commercially, till recently. I am told it was formerly very important, being first discovered, if I recollect aright, by that pioneer, O. O. Poppleton, near Tampa. He it was who first called the attention of beemen to this member of the mint family, and its importance to beemen, away back in the '80's. Latterly it is assuming more prominence. More of this later. Its best area is south of Tampa, probably south of Bradentown, and across the state, east and west, from about Bradentown, including most of the high pine lands south of that imaginary line.

WONDERS NEVER CEASE.

This year the orange bloom made me feel a perfect ignoramus in Florida seasons and sources. For sixteen years I have not known orange honey to be stored in surplus chambers after April 10. Mark well. Here it is the 23d, and bees are working harder on orange bloom than they did in the middle of March, our usual flood season for that

honey; and that, too, after practically a week's cessation altogether. I was facing a total failure, in fact. All beemen in orange sections had made up their minds to a failure. The bloom was so scant, to use a Cracker term, "It was the sorriest bloom since the freeze," and cold, during even that little bloom. No wonder we got no honey. And now, after a little rain, but mostly after genial and warm weather, the tardy growth of new sprigs is appearing, and in many instances these new growths are covered densely with little buds or "pinheads," we call them. Many are opening and yielding right now, and bees are storing in supers right along—not rapidly, yet, but more every day; and these new blossoms will be opening more and more for two or three weeks. I see no reason why half a crop, perhaps, may not still be secured in favored locations, and a fourth, perhaps, in most orange sections. That is better than nothing. The bees work well in the mornings. The yard roars as in the midst of swarming-time. About ten o'clock there is marked diminution, due to the heat and drouth combined, which dries up the nectar in the blossoms; but about two or half-past, in the afternoon, they begin again, and about four the yard is alive with flying bees again that continue to fall, weighted and weary, on the alighting-board till long after sunset. I had taken my hive off the scales, but have placed it back on, and am looking for some interesting data. More later. It is going to make our extracting come in May, tho, instead of April, as usual. You can imagine what splendid opportunities this gives us to requiren. I have practically requirened my entire home yard, and am going at the outyards now. Breed—I never saw anything like it—easiest thing in the world to get cells as long as the last joint in my middle finger, and, best of all, no swarming. Dr. Phillips, tell us why. I want to say more later about this swarming. We are getting some interesting data along that line this year. I have known of only two swarms in the county thus far this spring.

Book-keeper, Beekeeper.

While my duties as individual book-keeper in a bank keep me very busily employed I manage to secure some 3000 lbs. of honey each year from sixty colonies of bees. Many colonies give me 100 lbs. or more of surplus.
Pine Bluffs, Ark. J. E. Clarke.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

A MARCH HONEY CROP.

Contrary to our expectations, on account of the drouthy conditions early in spring, the mesquite bloomed very profusely, and almost a month earlier than usual.

The mesquite ordinarily blooms in April in south-central Texas, and again in July, in favorable years. This year the colonies were hardly strong enough to harvest the mesquite honey—at least in the fore part of the blooming period. As it lasted longer than the three weeks, however, the bees increased rapidly on account of the large amount of brood when the flow began.

Another obstacle was the coolness of the nights and early mornings, and the many days of high winds that interfered greatly with harvesting a good crop. An average of 35 pounds, half comb, the rest extracted honey, is about the quantity our own bees succeeded in storing.

FORCING HONEY INTO SUPERS.

This spring afforded us a most convincing experience in favor of a divisible brood-chamber. When the early honey came it did not take long for the bees to block up the upper portion of the brood-chamber with honey, and seal it. This soon crowded the brood-nest to a mere handful of brood, and also kept the bees from doing the best work in the supers above, on account of their dislike to work above sealed stores and far from the brood-nest.

Here was the same old condition of nearly twenty years ago, and for which reason I adopted the divisible hive. What did we do? When supering time arrived, and we discovered this condition of the hives, we did not place a single super on a divisible hive before first "switching" the two halves of the brood-chamber. We proceeded in this manner: We worked in forces of two men, one armed with smoker and hive-tool, for smoking the bees and prying the hive sections apart. The other then first lifted off the shallow extracting-super on the hive, setting it aside. He next lifted the upper half of the divisible brood-chamber and held it while the former, after smoking the bees as needed, lifted off the lower half, and set it on top of the former upper half that had been rapidly placed on the bottom-board by the assistant who held it ready for this purpose. Thus the two halves were completely reversed or interchanged. The objectionable sealed honey was now below, from which place the bees would remove it.

The biggest part of the brood was thrown right up to the top of the brood-chamber.

The new super, with foundation in full sheets, was then set on the newly changed hive, and the shallow extracting-super, more or less full of honey at this time, replaced on top of all, and the bees went right to work and yielded results over the loafing colonies of deep-frame hives that could not be thus easily manipulated. This manipulation, which is accomplished very rapidly, also stirs the colony into new life and activity. I have claimed that it "stirred new energy into the bees" when that question was up for discussion some time ago.

That it "knocks swarming in the head," as I have often claimed in these columns, there is not the least doubt in my mind. Besides putting the colonies to work, and where we want them to work, the new cell room provided in the center of the brood-chamber affords plenty of laying room for the queen and consequent contentment of the colonies. The combs were, before the change, more or less devoid of brood or honey next to the bottom-board. When placed above in the changing of the two halves of the brood-chamber this empty comb room came in the middle of the brood-nest. The bees removing the honey from what were the former objectionable sealed combs of honey above, but now below, also provided additional laying room. In fact, an entire reorganization of the brood-nest took place as well as of the whole colony, and that with excellent results. I cannot obtain them with the deep hives scattered in most of my apiaries.

MORE UNIFORM QUALITY AND BETTER PRICES.

There has been some complaint on the part of a good many beekeepers in regard to the low price of honey in comparison with other products. It has been a source of pleasure to me to have been so situated as to be enabled to look into such matters, perhaps, a little more thoroly. This opportunity has revealed that there are several causes in addition to supply and demand that have to do with the regulation of prices of any product.

During the last few months I have had an opportunity to observe the many varying methods of packing for market, not only bulk comb honey but extracted as well. Out of over fifty lots of honey observed during the last several months there were not two packed alike. There was also an exceedingly great difference in the flavor

and quality of the honey. Not any of it was packed according to the standard fixed so deeply in my mind.

In my opinion, a ruling of higher prices than we have been able to obtain need not be expected until there is a much more uniform method of packing the honey for the market as well as a more uniform grading. "Honey is not honey," as it used to be when the market was less educated. There is always a good demand for a better quality of honey, while the poorer kinds have to hunt for a market. But this is not all. The poorer grades affect the market materially in "pulling down" the price of the better grades. That is why we suffer from prices lower than they ought to be, even when the supply is not so large. Here is work for our organizations to spend a good deal of time on during this year, and before the new crop is ready for market.

THE PROPER TIME TO MOVE BEES.

I have tried to ascertain for some time whether there is any material difference in the time of winter or early spring moving of bees, and the effect upon the colonies of bees themselves.

In moving bees to new locations I have observed that those which are transported very early in the year or during the winter before any brood-rearing had begun to any extent continue in fine condition throughout the entire year. Apiaries that are moved somewhat later, with brood-rearing already well under way, but the weather yet quite changeable, and very cool nights predominating, seem to be more or less affected by the move according to the time and weather conditions prevailing. Later moves of bees to new locations, after the weather becomes more settled, altho brood-rearing was further advanced, apparently escape the bad results. It is apparent that there is a difference in the welfare of apiaries of bees moved at different times of the season and in different stages of development of the colonies as well as a marked difference in the honey yields.

Is it possible that colonies moved after brood-rearing has advanced to a certain degree, with unfavorable weather conditions still prevailing, may not be able to take care of the brood as properly as to preserve the welfare of the colonies? Is it possible that the disturbance causes not only the brood to suffer materially, but the old bees as well? The bees wintered over from the preceding season are becoming older from day to day, and dying off rather rapidly. The nurse bees are not of the proper age for best results. It is difficult, too, with bad weather conditions, to get water and fresh pollen; and even with a supply in the

hives, the cool weather is not very favorable for rapid progress in brood development; and the decreasing number of bees apparently often have a difficult time to keep the slowly increasing brood-nest warm. The colonies are in a critical condition at this moment, and the least disturbance must have an effect upon their welfare. Is it not possible, then, that this is not the best time to disturb them by subjecting them to the severe test of moving to new locations?

It seems that, in the event earlier moving is not possible, it is better to wait until settled warm weather has arrived, and the colonies have had an opportunity to build up in numbers so that the brood can be better cared for. Under such favorable-conditions there need be no bad results. Our experience has proven, in addition to the above, that colonies moved later, especially just before a honey-flow, show increased vim and vigor, and yield more excellent crops of honey than those not disturbed. It seems that the shaking-up of the colonies at this stage of development stirs them to greater activities.

* * *

The Guadalupe Valley Beekeepers' Association is a new district organization launched recently at Seguin, Texas. Guadalupe, Comal, and Hays counties are at present in this district, with adjoining counties to come in later. Jon. Donegan, Seguin, is President; John Herbold, Seguin, Vice-president for Guadalupe Co.; H. Franke, San Marcos, Vice-president for Hays Co.; Herman Oelekens, New Braunfels, Vice-president for Comal Co.; Louis H. Scholl, New Braunfels, Secretary. A vice-president from each county is provided for in order that the counties may all have proper representation on the executive board.

Besides the business of organization, there was other discussion on beekeeping subjects, making an interesting gathering. Much enthusiasm was shown by those present. Regular quarterly meetings were decided upon, besides occasional outings and picnics and field days. Except for an initiation fee of one dollar there will be no dues. Funds, if needed, will be raised by a nominal assessment of the members.

Prof. Paddock, State Entomologist, of College Station, was present and addressed the meeting on the foul-brood work and the importance of beekeepers organizing themselves for the purpose of obtaining the appointment of apiary inspectors. The district inspector of the new organization is John Donegan, of Seguin. A standing committee on program and entertainment, and a committee on bee-disease eradication is also provided for.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

NATURAL SWARMING.

"I am aware that the older bee-keepers work mostly for the prevention of swarming; but many of us beginners like to see swarms issue, and learn some of the ways in which these swarms may be worked so as to secure a fairly good return in honey. When may prime swarms be expected to issue?"

Prime swarms may be expected when the first queen-cell is sealed over; but sometimes they come soon after the first egg is deposited in an embryo queen-cell. Some idea of the situation can be had by looking at the entrance of each hive about ten o'clock in the forenoon at the beginning of the white-honey harvest, or a little before. Colonies that are at work strong at this time of the day, and that cluster out at the entrance and fan their wings near sunset, may be expected to swarm soon.

Most prime swarms issue between 9 A. M. and 2 P. M. So few will issue outside of these hours that it hardly pays to keep close watch for swarms at other hours.

"I am told that swarms very often run away. If this is so, how can it be obviated?"

The absconding of prime swarms can be almost certainly prevented by clipping the wings of the queens previously. This is most conveniently done about the middle of May, at which time the fruit-trees are in bloom. At this time, at about 10 to 12, the larger part of the bees will be out after honey, and the queen is more easily found among the limited number of bees. Moreover, there is no danger from robber bees making a raid on the honey while we are looking for the queen.

Some cut only one of the wings on one side the first year, the other wing on the same side the next year, then one wing on the other side the third year; and, if the queen lives that long, the remaining wing the fourth year. In this way the age of any queen is kept trace of. However, most apiarists cut about half of the two wings on one side, which entirely precludes the queen from flying. Some take hold of all the wings in picking the queen up, and cut all of them off about half way up to the thorax. Those who practice this, claim that queens so clipped are very easily found when it is necessary for the apiarist to look for them.

A clipped queen runs out with the bees

just as tho she had her wings; and as she cannot fly she goes anywhere from two to ten feet from the hive on foot. Generally a dozen to fifty bees will gather about her after she ceases trying to go further on foot; and as soon as the swarm misses her they will return to the hive from which they came, running in with fanning wings. This generally attracts the few bees gathered around their queen, when, if the hive is near the ground, so that bees on foot can reach it, the bunch of bees set forth with fanning wings, and they and the queen return with the swarm, so that not one queen out of ten gets lost, even if the apiarist is not on hand to oversee things. When he is, he can soon find the queen, let her run into a small wire-cloth cage, and lay her at the entrance of the hive from which she came. Then when the bees return, and most of them are in the hive, the cage is opened and the queen allowed to run in. Of course, unless the queen-cells are cut they will swarm again the next day. Sometimes, even with the cutting of all cells, the swarming fever keeps on; so the better way is to set the old hive on a new stand as soon as the queen is found, or before the bees start to return, and put a prepared hive on the old place with the caged queen at the entrance. Then when the bees return they will hive themselves; then the queen is allowed to run in with the last half of the bees. This generally stops all after-swarming, and insures a good yield of section honey from the new colony. For the highest success in the production of comb honey strong swarms are desirable, and hiving swarms on the old stand not only conduces to their strength but has also a strong tendency to prevent the issuing of after-swarms.

It is not necessary to climb and cut limbs except on rare occasions where queens are not clipped. Allow the bees to cluster where they please, and, nine times out of ten, with two or three light poles of different lengths to which a basket or wire-cloth swarm-catcher can be attached near the further end, swarms that cluster out of reach may be shaken off and secured. Having the bees in the catcher, so there is no danger of other swarms coming out and uniting with them, as would be the case were they allowed to remain where they clustered, plenty of time can be taken to set the old hive off its stand and put a prepared hive on the old place if desired.

GENERAL CORRESPONDENCE

A NEW HOBBY FOR GIRLS

BY E. S. BRINTON

I believe in hobbies. What it is makes little difference so long as it is something that calls forth the best that is in one and not the worst. It should be something so interesting and entertaining that it will absorb the leisure hours, provide food for thought during idle moments, and quicken the desire for study and reading.

In taking up this subject my mind turns first to the girl of limited means and opportunities. She may be living in town or country. She has had a public-school education, but is ambitious to do more—hungry for outside interests, and to have and do something for herself; yet, because of finances, family conditions, or health, she cannot leave home or make any radical change in the routine of living. To this girl especially, I recommend beekeeping. It opens a door of marvelous interest. Thru it is a wide field for mental and physical development.

At the very beginning I wish to say I am not an expert in any phase of beekeeping, and cannot boast of phenomenal increase, high-bred queens, or great harvests of honey. I started with my first bees eight years ago, and now have six colonies—quite enough for a back yard that is supposed to be the family playground. We have honey to eat, to cook with, and to give away. The bees have paid expenses, and I have had no end of pleasure with them.

The cost of starting with bees is small. If good judgment is used, this hobby will not only pay expenses, but also yield a reasonable interest on the money invested; and to a girl who must count every penny, this item alone is worth considering.

Notice the different vocations and professions in which a girl will gain knowledge in connection with her hobby of bees. First, local botany and geography. She must start with her immediate neighborhood; study the trees, shrubs, and wild flowers and the time of their bloom—learning which will yield pollen and which nectar. She must know the nature of the farming country and how it influences the bees. In other words, are there large acreages of swamps to yield a fall crop of honey, or is it an upland region of clover, alfalfa, or buckwheat? Seasonal temperatures and weather conditions should be noted; for while books and bulletins give general directions,

every locality differs, and each one to a great extent must work out her own problems of management and wintering.

A knowledge of simple carpentering, and the use of tools and painting, is necessary; for to buy the hives already set up is extravagance. Full directions for fitting the pieces of hives come from the manufacturer, and any one who can read the patterns of crocheting and knitting can understand these.

The possession of honey in quantity will bring a desire to use it in cooking; to make syrups, honey ice cream, cakes, and candy. The Farmers' Bulletin on this subject will be an incentive for experimenting in the home kitchen.

Selling the surplus is a problem all its own. Probably the whole question of profits will depend on whether the girl herself can also become a good salesman and create a market for her honey, bees, and wax. To do this she must mingle with people, overcome any shyness she may have, and learn to talk interestingly and intelligently. She must adopt some scheme of keeping records of hives and queens. She must learn to correspond with business houses, to handle money, to do simple book-keeping and accounting.

A very important question arises—"How shall I begin beekeeping when I do not even know a bee when I see it?" Begin slowly. Don't do as one young man did who advertised for twenty-five colonies of Italian bees. He was fresh from the city, and had never been in contact with country life except for summer vacations, but even then he should have known better. Of course, he became discouraged, lost his nerve after a few stings, and by the second summer his bees were not in evidence. One colony of bees, properly cared for, with the usual annual increase, is sufficient to engage all your spare time and thought.

Read Kipling's story, "The Mother Hive," found in his book called "Actions and Reactions;" also Maeterlinck's "Life of the Bee." Beekeepers as a rule have little patience with the latter book on account of the mistaken idea that it is a text-book. It is not. The author says in the first sentence he did not intend it for a treatise or a practical hand-book. I value it for its inspirational description of the inside of the hive

Under the apple-tree. Backlot apiary of E. S. Brinton, West Chester, Pa.

and the habits of the bee. To the mere on-looker, bees are nothing but a crawling mass of insects without method or reason. Maeterlink gives each bee a duty and a place in the kingdom, with such vivid words that the most casual reader can comprehend it.

Now as to getting the bees. The cheapest and easiest way is to get some plain dark bees in an old box hive and do the improving yourself. I bought my colony from a neighbor, paid three dollars for it, and helped carry it home and set it down in the midst of my flower-garden. That was in March. In the meantime I ordered from a supply house two hives and two supers in the flat. Putting these together was as fascinating as a picture puzzle. I split some pieces with poor nailing and made mistakes with others, and finally painted too many surfaces of the hive; but I did it myself, and was wiser for the doing. In fruit-blossom time the bees were transferred to the new hive. That was a wonderful day, for I had my first glimpse of the inside of a hive, and learned to recognize the queen on sight. I knew nothing of the operation, but was assisted by a brother who had had a year or more of experience. The bees were as quiet as flies. We discarded all veils and gloves so as to work unhampered, and two small children played about and enjoyed the dripping honey.

That year was one of the record-breakers for a white-clover harvest; and so, even with all my interruptions, the bees gave me two supers of honey and I was tremendously proud of them. Then everything seemed to go wrong. Those bees, hitherto so peace-

ful and quiet, and absorbed in their own affairs, became possessed of tempers like that of Satan himself. After the honey harvest I attempted to introduce Italian queens. All the books said this was the ideal time. Instead of flying off to the fields in the morning these bees just loitered around at home waiting for something to happen—there seemed to be literally millions of them, and finding that restless black queen was worse than finding a needle in any haystack. Also I had such confidence in my control of them that the matter of self-protection was overlooked entirely. I was dressed to be comfortable for the summer season—short skirts, low shoes, elbow sleeves. Oh, yes! I wore a thin net veil and some kind of short light-weight gloves, so my fingers would not be clumsy. That was according to the books, only some advised cutting off the finger tips. Talk about losing my nerve! Before that job was done I wished I had never seen a bee. I was willing to forego eating honey forever, if some one would kindly remove the creatures from my back lawn!

Well, winter came at last. On the first cold day I picked up the hives and carried them off to a corner sheltered by apple-trees, so that their flight-line would not be directly over the lawn. Before another swarming season I successfully introduced Italian queens. There were far fewer bees to search over, and those were improved in temper. Never will I advise a simple-minded beginner in beekeeping to requeen a colony of hybrid bees in late summer. Do it in the spring, when you can work with ease and confidence. It were better to lose

some honey than every ounce of courage and all love for beekeeping.

There have been many recommendations regarding the kind of garb a girl should wear. I acknowledge the men with trousers have a decided advantage in some ways; but, nevertheless, I am not going to follow suit. I have found that with clipped queens there is no climbing of trees or ladders, nor does any circumstance ordinarily arise where skirts are really dangerous. There is a possibility of bees climbing up, and some women have spoken of being decidedly annoyed that way. That has troubled me very little, chiefly because I make sure the bees never have such an opportunity. I make it a practice not to walk or stand at the front of the hive, at least without making sure there are no stray bees just under me. Then when operating I either sit or kneel with skirts well spread out.

My preference is for a dress of white with skirt long enough to meet high-topped shoes. White is the coolest material possible, and it does not attract the bees as does a thick dark goods. It seems strange that, while they sense one's vulnerable spots around hands and ankles, they seldom attempt to sting the body itself. I have noticed that it is perfectly safe to wear a waist of the thinnest, sheerest material, while at the same time it may be necessary for comfort to use gloves. My gloves are

of the ten-cent cotton variety, with long muslin uppers. At first these were dipped in linseed oil to make them absolutely bee-proof, but I do not mind now. I have become sufficiently inoculated so that a sting means not more than half an hour of discomfort. At first my arms would swell and throb so that sleep would be impossible for two nights. I use a wire veil. I have never known a bee to get inside. The wind does not disturb it, and it does not tear on rose-thorns or trees.

I do not advise the large-sized hives, now so popular among professional beekeepers. The time of year when the necessity for moving the hives is most liable to occur is at swarming season (when the weight is probably the greatest); and the ordinary person is so fearful of stings that assistance is always difficult to secure. The eight-frame hive weighs fifty pounds and over when full, and is quite heavy enough to handle.

I have spoken of the advantage of bees as a hobby; but there are other things that will come from an intimate association with them besides a mere study of animal life or a possible financial gain—gentleness of touch, a quiet manner, self-control, a keen sense of observation, a deeper, broader knowledge that will give a more sympathetic understanding of all the wonders of our universe.

West Chester, Pa.

A BEE IN A CALIFORNIA BONNET

BY FLORENCE B. RICHARDSON

The bee has been in my bonnet for so many years now that I cannot imagine a bonnet trimmed otherwise. My courage was pretty good when I first reached the Golden State, for I had read all the lovely railroad prospectuses and all Dr. Cook's interesting articles in *GLEANINGS*; and when a fine swarm alighted on a tree near our new home I promptly hived it in a fruit-box with a couple of slats hastily nailed in. You see, when a person has always lived in a city, and kept bees on a city lot, where swarming had to be kept down and no stray swarms ever by any chance allowed to get away, why, a whole big swarm in a tree with no one's name tagged on to it looked pretty big to me.

Well, that swarm never did seem to do much, mainly for want of attention, I guess, or may be it was because of too much—one is never sure until afterward that he did just the wrong thing at the right time or the right thing at the wrong time.

However, one of our valley winds—more like a hurricane—came along and entirely demolished combs, bees, and all. The hive remained as a reminder of what might have been had I done thus and so.

After a time, however, I had an opportunity to buy ten colonies of bees in old box hives at my own price, the owner saying he'd "much rather run into a bunch of wildcats than to tackle a colony of bees." To digress a bit, I've often found that these "wildcat" people have either *never been* stung, or else once or twice has been the limit of their experience; and to see them go fishing and get chewed alive by black flies, or to see them sit on their porches and get liberally stung by mosquitoes with never a murmur in either case, is, to a rabid beekeeper, a bit inconsistent, to put it mildly.

When I first saw those bees they didn't look very strong, and, with the exception of three colonies, I expected to have to re-

Susan E. Howard, Stoneham, Mass., demonstrating that she is not afraid to give bees a shaking-up. See editorial.

queen; but it is a difficult matter to tell what a box hive may contain, so I made the offer of \$3.50 for the whole outfit just as it stood. He was glad to get it, and said he'd be better suited when the last one was gone. My family insist that he gave me the bees and sold me the honey at half price.

It was not possible to get the bees at once after I purchased them; and when they were finally brought to the house, several of the colonies had gathered honey in such quantities that two men had a bit of a struggle getting the hives up the steep grade that separates river bottom from plain. From about six hives we strained out 300 pounds of honey, and rendered about 30 pounds of pure yellow wax.

There is no more fascinating thing in beekeeping to me than transferring bees from an old box into a nice modern hive, and then watching them hustle. Of course, sometimes the hustle is missing along with

the queen; but with good care they nearly always make good colonies, and sometimes a really choice queen is discovered, as in the case of one colony in this lot. She has eight out of the ten frames entirely filled with brood, and the cappings of their honey are pure white. Those white cappings are the only sign of black blood they show, and I never handled gentler bees.

Last year, on the invitation of Miss L. D. Clark, of the California University Farm Extension work, I went to Davis, Cal., where the 44th fruit-growers' convention was held, and spoke twice to crowds of women on the possibilities, profits, and pleasures of beekeeping for women. My! but it was great to see the interest shown, and I know there are women from Shasta County to San Diego who are keeping bees at present because they feel that a woman can do so successfully. She certainly can.

Hughson, Cal.

STARTING WITH A SMALL LATE SWARM

BY JEAN WHITE

My own first experience with bees came about rather unexpectedly. I had always been much interested, but had delayed purchasing any, fearing my lack of knowledge might cause me to lose them. I had a well-defined determination to own a swarm or two of bees some day, but hoped to have an opportunity to learn more about them than I could get from a book, altho I had read a good deal about them.

One hot afternoon in mid July the men came in from the hayfield and said that a swarm of bees had settled on the trunk of a small tree by the roadside about five feet from the ground. In my wildest dreams of honey and honeybees I had never dreamed that a swarm would come to me; but I had no mind to let them leave me if I could avoid it. The men were wet with perspiration, and dared not mix up with such fiery-tongued visitors, so it was distinctly up to me to take them.

I got out my bee-book and turned to the chapter on hiving, and hastily perused it. A veil and gloves and a box for a hive were needed. I found a box about fifteen inches square, and nailed a board across the open end, leaving a slit an inch wide not covered. I put on my shade hat, tied a big chiffon veil over it and around my neck; put on thick driving-gloves, got a big turkey wing and a white table-cloth, and started out to experiment. My heart pounded fiercely with fright; but I would not give up to it,

so I spread my table-cloth at the foot of the tree and as far around it as possible; set my improvised hive on the cloth with the opening toward the tree-trunk, and boldly began to brush that clustered mass toward the ground. They clung more or less to the wing, and I brushed them into the opening of the box with hand and wing, and here I discovered that tight kid gloves are not a very successful protection for my hands; for where the kid stretched tight over my knuckles they stung thru it, tho not able to leave the sting in the wound. After a while one got on my veil over my chin, and lanced me finely thru the gauze stuff before I had presence of mind enough to slap it and put a stop to its mischief. I kept at work, and soon had the satisfaction of seeing the crawling mass hurrying into the box. When nearly all were in I left them, as it was nearly night.

I did not go near the bees again until after dark. They were quiet in the box, and I wrapped it in a piece of mosquito-netting and carried it to the house. Then I drove to town and procured a second-hand hive. I wanted to shake them into it that night, but was told that I had better set my hive where I wished to establish it, and shake them on to the entrance-board in the morning. This I did, and accomplished the feat without accident. When I removed my veil the night before, I bathed the stung places with a strong solution of chinisol.

Beekeeping class of the Massachusetts Agricultural College on an excursion to the historic apiary at Colrain, Mass., where Langstroth carried on his experiments. See editorial.

They were not much swollen, and the next day were only a trifle sore. I found later that I was practically immune to the poison, for, tho stung occasionally, I never suffered any particular inconvenience from the stings.

How I watched those bees! I would sit for hours close to the hive and watch them carry honey and their overloaded pollen-baskets into the hive. I was anxious to know what was going on inside; and after a couple of weeks I opened the hive, but I had put no foundation in the frames, and they had built their comb crosswise, and it was all connected together, so that I could not remove the frames to look them over. There were signs of brood in some of the combs that I could see, so I left them alone, satisfied that all was going well. In the fall I began to feed them syrup made of granulated sugar and water half and half.

I always bore in mind the admonition in my book, to move quietly, and therefore I

had no trouble with them. As cold weather came on I put blankets over the hive, covering top and side except the entrance side. This faced south so as to get the warmth of the sun. The day before Thanksgiving it began to snow, and, first covering the entrance with netting so that the bees would not fly out the hive was placed in the house cellar, which is dry and cool. The comb they had made was filled and capped, all but a very little of it. I had not expected any surplus honey as the swarm was late and not a large one. The hive was raised about two feet from the cellar bottom and kept dark.

I love my bees, and shall always keep them. Should I lose all I have I should look for the cause, then buy more to start a new apiary, and try to avoid future losses from any known cause. Bees are interesting and profitable. Their wisdom puts to shame the wisdom of man, and their product is most delicious.

Glover, Vt.

A BOY'S START WITH BEES

BY J. A. ALLARD

When quite small I was impressed by the only two things which I knew about bees—that they could sting, and make honey. I think that I was more impressed on several occasions by the first-named quality.

My uncles kept bees, and it was when I visited them that my interest was aroused.

The rows of clean white hives on a green background, and the hordes of yellow bees glistening in the bright sunlight, and ever working and humming, made a beautiful picture indeed.

When my uncle came home from work I plied him with eager questions, and he will-

ingly unfolded the story of the queen, drone, and workers; of the brood-nest, eggs, larvæ, and pupæ, and explained that the half-depth boxes were to hold the surplus honey, and he showed me an empty hive and section-super.

He then started a fire in a queer-looking little furnace, the smoker, and invited me to go along and see the bees and queen. I pointed to a bee-veil near by and asked him if we did not need it, for I was very much afraid of getting stung. He replied that he seldom used a veil, and promised that, if I did what he told me, I should not receive a single sting, so I decided to take the risk and follow along.

He singled out a hive, gave two or three slight puffs of smoke at the entrance, and gradually pried the cover up, puffing some smoke under it at one side as it came up. He told me to stand perfectly still, and not to make any quick moves. I expected to see probably a handful of bees; but as he lifted the cover there was a great roar, and I saw the inside of a strong colony for the first time. I thought there must be millions of bees. They gave me a sort of crawly sensation, and I would gladly have run away, but was afraid to stir.

My uncle then removed the division-board and the three combs next to it, one by one, each comb literally crowded with bees. He told me not to blow my breath against the bees, and then shoved a comb in front of my face and pointed out the larvæ which I thought resembled the little white worms found in rotten wood. He then pointed out cells with eggs in, and, tho I could not see the eggs, I nodded my head and made believe I did, for I was afraid I would have to breathe, and I didn't know what those bees might do if I breathed. After he had removed three frames on one side of the hive, he pried all the frames over a little, and removed the frame next to the opposite side of the hive.

"There she is!" he exclaimed, and then pointed out the queen. I noticed that she had no stripes like the other bees. He then slowly replaced the frames. Only once did

a bee threaten me. It came up and poised within a few inches of my nose and stayed there for a second. I stood as straight as I could and held my breath, and I felt cross-eyed for about a week from keeping both eyes on it. But the bee left, and I was glad it did, for I was beginning to think seriously of leaving in a hurry. So I got off without a sting, as my uncle had promised.

After I got the hive home, my first wish was to get some bees. Happily a friend who kept bees, mostly in the old-fashioned way, knowing that I had a hive, and wanted some bees, promised me the first swarm he should have. I procured foundation from a supply-dealer and made my hive ready for the bees; and a swarm was given to me on Saturday, June 15, 1912. They built up rapidly, despite the fact that I inspected them at least once and sometimes twice each week day, handling each frame. There is no doubt in my mind now that those bees were glad to see Sunday come. Some time in July they swarmed, and I put the swarm in a standard hive which I had bought in flat and put together. The new swarm built up into a strong colony before winter, and the old colony gathered about twenty-five pounds of surplus.

To prepare these colonies for winter I placed them side by side, put a super filled with chaff on top of each one, and then put some rough boards around them and banked up with dirt. I happened to have a large box about one foot deep which telescoped nicely over both hives.

The next season I ran my bees, together with some others, on shares. But about this time I got a position in an office and was unable to give them enough attention. I started to work about 8:00 A. M. and quit at 5:00 P. M., and had my bees to handle and other tasks to perform besides. Thus I was unable to do anything well, and the bees were greatly neglected. However, I got a good crop of honey, mostly extracted. I was enabled to increase my own two colonies to fourteen, and get about fifty pounds of surplus extracted honey.

Osceola Mills, Pa.

CLERGYMEN AS BEEKEEPERS

BY THE REV. HERMAN W. WATJEN

Some time ago a noted clergyman, speaking in the city of Boston to a large gathering of ministers, mostly from country parishes, said, "Brethren, keep hens; they are profitable, and will add materially to your income." Had the good preacher known

anything about bees I am sure he would have changed that statement. He would doubtless have said, "Brethren, keep bees; they are more profitable than hens and require less care; they take up little room and make no noise; they can be kept almost

These bees are located in the center of Morgantown, N. C., a town of 5000 inhabitants. They fly from $2\frac{1}{2}$ to 5 miles to the sourwood.

anywhere—in your study, in your attic, in your church-tower, on your shed roof, in the corner of your back yard, anywhere, so long as they can get out; they are clean, and need not be fed except on rare occasions. They can be left to care for themselves during your summer vacation, and they will work for you even while you are preaching. Therefore, brethren, by all means look into the bee business.”

It was by accident that I became a beekeeper. It is not my profession but my hobby, my recreation, my pleasure. Since everybody ought to have a hobby he might as well have a good one, and I know of none better than bee culture. My deacon's wife offered me a swarm which had clustered on a low bush in her garden. They looked very inviting—a handsome, quivering bunch of large Italians. But my ignorance prevented me from getting them, altho I held a hastily constructed box, well besmeared with molasses, close to their noses for more than an hour. That tempting bait had no attraction for them, and I saw them sail away in a great cloud of joy. But my interest was aroused, and I purchased a colony. These soon multiplied, and with the increase came experience and

knowledge and honey and money. This was about ten years ago, and these have been years of genuine pleasure and profit. Half a ton of honey is my usual annual crop from about a dozen or fifteen hives. What does not go to sweeten myself, family, and friends, is sold, and the profit helps to pay taxes on a summer cottage and for the gasoline of an auto.

But the money profit is not the only consideration for the ministerial beekeeper. There is the vast field of biological knowledge to which the honeybee introduces him; and not only biology but botany, too, invites his renewed investigation. Every flowering shrub is alive with interest; and a walk thru the fields on a summer's day has added charms. Illustrations from nature are always interesting, and these multiply as the preacher makes first-hand investigations.

Yes, brother minister, try the honeybee for an experiment. Do not begin on a large scale. Get a colony of very gentle bees first. Timidity will soon vanish, and a few stings are quite exhilarating and healthful. Soon you will be immune to all discomfort, and then the real pleasure begins.

Warren, R. I.

CIRCUMSTANCES ALTER CASES—AND THE DISTANCE BEES FLY

BY L. E. WEBB

I am sending you a picture of my apiary of 13 colonies (three not showing) which have built up in two years from one colony, increasing the first year to 4 and last year to 13, with all but two headed with pure

Italian queens, altho I got stuck on several occasions by having impure queens sent me which gave considerable trouble in requeening; yet with my increase from 4 to 13 I secured for market about 300 sections

surplus and all in good shape for winter, and all have come thru the winter to date fine, and are starting a little brood-rearing and have heavy stores yet.

The picture was made Feb. 1, so you will see I am wintering outdoors in single-wall eight-frame hives and haven't lost, I don't believe, a hatful of bees, and the rough weather is over.

I am fully sure of the fact that I made a mistake in starting with eight-frame hives, as the season is so long and brood starting so early, and it seems this eight-frame proposition is upsetting lots of people who have profligate Italians down this way, as it keeps constant work in manipulating.

Our honey-flow is not steady; and after fruit and locust-bloom in spring there is a lapse of a couple of weeks and then a heavy poplar flow, and then a lapse and our

best and largest flow, sourwood, yielding the whitest and perhaps best honey made, and the flow is very rapid.

Sourwood is a tree of the mountains, and my sourwood is gathered from a mountain which, at its nearest place at the foot, is 2½ to 3 miles, and ranging up to 4½ to 5 miles at the top, and at some places that far to the foot of the mountain, and from this mountain the bees get their sourwood. This differs with the ideas of some in other sections as to distances bees go; but facts can't be altered, and I had several stands which averaged around 40 to 50 sections, or about two supers of pure sourwood, and one filling nearly three supers, and perhaps some would be ready to take issue as to distance; but I decided long ago that locality and necessity cause bees to vary largely in their habits.

Morgantown, N. C., Feb. 2.

THE LOCATION AND ARRANGEMENT OF OUT-APIARIES

BY CHARLES E. KINZIE

To get down to business in running out-apiaries we must figure ahead. I have had the best success by arranging for two supers to each hive; and for some, three or four supers. I use ten-frame hives only.

One out-apiary of 130 colonies I have divided into three rows, the rows 16 feet apart, and the hives 8 feet apart in the row. I find that this plan is a success; for when I am extracting and go to a hive tiered up three or four high, and tear it all down, the bees do not go to the next hive. Again, if I am treating the colony for European foul brood, the bees stay at home, and the neighboring colony, 8 feet away, is not likely to become affected. This apiary faces the east.

Another out-apiary has about 140 colonies in four rows. The first row faces the west, the second faces the east, so that the backs of the hives are 11 feet apart—just the right distance to run a cart or auto truck between. The third row faces the west, and the fourth the east. That makes two driveways 11 feet apart between the backs of the hives. The space for the bees to fly between rows two and three is 16 feet. By this plan, when going up and down the rows the bees do not get excited half as much. I expect to lay two lines of track in this yard, and have a car to run the supers of honey right into the honey-house, and then extend this apiary to 225 colonies.

I am just starting my third out-apiary. This will be the same—that is, I will provide it with tracks and a car.

When I take off my honey, I go to the further end of the yard, remove the cover, puff in a little smoke to drive the bees down, take out all the honey that is at least three-fourths capped over. I shake all the bees from the frames into the super, not on the ground. All combs of honey not yet capped over I put in the center of the super. In this way I have no difficulty in keeping the queen from going up above to lay.

I use only eight combs in each ten-frame super. Of course I have ten in the brood-chamber, all worker combs built from full sheets of foundation. Eight bulged-out combs of honey contain more honey than nine or ten combs could hold in the same super. You see there are eleven bee-spaces with ten combs, and only nine with eight; in other words, there is just that much more room for honey.

Many a time I have taken off and extracted fourteen or fifteen 60-pound cans in seven hours, using only a two-frame extractor. I aim to extract every twenty-five days, and I am not bothered by swarming. I do all the extracting at each yard and take the honey home each night, and empty it into large tanks at home. Then when I have time I case it up.

I inspect all brood-chambers as soon as the honey starts in the spring, and then do not disturb them again until August, when I give another good inspection.

My apiaries are eight and nine miles from home. A light auto truck is the thing

Development of the queen-cell from the transferred larva to the virgin.

for out-apiaries with a trailer when necessary. I move only the extractor and capping-melter from apiary to apiary. This year I expect to take a light one-horse wagon-gear, put on a flat top, bolt a four-frame extractor on one end, and the capping meller on the other. I shall remove

the shaft and put on a draw-bar; then when I move from one apiary to another, all I shall have to do is to trail the extracting-wagon behind the auto, run it right into the honey-house, and get busy. When the extracting is over I will wash up and go to the next apiary.
Arlington, Cal.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sights Among the Bees

BY H. H. ROOT

That bees prefer the edge of a comb for building queen-cells is a well-known fact. That some bees, at least, refuse to build them anywhere else we discovered last summer, for the bees of one colony seemed determined to have their own way.

Wishing to observe and photograph the beginning of natural queen-cell construction we dequeen a colony, making sure

that the combs contained young worker brood in all stages. We kept careful watch of all the combs, beginning the next day, but found no sign of queen-cells until the fourth day, when we found a cluster of them started on the lower edge of one of the central combs. In each case the cells were constructed over drone-cells, and from all appearances the bees were innocently proceeding to rear a queen from those drone larvæ. Of course, it is entirely possible that they had removed the drone larvæ and had put worker larvæ in their places. We watched the result carefully; but before the cells were sealed the bees apparently abandoned the undertaking in disgust. If they forgot to remove the drone larvæ I do not wonder that they gave up the thing as a bad job. But the weather was very changeable at the time, and the colony

Queen-cells built over drone-cells, and containing drone larvæ.

not overly strong, so that it is possible that the bees were unable to care for the cells, and that the larvæ in such an exposed place were chilled.

We carefully removed all traces of these cells, substituted another comb containing young worker larvæ, and gave the bees another chance; but, as in the first instance, they constructed cells again on one of the lower edges of the comb, and, as before, failed in bringing the cells to completion.

Bees prefer to build cells on the lower edge of a comb, not because of any desire to get the cells down near the floor of the hive, for in case of a double brood-chamber or a sectional hive the cells are just as likely to be on the lower edges of the upper comb. It is probably just because it is easier to build the cells down into an open space where there is no comb near by in the way.

The building of queen-cells makes an exceedingly interesting study. How all those bees engaged in the work are enabled to figure out the architectural problem in the building of the cells, caring for the larvæ, feeding them, keeping them warm, etc., is indeed a mystery. Instinct? Probably. But is not instinct really mysterious? In the work of bees we are shown wonderful results accomplished by a large force of individuals which carry out an intricate plan, but which work, nevertheless, without supervision. Probably the reason lies in the fact that all the bees share equally in the proceeds, and each bee has but one interest—the interest of her colony.

The second illustration shows the development of queen-cells from the time the tiny worker larvæ are "grafted" into the artificial cell-cups, to the empty cell from which the young virgin queen has emerged. It can be seen that, within twenty-four hours, the bees accept the artificial cells and crafted larvæ, and begin fashioning the outside to their own liking, meanwhile lavishly feeding the larvæ and clustering

over them, making it possible for them to grow. From six to eight days from the time the bees took hold of the work the cells are capped over, and, aside from keeping them warm and thinning down the wax wall toward the very last, the work of the nurse bees is over.

But within the cell the changes taking place are startling. The larva has been spinning its cocoon. The rapid change that

Larvæ and pupæ at different stages (enlarged).

takes place, which may be seen almost hour by hour, is wonderful. The dividing of the segments of the larva into the three main groups that are to form the head, the thorax, and the abdomen; formation of the legs, and the wings; the beautiful tinges of color from the creamy white to the pink, then the red, then the purple, and, lastly, the brown,

Swarm returning to the hive because the queen was clipped. From A. G. LUCIER, Powers, Wyo.

are all beautiful examples of Nature's handiwork. Who can comprehend it?

The changes in the larvæ may be seen, but it is impossible to record them adequately with the camera; and by the time the engravings are reproduced on these pages only a faint suggestion is given of what any beekeeper may see with his own eyes without the least difficulty.

The first small illustration shows a worker larva somewhat enlarged, about two days after hatching from the egg. When first hatched the larva is almost as small as the egg itself; but by eating constantly its growth is phenomenal.

The next two small illustrations show worker larvæ about four and seven days respectively after hatching.

The next shows the result of the differentiation of the various parts. It is when observing this stage that one feels almost like a spy on the work of creation.

The last illustration shows a drone seventeen or eighteen days after hatching from the egg—that is, twenty or twenty-one days from the time the egg was laid, and therefore at least three days before the time of emerging from the cell. The head has begun to turn purple, and the color is extending down over the thorax and abdomen. The bony frame (chitin) is beginning to grow tough and strong, and the bee is rapidly approaching the time when it will waken—for the first time—and finally emerge from the cell weak and trembling, but perfectly developed—a finished specimen.

THE PREVENTION OF SWARMING IN HOME AND OUT-APIARIES

A Resume of Some Plans that have been Found Successful; Separating the Queen from the Brood

BY R. F. HOLTERMANN

With the exception of the wintering problem there is, perhaps, no subject which creates more general interest among beekeepers than the question of swarm prevention. I propose to give the substance of a number of plans that have been given to me, altho I realize that they may have been made public in one form or another before.

I myself have had a very fair measure of success in preventing swarming since having plenty of drawn combs for the surplus-honey crop; but I have never considered it wise to abandon the practice of looking thru the brood-chamber for queen-cells, usually once a week, and at least every ten days. Many times, it is true, I find such

an examination unnecessary; but there is no way of ascertaining this fact previous to the examination. On the other hand, colonies have been found with the swarming impulse week after week, altho I continue to break down the cells, expecting that the bees will cease rebuilding them. If I could have foreseen this I would have shaken the bees from the combs and removed the brood, because, as we all know, such a colony will not gather the usual amount of surplus honey.

At the Michigan state beekeepers' convention, held at Grand Rapids last December, I learned that this subject was to be taken up, therefore I attended the convention and interviewed several of the beekeepers whom I considered authorities on the subject.

FRANK SLUSHER'S PLAN.

Mr. Frank Slusher, of Traverse City, Mich., uses the ten-frame hive, and winters his bees in a cellar. They are set out on the summer stands some time during the first half of April. He usually carries them out at night and contracts all entrances to a space 1 inch by $\frac{3}{8}$. He thinks by this plan he is able to prevent drifting. He prefers cool cloudy weather the day following, if possible, in order to keep the bees from flying too freely.

Mr. Slusher does nothing with the bees after this until the weather is warmer, and more settled, or until about the time they begin gathering pollen. Then all colonies are examined; those that are queenless are united with other colonies, the queenless colonies being set on top. If a strong colony is queenless it is set over a weak colony, while if a weak colony is queenless it is set over a strong one. A queen-excluder is pushed between the two colonies, care being taken not to disturb either colony.

When examining the bees, the condition of the stores is noted; and, if short, a frame of sealed honey is supplied. If this is not available the bees are supplied with enough candy to last until fruit-bloom, after which, if more stores are needed, the bees are fed a thin syrup until they can gather sufficient from natural sources.

About twelve or fifteen days before the clover or raspberry flow, Mr. Slusher gives all colonies that are sufficiently strong a ten-frame super provided with drawn combs if he has them; if not, full sheets of medium brood foundation. The queen is allowed full range of both stories.

Nothing further is done until four or five days before the honey-flow when he takes from one to three or even four frames of sealed brood (or as nearly sealed as can be

obtained) from the strongest colony. These are distributed among the weaker colonies, or, if not needed for that purpose, are placed in the second story if the queen has not yet taken possession. Provided the queen has already taken possession, the brood is placed in a super which the queen has not yet entered. Frames of brood removed from strong colonies in this way are replaced by full sheets of foundation. Mr. Slusher thinks this is an ideal way to get foundation drawn out. If there is no need of having foundation drawn out, an empty worker comb replaces the comb of brood.

The bees are now left alone until a week or ten days after the flow begins. At that time, all colonies are examined. The cover of the hive is removed, several puffs of smoke given to drive the bees down between the frames, in the hope of getting the queen down into the brood-chamber. The super is then lifted off and a queen-excluder slid between it and the brood-chamber below, the brood above being left to hatch, thus giving the bees more room for surplus. Four or five days later, each upper story is examined, merely by lifting two or three of the center combs. If eggs are found, it indicates that the queen is above. The bees are then shaken in front of the hive and the combs replaced in the super. This is not often necessary, as the queen is generally driven below by the smoke before the excluder is put on.

After this time the work consists in seeing that each colony has plenty of room. As supers are added they are placed next the brood-chamber over the queen-excluder.

E. D. TOWNSEND'S PLAN.

E. D. Townsend, of Northstar, Mich., likes to have a limited amount of spring protection. He winters out of doors, altho last winter he had two apiaries wintering in trenches—that is, buried in sand. On account of limited help he usually begins unpacking his bees about the first of May. It takes perhaps two weeks to do this.

Mr. Townsend puts on the upper stories early, and disposes of the brood-chambers of dead colonies by putting them over the strongest colonies, where they answer the purpose of the first super. During the first manipulation he equalizes stores, providing those that are short with stores taken from those having more than enough for present requirements. He puts the upper stories on all colonies likely to need them within two weeks, not waiting for the brood-chambers to get full. With distant out-apiaries and limited help it takes about two weeks to go thru the bees.

Mr. Townsend objects to heavy packing

in May, because it makes the bees rear drones and get ready for swarming, drone-rearing being the first step toward swarming. Later on he judges by the action of the bees; and if they are likely to swarm he examines the combs for queen-cells. I asked him if he thought black bees showed more by their actions and entrance the tendency to swarm. He answered by saying that in his opinion they do show it more than Italians.

In the examination, if queen-cells are found he takes the queen with the poorest comb of brood and places them in a new hive on the old stand, the remaining brood being put on top of the hive with the super. If he desires to make some increase to replace lost colonies, he sets the brood, within ten days, on a new stand, making a new colony of it. He sometimes gives such a brood-chamber an entrance so that the young queens can get out and mate. In that case he puts a queen-excluder between the brood-chamber and the super beneath it.

DAVID RUNNING'S PLAN.

David Running, Filion, Mich., has taken bees out of the cellar as early as March 15 and as late as April 27. He likes to get them out as early as the weather will permit. He contracts the entrances at first to 2 or $2\frac{1}{2} \times \frac{3}{8}$ inches, enlarging them as the colonies get strong. The bees are left entirely alone until fruit-bloom, but he makes sure the fall before that all colonies have plenty of stores. When the apple-bloom comes on he considers the colony strong enough to take care of all the brood in an eight-frame hive. He then clips the queens and equalizes the stores. He does not equalize brood on account of the danger of spreading disease. Any queenless colonies are set on top of other colonies, as he does not consider them worth while maintaining for the surplus honey-flow.

The bees are seldom strong enough for a super at the beginning of fruit-bloom; but as soon as they do become strong an extra super is added without a queen-excluder. A week or ten days later, or at the beginning of the clover flow, when the bees have nicely started storing honey in the upper story, the queen is shaken into the lower story, a queen-excluder put over it, an empty super added, and finally the super that was over the brood-chamber, the colony thus being three stories high. About a week later, during the heaviest of the honey-flow, all combs in the brood-chamber are transferred to the top story, and foundation, or empty drawn comb, put in its place. If foundation is used, one drawn comb is

put in the center for pollen and eggs. The position of the other super is left unchanged, an empty super being left next to the queen-excluder. If the honey-flow later on does not appear to justify the last-named empty super, this is removed.

A week after the queen has been shaken down below the first time, Mr. Running cuts all the queen-cells out of the combs shaken. This is very important. If he can find time he breaks down the cells built in the second lot of brood in the top of the hive next the cover. If increase is wanted, he sometimes sets these upper stories on a new stand before the queens hatch. By this time he does not consider the cutting of the cells very important, because the honey-flow is about over.

If a poor queen is found this hive is marked and the queen changed as soon as convenient. Extracting is begun about ten days after the honey-flow ceases, the supers being freed of bees by means of bee-escapes. The brood-chamber and first super are left undisturbed until September 15, when feeding for winter is begun after the super is taken off.

It was Mr. Slusher, I believe, who said that he started the prevention of swarming by putting empty combs in the brood-chamber with the queen, and the brood in the super above the queen-excluder, but he found this to be unnecessary. In any case, all three of the foregoing beekeepers claimed that, by giving the queen of every good colony the opportunity to deposit eggs in the upper story, and later shaking her down and giving her plenty of range to lay in the lower story under the excluder stopped swarming, or at least reduced it to a very small per cent. They also agreed that, if the combs of brood above the queen-excluder including the queen-cells were raised up and an empty super put between, there would be practically no swarming. Mr. Running, however, favors the destruction of the cells before they hatch, or else he makes a distinct brood-chamber of them with a separate entrance. Heretofore in my own practice I have not provided for fresh room in the brood-chamber during the honey-flow. This feature should be a valuable addition to our fund of knowledge regarding the prevention of swarming.

S. D. CHAPMAN'S METHOD.

S. D. Chapman, of Mancelona, Mich., uses an eight-frame hive and winters in the cellar. He puts the colonies on the summer stand, weather conditions being favorable, about April 15. He selects a time when the prospects are that it will not be warm enough for a couple of days for the

bees to fly. However, he does not want the weather to be extremely cold. He finds that, if the bees fly at once, especially if the weather is pretty warm, the bees drift and mix up more than one realizes.

From the time of setting the bees out in the spring until the beginning of fruit-bloom Mr. Chapman leaves the colonies alone and does not disturb the sealed covers of the hives. At the time of fruit-bloom he puts on upper stories, letting the bees have sixteen combs, but he does not put a queen-excluder between. When fruit-bloom is on he goes thru the colonies for the first time, marking their condition as to their strength, amount of stores, and condition of their queen. At this time he also equalizes by taking combs of brood from some that are particularly strong and giving them to the weak. His object in equalizing is to make them all of the same strength so that they will require about the same treatment during the season.

About June 1, or at the very beginning of the raspberry flow, three combs of the matured brood are taken out of the brood-chamber and put into the super above, three good worker combs being put in the center of the lower brood-chamber. If the queen has entered the upper story at this time (and of course she is likely to have done so

if the colony is strong) he shakes her into the lower story and confines her there by means of a queen-excluder. He now has two stories with brood, and other supers are added for the surplus honey as needed, the bees never being allowed to become crowded. The first extra super is required usually in less than fifteen days, and this is placed between the two stories containing the brood. This must go between the two stories of brood and above the queen-excluder over the lower story, because the combs in the upper story will have queen-cells. With the cells so disposed of, Mr. Chapman finds that the colonies do not swarm when the young queens hatch.

By the above system Mr. Chapman also secures plenty of room for the queens to lay in the combs in the lower story, to which she is confined at the time the surplus raspberry-flow begins. Three combs are entirely empty at this time. Furthermore, if the colony is strong, and the queen goes into the upper story during fruit-bloom, and until the raspberry begins to yield, young bees will have been emerging from the cells in the lower combs, giving just that much more room when the queen is confined below. By this plan, at any rate, swarming is almost entirely prevented.

Brantford, Ontario.

BEE-NOTES FROM HOLLAND

BY J. H. J. HAMELBERG

[This is the first of a series of articles on beekeeping in Holland. Later articles will discuss the question of hive and other equipment, the honey crop, wintering, etc.—ED.]

With us the common black or German bee reigns supreme. Italians or Carniolans are exceptions; and as to Caucasians, Cyprians, Banats, and other species, I have never seen them in this country nor ever heard of any one keeping them.

A few amateurs may like to have a colony of Italians or Carniolans in their apiaries, and I know of one dealer in beekeepers' supplies who regularly orders Carniolan queens from Austria to be used in his own yard; but surely nine-tenths of all the bees kept in this country are pure blacks.

Altho preferring the Italians by far, I consider it wrong to condemn the blacks altogether. They are cross, undoubtedly, and they have a nasty habit of running over the combs when handling them; but they have some redeeming qualities. They cap their cells beautifully, and in gathering honey from the heather (an important source of winter stores in this country) I don't believe they can be equaled.

In judging the blacks (or, rather, *our* blacks) it must not be lost sight of that they are probably a good deal degenerated. For years—nay, even for centuries—it has been the custom of our beekeepers every year to sulphur their heaviest colonies—in other words, their best honey-gatherers; and it can hardly be doubted that this practice must have had a very deteriorating effect upon the race. I remember once having seen a very large skep in which a first swarm had been put in the month of June, filled to the very brim with beautifully built comb or worker-cells only. Except on the edges of the combs, no drone-cells were to be seen; and all the cells, except those in the two or three lowest rows of the combs, were beautifully sealed. It was in the latter part of September when I found this skep, and I would willingly have given a hundred guilders for this colony if the stupid beekeeper had not already sulphured it and its parent colony, also a very good one, as well. Such practices, continued for centuries,

Handling bees in a Dutch apiary. From Hans Matthes, Breukelen, Holland.

must have brought down the standard of our blacks.

But judicious selection and breeding may, perhaps, be able to give us a strain of bees unsurpassed for the conditions of our bee-flora and our changeable climate.

The principal objection raised to blacks in the United States seems to be that they are not immune to European foul brood. But this objection does not carry any weight with us, as this disease is, fortunately, but seldom met in this country—at least I have never heard of any cases in which apiaries were ruined by it, or nearly so, and I myself have never seen a colony affected by it.

What I have against the blacks is their habit of sacrificing honey-gathering to brood-rearing during the latter part of the summer flow. If, for the thoro ripening of the honey, supers are left over a colony of blacks, they will entirely empty them to rear brood, when a sudden stoppage in the honey-flow occurs at this time. Considering that their main winter stores must come from the heather (which blooms in August and September), the bees very likely only follow in this their natural instinct, trying to get as big a force of workers as possible for the autumn-flow. But it remains an objectionable habit all the same, which, however, may possibly be outbred.

The buckwheat-flow having failed us last year I had a striking instance of the superiority of the Italians. The one colony I have of them, altho not very strong in spring, gave me over 60 pounds of extracted honey by July 15, while my best colony of blacks (and one which, in the early part of May, had been judged "a magnificent stock" by one of our well-known practical beemen, Mr. R. Tukker, see GLEANINGS for October, 1908), gave me only 15 sections, most of which were only partly filled.

To be fair I must say that, when ordering this colony from Italy, I paid something extra to get a superior queen. The colony has never swarmed; and, altho always having done better than my blacks, the difference has never been so glaring as this year, buckwheat seldom leaving us in the lurch

In Holland a mouth bee-smoker is frequently used, which leaves both hands free for handling the frames.

altogether. But I hardly need to say that, at present, all my colonies of blacks have been provided with a queen reared from brood of this Italian stock.

I have one colony of Carniolans. I have had these bees for some years, but I do not like them. They stop work a couple of hours sooner in the day than either blacks or Italians, and they don't make up for this by rising any earlier. I cannot complain about their excessive swarming, as none of my colonies of Carniolans ever swarmed more than once in a season, and last year they did not swarm at all. With me they don't excel in honey-gathering, and have not proven themselves superior to the blacks in this respect. I consider them a lazy strain of bees.

Soest, Holland.

SOME OF THE NEEDS OF THE PORTO RICAN BEEKEEPER

BY RAFAEL VIDAL

Porto Rican beekeeping suffers from a general lack of knowledge of up-to-date methods. No fault can be found with equipment. It is modern and practical, but too many persons have gone into the business with a superficial knowledge of the subject,

and with the idea that all there is to keeping bees is relieving the workers of their honey at frequent intervals, and disposing of the crop at fancy prices.

There has been a sad awakening since the depression came, caused by the war. Prices

Typical Porto Rican apiary. The beekeeper of the tropics has peculiar problems of his own.

are low; the crop has not been an average one, and many of the smaller beekeepers are "climbing off the bee-wagon." All this will improve matters in the end for the large-scale apiarist.

One of the greatest needs of the Porto Rican beekeeper is a strong association which will procure supplies at a material discount to the individual, and regulate, to a certain extent, market prices, and stimulate a live and active interest in improved methods and better management. The interest is present, but it stagnates thru lack of opportunity to exchange ideas with men in the same line of business. A short-lived association published a small periodical which, undoubtedly, was a factor in helping the island beekeeper. Its discontinuance is to be regretted.

Another handicap to better beekeeping is the use of poor, nervous strains of bees. This has resulted, among other things, in the almost universal use of gloves and veils, a practice with which the northern apiarists have little patience. The discomfort of heavy gloves under a tropical sun may be easily imagined.

The lack of definite knowledge in regard to blossoming periods is another element hindering the insular beekeeper. Not only

do the various localities differ in this respect because of differences in altitude, rainfall, etc., but the blooming periods for the same locality are apparently so inconstant that only a very close observance of the flora will give an idea when a certain bloom may be expected.

These difficulties of the Porto Rican beekeeper are not offered as unadulterated pessimism, but only to show that the way of the tropical apiarist is not the primrose path so many people imagine as they recall such phrases as "luxuriant tropical bloom." The beekeeper in the tropics has peculiar problems of his own which, as everywhere else, must be met with patience, experience, and common sense.

The bloom in Porto Rico is heavy, but is apt to come on with a rush, giving the bees more work than they can handle. Among the principal honey-plants are mocha (*Andira inermis*) and the leguminous trees so commonly used as shade in coffee plantations, guama (*Inga laurina*), and guava (*Inga vera*, not the guava of guava-paste fame). The guama is one of the best sources of pollen as well as the best honey-plant of the tropics. It blossoms from three to five times a year.

Mayaguez, P. R.

PENNSYLVANIA BEEKEEPERS MEET

BY GEORGE H. REA

The twelfth annual convention of the Pennsylvania State Beekeepers' Association was held in the Chamber of Commerce Hall, Lancaster, on Friday and Saturday, March 3 and 4. This proved to be one of the largest meetings of the association in point of attendance, and perhaps the most enthusiastic. Several things contributed to make it so. Perfect harmony prevailed thruout, and the contagious enthusiasm and zeal thrown into it from the start by Economic Zoologist H. A. Surface, president of the association, were probably the two most important factors in the success of the meeting. The secretary, Prof. H. C. Klinger, had the program so arranged that everything went off like clockwork. He was especially fortunate in securing the presence of all scheduled on the program, with one exception. The chief difficulty was in stopping the discussions on the important subjects in order to give sufficient time for the next number.

One of the notable features of this convention was the presence of several press reporters who stuck to their posts thru the sessions, early and late. As a result, complete reports of the convention were printed in various city papers. Some of the addresses were even printed in full.

Mr. L. B. Huber, chairman of the local committee, and his assistants, Samuel Gochenauer, E. S. Hacker, L. K. Hostetter, and Elmer J. Weaver, had everything in readiness for a warm reception for the visiting members. Mr. Huber, with his complacent smile and inherent good humor, was a prominent figure all thru the convention. He also contributed one of the most valuable papers given, entitled, "Constructive Farming and Beekeeping." He showed how one can practice better methods of farming while growing crops like the legumes and buckwheat that produce honey crops. Lancaster County is the richest agricultural county in the United States, having over 99 million dollars' worth of farm property and products. Mr. Huber, as one of its progressive practical farmers, spoke from experience.

Vice-president R. M. Reily, of the Chamber of Commerce, made the address of welcome. The kind hospitality extended by him was put into action by the local people.

Dr. H. A. Surface, in his annual address, said in part, "If, in the keen struggle for existence in the future, we are to compete with other nations we must be as economical as they. For example, it has been but recently announced that the German authori-

ties have issued a proclamation that the blossoms of various trees and shrubs, such as the alder, hazel, etc., should not be gathered for decorative purposes this spring, because, altho wild and uncultivated plants, they will furnish nectar and pollen for the bees, and, later in the year, yield nuts for the food of mankind. If the Germans, in their present stress, foresee the importance of such economy, can we not say that the beekeepers who are making it possible to gather and save the nectar from our various blossoms, and put it before the consumer in the form of honey, are performing a valuable service to mankind?"

Dr. Surface brought out the facts that in Pennsylvania there are about 22,500 persons keeping bees, with an investment of between one and two million dollars. About one million dollars' worth of honey are produced annually. He said, "There are at this meeting persons from more than fifteen counties scattered in different parts of the state. They represent the Pennsylvania Beekeepers' Association, which has the largest membership of any agricultural society in the state.

"It pays to advertise in local newspapers. There are no better educators in the country than the local newspapers. There are three hundred members of this association, and during this year each one in his own community should carry on a newspaper crusade to inform the public that there is a beekeeping industry in the locality; that there is local honey, local beekeepers, for the people like a local product best. Use printer's ink; do not be afraid of it; use lots of it."

He further urged that those in attendance should make notes on the good things said at the convention by the various speakers, and write them up for the local papers from time to time during the year.

The apiary inspectors, J. R. Rambo, John O. Buseman, and George H. Rea, reported 9384 colonies inspected in 1915, at a cost of about 20 cents per colony. In this connection Dr. Surface stated that he had records from owners of bees in certain infected territories, to the effect that their bees are doing much better since the services rendered by the inspectors. The educational value of apiary inspection is its chief merit.

Perhaps the most interesting feature of the whole convention was a paper entitled "Beekeeping a Hobby for Girls," read by Miss E. S. Brinton, of West Chester. [See page 393 this issue.—Ed.]

"Marketing honey" was handled ably by Mr. E. F. Strittmatter. Working the home market, the importance of neat and attractive packages, and personal canvassing, he gave as the main features of success. Advertising is very important, and satisfied customers are the best advertisement. Mr. Strittmatter has built up a large trade for his honey in tin and glass packages.

Dr. E. F. Phillips could not be present; but he was ably represented by his first assistant, G. S. Demuth. His talk on the four important periods to be taken into consideration by every beekeeper proved to be very interesting and valuable. These are: The late summer and fall period when the winter colony is reared; the winter period, or that of the conservation of the energy of the bees; the period of tremendous increase in the spring, and the period of the honey-flows.

During these periods, considering a normal colony with a good queen, etc., plenty of stores, protection, and room are necessary.

Queen-rearing, with its many difficulties and problems, was ably handled by Mr. J. R. Rambo and Mr. W. S. Sellers. Many valuable points in the producing of good queens were given to the beekeepers.

Three papers read before the convention, viz., "Getting Ready for the Honey-flow,"

by Mr. L. K. Hostetter; "Spring Management," by J. O. Buseman; and "Wintering," by Elmer Weaver, were full of good things, and had many valuable points taken from practical experience. The especial value of the fundamental essentials to successful beekeeping, good queens, lots of winter stores, and protection from cold, together with the proper manipulations at the right time, was emphasized.

"Habits of the Honeybee," by Economic Zoologist H. A. Surface, was the last number on the program. It is impossible to give a digest of this splendid paper, because of lack of space. Many fundamental truths necessary to be known by the beekeeper who would attain the highest degree of success, were presented by Dr. Surface, from the standpoint of a scientist as well as a practical man.

The election of officers was as follows:

President, Dr. H. A. Surface, Harrisburg.

First Vice-president, George H. Rea, Reynoldsville.

Second Vice-president, Mrs. Gertrude Weaver, Philadelphia.

Third Vice-president, R. L. Coons, Condersport.

Secretary-treasurer, Prof. H. C. Klinger, Liverpool.

About sixty members were present, and as many visitors.

QUEEN-REARING FOR THE BEGINNER

BY J. E. JORDAN

SELECTING THE BREEDING-QUEEN.

Early in the spring, the first thing to think of is a queen to breed from. There are many points to be kept in mind in selecting a breeder, if one cares to improve his stock, build up a business, and make beekeeping an art. Here are the points to be remembered:

1. She must be pure.
2. Her workers must be gentle.
3. She should have made a record for prolificness and honey-gathering. (This should be recorded on the slate at the side of the hive.)
4. Her bees must be the least inclined to swarm under trying conditions.
5. If pretty yellow queens are desired their bees must have yellow abdomens. This applies to the three-banded Italians.
6. Her workers must be large as well as herself.
7. Her drones must be large and of good light color. These drones should have been reared in colonies which are also pure and have made a honey record.

8. It is desirable that her bees cap the honey white.

WHERE TO KEEP THE BREEDER.

After selecting the queen, the next thing is to get her on shallow frames or small frames in order to make grafting easier, also that she may be found more easily.

To transfer this breeding queen to another hive with shallow frames, get two shallow frames of honey, placing one on either side of the hive. Next put in four shallow frames of sealed brood and larvæ, being careful that all bees are brushed from them. Place one empty shallow brood-comb between each pair of combs of brood. Then cage the queen and lay the cage on the top of the frames, next go to the colony where the breeder came from and get two or three frames of young bees. These frames must be well covered. Brush the bees thru an empty super placed on the shallow-frame hive, down into the hive. Cover the hive and contract the entrance down to about an inch and let it stand for one or two hours; then release the queen. By adding an emp-

ty frame each day, or, rather, a frame with hatching brood in it, and putting it in the same place every time we always have larvæ to "graft" of the right size and age. Grafting—that is, transferring the selected larvæ to prepared cells—may be begun four or five days after putting the breeder on the shallow frames. Remember, even if the queen lays immediately after her release from the cage those eggs will not hatch for three days, and it will then be another 24 hours before the larvæ will be old enough to graft.

If the above work is done in the early spring, or when a flow of nectar is not on, do not neglect to put in a feeder and give the colony a little syrup each afternoon about sundown or after. This will cause the bees to feed the larvæ better; and well-fed larvæ are what we want. They must be floating in the milky food.

Two days before grafting, in order to have a cell-building colony ready, dequeen a good strong colony that is overflowing with young bees, and place in the hive a division-board feeder. Feed this colony every evening about sundown until the cells are sealed. Feed all cell-building colonies and the breeder about a pint of syrup if there is no flow of nectar. I always feed at sundown or after, as there is less danger of starting robbing at that time.

GRAFTING THE LARVÆ INTO THE PREPARED CELLS.

At the beginning of the season, as there is no royal jelly available, graft the first lot "dry." Do not expect great results with this first lot. Take the frame of larvæ from the breeder; and, after making sure that the queen is not on it, shake the bees before the entrance. With a grafting-tool lift the larva from the cell by sliding the point of the tool under it so that it will float on to the tool. The larvæ should not be over 36 hours old. Place a larva in the bottom of each cell cup, which cups should have been previously prepared and stuck on thin sticks. Eighteen cups should be on each stick. Now give this lot of 18 grafted cells to the queenless cell-building colony, hanging them in with the open ends down.

Care should be taken not to injure the larva in lifting it from the cell, as an injured larva means a bad queen. Also see that there are no fine particles of wax or dust in the cell cups. Be sure to graft as much as possible from the center of the comb, as drone larvæ will sometimes be found around the edges, especially the upper edge next to the top-bar.

After placing the cells in the queenless

colony, make a record in the record-book of the number of the hive in which the cells have been placed; also of the breeder, the date when they are due to hatch, and the number of cells grafted. Cells should hatch 12 days after grafting if the larvæ are the right size.

Now dequeen another colony to have ready for cell-building three days later. Don't forget to put a feeder in this colony also. In grafting the second lot of cells one will have better luck, as there is by this time royal jelly with which to "prime" the cells. Go to the colony which has the first lot of cells and cut off an unsealed cell which is well fed. Take this cell and extract the larva, throwing it away; then with a small paddle stir the royal jelly until it becomes of uniform consistency. With the paddle, lift out some of this jelly; and with a small round stick, which has a small cavity in the end, take a drop of this jelly and place in the bottom of every cell cup. One well-fed cell should contain enough royal jelly to prime from 36 to 54 cell cups. In hot dry weather sprinkle the floor of the building, and the jelly will not dry up so quickly.

After priming the cell cups with the jelly, repeat the grafting operation as before, placing a larva in the center of each cell, *on top* of the royal jelly. Place the lot of grafted cells in the second queenless colony, being careful to make the record as before. Always have a slate on the outside of the hive on which to write the date the cells are to hatch, and the number of lots or cells.

After the cells have been sealed they may be put in the upper story of some good strong colony to stay until ready to be distributed. The queenless cell-building colony will thus be available for use again. In placing the sealed cells in the second story of a colony with a queen, two well-filled combs of larvæ must be raised to the second story, and the frame with the sealed cells placed between them. A queen-excluder must be put between the super and the brood-chamber to keep the queen from coming up and tearing the cells down. The cells may be left in this super until two days before they are due to hatch. They must then be taken out, care being used not to jar or turn them upside down, and cut from the stick. Each cell should be placed in a West queen-cell protector. After you have them all in the protectors, and distributed, one cell to each nucleus, which you have already formed, they can hatch out in their natural way.

Hang a slate on each nucleus with the date the queen is due to hatch, written on it.

One or two days after the queen has hatched go to each nucleus and examine to see if the bees have accepted her, at the same time removing the cell-protector. If the queen did not hatch, leave the cell and mark it doubtful by putting the slate on the cover with some grass under it. Then examine it next day. If she has not hatched then, or the bees have killed her, lay the slate on top of the cover without the grass. This signifies that the nucleus is queenless and needs a cell or a queen.

Never give a cell to a nucleus that has run out of brood, as it is useless. The bees will always kill the queens. Provide a comb of larvæ from another hive, at the same time removing an empty comb. In from eight to ten days (in good weather) after the queen hatches she will be laying.

CELL-STARTING COLONIES.

After the queen-rearing work is well under way, and the stronger colonies have brood in the second stories as well as in the brood-chamber, select one or two good strong colonies which are handy to the workshop; dequeen them, and use them for drone hives and for starting cells during the whole season. These colonies must be kept well supplied with brood in all stages. As fast as a drone comb is filled with brood, give it to these colonies to care for. Graft the cells in the usual manner and place them in these colonies for one day. The bees will begin drawing out the cell cups and feeding the larvæ; then put the cells in an upper story of a strong colony with brood in both stories, but with the queen below an excluder. Shift the frames every time new cells are given, putting the frames which are empty below and raising the ones filled with larvæ above. These colonies will finish the cells perfectly.

Do not forget to keep the drone or starting hives well supplied with nurse bees. When the flow of nectar is over, and the bees in other colonies begin killing the drones, collect all of the brood and place in these drone hives. Then drones will never be lacking. To get drone comb, place an empty frame in the brood-chamber between two frames of brood, during a flow of nectar. Do not put starters in this frame. Always remember that an old queen will lay drone eggs sooner than a young one. Keep a record of the number of the colonies in which the drone combs are placed, so that they may be more easily found. A few seconds in making records will save hours of time, needless walking, and labor. Every two days destroy any cells which the drone hives start from their own brood. This is very important.

FORMING NUCLEI AT HOME.

Take a frame of brood and a frame of honey, together with the adhering bees, and place both in a nucleus hive. Stop up the entrance, brush in half a frame of young bees and cover with a tight screen for 24 to 48 hours—in hot weather, never more than 24 hours. Then open the entrances and take off the screens after it is too dark for bees to fly. If this is done earlier, some will be lost and others robbed out.

Morgan, Ky.

MIGHTY POOR JUDGMENT ON THE PART OF THE BEES

BY RICHARD S. KIRCHBERGER

I have kept bees only a few years, and now have 8 colonies. This comb shown in the illustration was found about 150 feet from my hives, built in some wild shrubbery—absolutely in the open, with no protection whatever. It was built on a young

An unusual amount of comb for an outdoor colony.

wild black cherry and a wild honeysuckle. The weight of the comb pulled the branches down until the bottom of the comb touched the ground. The comb measured about 16 in. long by 12 wide. There was not a particle of honey left in it when found, and the bees, of course, were all frozen.

Highland Park, Ill.

Heads of Grain From Different Fields

THE BACKLOT BUZZER

Aunt Bertha Buckwheat says she doesn't believe it is possible to cross the bee with the lightning-bug so it will work nights, but she does think somebody ought to invent glasses for them so they could find a little more honey.

HM!

(There is nothing about bees in this. It is intended primarily for Don Marquis of the *New York Sun*, who, of course, will never see it, and, incidentally, for three other gentlemen who may.)

“It’s so easy it’s absurd,
Here a word and there a word—
Webster’s done the work, you know”—
Don Marquis admitted so.

So there’s nothing left for the poet to do
But spend the best part of a lifetime or two
Feeling his subject deep down in his heart,
Forming and shaping itself to his art;
Throbbing, himself, with the pulse of the
thing,

Helping it grow and hearing it sing;
Nothing to do but put in and cut out,
Polish it up and turn it about;
Nothing to do but build a new phrase
With smoother or swifter or winsomer ways;
Nothing to do but listen and feel;
Make of one verse a sabre of steel;
Make of another a shaper of wills;
Make of another a call from the hills;
Make of another a murmuring rest;
Make of another a dream-haunted quest;
Nothing at all for the poet to do

But labor and love for that lifetime or two,
Yielding his part to a rhythmical whole,
Giving his brain and his heart and his soul,
Giving his life and giving himself,
And then get put on a separate shelf!
Nashville, Tenn. Grace Allen.

Beeway or Plain Sections.

Dr. C. C. Miller:—Which is the best section to use—the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ inch plain, the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ inch four-beeway, or the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ inch two-beeway? I mean, which is the best in regard to swarm control?

I have ten colonies of bees; two colonies have three-banded Italian queens; the other eight colonies are the common black bees. Now, I want to Italianize the black bees, and on account of expense I want to raise my own queens. Is there any way by which I can keep the black bees from mixing with the yellow ones? How can I get the queens mated with the yellow drones?

Antioch, Okla.

Baxter Burnett.

I don’t think either section you mention is the best. The one that is in more general use than any other is the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ two-beeway. The fact that it is used more than any other, in spite of strenuous efforts having been made to push others ahead of it, is pretty good proof that beekeepers in general believe it best. So far as swarm control is concerned, I doubt if there’s any difference.

So long as there are other bees within a mile or two of yours you will find it difficult to keep yours pure. You can, however, control the drones in your own apiary by allowing them to be reared only in Italian colonies. In other colonies you can keep the heads shaved off all drone brood as fast as it is sealed, or, better still, cut out all drone comb and patch worker comb in its place. One thing in your favor is that, when you rear a young queen from an Italian mother, even if the young queen mates with a black drone, the drones that she rears will be pure Italians. By persistently rearing queens only from pure mothers you will gradually work out the black blood. It may be well also to mention that the first cross will generally be found as good gatherers as the pure bloods.

Marengo, Ill.

Dr. C. C. Miller.

What is to be Done with the Froth?

What is usually done with the froth that accumulates on the top of extracted honey? Is it of any value?

Do bees that are wintered in a cellar have to be put back on their identical stands in the spring?

C. C. Brinton.

Turkey River, Ia.

[The froth that rises to the top of the honey is not of much use, altho it would not need to be thrown away necessarily. It

could be thinned down with water and fed back to the bees.

It has been definitely proven that colonies wintered in the cellar do not have to be put back on their former stands. After so long a time in the cellar the bees mark the new location very thoroly, and there will be no more mixing up than if they had been located where they had been the previous season.—Ed.]

They Just Ate 'Em Up.

A year ago last April I put on three supers of sections—one on each of three hives. Two of the colonies were strong, while the third was not so strong. Each super contained full combs (not foundation) that each colony had made the year before. The bees put nothing in them that year, and so last May I put the combs on again. When I looked thru them in June there was not a vestige of comb in either of the supers—not even propolis. What did they do with it? Work it over, down in the brood-nest? I never heard of nor read of the like before.

Colchester, Ill. J. C. Schaufele, M.D.

[There is just a bare possibility that mice may have gnawed these combs down, altho we think it is more likely by far that, being kept as long as this, the wax had become very dry and fragile, difficult for the bees to work. This would be especially true if the wax had been kept in a cold place during the winter. Under such conditions the supers, being put on in May, when the bees probably did not need the extra room, they amused themselves by gnawing out the combs. We know that bees will sometimes gnaw combs and gnaw foundation if it is given them at a time when they do not need it; but we do not remember to have seen a report of whole supers of combs gnawed away.—Ed.]

If at First You Don't Succeed—

Five years ago I cut a bee-tree; and as I did not know how to take the bees out I sawed the tree off at both sides of the cluster, nailed a board on both ends, stopped up the hole that the bees went in and out of, and then loaded it in a wagon and hauled it home to put in the orchard. They did not do well, however. I was young, and kept fooling with them till they left the stump and went to the timber.

I was determined to keep bees. The following year I got four or five more stumps of bees, and, of course, they did not make much honey that year, but they wintered all right in those stumps. The following spring an uncle of mine who was a beekeeper, and knew more than I did, helped me transfer one colony to a hive, and I transferred the rest.

I had better luck that year. The bees made considerable honey and increased to seven. Then I rented nineteen more for the next year for half the honey and half the

increase, but did not make anything. My share of the honey just paid for the supplies that I bought. I had only about 675 lbs. of honey that year with which to buy so much, as I was just starting out. My share of the increase, with my old colonies, made nineteen in all.

About that time I subscribed for Gleanings, bought books, and secured all the information I could. I did not keep the rented bees any longer, but kept my own bees. Last season my bees increased to thirty-three colonies and averaged fifty pounds of honey each, spring count.

I am going to build an extracting-room next fall if my bees do well. I have an extractor, and use a steam uncapping-knife, and run for both comb and extracted honey.

Willow Creek, Mont. Jay E. Huller.

No Division-board for Me.

If I were going to use ten frames I would dispense with the division-board and use two springs, one on each end of the frames, against the wood or metal spacers. There would be nothing glued fast then when the two springs were removed.

On the other side, there is no bee-space between the wall and frame so the bees would put in some bee-glue here, which would be a nuisance to overcome. Cut one metal spacer in two, and push the metal spacing-frame against it, and tack it fast. If using the Hoffman wooden spacer, then tack fast a thin piece of wood against the inside of the hive so a bee will have plenty of room to get thru.

Highland, N. Y. Victor G. Berrian.

Cats Have Nothing on Bees in the Matter of Lives.

A few days ago I was walking around in my apiary, and found one of my colonies dead, and most of the bees were on the bottom-board. I took off the cover to make an examination to see what caused them to die, and found that they had starved out. The temperature was 10 below freezing. I removed some of the frames and searched around for the dead queen, and brought her to the house to show her to a friend. I was grieved over the loss of my queen, but I laid her on the table, and the first thing I knew she was crawling up the window. I thought I would see what I could do with the rest of them, so I brought the hive into the house by the stove, and in a few minutes the bees began to move. I sprinkled some warm syrup on them, and in a few minutes they crawled up on the frames. I filled two frames full of syrup and kept them in the house two days, and in five days the queen had laid three frames of eggs. How long can a bee live after starving to death? I will never dump any more dead bees out on the ground in the winter until I know they are dead for good.

OUR HOMES

Editor

She hath done what she could.—MARK 14:8.

Their works do follow them.—REV. 14:13.

This woman was full of good works and alms deeds which she did.—ACTS 9:36.

In *Our Homes* for August 15, 1915, I gave an obituary notice in regard to the life of my brother-in-law, Mr. James G. Gray; and in that article I had considerable to say about his wife, my sister, Mrs. Eliza J. Gray. Little did I think when dictating that article that this sister, too, should so soon follow her husband. But as she lived to be 82 years old, we can thank God for the long life, and especially for the *good* life, she lived. I mentioned in that article that my sister began teaching school when she was only sixteen years old, and wearing short dresses; and she taught the school very successfully, walking out to it a couple of miles in the country, and back again at night. You may readily infer that she had considerable of what the world calls "grit" or she would not have thought of undertaking such a responsibility at such an early age. It was characteristic of her, not only in childhood, but all thru more than four-score years of life, to push ahead, especially when things in this world of ours did not seem to be what she thought they ought to be. In her lifelong disposition to do her duty, whether it hit friends and relatives or not, she sometimes made a mistake (like the rest of us), and therefore had *some* enemies as well as a host of friends.

When I was about twelve years old, a younger sister and I "went to school" to sister Eliza. I well recollect one afternoon when she had reproved me once or twice without doing much seeming good. I had a sort of idea that, as she was my sister, she would be a little lenient on that account. Finally, fixing her eyes on me she said, "Amos, you may take your books and go home and stay there until you can come back and obey the rules of the school."

I think I attempted some objection, knowing that my father and mother would insist on knowing the full facts in the matter. But she shook her head decidedly, and I obeyed orders. As I think of it just now, I feel ashamed to admit that I was *not* always a diligent pupil; but in that particular country school district there were some bad boys, and, I fear, some bad girls too, who needed a good wise teacher, and I began to catch the general infection somewhat. My impression is that my sister united with the church at quite an early age; but, like many other professing Christians, in time she became what might be

called more or less "worldly." But when the Woman's Crusade broke out she was one of the first to enlist, and she went into it with vehemence. At that time I myself was in the habit of taking a glass of beer occasionally, as I have heretofore explained. Mrs. Gray took me in hand so effectually that I do not think I have ever tasted beer since the crusade started in the spring of 1874.

By the way, Mrs. Gray has all her life been not only a kind sister, but has, at times, especially since my mother has gone, exercised a maternal influence over me. Now, please do not smile, any of you, when I give you just one illustration, as the moral may have a good influence over some of the newly married men and women of today. When Mrs. Root and I began life together we made our plans, which is the wise and proper thing to do. And among other things we thought it would not be best to be burdened with "little prattlers" right at the start. But we soon discovered, like many other young couples (at least I hope so) that often, altho "man proposes, God (in his loving kindness) disposes." Mrs. Gray came into our home one morning when we two, young husband and wife, were wearing long and despondent faces. When she inquired what the matter was, and had been told, she replied something like this:

"Why, you poor foolish young couple! a baby in the household will be the very best thing that *could* happen. If it should be a boy, that boy will be, in just a few months, the sunshine of your home and the delight of your lives, perhaps clear down to old age. Instead of looking sad and sorrowful, go down on your knees and thank God for this new revelation of his loving kindness and wisdom."

It proved to be a boy, and we called him Ernest; and he was in very truth a delight and joy to us and the life of our household. I have told you how I used to show him the pictures in the *Scientific American*, and explain them to him, before he could talk. His antics and boyish jokes kept us laughing until we had no time nor inclination to worry about finances or anything else. In fact, he used to get off jokes on both father and mother before he could talk. And, come to think of it, I do not believe he has got over that trick yet. Those of you who know him have probably seen him avert trouble by some droll remark that set everybody laughing, and made them forget their differences.

I will not attempt to tell you what Mrs. Gray has done in her lifelong work as an officer in the Woman's Christian Temperance Union; but I expect to give you something in that line a little later. Since her husband's death she made a trip all alone to a state convention, and she was the only member present of the old original crusade of 1874. Her picture appeared in many of the dailies and in the temperance journals. Below is a clipping from the *Medina Gazette*:

Mrs. Eliza J. Gray, one of the sainted mothers of Medina, died in Akron, Monday morning of this week. Mrs. Gray has for many years been one of the conspicuous figures of Medina, having more than a local name for her temperance and W. C. T. U. work.

Eliza J. Root was born of sturdy New England stock, the daughter of Samuel and Louisa Hart Root, being one of seven children. She was born Sept. 17, 1834. At the age of nine years she moved with her parents to Mogadore (near Akron). She was educated in the public schools, but her education was supplemented by self-culture all her life. At 16 years of age she began teaching, and was united in marriage to James G. Gray at the age of 19, Jan. 19, 1853. Mr. Gray was at the time instructor in Folsom's Commercial College, Cleveland. To this union four children were born.

At the time of the famous "Crusade" in 1874, Mrs. Gray, with her family, was living in Michigan and engaged in the activity of the work there, moving a little later to her present home, Medina. She has been state treasurer of the W. C. T. U., serving for three and one-half years, and state superintendent of the literature department many years. She also has been a most efficient superintendent of the Demorest contests in Ohio, retiring only on account of failing health, and a loyal supporter of the Prohibition party, bearing criticism and even social ostracism with remarkable Christian spirit. With time and money at her disposal, she used both at all times for the advancement of the cause to which she had given herself. She was a devoted member of the Congregational church.

Her death occurred just before our return from Florida. It occurred so near the time that we had picked on for our return that we knew nothing about it until we reached Medina on the morning of April 20. As the children gathered about us, after the greetings were over I remarked that I must run right down and see my sister. When they exchanged glances without replying immediately, my heart began to sink, and then some one said, "Amos, we are sorry to tell you your sister has been worse."

I replied, "Dear me! I shall have to hasten right down."

Then some one added slowly, "She has been very much worse. You cannot see her."

Then another one added, "Amos, your sister has gone to her reward."

As in the case of a former sister, I could not take it in all at once. I could not realize it. Many of you know, dear friends, how such things affect us, especially when we

are getting to be old; and it has now taken days and even weeks for me to *realize* my loss. When I am upstreet on some errand I almost unconsciously start to go down to that well-known home; and when I open my mail, without thinking I say to myself, "Oh there! Eliza must see that." And then somebody asks in a letter about some phase of the prohibition work where I am not well posted, and I say to myself, "I will just carry that letter down to Eliza, and she can give me all the facts in the case."

Of course, I thank God again and again that she was permitted to live a good long life, and that it was always a busy life. Eliza, as I firmly believe, directed all her efforts to benefit poor and ailing humanity. In the language of one of our texts, "She hath done what she could;" and the result of her earnest and busy lifework will follow on thru generations to come. And the concluding text well applies to Mrs. Gray. She contributed to temperance and missionary work thru all her busy life; and altho she earned quite a considerable sum in different ways, together with her good husband, if I am correctly informed it was practically all given to the benefit of humanity, thru different channels devoted to the cause of temperance.

=====

FRICITION MATCHES; WHEN INVENTED.

Dear Mr. Root:—I know you wish to be accurate in dates as in everything, so I call attention to your second note, bottom of page 641, GLEANINGS for Aug. 1. You say "friction matches were not invented at that early day," etc., 72 years ago. The Century Dictionary, under "Friction Matches," says they were invented in 1827, and elsewhere that they were in pretty general use in 1830. I was born Feb. 11, 1837, and remember distinctly that they were cheap and plentiful in Hudson in 1842, and that my mother told of the days of her girlhood when they had none. Your people used coals as more convenient than matches for burning sulphur at the beehive, I presume, and not because there were no matches. I am three years older than you, but cannot remember when friction matches were not plentiful and cheap.

Hudson, O., Aug. 9. W. I. CHAMBERLAIN.

Many thanks, my good friend, for correcting my mistake. When I said "invented" I meant they had not yet reached our log house in the woods. I distinctly remember my brother going to a neighbor's to get a shovelful of coals because the fire was out; and I also remember later when father brought home some matches from town—the first the family had ever seen; and what a curiosity it was to see my father start a fire with the queer-looking things plentifully coated with brimstone as we discovered when we got too near! The roads were so muddy at that early day, and in such bad repair, that we did not get to town very often; and I fear we did not have a weekly

paper to tell us what was going on in the world. Later on I remember when Mr. Barber (father of the millionaire) had a match-factory between Akron and our Mog-

adore home; and my aunt Harriet worked for him. In fact, I am not sure but she was the first girl employed in Barber's little brick match-factory.

HIGH-PRESSURE GARDENING

SOME GLIMPSES OF OUR FLORIDA GARDEN.

Ever since I was big enough to get a look at things outdoors I have been interested in seeing things grow. My good mother was my first teacher in calling my attention to God's wonderful handiwork in making it possible for the tiny seeds to come to life and grow, and I believe I have always had a garden. I am particularly interested in plants that make rapid growth—especially so, since in Florida success with poultry depends largely on giving them a generous supply of green stuff for food. Two plants during the past winter have given me much gratification in the rapidity of their growth. The first is the collard. I believe they are grown largely in Georgia and further south. I am told they are a favorite with the colored people. Some time in February I sent by mail for one hundred collard plants. They started right up and grew in almost no time; and the severe drouth in February did not seem to disturb them a particle. As we had more plants than we had room for I set them in various places all over the garden; and in the poorest ground, with almost no fertilizer, they made great bushy plants in an astonishingly short space of time.

Figs. 1 and 2 show the collard. The photographer threw his hat down by the side of one so as to give an idea of the relative size of the plant, and you can see where I placed my hand on some of the foliage. Well, I have already pulled great armfuls of leaves from these plants for the chickens. I pulled off the lower leaves, of course; but

it seems the more leaves I pulled off, the faster they grew. Some of the midribs of the leaves were so large the chickens could

No. 1.—A Georgia collard, about sixty days after setting out the plant.

not readily break them up; but after they had eaten off the leafy part I took those midribs in my hands, holding as large a bundle as I could compass, and with a very sharp knife I slashed them in lengths of about an inch. In this way the chickens consumed every bit of the plant. Cut 2 shows two plants growing side by side.

The other plant I wish to mention is a radish I found in the catalog of the Burgess Seed Co., Galesburg, Mich. Here is a clipping from it.

SAKURIJIMA RADISH.

This is the giant radish from Japan. Often attains a weight of 15 pounds and sometimes 20 or 25. A great curiosity and a radish of extraordinary quality. Flesh solid, firm, and brittle, and of most excellent flavor. Planted in the spring, it keeps growing all summer, right thru the hottest weather, and never gets tough or pithy. Can be eaten during the summer, when it is difficult to grow other varieties, and can also be kept late in the

No. 2.—A couple more of the Georgia collards on comparatively poor ground.

winter if buried in sand. You will be pleased with it.

The upper picture shows one of the radish plants with its great bunch of foliage. The picture just below is the plant after I had pulled off a great armful of leaves. This radish, top and all, after being pulled up, weighed 13 lbs. The little holes in one side show where a hen and chickens picked into it. Well, the poultry will eat this great radish, top and all, every particle, if thrown out to them. The large mid-ribs in the leaves, also shown in the cut, have to be cut up in short lengths, as does the collar. Where you have many of them, and a great flock of chickens, you will need a cutting-box or vegetable-slicer. You may recall what I said a year ago — whenever you set a hen, sow some radish seed; and

when the chickens are old enough to eat "greens" the radish will be up just right. I think this radish is going to be a nice thing for poultry-keepers.

I notice by another catalog that this great root is good for table use when cooked as we cook turnips, and I think this may be true; but I did not have an opportunity to try it after reading the notice. I did notice, however, that slices from the great root are remarkably sweet—more so than the common small radishes.

Since writing the above I find the following in the catalog of the Greenwald Seed Co., Lincoln, Neb.

SAKURAJIMA.

A Japanese radish of immense size. Some single specimens of this variety weigh as much as 15 pounds. In shape it is oval, with cream-colored skin and pure white flesh. Roots are cooked like turnips, but no strong taste accompanies them, such as is frequently present with cooked turnips. The plants should be thinned out to from 12 to 15 inches apart in the rows, so as to admit of full development; must be sown in May; takes whole season to develop roots.

SWEET CLOVER AGAIN.

An account of an experiment with sweet clover will disclose its valuable features. On the farm adjoining ours there appeared one year a heavy

No. 3.—Upper picture shows the plant before a part of the leaves were removed as in the cut below, to show how the root grows partly above and partly below ground.

growth of sweet clover covering about six acres. The owner of the farm saw no value in it, and offered it to us in exchange for a load of timothy from the field. We accepted the offer, and prepared to harvest it. The seeds had formed on at least two-thirds of the plants, and some of the stalks were as large as a man's finger, and over six feet in height. Nevertheless we cut it, drew it into a yard, and made two large stacks of it. Every pleasant day during the winter, cows, young cattle, and colts were allowed access to it, as much for the exercise, perhaps, as for the eating of it. Greatly to our surprise they evidenced unusual desire for it, eating it in preference to hay of better quality. They would nose around the bottom of the stack seeking the weeds; they would chew on the large woody stalks until an observer would think the yard was used as a dump ground for refuse rope material, as there were strings of fiber four to six feet in length lying around. All of the stock looked well, hair was shiny and sleek, and the colts were as lively as colts could be. The cows, too, continued to give good messes. Every bit of the two stacks was consumed.

The next spring the manure from the stock which had eaten the sweet clover, and the manure from where the stacks had stood was applied to a meadow that had a poor growth of timothy thereon. The grass started, and along with it appeared numerous tiny sweet-clover plants. These plants soon outgrew the timothy, and covered the ground, all from the seed which the manure contained. When haying was begun, that field was one of the first to be cut; and when it was cut, when about half in bloom, what a field of hay that was—one sea of green, and

a foot higher than the wheels of the mowing-machine. We did not allow it to go to seed as had the field of the preceding year, hence it was in fine condition—no large woody stalks at all. The clover was cured as red clover usually is, and with no loss of leaves. It was stored in the cow-barn, and fed the next winter to the milch cows. It was fed following alfalfa, and with no loss of milk, and not a bit of stalk remaining. The bitter taste that is ascribed to it did not seem to be there, as the cows ate every bit of it with very evident relish. As much milk was made from it as was made from the best clover or alfalfa we ever fed.

The yield per acre was certainly two tons of cured hay, and at no expense for plowing, fitting, or for seed. It was just a crop from the seed in the manure. This teaches us that if we raise it and feed it we must not allow it to mature, then feed it, and then apply the manure therefrom unless we want some sweet clover in that field. Hay buyers do not like it in the hay they buy, although they have bought it without adverse criticism. We have conclusive proof of its value as roughage for dairy cows, young cattle, colts, and horses, and advise any farmer having it on his land to give it a trial.—W. J. Hagar, King Hill, Idaho, in *Seed Sense*.

TEMPERANCE

A LETTER FROM ARTHUR CAPPER, GOVERNOR OF KANSAS.

We clip the following from the *Associated Prohibition Press Bureau*:

THE HOUR'S TREND.

The splendid message below from the executive of the great state of Kansas is most significant.

It shows that we are rapidly nearing a psychological hour of realignment and coalition for the great reform. Governor Capper's letter reads as follows:

STATE OF KANSAS
ARTHUR CAPPER, Governor.

Topeka, March 14, 1916.

Mr. F. D. L. Squires,

The Prohibition National Committee,
Chicago, Ill.

Dear Mr. Squires:—I have your letter of March 10. I am firm in the belief that the time is here when the best citizenship of this entire nation should combine in a movement to put the saloon from us for ever. We know that the saloon is making more human wreckage than all other agencies. Why should we, an enlightened people, a scientifically informed nation, continue to license this great curse, knowing it to be our greatest enemy, our greatest hindrance to national well-being, the greatest destroyer of thrift and happiness, the greatest promoter of vice, crime, and disorder, the greatest menace to the life of every boy and girl in the land, the greatest source of expense in government, and its most corrupting influence? Could anything be more reasonable, more sensible—more necessary—than national prohibition!

Very respectfully,
ARTHUR CAPPER,
Governor.

May God be praised that we have at least one governor who can come out thus boldly and squarely on the liquor question. How many other governors have we who are not afraid to stand by him?

ALMOST \$1500 A MONTH SAVED IN THE COST OF FEEDING THE PRISONERS IN JEFFERSON CO., ALABAMA.

The above saving came about by the smaller number of prisoners in the county jail after the county containing the city of Birmingham was made dry. See the clipping below, from the *American Issue*:

Sheriff E. B. Knight, of Jefferson County, the county in which Birmingham is located, presents the following figures in a letter dated April 1:

The total number of persons confined in the Jefferson County jail during the year 1915 was 1666 less than in 1914, the last year of saloons. The total number confined during the last half of 1915, the first six months under prohibition, was 725 less than that of the first six months under saloons, or 1487 less than the corresponding six months of the previous year under saloons.

From an economic standpoint it might be of interest to note that it cost the people of this state \$8975.40 less to feed the prisoners in the Jefferson County jail during the last six months of 1915 under the prohibition law than for the corresponding six months of the previous year under saloons, or a saving in this matter alone of \$1495.90 per month for Jefferson County.

Several thousand half-pint bottles of whisky were shipped from Cincinnati, Ohio, a few days ago to Birmingham. The whisky was packed in piano-boxes and billed as second-hand pianos. The consignment was seized, and Uncle Sam is now ferreting out the wholesaler who shipped the stuff. He can be prosecuted under several sections of the United States law.

After reading the above, just think of the absurdity of the statement of the liquor party that, if we do not have the saloon revenue, we cannot keep up our schools to educate our children! The cost of feeding prisoners is something, of course; but, dear me! what does the cost of feed amount to compared with keeping from 1000 to 2000 able-bodied men in jail for a whole year?

RUSSIA'S EMANCIPATION FROM ALCOHOLIC LIQUORS, ETC.

We take pleasure in clipping the following from the *Akron Beacon-Journal* of April 22:

RUSSIA TO WIN A DOUBLE VICTORY, SAYS AMERICAN IN CZAR'S SERVICE.

NEW YORK, April 22.—Dr. Philip Newton, an American who holds a commission of brigadier general in the Russian army in recognition of his work for the czar's troops, will leave here within a few days for the eastern theater of war. He takes with him fifteen ambulances presented by Americans to the Russian army. Dr. Newton looks forward to a double victory for the Russian empire when the present war shall have ended.

"Russia is already victorious in a war greater than the one she is waging with the central powers," said Dr. Newton. "This glorious victory was gained in a single day by the czar's order prohibiting the use of alcohol within his empire. Great will be the

total of soldiers killed on the battlefields, but the number of people saved thru the abolition of alcohol will be much greater.

"The change for the better in the Russian people is manifested in many ways. For instance, the stress of war usually causes an increase in the number of insanity cases. War and absolute prohibition started about the same time in Russia, but the number of insanity cases has actually diminished since that time.

"Economically the change has worked wonders. This is forcibly demonstrated by the fact that since the beginning of the war the working classes have deposited a billion dollars in the savings banks of Russia. In the old days it was common for the workmen in factories to get drunk on Sunday or on any other of Russia's numerous holidays and waste a couple or three days recovering from the effects of strong drink. Now he is steady, works the entire week, and takes his wages home to his family. Both he and his family have more money than they ever had before, and so it is not surprising that the savings banks report many new depositors. Naturally the wealth of the country is increased by this great gain in the amount of work done.

"With brains cleared from the clouding caused by constant alcoholism, a decided mental development will occur in the peasant class. A logical result of this mental awakening will be a desire for greater knowledge. If the education of these people is conducted along sound lines, I do not think that the much-talked-of revolution will occur."

In view of the above, is it not strange that the United States of America does not seem to catch on and follow suit? May God be praised for what Russia has done for the whole wide world in the way of an object-lesson.

"READING BETWEEN THE LINES."

The Associated Prohibition Press Bureau sends out a sheet from which we clip the following:

United States Public Health Service has just issued a most commendable series of timely and reasonable suggestions to the citizens of America. They are issued under the general notation "Do You Know That—?"

We reproduce the text of this Bulletin below, with a brief suggestion as to the relation of its recommendations to the most important problem of health in our land today:

"DO YOU KNOW THAT—"

1. "Sags in roof gutters may act as mosquito-breeding places?"

True; and sags in civic conscience and civic government may and do act as breeding-places for the mosquitos of graft and the gnats of political corruption.

2. "America's most valuable crop is babies?"

Is that so? Then why vote loiger for any party that protects the greatest baby-killer in the world's history?

3. "The public cigar-cutter is a health menace?"

And that public life-cutter—par excellence—the saloon, is the place where the cigar-cutter is usually found.

4. "The United States Public Health Service maintains a loan library of stereopticon slides?"

The slides ought to include a series showing the government partnership with the liquor traffic which is still destroying the health and besliming the environment of millions which this bureau is trying to help.

5. "The typhoid rate measures accurately the community intelligence?"

And the per-capita liquor consumption rate is a perfect thermometer of the public moral intelligence.

6. "Whooping cough annually kills over 10,000 Americans?"

Meanwhile 200,000 liquor saloons are making ten times 10,000 victims "cough up" daily until the most of them end by going on a "whooping" drunk. But that's no cause for excitement, of course.

7. "Bad housing produces bad health?"

And bad liquor (which is any kind of alcoholic poison) keeps millions badly housed.

8. "Rocky Mountain fever is spreading by a wood-tick?"

But the whisky fever is spreading a thousand times faster than that with every clock-tick.

I wish to call attention to No. 4 in the above. Our nation's partnership with the liquor-traffic ought to be held up before our people and talked about and commented on until the head or heads of our nation get so wearied with our importunity that they will speedily wake up and do something. The expression, "besliming the environment of millions," hits the point exactly.

We clip the following from the *Methodist Episcopal Church Temperance Bulletin*:

BOOZE FOR BOYS! THE HOLLISTER DISTILLING COMPANY OF ST. PAUL CALLS FOR LISTS OF LADS.

The Hollister Distilling Company, at 129 East Third Street, St. Paul, Minnesota, wants the names of the little fellows in your town. If you will supply this list they will give you a quart of whisky.

The Martin County (Fairmont, Minnesota) *Sentinel* says that a rural mail carrier of that city has received a letter from the Hollister Distilling Company which says:

"I want the names of the boys in your town and on the rural routes. . . . I want as complete a list as possible, and a good list. If you will send me such a list I will send you your choice of a quart of old 1881 brand whisky or a quart of fine old imported Spanish Port wine. Get the postmaster to help you, also the bank cashier and the express agent."

The letter was signed by Elmer J. Jacobs, Manager.

When they say that "Prohibition doesn't prohibit," what do they mean? They mean that the American people do not have it within them to dominate the liquor evil. "Drink," they say, "is greater than your laws, greater than your constitutions, greater than YOU." Little do they know the exaltation, hot resolve, and burning determination of Columbia's heart this day.

Is it possible that there is no department of our government at Washington that can take up and punish an institution that sends out a circular like the above? May God help us when things come to such a pass that a distilling company is actually laying traps for our innocent boys.

A KIND WORD AFTER READING A SINGLE COPY.

I have read a copy of GLEANINGS, and it appeals to me as a first-class paper. I especially like Our Homes. Keep up the fight against the liquor traffic, as we need every bit of ammunition we can get hold of. The sooner we put this rotten business out of business the more God will prosper us. Billy Sunday has been down here preaching to Syracusans to give up "booze" and turn to Christianity. We have a much cleaner city by the work of this wonderful man. May God bless him and further him in his great work.

Syracuse, N. Y., April 1. FRANK M. WHITE.

BUY THE BEST

Why buy inferior queens when the best can be bought at the same price? You have heard of Dr. C. C. Miller's famous honey-gathering stock. How would YOU like to have a strain of bees like his? You CAN have. LISTEN, and we will tell you how.

We have made arrangements with Dr. Miller to furnish us breeders from his stock that has produced 266 sections weighing 244 pounds. These breeders are FINE. They are pure three-banded Italians, very gentle, and produce fine large daughters. Few people ever have a chance at the best in the world—so grasp this chance while you have it.

To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.
C. C. Miller, Marengo, Ill., March 1, '16.

Untested, \$1.00; tested, \$2.00; Select Tested, \$3.50; breeders, \$5.00 to \$10.00 each; virgins, 50 cts. each; 12 for \$5; 25 for \$10.00.
3-frame nuclei.....\$3.25
2-frame nuclei.....\$2.25
1-frame nuclei.....\$1.25

Colony in 8-fr. hive, \$6.00; 10-fr. hive, \$7.00.
Prices of colonies, nuclei, and pound packages do not include queens.

WASHINGTON, D. C.

EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

The A. I. Root Company . . . Medina, Ohio

Make money breeding PR squabs. 1910 demand biggest ever. Squab book free, telling money-making experiences. How to sell by parcel post. \$6 to \$8 doz. Start small, grow big. Many women customers. Write today. PLYMOUTH ROCK SQUAB CO., 815 HOWARD ST., MELROSE HIGHLANDS, MASSACHUSETTS.

Where are You Located?

IN OHIO?—Then your orders will naturally gravitate to Zanesville, the Bee-supply Capital of the state.

IN WEST VIRGINIA?—The large supply-house nearest to most beekeepers in this state is at Zanesville.

IN WESTERN PENNSYLVANIA? — You are a next-door neighbor.

ELSEWHERE.—Zanesville service will yet commend itself to you as being the best obtainable.

The leading line of bee supplies, unsurpassed shipping facilities, years of experience, and painstaking care in packing and forwarding goods, fair and considerate treatment, all insure a degree of satisfaction that can scarcely be duplicated elsewhere.

If exasperating delays or otherwise unsatisfactory service have been your past experience, give us a chance to demonstrate the superiority of the service we offer.

Ask for our free illustrated catalog.

E. W. Peirce,

22 So. Third St. Zanesville, Ohio

Distributor for the largest bee-supply factory in the world

Your Honey Crop

Depends on Your Interest in Bees

The greater the interest, the greater the crop. Increase your interest by studying what happens in the egg. Here the individual bee begins life.

The Embryology of the Honey Bee

Our 1916 catalogs now out. Postal will bring you one. Root's goods at Root's prices. Prompt shipment.

E. M. Dunkel, Osceola Mills, Pa.

For New England

Beekeepers, we have everything you need in the way of supplies. Remember we are in the shipping center of New England. Let me send you a new catalog.

H. H. Jepson, 182 Friend St., Boston, Mass.

DAISY FLY KILLER

placed anywhere, attracts and kills all flies. Neat, clean, ornamental, convenient, cheap. Lasts all season. Made of metal, can't spill or tip over; will not soil or injure anything. Guaranteed effective. Sold by dealers, or 6 sent by express prepaid for \$1.

HAROLD SOMERS, 150 DeKalb Ave., Brooklyn, N. Y.

Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's
Decision

The A. I. Root Co., Los Angeles, Cal.

Geo. L. Emerson, Manager, 948 East Second St.

If you want a queen for that queenless colony, we can send it to you by return mail. Young tested queens, \$1.00, \$12.00 per dozen. Untested, \$1.00; \$9.00 per dozen. We breed the three-band Italians only, and we breed for the best. Our thirty years of queen-rearing proves this. We never had a case of foul brood in our apiaries, and we guarantee every queen sent out by us.
J. W. K. SHAW & Co., Loreauville, La.

Queens now ready. Golden and three-band Italian queens. I shall do my best to fill all orders promptly. If any queen fails to give satisfaction I will replace her free. Untested, 75 cts. each; six for \$4.00. Send all orders to
E. A. SIMMONS, Greenville, Ala.

A daughter of one of *Dr. Miller's best honey queens*, and the *Beekeepers' Review* for 1916 for only \$2.00. A daughter of one of the very best honey-getting queens selected from 1100 colonies worked for extracted honey, from the yards of E. D. Townsend & Sons, and the *Review* for 1916 for only \$1.75. The queens will be mailed in June direct from our breeders in the South. A rare buy.
THE BEEKEEPERS' REVIEW, Northstar, Mich.

Carniolan, Golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, box 315, Buffalo, Tex.

Three-banded queens and bees by the pound, ready now. One untested queen, 90 cts.; \$9.00 per doz.; \$17.50 for 2 doz.; \$65.00 for 100. Tested, \$1.50 each; fine breeders, \$5.00 each; 1-lb. swarm with fine queen, \$2.25 each; without queen, \$1.50 each; 50 for \$7.00; 100 for \$135. Add queens at above prices. I can furnish you in any quantity from one to 1000 queens or swarms of bees at above prices from April 15, thruout the season. Write to Curd Walker, the Queen-breeder, your wants. He will give you a square deal. BOX 18, Rt. 1, Jellico, Tenn.

Special for May, express prepaid on 10 or more swarms of bees in packages, at my regular price of 1 to 49, 1-lb. at \$1.50 each, and 2 lb. at \$2.50 each, and 50 to 500 of the above at 12½ cts. less each. Untested Italian queens, 75 cts. each; tested Italian queens, \$1.25 each. No reduction on quantity of queens for April and May. Quality, service, safe delivery, and no disease, I guarantee. We spare no labor nor money to produce the best for you is why we cannot make a lower price. Early swarms get the honey. We can deliver the goods with pleasure to both of us. W. D. ACHORD, Fitzpatrick, Ala., the successful package-shipper and queen-breeder.

BEEES AND QUEENS.—Doolittle's Italian stock speaks for itself. They are gentle, resist disease, and are fine honey-gatherers. We breed this stock only, and guarantee delivery only to points west of the Rocky Mountains. Untested queens, 75 cts. each; \$3.00 per dozen; \$60 per 100; tested queens, \$1.25 each; \$12 per dozen; \$85 per 100. Three-frame nuclei, \$2.25 each; \$200 per 100. Bees, ½-lb. packages, 75 cts.; \$6.00 per 100; 1-lb. packages, \$1.00 each; \$85 per 100. Add price of queens to above packages. Complete catalog free on application.
SPENCER APRIARIES, Nordhoff, Cal.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei, with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can, therefore, supply you with the biggest and strongest nuclei you will be able to find anywhere. Send your order now, and money when you want them shipped. Can begin shipping April 15, or earlier, if necessary. Bees are all on standard Hoffman frames, and combs are all built on full sheets of foundation and wired frames. We guarantee bees to be free from disease.
THE HYDE BEE CO., Floresville, Tex.

This is the combination you have been waiting for: Your *Dr. Miller queen* introduced to a 2-lb. swarm; listen: Two pounds of bees, \$2.50; 1 *Dr. Miller queen*, \$1.50; the *Beekeepers' Review* for 1916 (we have the back numbers), \$1.00. Total amount, \$5.00. Send us only \$3.75, and your *Review* will begin coming immediately, and the two pounds of bees with a *Dr. Miller queen* introduced will be shipped by express in June. The reason we make this extraordinary offer is, we want to put the *Review* in the hands of every subscriber of GLEANINGS, and we take this way of introducing it to you. Address, with remittance, *The Beekeepers' Review*, Northstar, Mich.

Southwest Virginia five-band Italian queens, a fancy comb-honey strain; gentle to handle. They will please you. Try one. Untested, \$1.00; 6, \$5.00; 12, \$9.00.
HENRY S. BOHON,
Rt. 3, box 212, Roanoke, Va.

We have available at Ashland, Mo., and subject to previous sale, twenty bushels of nice Japanese buckwheat which we offer at \$2.75 per 100 lbs., \$1.50 per bushel of 50 lbs., bag included. We have also here at Medina a limited amount of this variety as well as of silverhull, which we offer, while it lasts, at the same price. If in need of seed send in your orders while the supply is available.

PRICES ADVANCED ON VARIOUS ITEMS.

We announce the following advances in price of various articles listed in our catalog for 1916, to take effect from and after this date:

Beehive paint, \$2.75 per gal.; \$1.40 per half gal.; 75 cts. per qt.; 40 cts. per pint.
Tinned wire, $\frac{3}{4}$ -oz. spool, 4 cts. each; 5-lb. coil, \$1.20.

Crate staples and end-space staples, 20c per lb.
Three-wire strips for honey-boards, 18 $\frac{1}{2}$ in. long, \$2.50 per 100.

Seven-wire strips for honey-boards 18 $\frac{1}{2}$ in. long, \$5.00 per 100.

No. 3 eight-frame, 7-wire-and-wood honey-boards, 13 $\frac{3}{4}$ x 20, \$4.00 for 10.

No. 4 ten-frame 7-wire-and-wood honey-boards, 16 $\frac{1}{4}$ x 20, \$4.50 for 10.

No. 7 ten-frame 3-wire-and-wood honey-boards, 16 $\frac{1}{4}$ x 20, \$4.20 for 10.

No. 8 eight-frame 3-wire-and-wood honey-boards, 13 $\frac{3}{4}$ x 20, \$3.70 for 10.

These advances are made necessary by increased cost of materials, and a corresponding advance is made in the wholesale and jobbing prices. Other advances on metal goods will be announced in the near future.

SECOND-HAND FOUNDATION MILLS.

We have to offer the following list of foundation machines which have been used but are in fair condition. In many cases they will answer as well as a new machine where you have only a moderate output. Send for sample of foundation from any mill in the list which may interest you.

No. 0153, 2 $\frac{1}{2}$ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.

No. 0156, 2 $\frac{1}{2}$ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.

No. 0165, 2 $\frac{1}{2}$ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.

No. 0183, 2 $\frac{1}{2}$ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.

No. 0214, 2 $\frac{1}{2}$ x 6 hexagonal light-brood mill in poor condition; rolls quite badly pitted; will make fair foundation. Price \$13.00.

No. 0230, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.

No. 0233, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in poor condition; cells bruised. Price \$14.00.

No. 0234, 2 $\frac{1}{2}$ x 6 extra thin-super mill in very good condition. Price \$12.00.

No. 0237, 2 $\frac{1}{2}$ x 6 thin-super mill in fair condition. Price \$10.00.

No. 0238, 2 $\frac{1}{2}$ x 6 thin-super mill in fair condition. Price \$10.00.

No. 0239, 2 $\frac{1}{2}$ x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.

No. 0241, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

No. 0242, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

No. 0243, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

No. 0244, 2 x 10 round-cell medium-brood mill in good condition. Price \$14.00.

No. 0245, 2 x 10 hexagonal medium-brood mill in very good condition. Price \$18.00.

No. 0246, 2 $\frac{1}{2}$ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

THE A. I. ROOT COMPANY, Medina, Ohio.

SPECIAL NOTICES

BY A. I. ROOT

PLANT PROPAGATION; GREENHOUSE AND NURSERY PRACTICE.

The above is the title of a new book dated March, 1916. It contains 322 pages and 213 illustrations; so you see there are "pictures," one or more, on nearly every page in the book. This work is an attempt to take in every improvement up to date in the way of propagation of plants. I was pleased to see three pictures that looked familiar, and I found they were furnished by my good friend E. N. Reasoner, of the Reasoner Brothers' Palm Nursery, Onea, Fla., close by our Florida home. In early childhood when my mother taught me how to plant seeds and watch them grow I was delighted. Later on, when I found certain plants could be grown without seeds I was still further delighted. You know how a woman grows geraniums and other plants from "slips." Well, this book is largely devoted to propagating by layers, grafting, in-arching, etc. Short cuts and improvements in the propagation of plants are advancing so rapidly that it is a hard matter to know all about what is going on in the world, especially the greenhouse world. But Prof. M. G. Kains (Professor of Horticulture in the Pennsylvania State College) has done his work remarkably well. The book is published by the O. Judd Co., of New York. The price is \$1.50.

SOME GOOD BOOKS FOR A SMALL SUM OF MONEY.

In rearranging our office and stock of books on agriculture, etc., we found 15 copies of a book that made quite a sensation in 1885 and later. The title is "The Waters Led Captive." The book is devoted to a sort of sub-irrigation. Its author was an enthusiast, and, as has often happened, put, perhaps, an extravagant estimate on his invention, or, perhaps, we might say, discovery. The plan was to make a sort of subterranean reservoir to hold water. This was filled with stones up to a certain height, and on top of the stones were put brush, straw, weeds, or anything that would rot and make humus; and on top of the brush and straw some stable manure. The ground was then filled up with soil. The theory was to permit the roots of the growing plants to go down thru the humus, brush, etc., and help themselves to water. In a clay soil water would almost always be found in these underground reservoirs more or less. With such an arrangement

I grew the finest melons and squashes I ever grew in my life. I made quite a success of it until the growth of our factories compelled us to dig up my "new agriculture." Father Cole claimed that the great trees of California were the product of underground water on a similar scale built by nature's handiwork. The book gives full directions, and is fully illustrated, with plans for the new agriculture in every back yard or dooryard. For many years we had a most excellent garden over these reservoirs. I hardly need add that slop from the kitchen, and sewage of every sort, can be turned into these reservoirs; and growing trees, especially fruit-trees of all sorts, respond wonderfully to such treatment. The price of the book was \$2.00; but for the sake of closing out the 15 copies left on our hands (by accident) we will make the price \$1.00 as long as they last.

One other book we have left is entitled "What to Do, and How to be Happy While Doing it." This book was put out in 1888, and is devoted mostly to market-gardening. It also has much to say about the "new agriculture." It tells how I managed and how I succeeded in astonishing Medina Co. and a good many other places by the possibilities of "high-pressure gardening." An appendix to bring the book up to date was put out in 1900. Many of our readers are doubtless familiar with this book. Quite a number of successful market-gardeners and florists who have built up a great business got their first start from the book "How to be Happy," etc. I remember one young man who became so enthused with it that he used to go over to see his "best girl" before they were married and read the book to her. Since then they, too, have built up a great business in the floral line. I refer to S. W. Pike, of St. Charles, Ill. We printed so large an edition of this book years ago that we have 1000 or more copies still on hand. The regular price of the book, cloth bound, was 50 cents; paper, 35. It contains 206 pages, and is fully illustrated. While the edition lasts we will make the cloth-bound copies 25 cents, postpaid; the same bound in paper, 15 cents. Or anybody who sends \$1.00 for GLEANINGS may have the latter postpaid as a premium; or anybody who sends us \$1.00 for a new name may have the cloth-bound copy postpaid as a premium.

A KIND WORD IN SPITE OF LOSS OF BEES.

I suppose "Pa Root" will soon be back with you again. Long may he live to carry on his work. Heaven bless him and you all. We have had a bad winter and very late spring. I suffered nearly a 50-per-cent loss in stocks this winter.

WM. WRIGHT.

New Westminster, B. C., April 20.

A KIND WORD FROM AWAY OFF IN CANADA.

I can hardly write on account of looking at the beautiful snowfall without. The snow is almost up to our window sills, and is as fluffy as down. The spruce and pine look like so many umbrellas with their limbs bent touching the snow beneath. It is a scene well worth any artist to paint. You might tell A. I. Root that Florida "isn't in it" for health and beauty compared to northern Ontario. We can enjoy two things at the same time, while he can have but one. We have the cold dry bracing winds without, while at the same time we enjoy the warm Florida weather by the fireside.

130 DUCK EGGS WITHOUT A MISS.

Our Indian Runner duck began laying the last week in February, and laid 130 eggs without stopping. The last day she laid two eggs. One of them had a soft shell. Altho I hatched several settings, the bees killed every one of them. The ducks would persist in going to the hives and rattling around the entrances with their bills.

"One man's meat is another man's poison." While A. I. Root enjoys his meals of fruit we enjoy our meals of flesh. We cannot raise apples, plums, or peaches successfully, but we can raise beef, mutton, and eggs, while our waters teem with fish and our woods abound with game. The man in the South eats fruit as a cooling food. The man in the North eats meat as a heating food. "Let not him that eateth despise him that eateth not." I think the trouble lies, not in what we eat, but that the most of us eat too much. J. M. MUNRO.

Slate River Valley, Ont., Jan. 13.

Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER. By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE. By "The Spectator," of the Outlook. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES. Our new complete catalog mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER. Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES. The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING. Just the thing for the up-to-date housewife. Price 10 cents.
- BEES AND POULTRY, how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES. A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE. A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES. A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cts.
- THE BUCKEYE HIVE, or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET-CLOVER, the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE. A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth. \$1.00 postpaid.

Be sure that the following coupon is carefully filled out.

SPECIAL BARGAINS

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

HIVE-HANDLES.

We have a surplus stock of handhole cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of both 8 and 10 frame packed single and 5 in a package, which we offer, to close out, as follows: YW 5/8, one story, with frames, eight frame; 8 packages, one hive each, at \$1.75, and 12 packages, five hives each, at \$8.00. The same in 10-frame size, 2 packages, one hive each, at \$1.85, and 3 packages, five hives each, at \$8.50.

NO. 2 OR B GRADE HOFFMAN FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

METAL SPACERS SLIGHTLY DEFECTIVE.

In making the metal spacers for the metal-spaced frames there are a percentage which come out either sheared a little scant on one side, or with slight breaks in the tin where it is drawn up into the spacing-boss. These are hardly passable as perfect stock, but in actual use they will answer every purpose as a spacer. Rather than throw these into the scrap we will offer them while they last, including nails to nail them on, at 20 cts. per 100; \$1.80 per 1000. Transportation charges extra.

1 3/4 H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1 1/2-inch tire, and solid cast hub holding spoked and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

SUPERS FOR EXTRACTING OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. b. Medina.

200 D9/10, nailed and painted, with top and bottom starters, nine frames in each, new. Sell new for \$1.20; offered at \$6.00 for 10; \$55.00 per 100.

410 D8/10, nailed, and some painted two coats, some one coat; 273 not painted. Sell new for 90 cts.; offered at \$5.00 for 10; \$45.00 per 100.

180 8/10 supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first two lots are the 5/8-inch supers with hanger cleats and shallow Danz frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

ALEXANDER FEEDERS FOR EIGHT-FRAME HIVES.

The Alexander feeder as we now make it is adapted to either eight or ten frame hives. Formerly we made a shorter length for the eight frame than for the ten-frame hive. In cleaning up old stock we find 300 of these eight-frame feeders which we offer, to close out, at half regular prices—viz., 15 cts. each; \$1.35 for 10; \$11.00 per 100; \$30.00 for the lot.

TIN COMB-BUCKETS.

While these are listed in the catalog in one line at \$1.50 each, their convenience in carrying combs to the extractor shut up from robbers is not set forth. We have a surplus stock, and offer them, to reduce the number on hand, at \$1.25 each. You can place four Hoffman frames or five non-spaced frames of Langstroth size in each bucket.

JONES HONEY-KNIVES.

This is a form of honey-knife used largely in Canada, and preferred to the Bingham by those who have tried it. The blade is 1 1/2 inches wide, and a flat V or triangular shape. We had a lot made to supply a call we had, and still have in stock 28 of them. We offer them at 75 cts. each. Mailed as a pound parcel when packed.

SHIPPING-CASES FOR 12 AND 24 SECTIONS.

When we discontinued listing shipping-cases to hold 12 sections we still had quite a stock of various styles on hand, many of which are still in stock. We have also some of the older styles of cases for 24 sections of various sizes. We offer these various cases to close out at the following bargain prices. Here is an opportunity to lay in a stock of cases preparatory to the honey crop near at hand at very low prices. None of these cases, except as noted, are large enough to take sections with cartons or corrugated liners, except the bottom sheet, 12-lb. 2 or 3 row cases with 2 and 3 inch glass for the 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, 4x5x1 1/2 sections, packed 50 in a crate at \$4.00 a crate; packed 10 in a crate at 85 cts. a crate. A few crates of cases for 16 sections 4 1/4 x 1 1/4 at \$4.50 per crate of 50 or 95 cts. per crate of 10. A few crates of cases for 24 sections, 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, and 4x5x1 1/2 at \$8.00 per crate of 50; \$4.00 per crate of 25, or \$1.70 per crate of 10. The 12-lb. safety cases, which we no longer list with safety cartons, and 2-inch glass for 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, and 4x5x1 1/2 sections, per crate of 10, \$1.20; per crate of 25, \$3.00. Without cartons, but including corrugated liners and glass, \$4.50 per crate of 50.

NO. 2 OR B GRADE SECTIONS.

We have a surplus stock of B grade sections in all the commonly used sizes and styles, and are behind on orders for No. 1 or A grade in some kinds. To insure prompt shipment it may be advisable to order B grades if you can use that grade. In beeway style the B grade costs 50 cts. per 1000 less than A grade, while in the plain or no-beeway styles the reduction for B grade is 75 cts. per 1000. The loss from unusable sections in B grade is very little more than in the A grade. Try them if you have not done so.

SWEET-CLOVER SEED.

We have a good supply of very choice hulled white-sweet-clover seed scarified for quick germination, requiring only 10 lbs. per acre for a good stand. We offer this for a short time to reduce stock at \$18.00 per 100 lbs. Now is the right time for sowing with a nurse crop to produce hay or bloom with seed next year. We have also choice hulled yellow which we will sell at \$15.00 per 100 lbs. A thousand pounds of hulled white for shipment direct from Des Moines, Iowa, not scarified, offered at \$15.00 per 100 for prompt acceptance.

HULLED YELLOW ANNUAL SWEET CLOVER.

This makes an excellent mulch crop in orchards, and at the same time helps to enrich the soil. It will bloom in 60 to 90 days after seeding. We have a surplus stock of seed, which we are offering at \$4.00 per 100 lbs.; 25 lbs. for \$1.25; 60 cts. for 10 lbs., bag included to ship in.

HONEY - CANS

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

Select Tested Queens	1 for \$1.75; 12 for \$19.25	1 for \$1.65; 12 for \$18.00	
Very best queens for breeding,	\$3.00. 1 lb. bees in package, \$1.25; 2 lbs. in package, \$2.00.		

Add price of queen. If any of our untested queens should prove to be misnamed we are willing to replace her free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

W. D. ACHORD, FITZPATRICK, ALABAMA

BEE-LINE QUEENS GOLDEN AND THREE-BANDED ITALIANS

About 1000 Queens ready to go by Return Mail after May 15

From Caraway's prize-winning stock. Every queen purchased of me I will guarantee to give satisfaction. If she does not I will replace her with another queen or refund your money. They are hustlers, long lived, not inclined to build burr-comb, cap their honey white, and are not given to swarming, and are gentle to work with.

My bees and queens are winners of over 100 first premiums in the past eight years. This speaks for itself. If you are going to buy queens you cannot do better than buy the Bee-Line Queens.

Queens are postpaid, and safe arrival is guaranteed to all points in United States and Canada. No diseases of any kind in my apiaries.

State inspector's health certificate with each shipment.

PRICES FROM MAY 10 TO NOV. 1.

Italian Queens: Untested, one for 75 cts.; six for \$4.00; twelve for \$ 7.75
 Tested one for \$1.00; six for \$5.00; twelve for \$10.00
 Select Tested one for \$1.50; six for \$9.00; twelve for \$17.50
 Untested by the 100: May, \$70.00; June to November, \$65.00.
 Breeding queens. Fair, \$5.00. Extra select, \$10.00.

One-pound packages of bees: . . . One for \$1.50; . . . six for \$8.50; . . . twelve for \$16.00.
 Two-pound packages of bees: . . . One for \$2.50; . . . six for \$15.00; . . . twelve for \$29.50.

These prices are without queens. Safe arrival guaranteed on bees by the pound when they are not over six days in transit. No orders filled unless cash is sent with order. Prices quote on large lots for bees by the pound, also frame nuclei.

The Double-walled Massie Bee-hive

Surest Protection for Bees--Increased Supply of Honey--the Best Hive for any Climate

The Massie Hive for Comb or Extracted Honey

Furnished in the clearest of lumber, in either Cypress, White Pine, or red-wood; all brood and extracting frames are made from White Pine.

The Dovetailed Hive for Comb Honey

THE VENTILATED BOTTOM admits fresh air into the hive, lessening the chance for swarming, and gives renewed energy to the bees. It is also equipped with a feeder without extra cost. Fifty years in the bee-supply business has shown us that the MASSIE is THE VERY BEST HIVE, and testimonials to this effect are received daily from those who are using this hive.

Why not give us a trial order? Satisfaction fully guaranteed. Early Cash Order Discounts..

We are also extensive manufacturers of DOVE-TAILED HIVES and all other apiarian supplies. If you are in the market for supplies be sure to get our prices before buying elsewhere. We will mail our large illustrated catalog and SPECIAL price list to any one upon request.

KRETCHMER MFG. CO., 1000 3d St., Council Bluffs, Ia.

YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be *profitable* in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book—send for it today.

Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

204 Walnut Street

Cincinnati, Ohio

EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A postcard will bring it to your address free.

Red Catalog, postpaid.

where the good beehives come from.

HONEY GRADING RULES

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,
FEBRUARY 6, 1915.

COMB HONEY.

FANCY.—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER ONE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

NUMBER TWO.—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

Comb honey that is not permitted in shipping grades

- Honey packed in second-hand cans.
- Honey in badly stained or mildewed sections.
- Honey showing signs of granulation.
- Leaking, injured, or patched-up sections.
- Sections containing honey-dew.
- Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight. All such honey should be disposed of in the home market.

EXTRACTED HONEY.

This must be thoroughly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each

five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

Honey not permitted in shipping grades.

- Extracted honey packed in second-hand cans.
- Unripe or fermenting honey weighing less than 12 lbs. per gallon.
- Honey contaminated by excessive use of smoke.
- Honey contaminated by honey-dew.
- Honey not properly strained.

NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES

Adopted at Cincinnati, Feb. 1913.

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

III. WEIGHT.

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium*.—No section designated as medium to weigh less than twelve ounces.

3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

ALBANY.—Very little honey is moving on this market now. The extracted honey is all sold, and some comb honey unsold. This is the off month for this market. Demand will not begin again until August. Beeswax brings 28 to 30.

Albany, May 18.

H. R. WRIGHT.

INDIANAPOLIS.—Comb honey as well as extracted is moving very slowly at this time. This, of course, is due to the weather conditions. Comb honey is selling from \$3.50 to \$4.00 per case. Extracted is bringing 9 to 11 cts. We are paying producers 28 cts. cash or 30 in trade for good average wax delivered here.

Indianapolis, May 20.

WALTER S. POWDER.

CHICAGO.—Not enough is doing in the comb-honey market to make quotations really on. People who want a little, buy it; but speculation has ceased. Prices do not vary much, but sales are made chiefly around 13 cts. per lb. for the best white grades. Extracted is also dull, some going to manufacturers; but most of them are holding off to see what the harvest is to be, and it is difficult to make sales in any quantity. White grades range from 7 to 8, and the ambers 6 to 7. Beeswax brings 30 to 32.

Chicago, May 17.

R. A. BURNETT & Co.

KANSAS CITY.—The demand for honey, especially comb honey, is very light, and stocks are very light. We quote No. 1 comb honey, 24-section cases, \$3.00; No. 2 ditto, \$2.75. Regarding extracted honey, the demand is fairly good. Light-amber alfalfa is selling at around 7 to 7½ cts. a pound. Some grades of dark amber are selling as low as 6. Stocks are very light, and we expect to see all of the old honey cleaned up before the new comes in.

C. C. CLEMONS PRODUCE Co.

Kansas City, May 15.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: No. 1 per case of 24 sections, \$2.93; No. 2, \$2.70. White extracted, 8½ to 8¾; light amber, 8 to 8¾; amber, 7 to 8. We pay 26 cts. per lb. in cash and 28 cts. in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.

Denver, May 6.

F. Rauchfuss, Mgr.

ST. LOUIS.—The local demand for comb honey has been very light, but the demand for extracted honey has improved considerably. We quote southern strained amber in barrels, 5½ to 6; in cans, 6 to 7; dark, ½ to 1 cent per lb. less; No. 1 white comb honey, 24 sections to the case, \$3.25 to \$3.50; bright amber, \$2.50 to \$3.00; under grades, less. Beeswax is steady at 30½; impure and inferior, less.

R. HARTMANN PRODUCE Co.

St. Louis, May 22.

ZANESVILLE.—There is no particular change in the honey situation here, the demand being about normal for the season, and prices practically unaltered. In a small way best white comb brings around \$4.00 a case. Some western sells for \$3.75. Jobbers are allowed usual trade discount. Extracted is in limited demand at prices as heretofore, 9 to 10 cts. for best white; darker grades correspondingly less. For good clean beeswax we pay producers 29 cts. cash, 31 trade, and invite shipments on this basis.

Zanesville, May 16.

E. W. PEIRCE.

MATANZAR.—Honey today is bringing 45 cts. per gallon.

Matanzas, Cuba, May 17.

Make money breeding PR squabs. 1916 demand biggest ever. Squab book free, telling money-making experiences. How to sell by parcel post, \$6 to \$8 doz. Start small, grow big. Many women customers. Write today, **PLYMOUTH ROCK SQUAB CO., 615 HOWARD ST., MELROSE HIGHLANDS, MASSACHUSETTS.**

Woodman's Section-fixer

A combined section-press and foundation-faster of pressed-steel construction. It folds the section, and puts in top and bottom starters at one handling, saving a great amount of labor. Hundreds of them in use. The sale this year has increased wonderfully, and they give perfect satisfaction in every case when properly operated. Dadant & Sons say, "The sale on Woodman section-fixers now far exceeds all others."

With top and bottom starters the comb is attached to all four sides, a requirement to grade fancy. Increase the value of your crop this season by this method. The best and most successful producers such as Dr. Miller use top and bottom starters. Their honey would ship across the continent without breaking down, even if only half completed.

Price \$2.50 without lamp. With lamp, \$2.75.

Weight, 5 lbs.; postage extra.

Adjustable to any standard size of section. Send for special circular with large illustrations.

Martine Foundation-Fastener

Patent applied for.

Latest and best device invented for fastening foundation securely to the frame or section with a tiny stream of hot wax.

Prevents breaking down of foundation with the weight of the bees. Saves expense, time, and labor.

One filling of the fastener is sufficient to fasten the foundation in five frames and can be done in one-third the time required by any other device.

Price 50 cts. postage prepaid.
Satisfaction guaranteed.

On Sale Only by

Root's Beekeepers' Supplies at Root's Prices

206 East Jefferson St. Louisville, Kentucky

PENNSYLVANIA BEEKEEPERS

Our 1916 catalogs now out. Postal will bring you one. Root's goods at Root's prices. Prompt shipment.

E. M. Dunkel, Osceola Mills, Pa.

For New England

Beekeepers, we have everything you need in the way of supplies. Remember we are in the shipping center of New England. Let me send you a new catalog.

H. H. Jepson, 182 Friend St., Boston, Mass.

Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

"If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-cscares, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

No. 11

The High Price of Sugar

SUGAR is already up to 8½ cts., and there is a prospect that it will reach 10. While sugar is expensive, the price of sugar will naturally have a boosting effect on the price of honey.

Winter Losses in New York

LATE reports from New York indicate that the winter losses are more severe there than elsewhere in the country. Our revised reports will stand about as follows: Winter losses in Montana, parts of Canada, and New York. There were scarcely any losses reported elsewhere except as a result of starvation. The high price of sugar and the open winter are responsible for this.

Fruit-bloom in and about Medina

PROSPECTS were never better for a good yield from fruit-bloom during the first week in May this year. Just as the bloom had opened at its height, and when the bees were storing fruit-bloom heavily, a cold rainy spell, as noted elsewhere, set in. In the mean time the bloom disappeared; but, fortunately, the weather maps show that in and around Medina it was much colder than in almost any other part of the United States.

The California Situation

THE *Western Honeybee*, after gathering together a bunch of reports from various parts of the state, thus summarizes the crop conditions:

The orange-honey crop of the citrus sections of the state has been less than was expected, only about two-thirds of an average yield having been harvested. The season was unusually early, having ended before May 1. The new crop is of fine quality, and has already been nearly all picked up by the shippers and local buyers, mainly at 6 cents. A moderate crop of sage is being taken in most localities of the sage belt, but will be shortened by lack of spring rains. Little damage is reported from the sage weevil. Grasshoppers are doing some dam-

age to alfalfa in Imperial Valley, but most of the alfalfa sections will probably harvest a fair crop. Some damage from brush fires has already occurred in the southern counties.

A Long Journey for a Large Piece of Wax

OUR cover for this issue shows an unusually large piece of wax that was shipped clear from California without being broken, with nothing for protection but two thicknesses of burlap. The weight of the cake was 266 pounds.

For shipping beeswax, burlap sacks are better than wooden boxes, for they are lighter, and the wax is more likely to reach its destination in good condition. Usually, however, it is better to use two sacks, one inside the other, so that in case there is a weak spot in one sack the other will furnish the strength. Unless the sacks were in very bad condition it would not be likely that two weak spots would occur at the same place.

The New Edition of the A B C and X Y Z of Bee Culture

WE are working almost night and day in preparing copy for the new edition of the A B C and X Y Z of Bee Culture. A large number of the articles are being entirely rewritten. In addition many new subjects are being added. The A B C and X Y Z is in reality a collection of monograms, each article being complete in itself. Each of the monograms has many cross-references back and forth, so that practically everything known on a subject can be gathered.

During the past three or four years many new methods and ideas have been developed, and these are being carefully incorporated into the old matter. The chapter on European foul brood has been entirely rewritten and the revised copy has been submitted to the best authorities in the United States for correction. Alfalfa and sweet clover have received an entirely new treatment. Extracted Honey and Bottling Honey have been entirely revised.

When the work is completed it will contain between 900 and 1000 pages, and will be sold at \$2.50; but in the meantime all orders up to September 1 will be accepted at \$2.00, because the old edition will be exhausted within a month or six weeks.

Clover Prospects

THE United States Weather Bureau maps show that thruout the clover area of the country there has been a large amount of rainfall. Clover was already in prosperous condition, and recent rains had given it another big boost. Unless we have a very severe drouth and cold weather during the latter part of May and the first of June a big crop of clover is almost assured. Reports from all over the clover districts confirm the Weather Bureau maps. The question now is, "Are beekeepers ready?" It is a fearful mistake to be only half prepared and then get only half a crop when a whole crop might have been secured by having proper appliances on hand ready for the flow.

Long-range Weather Predictions

UP till very recently, at least, the United States Weather Bureau has given out that it could not make accurate predictions very much beyond 48 hours; but recent developments have taken place, showing that in some cases, at least, the Bureau is able to forecast the weather for a week in advance. In our locality, for example, last Saturday, May 13, the Bureau sent out the report that in northern Ohio there would probably be a week of bad weather—cold and rainy, interspersed with sunshine. The Sunday following was beautiful, weather hot, and it looked as if the prediction were considerably strained. Monday began to show rain-clouds, but it was warm. Then it began to turn colder, and for nearly a week we have had bad weather, just as the Bureau predicted.

Shipments of Bees in Combless Packages and How they can Make the Difference between Profit and Loss

THIS is, apparently, getting to be quite an industry in the United States. Many shipments are constantly arriving from the South to boost colonies in the North below par up to honey-gathering pitch. The thing works out nicely, because the Southern producer, after his crop is secured, can ship to the Northern producer the bees that would otherwise be useless consumers, but which, when sent north, are ready for busi-

ness again. While the Southern-shipped bees may die before the beginning of the Northern harvest, they help immensely in making more brood possible, and of course a large force of young bees of the right age for a crop.

The value of these pound shipments will be better understood, perhaps, when it is remembered that a colony slightly below honey pitch will do but little more than hold its own. A little boost of a pound or two pounds of bees early enough will make all the difference between a good surplus and no surplus. A colony that does no better than hold its own is a dead weight on the business.

Those who have colonies that are below par would do well to consult our advertising columns, and other things being equal, purchase of the nearest man who has combless bees for sale.

Dr. Nelson's Book

WE beg to call attention to the sketch by Doctor Nelson on the development of the bee egg, on page 447 of this issue. Until Doctor Nelson finished his job, we were without any reliable account in the English language of this interesting and important part of the life of the bee, and the accounts published abroad were all old and out of date. The changes which occur in the egg are very intricate, and a whole volume is necessary to describe them. The article to which we would call the reader's attention is only a brief sketch, but it may at least awaken in our readers an interest in this part of the bee's existence which has been to most of us a sealed book.

Our readers may be interested in knowing that, in addition to the commendatory notices of Doctor Nelson's work which have appeared in the beekeeping press, this work has been favorably received by such journals as *The Canadian Entomologist*, *Entomological News*, *The Journal of Economic Entomology*, *Science*, and *The Nation*, on this side of the Atlantic; in England by *Nature*, and *The Entomologist's Monthly Magazine*, and by *Miscellanea Entomologica* in France.

Bees — How Long Can They Remain in a Chilled Condition and Revive?

ON page 416 of our last issue, Mr. H. F. Bohon reports a rather interesting case of how he discovered that the bees of one of his colonies had starved and dropped down on the bottom-board and lay there in a chilled condition, apparently dead. He picked the queen up and carried her to the

house, and was surprised later on to find she had revived. Thinking that the bees might follow suit he scooped them up and brought them in, and they, too, revived. He fed them sweetened water, and they seemed to be as well as ever.

Bees will remain in a chilled condition for several days, as we have proved by experiment; but we have never had them last longer than ten days, because, apparently, they starved to death while in that condition.

The presumption is, in the case cited by Mr. Bohon, that the bees dropped from the combs from sheer exhaustion resulting from a want of food. A cold spell came on, and they chilled while in that condition. It was a case of what might be called suspended animation. Mr. Bohon happened to come around at the strategic time, and warmed them up and fed them. They would not have survived much longer probably.

Bees suddenly chilled in a zero atmosphere will die, while bees gradually chilled and gradually warmed up will sometimes survive. How low a temperature they will stand we do not know; but we do know that a sudden chilling kills them.

There are some interesting problems in connection with this matter; but from present data at hand it is apparent that Nature has made it possible for bees to be chilled thru and remain in that condition for several days. A warm spell coming on, the bees revive and move on to fresh stores.

Stirring up a Hornet's Nest; Legislation too Drastic

WESLEY FOSTER, in his department in this issue, expresses himself in favor of legislation "prohibiting the shipment of comb honey and extracted honey from an infected apiary." He thinks it is doubtful whether such a law could be enforced, but believes we "shall have it sooner than many of us think." He admits that "it will cause a *furor*, the like of which the hubbub over the net-weight law will be tame."

Right you are, Bro. Wesley. If your program can be carried out you surely will stir up a hornet's nest, or, more exactly, a "*furor*" among your fellow beekeepers. We doubt if such exclusion of honey shipments would be wise. Here is a beeman who has \$2000 invested; and if he cannot ship any honey out of his apiary for a whole year or longer because he is cursed with careless neighbors, he might as well apply the torch to the whole business. Moreover, neither European nor American foul brood is a serious menace to the up-to-date bee-

keeper. He can keep them under control—the European by the introduction of resistant strains, and by dequeening, and the American by shaking. Indeed, there are not a few progressive beekeepers who feel that foul brood is a blessing in disguise, because it eliminates from the neighborhood the careless or irresponsible, leaving only the "survival of the fittest."

In the same way, we doubt the wisdom of legislation that prevents the shipment of combless bees or queens in interstate business. The man it would hit the hardest is the producer, not the queen-breeder, because the latter can produce honey.

A bill that would meet the strenuous opposition of a considerable number of beekeepers could hardly pass any legislature. Our law-makers, if past experience is any criterion, will not pass any act unless it can have the *undivided support* of those *in whose interest it is made*. Several of the states would have good foul-brood legislation today were it not for the opposition of a very small minority of beekeepers.

There is also danger of "reciprocity legislation" that would virtually work out a boycott, provided one state passes legislation that would be hostile to another. It is a dangerous proposition at best. If the other states should retaliate against Colorado that seeks the market of the country it would be serious business. Colorado must and should have the markets of the world for her honey.

The interests of beekeepers can be adequately safeguarded by a federal law requiring that all shipments of combless bees and queens by freight, express, or mail be accompanied by a certificate of inspection, or a sworn statement to the effect that the honey in the food has been boiled to conform to the requirements of the Postoffice Department. Such regulations, so far as queen bees are concerned, are already in force.

Wax Production a Specialty, Not a Side Line

IN countries where honey must be shipped long distances to a market so that the net price which the beekeeper receives is therefore low, there has been much speculation regarding plans for turning such honey into wax. When we received a request for a special number on wax production we hoped that we might be able to get reports from beekeepers who were actually doing this very thing, making a specialty and not a side line of wax. We are not able to present as much information on this particular part of the subject as we had hoped.

In this connection there is a very interesting chapter on this subject in a bulletin by Dr. E. F. Phillips, No. 75, Part 5, of the Bureau of Entomology, entitled "A Brief Survey of Hawaiian Beekeeping." We quote here in full what is given in regard to wax production.

The price of honey fluctuates relatively much more than that of beeswax. On account of the fact that Hawaiian honey has been selling for a low price, and also because of the peculiar character of most of the honey, the beekeepers of the islands are desirous of converting their honey into wax, if it can be done, even at no great profit. The long shipment necessary to get their honey to market means more or less loss by leakage and heavy freight. Wax does not lose anything in transit, and naturally, also, wax weighs much less than an amount of honey of equal money value, and the freight would be very much reduced.

When the author arrived on the islands one of the first questions asked him was how to bring about a production of more wax and less or even practically no honey. After getting the available data, which were freely given, a method was suggested which promises to give some results, if we may judge by results obtained in some experiments conducted in the short time which could be spent in Hawaii. Before outlining this proposed method it will be well to review the basis for the recommendations.

It is a well-known fact among beekeepers that at the time a swarm is hived the activity of the inmates of the new home is at its height. The bees not only collect nectar with great vigor, but, there being no wax in the hive under natural conditions, the wax-secreters become very active, and in a marvelously short time the hive is supplied with combs. It is also true, of course, that wax is secreted at any time during the active season when it is necessary that more combs be built to accommodate brood or stores, provided, of course, there is room. If a comb is removed from the center of the brood-chamber or from the super, it is replaced as needed, but, as a rule, not so rapidly. The rapidity of the honey-flow influences this wax secretion greatly.

The amount of honey consumed in the secretion of a pound of wax is a much-debated question among students of bees, the various estimates ranging all the way from 2 to 20 pounds. There seems to be little hope at present of arriving at anything definite on this question, and the author is strongly inclined to the belief that the reason for this great variation in estimates is due to the fact that the same amount of honey is not always needed to bring about a desired result. It would be bootless, therefore, to pay any attention to this phase of the question in trying to get a method of wax production. Sylviae, in a series of articles in *L'Apiculteur* for 1901, offers evidence that the amount of honey consumed in se-

creting a pound of wax is least following swarming, and this quite coincides with the fact that wax-building is most rapid at that time.

In dealing with wax secretion on a commercial basis, data must be drawn from the receipts per colony under different methods of management. The actual consumption of honey becomes of minor importance. It was learned that the average annual return per colony, after deducting freight charges, leakage, and other expenses incurred after the honey leaves the apiary, would not exceed \$2.50. The hives are on an average two stories high during the entire year, and, during the height of the honey-flow, are often higher. All figuring was done on a basis of two-story colonies. The wax in such a hive weighs over 6 pounds, averaging in value \$1.80, Hawaiian wax being of the finest quality.

As additional data, it was learned that it is possible to increase the number of colonies very rapidly. In one remarkable case reported, 20 colonies were increased to 420 in eight months. This fact shows that a colony of bees can build up very rapidly under the conditions existing on the islands. It must also be remembered that in cane sections there is practically no stopping of the honey-flow.

In view of all these facts it was obvious that, if the wax be taken from each colony, it will form a good beginning in the annual return from a colony. If, then, the colony is in as good shape in a year's time as it was when the wax was removed, there will be honey enough stored to make the annual money return higher than if the colony had been run for honey alone.

The method recommended is to shake the colony on to starters of foundation. The brood is placed over another colony to develop so that it may not be lost; the honey is to be extracted. By dividing the apiary into two parts, one half may be shaken and the brood piled on the other half. These in turn may be shaken in three weeks or more, and their brood added to the colonies shaken at first. This manipulation is identical with the shaking in treating for bee disease. Similar methods are often employed in honey-producing to prevent swarming and to cause bees to work in the supers. In the present instance, however, there is an entirely different reason for the practice.

In the trial made with a view to wax production, a surprising showing was made, and it seemed obvious that the operation could be repeated in not more than three months' time, and probably less. If this be true, then there will be removed \$1.80 worth of wax or more at each shaking, which means a considerable gain.

No positive statements of results can be made until the method has stood trial for a time. If this plan serves the purpose in Hawaii, it will also be valuable in other regions where there is a heavy honey-flow for a long time.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

CHARLES E. KINZIE gives, page 401, a kink worth noticing. He keeps always in the first story of extracting-combs combs partly filled with honey in *the center*. If a simple thing like that will prevent

the forming of a brood-nest there thus saving the use of an excluder, it's well worth while.

J. E. JORDAN, you say, p. 413, you graft larvæ 24 hours old, and then say, "Cells should hatch 12 days after grafting." Are you not going by traditions rather than your own observations? With best conditions for queen-rearing should there be as long a time as 16 days from the laying of the egg to the emergence of the queen? [See reply to another straw on this page.—Ed.]

THAT illustration, p. 376, showing that it has not yet "all been done" in the way of improved machinery, applies also to bee-keeping. Advance has been made that seemed impossible 25 years ago; some things have happened that are hard to believe even now, and the next 25 years may show even greater advance. Young fellow, keep your eyes open. Who knows but you may be the one to stumble upon something valuable?

ARTHUR C. MILLER, p. 366, says bees sometimes put honey in a cell that contains an egg. That's a new one. I never saw anything of the kind, so that proves he's wrong. But my testimony is like that brought in a case where three witnesses swore to seeing a man commit a crime, and he brought six witnesses to swear they *did not* see him do it. Anyway, I'd like to know if it's a common practice, and just how we can prove it on 'em.

J. E. CRANE says, p. 359, that removing brood is much more effective when first preparations are made for swarming, and the longer it goes the harder to stop them, until sometimes they'll swarm with all their brood taken away. Sounds strange, but it's true. Once I kept thwarting and thwarting a colony by taking away brood, but not enough at first, and finally it swarmed, leaving in the hive only foundation with just one egg, and that in a queen-cell.

SEVERAL of the interesting plans for prevention of swarming given by R. F. Holtermann, p. 404, have as a chief factor an old plan that every now and then bobs up as something new. It was given years ago by G. W. Demaree, Christiansburg, Ky. (I

wonder if he's still alive), and is this: Put all the brood in a second story over an excluder, leaving the queen below with drawn combs or foundation. That's all, I think that Mr. Demaree gave but it's considered better to leave one brood below. Unfortunately it cannot be worked with section honey.

H. H. ROOT, I'm glad your sharp eyes are searching out things new and old in the hive. That starting queen-cells from drone-cells, apparently with drone brood in them, with plenty of young worker larvæ present, I would have supposed impossible. I wonder if you could have it repeated, and then let the cells go on to a finish and find out whether or not the drone larvæ were exchanged for worker larvæ.

That colony chose drone-cells rather than to use worker larvæ away from the edge, yet not two hours before reading your article I saw in a normal colony a cell cup built right in the center of the comb, apparently upon the sealed surface of worker brood. Perhaps it was because of continuously cold weather, so the edges were too cool. But why build cell cups at all at such a time?

Isn't there something a bit askew with your figures where you gave larvæ, and say "From six to eight days from the time the bees took hold of the work the cells are capped over?" I've known cells sealed in less than five days after the larva left the egg, but does it ever happen in more than five days?

[Mr. Mell Pritchard has reared towards 20 thousand queens, and is a very close observer besides. I have just shown him my figures on page 403, and your comment. He says that it takes 15 to 17 days from the time the egg is laid for the queen fully to develop and emerge from the cell. Dividing up the shorter period, 15 days, he gives 3 days for the egg to hatch, 6 days for the bees to feed the larva, and 6 days for the cell to remain sealed. If the weather is unfavorable, so that 17 days are required, the periods are lengthened. According to Mr. Pritchard, therefore, it is 5 days after the larva is grafted before it is sealed, since the average larva is about 24 hours old when grafted. Apparently, therefore, the truth lies between your statement and mine—tho I'll have to admit that you are nearer to it than I. However, this does not surprise me, for you have been keeping bees toward 75 years and you ought to know better.—H. H. Root.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Locust came, with all its inviting sweetness, in late April, and white clover so early in May that they lapped. Right now (mid-May) the honey prospects are very bright, tho of course city backlotterers always remember their limited pasturage and keep their expectations modest.

* * *

Prof. Baldwin, it was long before you came into the GLEANINGS family that I wrote my protest against your advocacy of the separate-shelf policy. Now I do most heartily join my welcome to the others, and hope you will make yourself at home on any shelf whatsoever in the apiarian library.

* * *

Dr. Miller, I wish you could see me working among the bees this spring, for I do it sitting on a new really-truly hive-seat, apparently thru forever with merely kneeling by the hives. And I admit it is comfy. Along with the other useful things stored away in the yawning boxes on either side I keep a note-book and pencil, and jot down different memoranda as I go—like this.

* * *

Those moldy north-side combs, mentioned May 1, are all cleaned up now and filled with either honey and pollen or honey and brood—all, that is, but one. That one the record of March 24 refers to as "*very moldy*." And on May 14 about two-thirds of it has disappeared, evidently cut out and ground up, for on the bottom-board beneath was a thick deposit of fine, dry, brown powder.

* * *

What Dr. Phillips is reported as saying about the beekeepers of the South Atlantic states, page 259, April 1, reminds me that right here in enlightened Nashville, that calls herself the "Athens of the South," because of her many schools and colleges, a young lady who was recently told that we kept bees mentioned with considerable interest the necessity(!) of informing the bees of the death of any member of the family. Amazed, but certain that she must be playing, I replied that as we had no deaths, I was unfamiliar with either the requirements or custom or etiquette of the occasion in its relation to the beeyard. Whereupon she solemnly assured me of the genuine necessity of this procedure!

* * *

When I quoted, page 263, April 1, from the letter of Mr. O. J. Jones, giving his method of clipping queens, I liked the way

it read, but had not yet tried it. Now that I have tried it, I like it still better, for it works beautifully—more easily, for me, than the more orthodox method first mentioned, the one I had always used till this spring. Of course if ever a queen should pull away, minus a foot or two, left between my grasping thumb and finger, I should be greatly distressed. But so far no such catastrophe has occurred. Not only did I somehow do it with far less nervousness than previously; but the queens themselves took it with entire matter-of-factness and coolness, two that I watched going right on laying as soon as returned to the frame, tho one of these did act a trifle flighty, perhaps, for she deposited her eggs on top of sealed brood and on the edges of cells and just anywhere at all. I watched a worker take up one of these misplaced eggs with her antennae; but before she had a chance to carry out her plan, puff! came a little breeze, and the tiny egg blew quite away.

* * *

Claiming Life's Flowers

(Written after a recent illness—hospital, operation, etc.)

Around my quiet days and hours
My joys were blossoming like flowers,
Flowers of love and deep content
And shy, quaint flowers of wonderment.
One by one I drained their sweet,
So close they grew about my feet.

Then sharp across one startled day
A sudden voice from far away
Came shrilling; and at once I knew
Some field where strange, wild flowers grew
Had bloomed, and called, and I must go,
Like bees when clover blossoms blow.

Dread—dread—grew there; but, close beside,
Courage, erect and laughing-eyed,
Pain, and the will to smile at pain,
And love of life thru sun or rain;
While in their midst, with haunting breath,
Blew eager fearlessness of death.

And here my gay bravado shrank;
And yet I drank—aye, deep I drank,
Of every drop my soul could press,
Whether from joy or bitterness.
(I want the flowers by the friendly wall
And the brave wild flowers and the thorns
and all!)

Today I watch my bees take flight,
Unafraid across the light,
And pray my heart may never quail
In its quest for something akin to the Grail—
A glory in life and the grace divine
To drain each drop like holy wine.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

It is not generally known that there are two varieties of wild buckwheat, one of which blooms several weeks in advance of the other.

Bro. Baldwin, I greet you as a department editor. Were it my privilege to assign you a task I would give you the problem of introducing a bee into your state that would fly more than $1\frac{1}{4}$ miles for nectar.

And now comes Allan Latham openly confessing that the much-famed "let-alone plan," of which he is the originator, has failed. Foul brood is given as the cause of failure, which I think would make it a shaky plan in many parts of this land. We must admire Mr. Latham's thought in working out the plan, if nothing more, for he really has made many of us think new thoughts.

Every season for the past twelve years we have been handicapped by fogs during April and May. We have long hoped that a time might come when these conditions would not prevail. This year we were spared the fogs, with the result that the moisture escaped more rapidly than ever. I have been guilty of condemning the weather in past years; but from this time on I shall try to be satisfied with it as it comes.

I have been watching closely the work of bees on the orange to prove the idea (my idea) that they gather pollen from the navel orange. Well, I give up; there seems to be none there. Mediterranean sweets, St. Michael's, Valencia's, and the common un-budded seedlings, have all yielded pollen under my eyes; but the navel, none. So, in the future, when the orange-grower asks me how many bees would be necessary to pollenize the navel groves of Redlands district, which comprises about 10,000 acres, I shall be compelled to say that one colony will be sufficient.

When I read the article of George H. Rea on black brood and his treatment of it I thought of my mother who, years ago, in administering to my ailments with some medicine to which I raised objections, would say, "Well, if the remedy is worse than the disease you will have to get along awhile." Mr. Rea's remedy is surely vigorous treat-

ment, and I doubt if it is altogether necessary. *Melting* up all infected brood-combs, to my notion, would be sufficient. Mr. Rea says, "Combs containing diseased brood, if bad, are burned." There is where I disagree most emphatically. Why burn any thing of value about the apiary?

I am a friend of the excluder, believing it to be a necessary appliance; but this season, for the first time, I believe they have been a detriment to my honey crop. It was not exactly the fault of the excluders either—more the fault of myself in getting in a hurry to confine the queens to the brood-chamber, when the immense flow of nectar and the small force of bees so early in the season left no room for brood-rearing. The force of bees, as I have said, was too small to operate in all parts of the hive at the same time. If I had left the excluders off I feel I should have had more brood early, consequently more bees now for the harvest at this date, as the queens could have forced a retreat somewhere. This season, to be sure, is a very great exception, and the same condition may not happen again in fifty years.

There is an old adage that "one swallow does not make a summer." Neither does one rainstorm or one wet spell make a honey crop. Late in January our state was flooded, the hills were soaked—indeed, the ground was so thoroly soaked that landslides were frequent, even on the foothills where such things were rare. Beekeepers were jubilant, enthusiastic, and satisfied; but, alas! the rain ceased abruptly, the sun came forth in all its brilliancy, and the moisture began to go rapidly. Today, May 6, I read that $\frac{1}{4}$ inch of rain has just fallen in San Francisco, the first for 44 days, leaving the record for April the driest since 1857. There is a great lack of moisture all over the state, and honey-plants are the sufferers. My scale colony is making about two pounds net per day in the middle of the button-sage bloom, when I had every reason to believe that I might now be getting ten pounds at this period. Everything is all out of season from the very beginning. Orange bloom was over by the time it usually begins to bloom well. The sage followed in about the same unseasonable time, and other things in the same roll, with no moisture to help secrete nectar. So near and yet so far! so good and yet so poor!

NOTES FROM CANADA

J. L. Byer, Markham, Ont.

I have received a few pound packages of bees from the South by way of experiment. Shipment arrived in good order except one package that was starving. The bees had reached the "quiver" stage. Cages were soiled somewhat; and when the bees had their first flight, visible marks of their confinement were in evidence. Evidently, "dysentery" (?) can be caused without any cold weather, and by so short a confinement as five or six days. I had no trouble whatever in getting bees on to the combs in the hive; and after four days I found all queens laying nicely. While I could have given them brood to help them along, not a single comb did they get. They were supplied with combs and honey, and it will be a case of each one "paddling his own canoe." That is the only way to give a fair test to see what they will do in the way of building up and producing a possible surplus. As to the latter, while the bees are in good condition I would be willing to dispose of any possible surplus from them this season at a very moderate figure indeed.

SUGAR \$9.00 A HUNDRED.

The spring of 1916 will be remembered by many Ontario beekeepers as one of the most backward in years. To make matters worse, during the exceptionally warm January preceding, heavy brood-rearing was carried on by the bees, with the result that consumption of stores was abnormally heavy. With bees all in packing-cases, and with a knowledge that most of them are strong, but on the verge of starvation, continuously cool and wet weather right up to date, May 15, has a tendency to get one worrying a bit unless he is entirely proof against such folly. Wild-plum blossoms are not yet open as I write this, for May 15 is late, even for Ontario. Bees at our north yard had a late light flow of honey last fall from aster, etc., and as a result many old bees died off earlier, leaving colonies in good condition, but not so populous as here in York Co. The result is that the north bees are in fine order, and few are short of stores, while here in York Co., while bees are in fair shape as a rule, yet in my four yards I doubt if the bees have two pounds of old honey per colony. It is needless to say we are hoping that conditions will soon get better so that bees will get something from dandelion, fruit-bloom, etc., to tide

them over till clover. Otherwise, buying sugar at near \$9.00 a hundred is the alternative confronting us. But clover looks immense after all the rain we have had; and so, no doubt, all will try to tide their bees over, even if it does mean a heavy expense for the time being.

MORE THAN ONE QUEEN IN A HIVE THRU THE WINTER.

From an experience we have just had, I am led to believe that possibly more than one queen is sometimes in a hive at the same time when the apiarist is not aware of the circumstance. In April, 1915, we found a clipped queen and another one unclipped, both on the same comb of brood. The young queen appeared to be fertilized, and I thought little of the occurrence, expecting that the old queen would soon disappear. Later on in May again, the two queens were still there, and, if I remember correctly, we saw them again in June. After that, being very busy, the colony was not examined again. They were prepared for winter with the other colonies; and as I noticed brood in the hive at the last examination I naturally presumed that the young queen was now alone on duty.

This spring I noticed this colony was not building up any too well; and, altho the day was not any too warm, I opened the hive, and—imagine my surprise to see the old clipped queen still on duty! Altho not very strong, yet some drones were being reared, and I concluded that the young queen, noticed over a year ago, and later as well, had not been fertilized and had been disposed of. I sent for a queen at once, and a few days ago my son and I went to hunt out the old clipped queen. As they are very gentle Italians she was soon found and disposed of. I was about to close the hive, when, on second thought, I decided to take another look for fear the young queen might still be there. On the very next comb, sure enough, there was the other queen, apparently a fine one in so far as looks go, and in the act of depositing an egg in a cell. No question as to any mistake in the matter whatever; and will some one please explain why these two queens were together a whole year? As the two together were not doing as good work as one queen should do, we broke up the dual monarchy by pinching the head of the young queen, even if she was all right in so far as appearances go.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

Almost everything in the arid regions needs special methods adapted to our special conditions. As an example, take the water treatment for foul brood. Some let the hives down very slowly into the water, or, rather, push them down, and, when clear down, put a heavy weight on top to hold them down. Here in the West we have a very easy method. We irrigate the foul brood. Go to the edge of the irrigating-ditch and dig a nice square hole, about six inches or so larger than your hives to be treated; then place your foul colony in the hole with the new hive on top, and a sufficient weight on top of that (sit on it if you want to). Dig a little ditch from your irrigating ditch to the hole, and let the water run in slowly and fill the hole. When you get one colony treated, take the old hive and comb out and dip out the water and treat another in the same way. One disadvantage of the water treatment is that the old hives and combs do not burn very readily; but suppose you have just one hive to treat—you can dig the hole a little deeper; and when you get the bees all out just cover the whole thing with two feet of earth.

Transferring box hives can be done by the water method; but the loss of brood will be considerable unless the box hive has cast a swarm one week previous to the treatment, in which case nothing of value need be lost by the treatment with water, as the honey is not hurt for bee-feed, and the wax is not injured. The hive, being only a box, is worth nothing anyway.

CONTROL OF BEE DISEASES BY RESTRICTING SHIPMENTS OF BEES AND QUEENS.

The development of beekeeping to its highest possibilities cannot be accomplished without the shipping of bees and queens from one point to another; neither can it be accomplished without certain restrictions. American foul brood cannot be transmitted, it is believed, by shipping bees and queens in combless and honeyless packages. European foul brood has been pretty certainly carried by sending queens thru the mails. American foul brood is easily transmitted in extracted and comb honey shipments. What are we to do in these contingencies?

Here in Colorado it has been recommended to the beekeepers that they refrain from purchasing bees and queens from outside the state. Inasmuch as we have European foul brood that may have been introduced by receiving queens from an infected dis-

trict in another state it has been decided to caution beekeepers. And we are just as anxious and just as much concerned that no bees or queens shall be shipped out of this infected district. We believe we should take our own medicine, and are taking more of it than we ask any one else to take. Therefore beekeepers of Colorado are cautioned against buying bees and queens outside the state, and shipments of bees and queens are prohibited from the district infected with European foul brood in so far as our law will permit.

Shipments of infected honey are not allowed to go into general trade. They are directed to cracker-factories. However, beekeepers are too careless and indifferent in this regard, and we must mend our ways. An act prohibiting the shipment of comb or extracted honey from an infected apiary would meet with the writer's approval. At the present time it would be doubtful if it could be enforced; but we shall come to it sooner than many of us think. It would cause a *furor*, the like of which the hubbub over the net-weight law would be tame. In three years after such a restriction is passed the country would be freer of foul brood.

If the beekeepers would have notice served upon them that in two years all diseased apiaries would be prohibited from shipping honey until such apiaries are free from disease, it would make us hustle.

The editor of GLEANINGS recently spoke of too strict legislation in some states, and there is no doubt that some of the laws are more detrimental than helpful to beekeeping interests. I should like to see full and free discussion of the points over which there is dispute. The editor mentioned that if shipments of bees and queens were prohibited from one state to another the beekeepers would be handicapped in getting disease-resistant stock. But it is probably true that there is not a state but that contains beekeepers who have vigorous Italian stock that could be secured without going beyond the state lines for it.

Personally I do not believe that there is such a thing as stock becoming immune to the disease by long contact with it. There is no immunity without strong vigorous colonies headed by young prolific queens. And I have observed no advantages of the Italians over hybrids, strength and vigor considered.

A vigorous black colony so cross that no drifting bees are allowed to enter will furnish good immunity. [See Editorial.—Ed.]

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

AVOIDING BEING STUNG.

"Can you tell us how to avoid being stung? I do not mind an occasional sting, but my bees seem persistent in stinging me, so that some days I get from 20 to 50 or more stings."

Quite a little depends upon the individual in regard to this. If a man works at the bees with quick or jerky motions, when lifting hives, frames, or sections, he is apt to jar the bees more or less, and even kill many of them. A man having 20 colonies desired to come and work with me for a day or two to learn something more about the proper way of handling bees; so I told him to open a colony of my most peaceable bees just as he did his own, and if he lacked in any part I would show him a better way. The first thing he did was to throw (or, rather, drop) the shade-board on the ground in such a way that it fell over against the body of the hive with a heavy jar. I called a halt, telling him that in all the manipulations about a colony of bees everything must be done with a view to making as little disturbance as possible. He then commenced to pry the frames apart, and did it about as a man would pry up sticks of timber were they frozen down. I was about to call a halt again when he grabbed one of the loosened frames and brought it out with a trembling, jerking motion, causing the end-bars to strike the hive, and the one next to it, so that from 50 to 100 bees were crippled for life. In a short time he was getting out of the beeyard with more stings than I would get in two months.

A man must learn that much depends upon the flow of nectar and the weather. A cloudy or cool rainy day, when all the bees are kept at home, is the worst time to open hives unless it is a day when the bees have been robbing, or a cool day following a sudden stoppage of the nectar flow. If it is really necessary to handle bees at such times, the thoughtful apiarist will first make sure that his smoker is in good order, and is ready to give off a good volume of smoke. He will blow in a little of it at the entrance, and then pry up the cover a little very gently. As he does so he will send a stream of smoke into the crack made by the screw-driver or other tool he uses. This drives down the guards, and then the crack is made a little wider, and more smoke is driven in, when the cover is removed. If the bees appear nervous, and stick their heads

up all along the spaces between the top-bars of the frames, standing high on their legs, and follow every motion with a turn of their heads, they should be given a few more light whiffs of smoke until they are subdued and show it by keeping mostly down below the top-bars among the combs. Using the hive-tool, the frames should be loosened very gently, the smoker being held in the other hand. If the bees stick their heads up at any time ready to show fight, they must be driven back again, and then the first frame very gently removed, care being taken that no bees are rolled over and bruised by the frame coming in contact with any part of the hive or other combs with force enough to cripple any of them. After the first frame is out, when working in this way the bees rarely show much fight; but if they do, a few whiffs should be given as they become restless.

In warm weather, with a nectar flow, I rarely blow smoke in at the entrance. Just a little in the crack when removing the cover, and a little smoke on its arrival, is all that is necessary with nine out of ten colonies, if care is used. I do not think that there is a colony in my yard that I could not go out and manipulate without either smoke or veil, and receive no stings, yet I would be obliged to work very slowly and carefully. It often happens that I wish to do just a little work with the bees—see if a queen has been released or if she has begun laying, or if the bees are working in the sections—and I neither light a smoker nor take a veil. I just work slowly and carefully. But the use of a smoker is a great saving of time. So is a veil, as one need not be quite so careful. I do not mean by this that I work roughly or mutilate the bees. I mean simply that I can do faster work.

A man accustomed to bees can go into an apiary where the bees are quite cross, and stay ten or fifteen minutes; and if the hands are free to use in protection, no stings will be received. At the same time a novice might be stung almost immediately, and a number of times, if he stayed that long. Pulling down the hat over the eyes, shading the face with the hands and arms, etc., help to disconcert the bees.

If a colony should get unduly stirred up so that a score or two of ugly bees follow about in an angry mood, I carry a wire-cloth "paddle" in my tool-box, and with this a few quick blows will kill the whole lot of them, so that peace is restored.

GENERAL CORRESPONDENCE

CONDITIONS UNDER WHICH WAX PRODUCTION ALONE IS POSSIBLE

BY LESLIE BURR

The beekeepers of the Hawaiian Islands produce but little beeswax. There seem to be two reasons for this. First, they have been contented in the past with producing honey; second, they have no bee diseases, and so have never had to do any wholesale cooking-up of combs, as beekeepers here had to do in many parts of the world. The only wax that is produced is from cappings.

In handling the cappings the Hawaiian beekeepers have adopted the usual method employed in California—that is, they use large solar extractors to melt the cappings, and then later cook the wax in large tanks or vats and run it off into cakes. These extractors are merely glass-covered boxes, bee-tight on top and honey-tight at the bottom. They are divided into two compartments by a screen. This screen is placed midway between the glass and the bottom of the tank, and it is on this screen that the cappings are placed. The honey in the cappings finds a ready passage thru the screen; and the wax, after having been melted by the sun, follows.

MAKING A SPECIALTY OF WAX PRODUCTION.

On the surface, conditions here in the Hawaiian Islands appear to be such that bees could be worked for wax as well as honey. These conditions that make for wax production are: A large portion of the honey produced is of very low quality, and an equally low price is obtained for it. Then there is the matter of transportation. The islands being located near the center of the Pacific Ocean, it is a long journey to any market. Ocean freight rates are by the ton, and the value of the freight makes but little difference in the rate charged. Then, too, wax is worth almost the same price here as on the Coast.

Just what procedure should be followed, or what can be done in the matter of wax production here, I do not now feel qualified to say. I have been here but six months, and during the time of year when the bees have least to do. It may be that the present method of working bees secures all the wax that can be obtained at a profit, yet I doubt it.

CONDITIONS IN THE HAWAIIAN ISLANDS.

Beekeeping everywhere is a matter that has to be worked according to local conditions. The time of year at which the sur-

plus flows occur; the temperature, and the kind of weather; length and nature of flows, and many other matters all have a bearing. While it is safe to say that, as a rule, bees will do like things under like circumstances and conditions, yet there are very few localities where identical circumstances and conditions exist. For example, take Cuba and the Island of Oahu. Both islands are north of the equator, and located at just about the same distance from it, yet the honey seasons are reversed. In Cuba the honey season is during the winter months, while on Oahu the flow is during summer. The temperature of the two islands, I think, is almost identical, month for month, yet the general weather conditions differ greatly. In Cuba the rains come in the summer, while on Oahu the rains are generally during the winter months. So, because a thing can be done in Cuba it does not necessarily follow that it can be done in the Hawaiian Islands, and *vice versa*.

One thing that was a surprise to me here was that, among those interested in bees, at least among those I have met, I have as yet to find the first person who seems to have any interest in increasing the output of beeswax. In fact, none claims to have given the subject a thought.

In Cuba, years ago, wax production was one of the common topics of conversation among honey-producers—at least it was a common topic every time the price of honey went down. Some of the honey-producers used to advocate the working of bees for wax alone, their idea being to locate an apiary in some of the out-of-the-way places, where the territory was exceedingly good (or at least supposed to be of that nature), such as some of the locations up in the mountains, or down in the mangrove swamps on the Caribbean coast. The usual plan of management advocated was to use native hives—that is, hollow logs, and then work the bees native fashion by cutting out the surplus honey first from one end of the log and then from the other end. The natives place the log hives in rocks in a horizontal position. The honey, after taking out the wax, was to be fed back to the bees, over and over again, until nothing but wax was left. However, so far as I am aware none of those who advocated such methods of beekeeping ever tried to put their plans

into operation. Such discussions were generally looked upon in the light of pastime. Perhaps some of those who used to discuss wax production to the exclusion of honey may have been serious enough to hope that some person would try the scheme and thereby satisfy curiosity.

The bee is primarily a honey-producing insect, and I don't think that man will ever be able to alter its nature enough to change it into an insect whose principal object in life will be to produce beeswax.

While working bees for wax alone—that is, to the exclusion of honey, may be but a dream; yet working bees in such a manner as to increase the amount of wax obtained, and the profit from the apiary thereby, is, in my opinion, possible in most localities—at least that is my belief. The basis of this belief is that during a flow of honey the bees will produce a certain amount of wax without any appreciable decrease in the amount of honey that is gathered, and that the average beekeeper does not secure all of this wax.

As to methods of securing this wax, the most simple is by proper spacing of the frames in the super, and by the proper uncapping of the combs. By proper spacing I mean wide spacing; that is, eight frames to a ten-frame super. I have visited apiaries of many extensive beekeepers and found the frames in the supers spaced the same as in the brood-nest, and have heard some of these same beekeepers boast as to how thin they could slice off the cappings. They were working their bees so as to get as little wax as possible, and prided themselves on that fact.

In the matter of spacing, my experience has been that just as much honey can be obtained when the combs are spaced wide, and, when uncapping, slice the comb down even with the wood of the frame. This also makes it easier to take out the full frames of honey from the supers; and it is also easier, when uncapping, to slice off a good thick slice of comb than merely to remove the bare cappings.

In this matter of wide spacing, conditions also play a part. With strong colonies the combs can be spaced wider than in weak ones; and during a heavy flow of honey wider spacing can be practiced than when the flow is light. This wide spacing, I also think, holds down swarming in a measure.

In tropical or semi-tropical climates where there are long spells during which time the bees gather merely enough honey on which to live, considerable comb can be obtained by having it built in the brood-nest. Under such conditions combs so built

are clear gain; for if the bees are left to their own devices, nothing is obtained from them.

In the matter of working bees for wax alone, there are certain conditions under which it can be done. I know this to be a fact, because I have done it. I think I have told of the manner in which it was done, in previous articles to GLEANINGS. But as that was some years ago, and I suppose most of the readers have forgotten what I then said, or that I ever wrote anything on the subject, I will risk telling the tale again.

HOW BEES WERE WORKED FOR WAX ALONE.

In Cuba, that is, in most parts of it, the principal honey-flow is during the winter months, the heaviest flow being during December and January. In summer the bees are practically idle; but in early spring and early fall there is a light flow of honey, during which the bees breed like mad, and swarm accordingly. As a rule the honey gathered during these spring and fall flows is of very poor quality, and of little value, even if it were possible to secure it, which is not the case, for the bees have no desire to store this honey in the supers, their sole idea being to turn it into brood. It was during this spring flow that the bees were worked for wax. The process was simple. Care was taken that none of the combs in the brood-nest contained any drone comb; then the queen was confined below with a queen-excluder. In the super the combs were interspaced with empty frames, care being taken to see that those combs in the super contained no drone comb. Under those conditions the bees were possessed with the idea of building drone comb. As the queen was below she could not lay in this new drone comb when built; and as the bees desired drone brood the comb was held open for the queen to lay in, no honey being stored in it. After the hives had once been prepared in the manner indicated, the production of wax was a simple matter. All that had to be done was to make the rounds of the supers twice a week and cut out this newly built drone comb. When the early flow came on in the fall, all combs needed for the winter flow were drawn out.

By the foregoing procedure considerable wax was obtained when, under ordinary practice, nothing could have been obtained from the bees but increase; and as increase was not desired, the wax obtained was just so much clear profit.

In conclusion I wish to say that I think I have made it clear that I do not believe that bees can be worked for wax alone—that is, to the exclusion of honey, under any

other conditions than those described as existing in Cuba.

As to producing wax by having comb built in the brood-nest: I was able to do that two seasons out of three in San Diego, California—that is, in the city of San Diego. The same conditions did not exist outside of the city.

In the northern states I doubt whether conditions will allow of the increased production of wax by any other means than wide spacing—at least I believe such to be the fact in most locations and under normal conditions.

Honolulu, H. I.

THE PRODUCTION OF WAX IN CUBA

BY FRANK REIMAN

The production of wax in Cuba is of almost equal importance to that of honey, as the statistics of exportation show. By the old system of keeping bees in hollow logs, one pound of wax was produced for every gallon of honey, which was from two to five gallons according to the year. By my system I secure about five pounds of wax and ten gallons of honey a year. The past year was the greatest failure I ever had. My honey crop was only 75 barrels and 2000 pounds of wax. The spring crop was very poor, because no rain fell until the last of April. In July the rains, which were scant, stopped entirely, and we are now over seven months with less than half an inch of rainfall all told. This is the driest spell I ever saw in any country. The cold was also so excessive that neither honey nor wax was produced. From the middle of October until Feb. 1 the thermometer stood at about 50 degrees each morning, rising to about 60 or 65 by noon. Some mornings it was as low as 40, with cold winds and clouds all day.

I am confident that the people of the United States believe that it is very warm in Cuba all the year round. This is a mistake. I have seen the thermometer at 34 in the morning, without rising above 40 all day. I have also seen the winters so warm that the bees swarmed February 10.

I use a long ten-frame hive which has frames 20½ inches long by 6 deep. I use neither foundation nor wire—ten frames below and nine in the super. My new combs I raise exclusively in the super, for in the super the bees work to the bottom-bars. In the bottom of the hive they leave half an inch of space between the comb and the bottom-bar. I use five empty combs with four frames alternately in the super. In a week they will fill the four empty frames. If they are drone comb they are worth five cents each for wax. If they are worker comb they are worth at least ten cents each to use for brood. When not enough honey comes in to extract I look at all the hives each week, make new swarms

with the good combs, and cut out all the drone comb except in special hives for breeding, and all old comb without honey.

In extracting, a woman cuts all the drone comb and old combs, which usually makes from 25 to 50 pounds with the cappings in extracting one beeyard.

I have never tried feeding back honey to make wax; but I am sure it will not pay here, as enough honey usually comes in all the year—enough for the bees to make some wax. I have fed back to finish sections of comb honey, and find that the bees made only about one section a day, whereas they naturally would make at least five with honey coming in from the fields; and, besides, the honey was darker. In the spring and summer months the wax must be made up every day, if possible, or it will ferment and spoil on account of the drone brood. The moths will also eat the combs all the year round. Dogs will also eat the combs if the combs contain honey or brood. To learn this cost me several dollars. I left a box of comb out over night, and in the morning it was cleaned up. The neighbors told me the dogs did it.

My mode of rendering wax is simpler and less expensive than any other method I know of. The outfit consists of six empty five-gallon gasoline-cans, a peanut-sack, a barrel cut in two, and a pair of stout sticks securely tied together with a stout cord. I place the cans three in a row. Over them I run bars about six inches from the ground so I can heat six cans with one fire. I fill the cans one-third full of water; and when the water boils I keep putting in combs until the can is two-thirds full. When the combs are melted, and begin to foam, I pour the contents of the can into the sack which is suspended over the half-barrel. I begin pressing the sack between the two sticks, working the two sticks up and down until no more wax comes out. I then throw the refuse away. When there are two persons you can use eight cans and make from 200 to 500 pounds of wax a day according to the quality of the combs.

When there is much wax to make, it is advisable that there be two to work at rendering, as they can work to better advantage, and press the wax cleaner. The second person twists the bag while the first holds it between the two sticks. Combs or cappings with honey should be first melted with a little water to get the honey out over a slow fire, and should not be heated until the wax boils, as it will spoil the honey, and the wax will be harder to render afterward. When the wax is rendered with a quantity of honey in it, it comes out in a mess of granules like shot when cold, and must be melted again.

The cans cost here 15 cents each, and last about three months. A bag lasts long enough to make from 500 to 1000 pounds if it does not get bad treatment by pressing hard enough to tear it. The wax, when melting, should be constantly stirred from the bottom upward, and not pressed down from the top, else it will burn the cans, and the wax will have a burnt flavor. When wooden utensils are used to hold the melted wax they should be soaked with water first so the wax will not stick to the sides. When tin cans are used they should be about two-thirds full, and inclined at an angle after the wax is in the can so it will come out

easily when cold. This trick I learned about ten years ago when I had a can that leaked on one side when I inclined it to stop leaking. In the morning the can let the wax out easily, while I had to work at the others to get the wax out. For the last ten years I have always had about 1500 hives of bees in eight to ten yards. My average crop of wax is about 5000 lbs. a year.

At present the price is 40 cts. per gallon for honey and 24 cts. a pound for wax. Russia is our chief buyer of wax, which market is at present shut off by the war. The honey moves as usual, being shipped to Germany via Holland.

Canto el Paso, Cuba.

[Different parties who make a business of buying up slungum and rendering it into wax report that the refuse left when combs are rendered by the hinged-board method yield from five to fifteen per cent of its own weight in wax. In our opinion, for a wax crop of 5000 pounds a year a large-sized powerful press should be used in a can or tank to permit the combs to be under boiling water during the pressing. We do not believe there is any other practical way of getting all the wax. See report by F. A. Hooper, page 458.—Ed.]

GIVING WAX THE MAIN TRACK WHERE THE COST OF GETTING HONEY TO MARKET IS PROHIBITORY

BY W. G. HEWES

In this locality the price to the producer for extracted honey during the past two years has been $3\frac{1}{2}$ cents a pound. Beeswax has brought from 27 to 32 cents or from eight to nine times as much as honey. It seems to me that, under these conditions, it would be wise for the $3\frac{1}{2}$ -cent honey-producer to run his bees for wax and let honey be the incidental instead of wax, as is now the case.

Between my bees and a depot are fifteen miles of awful road. Twelve cases of honey weighing 1600 pounds is a load for two horses. Such a load, when delivered in Yuma, is worth \$50.40. A load of wax of the same weight is worth \$432. In other words, it costs more than $8\frac{1}{2}$ times as much to get a dollar's worth of honey to town as it does to get a dollar's worth of wax. The wax is shipped in sacks, which, so far as I am concerned, cost nothing. It takes 20 per cent of what my honey sells for to pay for the cans and cases. Were that old chestnut true, about its taking twenty pounds of honey to make one pound of wax it would

not pay to make a specialty of wax production, even if it is worth eight times as much as honey. But that is fol-de-rol. During a honey-flow I don't believe a hive having plenty of young bees will consume five pounds of honey to make a pound of wax. But here is another point: If the producers of three-cent honey would so generally turn from honey production to wax production as to make a material reduction in the honey crop, the short supply would cause an advance in price, and probably sell for as much as would a large crop.

Four years ago cotton was selling for 16 cts. a pound, buyers believing the output would be 12,000,000 bales. When the Government came out with its report, saying the output would be 15,000,000 bales, the price dropped so that the large crop sold for several hundred million dollars less than the small one would have done. The cotton-growers would have been better off had they fished more and worked less. Put this old world on half rations, and it treats you well. You can sport around in automo-

biles; but give it a full ration, and your only show for an automobile ride is when the police run you in as a vagrant.

To raise more wax and less honey, begin in the spring by cutting out and melting up everything but perfect brood-combs. Then replace the empty frames; and when they are filled with new comb and honey cut out the combs, drop them into some receptacle like a McIntyre uncapping-box, from which, after being crushed and chopped up with a short spade, most of the honey can drain off into a tank. A capping-melter will get the rest and the wax. I have queen-excluders for all my hives, and would consider

them an essential in wax production, so as not to be bothered by brood, for queens dearly love to lay eggs in new comb.

I shall try this season to see how much wax I can get from my 250 hives; and if the beekeepers of the West Indies and our southern states—Arizona, Imperial Valley, and northern California, would do likewise, I feel sure it would be advantageous to us all.

Yuma, Ariz.

[We hope that our correspondent, after he runs his bees for all they are worth for wax, will make a further report.—Ed.]

USE SOFT WATER TO FACILITATE WAX-RENDERING

BY W. B. BRAY

In the method I use in rendering the wax from old combs I am able, in the one operation, to get the wax into large clean blocks ready for market. I melt the combs in a large copper boiler and press them in a Hatch press, which I consider is the most useful press for any beekeeper. I cut out an extra melting operation by catching the wax and water from the press in a benzinetin *which has a small tap soldered in at the bottom*. When this tin is full I keep on

drawing the water off at the tap, and return it to the boiler. By using the same water all the time, I save firing, do quicker work, and the wax remains hot in the tin. When it is nearly full I strain the wax and some water into a clean tin, which is then well covered up so that the wax will cool very slowly. A couple of-days after, I can take the block of wax out and scrape all the dirt off the bottom. Even this dirt contains a small quantity of wax, so I put it in the

Wax rendered by members of the apicultural class at the Massachusetts Agricultural College. Different processes are demonstrated by the students under the direction of Dr. Burton N. Gates.

solar extractor, which makes a thoro job of removing it.

A most important point in all wax-melting operations is to use soft water. I am sure that hard water accounts for the loss of tons of wax in a year.

Speaking of tons reminds me that our

ton is 2240 lbs. We call the American ton, 2000 lbs., "short ton." Your five-gallon can holds 60 lbs. of honey, so the gallon of honey must weigh 12 lbs. Our gallon holds $14\frac{1}{4}$ lbs. of honey—a matter of "locality" again.

Wainiu, New Zealand.

RENDERING CAPPINGS INTO MARKETABLE WAX

BY J. L. BYER.

Some years ago while buying honey in Ontario a beekeeper, after showing me his crop of 4000 pounds of honey, and stating the price he wanted for it, incidentally remarked that, "in taking off that lot of honey, not a handful of cappings were removed." That was a "record" all right, and I promptly told him so, adding at the same time some remarks that I fear were hardly complimentary to such a method of harvesting a crop of clover honey. The honey was very white, but, needless to say, light in body, and lacked that characteristic flavor that is obtained here in Ontario, at least, only by allowing the bees to cure the honey on the hive—a process that calls for the most of the honey to be sealed over before being extracted.

The man referred to represents the extreme view on the part of a very few, fortunately, who produce extracted honey. While he had not a handful of wax from 4000 pounds of honey, it is natural to ask how much wax can be secured from a given amount of honey. Of course the answer all depends upon certain factors, such as to whether we cut deep or shallow when uncapping, and also to the proportion of the combs capped over when the honey is extracted. Last year we had a good crop of honey at our north yard; and as we were busy during the honey-flow, and also had a full complement of extracting-supers at that yard, all honey was left on the hives till the close of the white-honey flow. There was no buckwheat to make us hasten operations. In York Co. the crop was very light—about 25 pounds to the colony, of white honey,

and we had a second flow from buckwheat of about the same amount. Of course at the north yard we had a much larger amount of cappings than here at home, as up there the supers were filled, while down here in York Co. very few supers were filled, and the majority of the combs had quite a lot of unsealed honey in when extracting was done. About two-thirds of our crop of 36,000 pounds of honey was produced at the north yard; and as the cappings were all melted together here at home, I cannot give the exact proportion from any one yard as compared with another. However, the general average is about the same as for other years; and after weighing up the wax from the cappings I find that we get about one pound of wax to every 100 pounds of honey extracted.

The picture shows the wax just as it came from the press, and that pile represents 365 pounds of very nice wax, altho the cakes were cooled too rapidly, as can

365 lbs. of wax obtained from cappings from 36,000 lbs. of honey.

be seen by the checks in some of them. On this basis we must have had much more than one pound of wax to every hundred of honey at the north yard, as at a rough guess I should say that not more than half of the honey here at home was sealed over, while at the north yard nearly all combs were about solid. Unfortunately we have never had a full crop in both counties at the same time; and as cappings are always rendered up in winter, and all put together, results have always been about the same. At any rate it looks as tho one should expect a pound of wax to 100 of honey, provided the crop is average in quantity. How does this accord with the experience of other extracted-honey producers?

We are often asked how we dispose of the cappings. After trying a capping-melter a few years ago with indifferent results at best, we are again back to the old-style methods we have used for some time. I am told that the new-style melters are all right in that they do not color or "cook" the honey; but I have not tried them, so cannot speak from experience. One thing objectionable with all of them is that it means extra heat in the building at a time of the year when we need nothing extra along that line. We use the old-style divisible capping-cans, and like to have two at each yard. One will about handle the cappings for a single day's work, and with two cans the cappings can be left to drain much longer than when only one is used. The only objection that we have found is that they are too deep to allow as much drainage as a longer and shallower uncapping-device. On the other hand, they are bee-tight, can be easily taken from one place to another if

necessary, and they also take up little room. In crowded buildings this latter point is a strong one in their favor. After draining the cappings as long as we can leave them in the cans, they are dumped into empty barrels till we have time later in the fall to attend to them.

Formerly we put the cappings all thru the capping-melter in the winter, removing all the honey, and then the wax and all refuse with it was melted up and run thru the press, and then into the flaring tins we use for the purpose. But that was too slow a job, so we now put a pail of water in a large kettle outdoors, and then fill up with the cappings. The mass is heated till all is thoroly dissolved, but not boiling, and then removed from the fire and allowed to cool. Of course the honey with the small amount of water will all be at the bottom, and wax can be lifted off the top. When all the cappings are treated like this, then the wax in the rough, as it will be, is broken up and remelted in a warm room. We have a stove in our furnace-room and do the work there. The honey and water taken from the cappings is, of course, unfit for market, but it will not sour or granulate, and in the spring it makes first-class food for the bees if any feeding is necessary. Before feeding we add some more water and then bring all to a sharp boil to avoid any chance of disease.

This method of handling the cappings is, no doubt, out of date in some ways; but until we decide to use a melter while extracting, and thus dispose of the cappings at once, I expect to continue as at present, as it is about the quickest way we have found of solving the problem.

Markham, Ont.

RENDERING FOUL-BROOD COMBS INTO WAX

BY EARL F. TOWNSEND

In talking with a beekeeper regarding the control of American foul brood he informed me that, after shaking the bees, he burned the remaining brood-frames and combs. This seemed to me rather wasteful, as I have recently sold a quantity of prime wax rendered from foul-brood combs to a large manufacturing concern at 45 cts. per lb. Had I followed his method these combs would have been an entire loss. It occurred to me that some of the newer beekeepers might be interested in our method of rendering such combs.

We do not shake for American foul brood at all, never having had very flattering success with the plan (altho possibly this may have been my fault); but when we

come across an affected colony during our regular inspection we make a note of it; and as we usually find them before they are very weak, we contract the entrance and run them for all they are worth during the honey-flow, allowing what bees remain in the fall to starve. During the winter we render the combs.

After putting the wax thru a Hatch press, we again melt the refuse with a small amount of water, and put it thru the press again, this time placing inside the burlap cloth a piece of coarse unbleached cotton cloth which catches any small particles of dirt which may have come thru the burlap at the first pressing. We pour the wax into a metal dish having flaring sides, larger at

the top than bottom, and allow it to stand until the wax is solid, when contraction will allow it to slip out smoothly in beautiful cakes.

When cutting combs out of the frames we place frames back in the hive-bodies until wax-rendering is finished, when we have a "boiling up" as follows:

In an ordinary wash-boiler about half full of water we place half a can of lye, and in this boil as many frames as can be placed upright therein. As this amount of water will not entirely cover the frames, after boiling a few minutes we reverse them and boil, possibly five minutes. This boiling cleans the frames nicely, leaving them almost as nice as new ones. We then scorch the hive bodies inside, and wash the outside with a strong solution of some disin-

fectant, usually the cheap coal-tar products, such as krese or hygens A. Since carbolic acid, due to the European war, has become a luxury, we also scorch the bottom-boards. We then rewire the frames, and fasten full sheets of brood-foundation.

This "occasional cleaning up" is an advantage, as it gives us some very nice new combs at the end of the following season, in place of a lot of old ones, many of them filled half or more with old pollen—too old, probably, for the bees to make much use of. We try to be very careful not to carry any foul-brood germs out of the room where the rendering is done, by stepping on particles of comb which may become scattered when cutting combs from frames. Before leaving the room we wash the bottoms of our shoes with the disinfectant mentioned.

EXTRACTING THE HONEY FROM CAPPINGS BY CENTRIFUGAL FORCE

BY C. E. FOWLER

I have been using folding pockets for extracting the honey from cappings, small pieces of comb, or even sections that are not salable.

The pocket is made of two frames of $1\frac{1}{2} \times \frac{7}{8}$ strips, hinged with leather. By making the lumber thinner the pockets could be made to hold eight sections $4\frac{1}{4} \times 4\frac{1}{4}$, or a gallon of cappings.

Large beekeepers may not want to bother by extracting cappings; but for the small beekeeper it saves a lot of fussing, and finishes the job all at once, even to rendering the wax; and the room can be all cleaned up the same day. The mesh of the netting is $4\frac{1}{2}$ to the inch, but finer would probably be just as good, or better.

Hammonton, N. J.

Folding pocket for extracting cappings in an ordinary honey-extractor.

A RACE BETWEEN HONEY AND WAX

BY A. J. WRIGHT

Possibly some of my experiments may be of interest along the line of wax production in the season of 1912, the best season with me for the production of honey in this locality for several years. I selected two strong colonies, one intended for wax production only, and the other for honey. Both colonies were very strong. I may say that the colony selected for wax in previous seasons had shown a marked proclivity for depositing wax in every available place inside the hive, and giving a comparatively small surplus of honey. The colony selected for honey production showed opposite traits in a marked degree, everything being clean and neat, and the honey going where it should. Having decided to let the wax colony have its own head, I also decided to put it in financial competition with the honey colony referred to.

About June 1, when white clover began to appear, I put on the wax colony an eight-frame hive-body, the same as the lower hive, without a queen-excluder: The upper hive contained eleven boards, the same dimensions as the regular frames, but only half an inch thick. The hive was leveled, and the half-inch boards had a wire nail driven in each opposite end, near the top to rest on the tin rabbets. No spacers were used, the boards being spaced by guess $\frac{1}{2}$ inch apart. A $\frac{3}{4}$ -inch strip was tacked on the top of the upper hive to give wax space under the cover. A similar hive-body was prepared and set aside to be used later on. A single frame of brood in various stages of development was taken from below and placed above (removing two of the boards for the purpose). I was careful to leave the queen below. This brood was for the sole purpose of inducing the bees to go above. Altho no excluder was used, yet the queen was never found above thru any of the manipulation that followed. The capings of all honey below for two inches or more below the top-bar were broken by passing a knife flatwise over them but not enough to make the cells leak. Before the wax-boards were placed in the upper story each board was painted with a thin coating of hot wax, both sides. The following outfit I found necessary: A knife with blade long enough to reach to bottom of the hive, and turned up at the end like a miniature hoe, and a scraper. The knife was used to scrape the wax from the wall of the hive by an upward motion, and the scraper to remove the wax from the top of the frames

in the lower hive, from the under side of the cover, and from the wax-boards in the upper story. I used a wooden device to remove the wax from between the frames below. The small end, which was $1\frac{1}{4}$ inches long, was inserted between the top-bars, and a downward motion on the handle raised the wax to the top of the frames. In addition to the above there should be a pan long enough to allow one of the wax-bearers to stand on end, and of sufficient width and depth to hold the comb or wax scraped off.

Everything being ready, developments were watched with interest. The honey-flow was now on in earnest, and in three days' time the cover was removed, and wax in a limited amount was found in patches between the cover and top of wax-boards. One of the wax-boards was removed, and spurs of wax or comb were built out from the sides of the board and the adjoining one, and also from the sides of the hive, but I decided not to remove any at this time. Four days later I decided to remove what there might be anyway. I undertook to remove the cover; but in doing so I snapped off the blade of a new knife. I then inserted a hive-tool, and, removing the cover, I found parallel ridges of wax following the tops of the wax-boards and the top of the frame. I then removed the upper story entire, and put the one prepared as mentioned above in its place, first removing with the wooden device all wax from between the top-bars of the lower hive, and with the scraper all wax on top of said top-bars. I then removed each wax-board and shook the bees on to the wax-boards in the upper story; then the end of each wax-board was placed in the pan, and with a downward motion of the scraper the wax was removed from each side of the wax-board, and so for each one, but leaving a coating of wax on each board as a foundation for future work. The frame of brood was now returned to the lower hive after carefully assuring myself that no queen-cells had been started. I weighed the comb gathered, and found I had 12 ounces before rendering. The following week I took 18 ounces, and after that I removed the wax every four days during the honey-flow. The largest yield in eight days was $1\frac{3}{4}$ pounds. The total amount of wax received from this colony after rendering was 16 pounds. This, at 32 cts., made the gross receipts \$5.12. The colony set aside for comb honey gave a surplus of 152 lbs., at 15 cts. per pound for

60 pounds white, \$9.00; 12 cts. per pound for 92 lbs. dark, \$11.04, making the gross receipts from this source \$20.04.

My conclusion is that wax in this locality as a main crop is not practical. In some sections, no doubt, it might pay where the seasons are long, and an inferior or cheap grade only of honey can be produced.

For wax production the following I regard as absolutely necessary: A very strong colony, and one especially given to wax production; an extra good honey-flow, and a warm super, so that wax can be worked by the bees at all times.

Bradford, N. Y.

AS GLIMPSED THRU THE CAMERA

Some Common and Uncommon Sightings among the Bees

BY H. H. ROOT

In factories where comb foundation is made and wax is bought in large quantities it is necessary to break open every piece of wax in order to tell its color so that it may be graded. Two grades are usually made—one for brood foundation and the other for super. In this process some very amusing cases of adulteration are occasionally found. If I were going to adopt dishonest practices in order to gain a livelihood, beeswax is about the last thing that I would try to adulterate, for such adulterations are so easy to detect.

Here are two instances of adulteration that are almost laughable. The first illustration shows a cake of wax, the inside of which is tallow. The party who fixed this up evidently placed a few pieces of tallow

in the dish and then poured in the melted beeswax. The first crack with the hammer revealed the tallow, which, as the photograph shows, can be seen very plainly. And if the tallow had been melted and thoroly mixed with the wax it would have been even easier to discover, for a very little tallow mixed with wax makes a "sticky" combination, entirely different from pure beeswax.

The second illustration shows a couple of zinc fruit-jar lids surrounded by beeswax. If the price of zinc continues to go up I wonder if the time will not soon come when this particular man would find it more profitable to pour wax into the lids and sell them as scrap zinc!

For a good many years I have read all

A cake of wax adulterated with tallow. If the tallow is melted and mixed with the wax it makes it feel sticky. In this instance hot wax was poured over pieces of tallow, which showed very plainly when the cake was broken up.

the discussions in GLEANINGS on the subject of the amount of honey or syrup required to enable bees to secrete a given amount of wax, and I confess to a growing feeling of "you'll have to show me" in regard to the statement that it takes fifteen (or even seven pounds) of honey to produce one pound of wax. The amount of comb that bees sometimes build when confined in a cage tends to disprove these theories. No doubt, under certain circumstances, if fifteen pounds of honey were fed to a colony, not more than a pound of wax would be secreted; but what of the amount that the bees feed to brood, and actually consume for their own sustenance?

How a sheet of foundation does "grow" when the bees get at it! In case of foundation they draw out the cells about $\frac{3}{8}$ inch, on the average, before being obliged to add new wax. But when a strong force of bees clusters on a sheet of foundation during a warm day when honey is coming in just

right, and they need the room, they will go far toward changing the foundation into comb in ten hours' time.

Zinc fruit-jar lids make a novel form of adulterant for beeswax.

Full sheet of comb foundation partly "drawn out" into comb.

PROFITABLE PRODUCTION OF BEESWAX

Running Combs, Honey, and all thru the Solar Extractor

BY JOSEPH GRAY

The editor has struck a line of thought that interests me greatly since honey is going down in price and wax rising. Furthermore, the cost of cans and cases is going up. For 500 lbs. of beeswax we need only a few sacks for shipment, and a one-horse rig will haul it. At 30 cents per lb. it represents a value of \$150.

I was well satisfied with last year's wax production, which I considered as important as the honey production. In certain parts of the season, ready-built comb is a big advantage; yet there are times when bees want and will build comb. When honey comes rolling in I space eight combs in a ten-frame super. This makes the combs weigh 8 to 10 lbs. each; and when uncapped they yield an abundance of wax. To uncap I use a butcher's saw, and use it in the same manner as a butcher uses it — with a downward cut and a sawing motion. The thin narrow blade cuts the cappings readily. I have a wet sack in my uncapping-box, and when full of cappings it is lifted out so that there is no handling of mussy cappings. An extra tub is handy to carry the sack of cappings.

The illustration shows my solar extractor which was originally a milk-cooler—the best solar I ever used. It is 6 feet long, 3 wide, and 1 deep, with a 1½-inch faucet. The cappings are carried and dumped on to a loose canvas tray, the tray supported by wire cloth, and having an extra canvas fastened down with the wire cloth. A catch tin is slipped under the lower end of the canvas tray, which holds back the refuse. This is made out of the end of a five-gallon can. The honey and wax run into a five-gallon oil-can that has a turned spout. The honey, when it reaches the level of the spout, runs out into the lower end of the solar, and is drawn off by the faucet. The sack shown in Fig. 1 protects the honey from the direct rays of the sun. The wax furnishes all the protection needed in the wax-mold. The mold is in the sun all day, so that the wax keeps liquid and makes a uniform cake

which cools during the night. In the morning the wax is taken out and left to finish cooling, and a fresh mold put in. It facilitates the work to have an extra catch pan and canvas as well as an extra mold.

There is no better material for a mold than the thin tin of a five-gallon can. The sides will spring out and release the cake of wax. The cake of wax is washed, and, if necessary to free it of honey, scraped on the under side, leaving it in good condition for market.

So satisfied am I with wax production on account of its low cost in labor, etc., that I have been seriously thinking of extending

its production by cutting out the combs one inch from the top-bar and increasing the number of solars. I would melt everything in the solars, discard the uncapping and extracting, and I would put back the frames with one-inch strips of comb and allow the bees to rebuild the same above an excluder. My reasons for doing this are threefold:

1. Less work; the manipulation of combs in the solar, instead of uncapping and extracting, would cut the labor bill in two.

2. We have sufficient sun heat to make it a success here in Imperial Valley—no cost for artificial heat.

3. By the method used in my arrangement of the solar, the honey, as soon as it is melted, is under cover, and never burned. In fact, it is improved rather than impaired by passing thru the solar. I figured that, when I had once a full set of combs, the work would be clean—no refuse—and I would have a fine grade of honey and

wax. Excluders would have to be used, and it would be best only to half empty a super at one taking, alternating the combs.

To feed back honey in Miller feeders, and produce wax only, would not be necessary for me, as I am close to railway facilities; but if I were located where nothing could reach me but pack mules, then I certainly would produce wax only.

Honey nets us 4 cents per lb., and wax 26 cents. It takes the bees an average of six pounds of honey to produce one of wax—a gain of 2 cents. Combine this with the low cost of production less risk of thief, cheaper hauling, warehousing, freight, it ought to pay at present prices.

Heber, Cal.

COLLECTION AND EXPORTATION OF THE WAX OF WILD BEES IN AFRICAN COLONIES

BY A. S. ASHTON

Michel E. (Agricultural Engineer at the Ministry of the Colonies), in *Bulletin Agricole du Congo Belge*, Vol. V., No. 2, pp. 385-395, Brussels, June, 1914.

This paper contains information on the wild-bee honey in the African colonies, a description of the native methods of bee-keeping in the Belgian Congo, in the Soudan, and in Tunis, and of the improved methods of separating wax (melting by solar heat, in a stove, in boiling water).

The trade in wild beeswax is constantly increasing in most of the African colonies, especially in Gambia, Gold Coast, Nigeria, Soudan, Uganda, British East Africa, German East Africa, Mozambique. A few years ago the exportation of wax from these countries was insignificant, while now it amounts to many tons. Wax occupies the third place in the export trade of Angola (Benguela supplying 90 per cent of the exports of the whole province). Angola exports every year 600 to 700 tons of wax; Mozambique about 100; Portuguese Guinea, 50. The wax is exported in cakes

weighing 253 to 264 lbs. each. The quantities of wax exported the last few years from German East Africa and from the British African colonies are given by the following table:

	Year	Export of Wax	
		Weight lbs.	Value
German East Africa.....	1911	802,347	\$197,175
Gambia	1912	19,498	5,602
Nigeria	1912	12,862	1,875
Uganda	1912-1913	263,408	
British East Africa..	1912-1913	139,207	36,630
Nyasaland	1912-1913	110,609	26,675
Soudan	1912	43,704	11,585

Wild beeswax, when well purified, is comparable to European wax. The Central Administration of the Belgian Congo had some samples of wax from the Colony examined, and among them many of good quality were found. Bees are widely spread in the Belgian Congo. The natives extract honey, but do not make any use of the wax, the value of which is unknown to them.

Beauharnois, Quebec, Can.

NIX ON THE SOLAR

BY W. J. OATES

I consider the solar wax-extractor the biggest nuisance in the apiary. In the first place, it does not put either the wax or honey in *merchantable shape*; next, in out-yards, where the cappings are left to melt out, and you are not there for ten days, they condense all the moisture in the atmosphere, and your *honey is sour*. Then it's one of the stickiest messes to clean that ever was.

The cost of glass is a big item, unless everybody else plays in better luck than myself. What the carelessness of the help, and wind, and mischievous boys, etc., all thru the experience of 20 years they are by far the most expensive thing to keep up connected with beekeeping when one figures the usefulness of them. But away and

above all the foregoing objections is the fact that they are the worst disseminators of disease we have. In my duties as inspector I can trace the loss of hundreds of colonies to the solar extractor. Combs full of disease thrown in them are afterward scooped out and put in a box or thrown around any way, so that everybody's bees can help themselves. Over 90 per cent of the solar wax-extractors that I have come in contact with are either leaky or so ill fitting from the moths that bees can get in and perish by the thousand.

A German wax-press costs but little, and it is the finest place for scraps there is, and when it is full one can squeeze out the honey in no time; and it is good and not discolored, or half water, as when left in a

sun extractor. The press can then be put on a fire and melted out right away if desired.

My method for outyards is to let cappings drain as long as I can, or perhaps until the next extracting, then squeeze all the honey I can get out of them. Sack

them up, and haul home. At the end of the season, or whenever there is a slack time during the season, I throw them into a large vat with plenty of water and melt down, and dip and strain it into molds at the rate of 1900 lbs. a day, and the "mess" is over with.

Lompoc, Cal.

USING THE SEVERIN SEPARATOR WITH THE PETERSON MELTER

BY J. E. JORDAN

The Peterson melter and the Severin separator are the best two articles which I have yet found to get all of the wax and honey from the cappings at extracting time. To use the Severin separator with the Peterson melter you must elevate the rear of the melter so the melted cappings will run to the outlet. If the outlet of the melter is left as it is at present, small pieces of unmelted cappings will run out and into the wire basket of the separator, and in time will choke it up so it will fail to work properly. In order to prevent this I make a framework of wood to which I tack heavy wire cloth (see No. 5), and place this in the melter across the part where the outlet begins to narrow. As the surface of the melter bows up a trifle, there will be a small space at each end, large enough to allow melted wax and honey to escape, but narrow enough to keep back all unmelted particles. Pieces of cappings will sometimes pack at the outlet. In order to prevent this I have a small paddle handy with which to rake them back every now and then allowing the liquid to pass and go into the separator basket.

For the benefit of those not familiar with the Severin separator I will give a brief description of it. The specifications of it have been given in GLEANINGS, but new subscribers who missed that issue would not have access to it.

The separator is a tank of galvanized steel, $21\frac{3}{4}$ inches long, $10\frac{1}{2}$ inches wide, $9\frac{1}{4}$ inches deep. This is the outside tank. There is a partition in one end $5\frac{1}{2}$ inches from the end, which extends nearly to the

bottom of the tank. The liquid from the melter drops into the wire basket which strains it, catching all of the dirt and slumgum. The honey, being heavier, goes to the bottom and under the partition; and, when the pan is full, thru the square-lipped opening at the further end. The wax, being lighter, continues to rise until it reaches the lipped opening in the partition, thence into the pyramid-shaped wax-pan. When the

day's work is done, beat the slumgum out of the wire basket. This slumgum should be kept in a small can, and at the end of the year's work it should be rendered again to obtain the remaining wax. Do not draw off the honey from the separator until everything is cold. The cake of wax in the pan will be clean, light in color, and ready for market.

When first started to work, the separator should be primed with warm honey over the partition opening into the bottom of the tank, else some wax may find its way into the honey.

Morgan, Ky.

AN EFFICIENT SOLAR EXTRACTOR

BY C. D. CHENEY

It is a known scientific fact that a bright polished surface radiates much less heat than a dark dull surface. Tin and galvanized iron are materials mostly used for lining the solar extractor, which, in view of the fact just mentioned, are not well suited to the purpose. Therefore, applying the principle, make the lining of "black iron," also known as stovepipe iron. I believe there need be no fear of the iron affecting the wax, nor of any rusting inside. It would be advisable to paint the outside to prevent any rusting there. Put in some sort of insulation (the more the better) between the lining and the case. I would say, preferably several layers of old woolen carpet or horse-blanket, neatly fitted and securely tacked in place before the lining is set in. The lining should fit snugly against the insulation all around.

An apparatus of this kind deserves as much care in construction as any capping-melter or honey-tank, if compensating results are desired. It will be readily understood that the purpose of the black iron and insulating material is to get as much absorption of heat as possible during sunshine, the same to be conserved and utilized to the limit.

Then, departing quite radically from present practice, place the extractor the long way from east to west (assuming it is made longer than wide), with the bottom pitched toward the south; and have the lower (or front) angle of the lining slanted from the ends toward the center, where the outflow should be, at the lowest point, so that the wax can get away from the residue by the shortest route, and find a gutter free from obstruction to the outflow.

Then, again, make the case something like a hothead frame, shallow at the front and deeper at the back (north) side, say 3

inches at the front and 6 at the back. This may seem rather shallow; but it should be remembered that the combs are melted by the direct rays of the sun, so that piling combs one on another causes a positive loss in efficiency, at the same time causing the melted wax to flow down over unmelted combs where it may be held indefinitely instead of flowing promptly to the outflow.

The main reason for this shallowness is to bring the glass as near to the combs as practicable, and, no less important, to eliminate useless air-space, so as to utilize the solar rays with the least loss and to the best advantage.

If greater capacity is required it would be better to increase the superficial area rather than to increase the depth at the loss of efficiency.

It may be necessary to make a sash specially to suit the sidewise pitch; but aside from this no additional cash expense is involved. No crevices or openings should be allowed—in fact, a solar should be as nearly air-tight as possible, not considering the outflow. The sketch will make the description more plain.

Hoboken, N. J.

THE CHANGES WHICH OCCUR IN THE EGG

BY DR. JAS. A. NELSON

[A book has been recently published by Dr. James A. Nelson, of the Bureau of Entomology, entitled "The Embryology of the Honeybee." We gave an editorial notice of the book on page 966 of our December 15th issue, and the same is now advertised in our columns. It is evident that beekeepers have supposed this work to be too technical to be of any practical use. As a matter of fact, it can be and should be of immense help to them. In order that the reader might have some idea of what it is, we have asked Dr. Nelson, the author, to tell us very briefly some of the things that are in the book, especially those relating to the changes that occur in the egg. This is the time of year when beekeepers can take a look into the hive and see some of the things that Dr. Nelson describes.—ED.]

The editor has suggested that I write for the readers of GLEANINGS a brief summary of the results embodied in my book "The Embryology of the Honeybee." This is a difficult task, since changes which take place

in the egg are so wonderfully intricate that they cannot all be successfully condensed into a summary which would not seem dry and technical. Instead I have endeavored to sketch certain phases of the

development in the egg, which may be of special interest to the beekeeper.

The vital processes which take place in the egg of the bee after it is laid, and by which it becomes a larva, are as much a mystery to the average beekeeper as are the problems of human consciousness or the extent of stellar space. It is to be feared that to him an "egg is an egg," just as in Wordsworth's much quoted lines in "Peter Bell:"

A primrose by a river's brim
A yellow primrose was to him,
And it was nothing more.

One of our leaders in science, a well-known university professor, used annually to quote to his classes the following lines (and does yet, for all we know!):

Flower in the crannied wall,
I pluck you out of the crannies;
I hold you here, root and all, in my hand,
Little flower; but if I could understand
What you are, root and all, and all in all,
I would know what God and man is.

This is surely a more reverent attitude to take in the presence of the miracles of Nature.

It is not possible to know or understand all that takes place in a living organism; but by patient investigation we can learn to know much, and this knowledge is of inestimable value, even altho it teaches us to recognize only the infinite extent of the mysteries of Nature and the relatively infinitesimal extent of human knowledge.

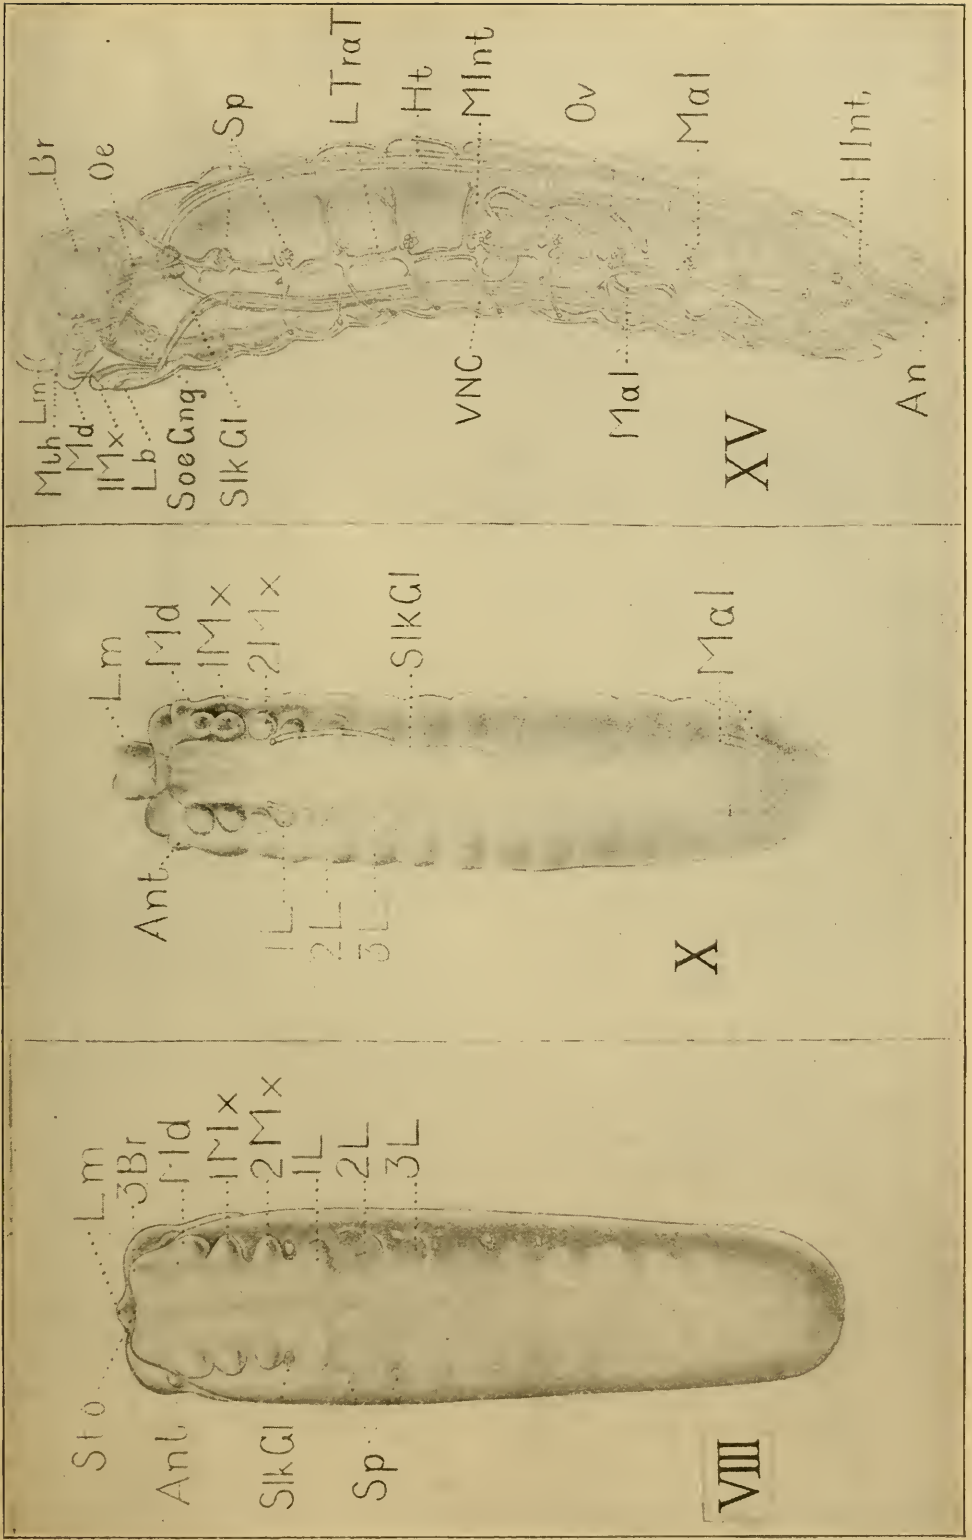

An investigation of the development of the bee's egg of course brings to light many interesting and curious facts. Among them one of the most striking is the rate at which development proceeds, or, rather, appears to proceed, since we can judge the rate only by what we can see, and we have no means of valuing the amount of energy required by the different developmental processes. The whole course of embryonic development may be divided into two periods: 1. That in which is prepared the material required for the formation of the embryo. 2. The actual visible construction of the embryo from these materials.

The bee-egg, like every other egg, commences its embryonic development as a single "cell." This "cell" is the unit of structure in all living organisms, and for present purposes it may be considered as a minute portion of living substance, having the power to reproduce its kind by self-division. This cell is in the bee egg imbedded in the yolk, which makes up the bulk of the egg, the entire egg, of course, being enclosed in a thin and tough membranous shell, the "chorion." This single cell divides into two

cells, these into four, and so on until a considerable number are scattered thru the yolk. Then these, still continuing to divide, come to the surface of the egg and, "joining hands," so to speak, form a layer all over the surface of the egg, and this layer by a further increase in the number of the cells becomes a sort of skin, the "blastoderm." The number of cells making up the blastoderm is several thousand at least. In regard to their shape and arrangement, they may be imagined as extremely minute paving-stones. This stage is not reached until about thirty hours after the egg is laid—much more than a third of the time required for complete development, 76 hours. During the next fourteen hours the blastoderm becomes folded lengthwise of the egg in such a way that three layers of cells are formed over the whole length of the egg on its longer curved side. A number of cells are also heaped up at the two ends of the egg, and these last cell-heaps are destined to form the entire stomach or "mid-intestine" of the larva. This closes the first period. The materials for the construction of the embryo are now all prepared and laid in the proper places. It is important to note that the egg is now nearly two days old (44 hours), and that all this time has been consumed in the preparation of the material. During the next 32 hours, Dame Nature gradually molds these materials into the form of a bee-larva. At 46 hours (Fig. VII.) the rudiments of the brain and of the appendages—mouth parts (Md, 1Mx, 2Mx) and legs (1L, 2L, 3L)—make their appearance as rounded swellings. The mouth (Sto), the silk glands (SlkGl) and the tracheæ (Sp. —) also show themselves as pits or inpushings of the surface layer (ectoderm). The remainder of the development consists principally in the elaboration and completion of the parts already laid down as rudiments.

The material required for formation of the cells themselves, and the fuel necessary to supply the energy expended by them in their movements and subsequent metamorphosis into organs and tissue, is furnished by the yolk, which gradually shrinks away from the ends of the egg, and, later, from its lower side. Finally the yolk becomes enclosed by the mid-intestine (stomach) of the future larva and is then completely digested.

One of the first external evidences of commencing development is the shortening of the egg within the egg-shell, and the spaces left at the two ends of the egg, between the egg and the shell, are filled with a clear fluid. The egg continues to shorten

Some of the changes that take place within the egg of the bee.

slowly while the embryo is developing. At hatching, the embryo, now a completely formed larva, suddenly lengthens, and after hatching is considerably longer than the egg from which it came (Fig. XV.).

The process of development has been spoken of above as a molding process, guided by an external force, and so it seems at first glance. It is, however, much more wonderful, since it is really accomplished by the cells themselves, each of which has its proper destiny to fulfill, whether it be to form a nerve-cell, a skin-cell, or a stomach-cell. One is almost tempted to think that every cell "knows what to do"—where to go and what form to take—so accurately do the cells, at first all alike, group themselves and change in accordance with the duties they have to perform. It is like a colony of bees, some of which act as guards, some as nurses, some as gatherers, etc.; only in the egg the organism is much more precise and the final effect much more harmonious and complete. This is the real riddle of development. It still remains unanswered.

Some one may ask, "What good is such knowledge to the beekeeper?" The answer is that it is of no *immediate value*, in dollars and cents; but that to make effective progress in beekeeping a thoro scientific knowledge of the bee is necessary, and this knowledge comprises the anatomy, the behavior, the physiology, and the development of this insect. No intelligent beekeeper will deny that a knowledge of the structure, development, etc., of the larva might become of great practical value in queen-rearing, and yet the larva cannot be thoroly understood

without knowing its earlier development in the egg. Moreover the thoro study of any scientific problem, especially if it relates to an animal or insect of practical importance, is reasonably certain, sooner or later, to prove of value, often in the most unexpected way. The greater part of our marvelous advances in applied science and invention rest upon a basis of investigation which in its beginnings held no promise of ultimate commercial value. For example, the study of entomology for many years—in fact, up to quite a recent time—was regarded as merely an intellectual diversion for cranks having leisure and means. Yet the work of these supposedly harmless lunatics forms the basis for the tremendous annual saving to the farmer and fruit-grower by the prevention of insect injury.

The table given below will serve to summarize the brief account just given, and shows the principal changes taking place in the egg, and its age in hours at the time that these different changes take place.

TABLE SHOWING RATE OF DEVELOPMENT IN THE EGG OF THE BEE.

Age in hours	Stage of Development
1-16	Cells increase in number by repeated division.
16-30	Cells unite on surface of the egg to form blastoderm.
30-44	Blastoderm folds to form germ layers. Formation of embryonic membrane. Preparation of materials completed.
46	Rudiments of mouth parts, legs, brain, and all important organs become visible. Fig. VIII.
54	Mouth parts, legs, and organs well advanced in development but not complete. Fig. X.
76	Development of egg completed. Egg hatches. Fig. XV.

MASSACHUSETTS MEN INDEPENDENT

BY B. N. GATES, SEC.

A most successful meeting of the Hampshire, Hampden, Franklin Beekeepers' Association was held in the Board of Trade rooms, Springfield, Mass., on May 13. This, the annual meeting, was postponed from March 16, when it was to have been held in Amherst in conjunction with the beekeeping meetings during Farmers' Week.

Much the same program was followed. The election of officers resulted as follows: President, C. M. Smith, Florence, Mass.; Vice-presidents, A. C. Andrews, Hayes Ave., Chicopee, Mass.; Rev. D. D. Gorton, W. Springfield, Mass., and L. R. Smith, Hadley, Mass.; Secretary-treasurer, B. N. Gates, Amherst, Mass.

Among the other official business was the amendment of the constitution, whereby

action of June 13, 1912, for the affiliation of this society with the National Beekeepers' Association, was rescinded. Unanimous vote also re-established the annual fee to fifty cents per annum. Further modification of the constitution and by-laws was of minor importance.

Among the papers read was the annual address of the President, C. M. Smith, who presented numerous "Timely Suggestions to Beekeepers." By way of a report of progress for the committee on honey-labels and standard packages, Dr. B. N. Gates, chairman, explained what constitutes an attractive label. Mention was also made of the standardization of honey-containers, particularly small glass containers. After the report, discussion followed, wherein it

was particularly emphasized that beekeepers give more and more attention to supplying their customers sixteen ounces for a pound package and eight ounces for a half-pound package. It is being considered by the association to adopt a label which members of the association may use. This attached to their products indicates their affiliation with the local society and is thought to be of advantage in selling local products.

A most interesting address followed by A. W. Yates, of Hartford, Ct., entitled "Spring Handling of Bees."

A committee consisting of the president as chairman, the three vice-presidents, and

the secretary-treasurer, was appointed to wait upon the managers of the agricultural fairs for the purpose of obtaining proper recognition of beekeepers for displays of beekeeping products at these fairs. It was left to the Executive Committee, and the Secretary particularly, to arrange for the society to hear Mr. C. P. Dadant, of Hamilton, Ill., when he visits the East next August. This will constitute the field meeting of the association.

The meeting adjourned shortly before five o'clock, there having been a good attendance.

Amherst, Mass.

ISLE OF WIGHT DISEASE SHOWS VARIOUS SYMPTOMS

BY B. BLACKBOURNE

One of the peculiarities of the Isle of Wight disease is the different symptoms exhibited by different stocks of bees suffering from it. In some cases the sick bees appear shiny and black, active on their legs, tho unable to fly. In others they are sluggish, with swollen abdomens and dislocated wings. Some stocks die out in a few weeks, while others hang on for months, and still

others will be found almost completely depleted of bees without having shown any crawlers or dead bodies in front of the hives.

In the spring of 1913 I was greatly disturbed by seeing crawlers and sick bees being thrown out of my hives, and took it for granted that I had miserosporidiosis. As the year advanced, however, these symptoms disappeared, the bees did very well, and appeared in normal health, so I concluded the trouble was a touch of paralysis. The next year the same thing happened; but that one stock, which did not appear to be doing much work, when examined was found to consist of brood from top to bottom (20 standard frames), and the queen laying freely, but not an old bee in the hive. Where had they gone, for there were no dead outside?

In 1915 there was no doubt that I had the real thing. There were always numbers of bees hopping about on the grass, trying to fly, and the characteristic mud-colored excrement was in evidence practically all over the hives. The worst affected was the strongest stock, which required supering, and built queen-cells in preparation for swarming long before any of the others. Practically all the stocks were affected, tho some only very slightly. Just before fruit-bloom I had to go away from home for a time, and left my apiary in charge of a young man who had been with me for a couple of years. It is a curious fact that diseased bees are frequently given to excessive swarming, and my man was kept busy living swarms. Very often the swarm will show the characteristic symptoms before the stock from which it sprang. Presumably this is because the greater proportion

Dead bees on the floor of a hive containing a colony badly affected with Isle of Wight disease.

A little group of bees in the last stages of Isle of Wight disease.

of bees in the colony are old ones, having the disease in a more advanced stage.

One stock is especially worth mentioning. It consisted of Italian bees, did extremely well, giving me an 8-lb. swarm and over 100 lbs. of honey (which is good here), and did not show a sign of disease all thru the year. I began to think that there must be something in the immune theory, for here, surely, was an immune stock. I took care to tell my beekeeping friends all about it. Alas for my hopes! late in the autumn I lifted the quilt and found not a handful of bees left. There were just a few with the queen clustered on one frame, similar to those in the photo.

As I expected to be leaving the country before the spring, and most of the stocks appeared too weak to winter, while it was

out of the question to sell them, I sulphured all except three of the strongest. One of these to which I had introduced an Italian queen is still alive, but diseased, and this will have to go the same way as the others.

I may say that I have tried some of the so-called cures, but have no faith in medicinal treatment. Those who are investigating the disease on behalf of the Board of Agriculture believe that they have discovered a drug that will cure the trouble, and are to experiment this year with 40 hives. If it were possible to treat all the bees in the country at one and the same time there might be some hope of success; but even supposing some stocks are cured, what is to prevent them becoming reinfected as soon as the treatment is stopped? One cannot always be feeding bees.

Ramsgate, England.

THE PORTABLE EXTRACTING-OUTFIT VS. THE CENTRAL PLANT

BY J. F. ARCHDEKIN

It was our intention at first to do all our extracting at home, using a car to move the honey home and take the combs back. After we arrived here and considered the problem very thoroly we changed to a portable outfit. We run a six-frame power extractor, and use a sectional wire-cloth house, 6 x 8 feet, with a canvas cover to work in. It is very cool; and all the machinery, including the house, is moved in three loads

on the Ford. The outfit can all be set up and made ready to run in less than half an hour, and then all our work is right at hand, nothing depending on what two or three men several miles away do or don't do. The honey is run into barrels, and these are taken along on trips home from work. Of course we have some exasperating delays when some necessary article is left at home, or when something gets out of

fix. Nevertheless, I believe thoroly in the portable outfit.

A central plant is a fine thing, and one can have it arranged more conveniently than a movable one. The greatest trouble is that it is more or less distant from a considerable part of the honey, and this fault is fatal. If the men who take off the honey shirk, it delays things. The car may have an accident, and lose more time. Or the extracting force may get behind, and the honey pile up on them. Then the owner needs to be present in all three places to get the best results. When anything gets

out of fix, hired men are apt to sit down and talk it over unless the boss is there to speed things up.

A car will stand up well the first year hauling honey home; but it nearly always develops trouble the second year. Every mile a car is run is that much of its life gone; and if it carries heavy loads most of the time, its life is still further shortened. If a hired man drives it he is not going to be any too particular with it either. Then there is the cost of gasoline and tires, and at present prices the gas-bill is quite an item.

Bordlonville, La.

MY SYSTEM OF SWARM CONTROL FOR COMB-HONEY COLONIES

BY G. C. GREINER

With the exception of a very superficial examination as early as the weather will permit (it took place April 7 this year) to make sure that all colonies have plenty of stores to carry them to the first natural-honey sources of our locality, I do not molest my bees until the apple-trees are in bloom. Then they are thoroly inspected and graded for spring management.

If I can judge other beeyards by my own they all consist at this time of these three classes: Strong, medium, and weak. According to the way they have wintered, one or the other end of the line will predominate; but the three classes are there just the same. The two latter groups are run for extracted honey; and by keeping them well supplied with empty combs in their supers it is no trouble to keep them from swarming.

The colonies in the first class (the strong) include everything that has six, seven, or eight combs of good solid brood, and the hive reasonably well crowded with bees. It is needless to say that the queens must be of the young vigorous type, for the colonies would not have come up to the necessary requirements if the queens had been deficient in this respect. Any of these colonies are likely to swarm almost any time after the apple-bloom inspection, and even if run for extracted honey it is a puzzle to keep them under subjection.

To escape this annoying swarming nuisance the colonies are divided about May 15 to 20, beginning with the strongest, that show from outward appearance any inclination to swarm, until all are taken care of; and they are divided in the old-fashioned way of taking two combs of brood with the old queen from the parent hive, and introducing a young laying queen into

the latter at the time the division is made. On account of the earliness of the season, southern-bred queens are used for this purpose. The two combs of brood with the old queen are placed in a new hive with three additional empty combs, and the rest of the hive filled out by three chaff division-boards. These latter are the same thickness as one brood-comb with its bee-space, so that every removed division-board will give room for a brood-comb. This hive so prepared is left on the old stand to catch the flying bees, while the parent hive with its introduced young queen is also filled out by two division-boards and moved to a new stand some distance from the old one.

As soon as the old queen has started brood again in those empty combs, which she generally does in about a week, one of the division-boards is removed, the brood spread, and an empty comb inserted in the center of the brood-nest. In about another week the new comb is again stocked up with brood; another division-board is removed, and a second comb inserted in its place. The same procedure is repeated with the last division-board, so that, by the time the white-clover flow is opening, the brood-chamber is filled with brood, and all the incoming honey has to go into the super. However, it must be remembered that this is only an outline. Time and space will not permit to give all the connecting details, which must be left to the judgment of the operating beekeeper.

The removed parent hive is managed in practically the same way as the newly formed swarm with the old queen. As it takes a few days longer for the introduced queen to be liberated and laying, the exchanging of division-boards for empty combs will be delayed that many days. But

after she is well established in her new home she will keep the empty combs, which are also placed (one at a time) in the center of the brood-nest, well filled with brood; and by the time the white-clover flow begins, these colonies, too, are compelled to store the incoming honey in the sections. From these colonies, if I do not use all of them for this purpose, I select my comb-honey producers. They are in the very best condition for surplus-honey production, without letting their ambition and energy run to swarming. The question, "Why don't they swarm?" is easily explained. They have a young queen which is not likely to swarm; all their working forces are young, ambitious bees, every one being eager to gather honey, and not one old enough yet to let thoughts of increase by swarming trouble its mind. Then by the judicious use of added supers with full sheets of foundation and bottom starters, and a liberal supply of bait-combs, swarming is practically out of the question.

One super at a time will accommodate the strongest colony that any hive contains;

but another must be given, when needed, and a third one added whenever conditions require it. It is not the amount of empty super-room given at one time that keeps bees from swarming, but the gradually added working surface as fast as the bees will occupy it. As a rule, to assist bees in drawing out foundation, two supers are all they should have at a time—three for a short time may be permissible. If more room is needed, another may be given below, and the top one removed by means of the beescape. This crowds the working forces again on to the new foundation, and keeps them busy drawing out and storing. No matter if there are still some unfinished sections in the upper one, they can be easily finished by feeding after the honey-flow.

Equalizing at the beginning of the honey-flow by way of exchanging heavy combs of honey with adhering bees from the supers of overly strong colonies with empty combs from the supers of the weaker ones will also tend to prevent swarming. I apply this same principle to rows of sections from the supers of the comb-honey producer.

LaSalle, N. Y.

THE IDEAL BROOD-NEST FOR OUT-APIARIES

An Eight-frame Hive-body and Shallow Extracting-super Make an Ideal Brood-Apartment

BY J. J. WILDER

When Editor Root visited me a few years ago we were getting our bees in shape for the first great honey-flow in early spring. He asked whether we were supering the bees at that early date, for all our hives consisted of one eight-frame body and a shallow extracting-super on top. I told him that this was our regular brood-apartment, and we went fully into the merits of such an arrangement. It provides greater bee production, quicker manipulation, and reduces swarming almost to a minimum. At the same time the greatest possible amount of honey is harvested, and of the fanciest grade.

With a good equipment almost any apiarist can produce extracted honey; but it requires more skill to produce comb honey in one-pound sections or bulk comb honey, when it will make the greatest and best pack. This is all the more true when it comes to producing it in a wholesale way with the smallest amount of labor.

I have bees in all kinds of southern locations, and the short cuts to great results has been my aim all the time. There are a great many locations where a single eight-

frame shallow extracting-super makes an ideal brood-chamber without any additional room, and there are still a greater number of locations where the brood-nest should never be larger than the capacity of a regular eight-frame hive-body. But in such locations we are troubled but little with swarming, and no great crops of honey are ever expected. It does not require the skill, etc., that a location does where there is a great abundance of pollen, and where brood rearing is kept up at a great pitch, especially at certain times, when the bees contract the swarming fever. Under such conditions it takes an ideal arrangement for the apiarist to cover a great field. This we have in the eight-frame hive-body and shallow extracting-super with the regular frames that go with them. The hive-body contains the regular continuous nest, and this we do not break up any more than we can help. The super we place either over or under this.

This super, with more or less honey, is left on over winter. (Of course in the North, where bees are wintered in the cellar, they could be removed and set away; and

when the bees are set out the following spring the heaviest supers placed on the lightest colonies, thus equalizing stores, without greatly disturbing the bees).

On our first round, which is about the first of March, these are raised up a little at one end, a peep taken at the bees and stores, and if anything is wrong a mere glance reveals it. If the bees should be short of stores they are smoked out of the super, and a heavier one given from some heavy colony, but in most cases the light frames are exchanged for heavier ones, and thus the stores are kept equalized.

Ten or twelve days later the super is tipped up again to see how brood-rearing is progressing; and if the bees are crowding into the super we know all is well. If not, the super is set off and we examine the nest below and mark the colony by laying a stone or a stick on it so that at the next round we may know the ones needing special and immediate attention.

The others in the yard are making progress, and ten or twelve days later we do not tip the super, but just tip or remove the covers. By this time the queens are moving up in the supers, and we can easily find and lift out some frames of brood from the super and exchange them for empty ones in the weaker colonies; but if there should be no bees in the super of the weaker colony this is not done, but the entire super is removed and placed under one in which the queen had made great progress, thus giving her more room at a time when such colonies would soon be contracting the swarming fever.

On our next round, which is only about eight or ten days later, the weaker colonies are ready for a super of sealed brood and therefore they get a super back. At this time the queens in the strongest colonies are occupying all combs not filled with honey. On our next round, six or seven days later, we might expect just a little honey coming in, so the supers nearly filled with brood in all stages of development are removed and placed under the lower story, and a storing super placed on top. On the next round, in six or eight days, many of the colonies are ready for this, and on this round our regular ferring-sticks are placed on the bottom-boards, thus giving the hives a good under ventilation from end to end, the sides of the hives being supported by sticks one inch square and the length of the hives. By the next round all hives are expected to go into the honey-flow are thus ventilated. Sometimes a little brood may be chilled and thrown out on account of so much ventilation; but in case of a sudden short cold

spell, when we might expect considerable damage from this, the bees are stayed from the field, and they cluster under the frames and completely stop the under current, which saves the brood.

Now, our trips around occur every six or seven days during the spring flow; and at each visit storing room is added in the usual manner, the empty supers inserted next to the brood-chambers. At each visit we tip the hive-body from the super and glance over the brood-nest in both apartments, looking upon and between the combs, and perhaps separating them just a little, the object being to see if any preparations for swarming have been made. If any queen-cells have been started this quick examination reveals them. If there are cells we stop and go thru the hive and remove them. But we rarely have much of this to do, and but little time is lost in this way. We must make sure of it, however, so we have this little work of tipping up to do.

At this critical time the queen is occupying all comb in the hive-body, for nearly all the honey the bees had at the beginning is in the super, which allows the queen full access to all comb in the body. At the same time, she has more than twice occupied all comb not filled with honey in the super, and she has not lacked room. At the same time, this broad open entrance has kept the bees from contracting the swarming fever, because they have had to protect the brood in the super, during rain or sudden short cool spells, at which time they always contract the swarming fever if they are in closed-up close quarters, for they seem to have nothing else to do. With an open hive, with brood right at the bottom or almost in the open, conditions are right the reverse, and it seems to cure and keep them cured of swarming.

When the honey-flow is coming to a close, and the supers are nearly all filled, the super is removed from the bottom and placed on top of the body; and as the queen at this time is fast diminishing in egg-laying the bees will store some honey in it, the amount depending, of course, on the extent of the flow, and thus they have sufficient stores; and if there is not another great honey-flow expected, the super is left on top the remainder of the season. In it the bees will store the odds and ends of small or light honey-flows. This leaves them heavy with stores, and in the best possible condition for the coming season.

Suppose increase is wanted at any time. What is more ideal than the arrangement I have described? When the brood in the

super is nearly all capped and some emerging, just set it on a new stand and contract the entrance, making sure the queen is left with the colony on the old stand. At the same time give the new colony a ripe queen-cell, or, better, a queen; and when the little colony is ready, give it a body of ready-built comb or full sheets of foundation, and soon they are a normal colony in strength.

If a great amount of increase is desired, the strongest colonies should be given an extra super in the early spring, and the queen allowed to occupy both as early as

possible. Later, when some brood is emerging, use the best super for the increase.

This super is never used as a storing-receptacle by the bees as long as it remains *under* the body and it is quietly out of the way and well protected while left there.

Some might think that serious robbing might result in such wide-open hives; but such has not been my experience, for the colony has a good chance to ward them off, and at the same time a great swarm or army of robbers will not attack such a colony.

Cordele, Ga.

COMB HONEY IN A CALIFORNIA OUT-APIARY

BY C. T. AND M. B. WISE

We run two out-apiaries for comb honey. Our Kentucky Springs apiary (so named from the spring which furnishes water for the bees as well as ourselves) is situated about eight miles east of home, and is usually visited once a week during the working season. The trip is made in a buggy or light wagon, and it usually requires two days to attend to the work (100 colonies). We camp over night at this yard.

The other yard is two miles west from home, and is usually visited twice a week, making the round trip on the day of each visit.

As soon in the spring as the bees begin to crowd the brood-chamber a second hive-body is placed on the hive. In this second body should be placed all combs from the colony that are filled with honey, and the space so made in the lower hive filled with brood-frames containing full sheets of foundation or drawn combs. We get better results from using foundation on the stronger colonies, and usually reserve our extra drawn combs for use with the weaker colonies. Should the hive contain brood in all frames when the second body is added, put about half of the brood in the upper hive, proceeding as before. When foundation is used we get better results by putting the foundation together as much as possible, as the bees make better combs when several sheets of foundation are side by side than when they are alternated with drawn combs.

A week or two later both hives should be well filled with bees and brood. If they are not so filled at the next visit, leave them until they are full of bees, brood, and honey. We then place the combs containing the greater part of the honey and well-ripened brood in the top hive with one comb in the center of the hive that has eggs or very young larvæ suitable for rearing queens.

Now set the top hive to one side and put a *baited* comb-honey super on the lower hive and a second comb-honey super containing foundation upon that; next put a queen-excluder or a screen with a fly-hole two inches wide on the last comb-honey super (we get best results with the screen); place the top hive on this stack, and leave it for one week.

We then carry the upper hive to a new location and introduce a young queen if we have one. If we have no queen to introduce we leave them to raise one from the cells within their own hive. At the time of carrying off the top hive we examine the comb-honey supers before placed on the parent hive. If the bees have accepted them and gone to work we lift the baited super off, placing the one with the foundation beneath it, and put a third empty super on top. When the bees begin to work in their *third* super we put it at the bottom, and so continue thru the season.

Our seasons last, in favorable years, from May to September, and we sometimes have ten or more unfinished comb-honey supers on a hive.

After the bees are working in the third super we seldom find any inclination to swarm; but when we first carry the upper hive away the bees sometimes refuse to go into comb-honey supers, when we "begin at the beginning," and repeat the treatment. When handled by this method I do not believe we have more than one per cent of swarms ordinarily, but in 1915 we had 90 per cent of our bees to doctor for European foul brood, and endeavored to hold them strong for comb honey and requeen by rearing queens (by introducing cells) in the sick hive at the same time. As a result we lost about 15 per cent of prime swarms, as we judged by condition of the hives later.

Heads of Grain from Different Fields

THE BACKLOT BUZZER

BY J. H. DONAHEY

Uncle Jeremiah Motherwort is doing a lot of worrying this spring. He read in the bee-book that extra-fancy sections were to be evenly filled and all combs firmly attached to the four sides. He says he don't know how he is going to hand the information over to the bees.

The Bee

Thou risest ere the rosy hands of morn
Have brushed the glowing dew-drops from
the thorn,

And on thy wings of frailest gossamer
Thou fliest far where rarest blossoms are.
Across the fields of clover dost thou pass,
Across the wild sweet flowers in the grass,
Across the apple orchards pink and white,
Across the garden riotously bright.
Thou gatherest from every bud and bloom,
And, in the hive's secluded, dusky gloom
Where thou hast fashioned with omniscient
art

The cells in whose design man had no part,
Thou blendest all the sweetness thou hast
brought

Into a harmony beyond man's thought.
Thou soon must die; but, oh thy great be-
quest,
Field, garden, wood, in one great thought
compressed!

Thou teachest man to draw the best earth
yields

Of wholesome wild and cultivated fields,
To blend all knowledge in a thought sublime,
And, dying, live in his bequest to time.

Annie O'Conor.

The Fowls Method of Swarm Control.

I read the editorial, July 15, "A New-old Method of Swarm Control," inviting discussion relative to the Fowls plan, but I have seen nothing in Gleanings about it since.

Taking the hint from the first Fowls article I tried a few colonies last summer. The main objection I had to it, with my very limited trial, was that the queen did not get sufficient support during the time that treatment was in progress; in fact, none in some cases, which is not to the best interest of the colony.

There is no denying the fact that the old hive with combs and brood has a great attraction—in fact, more than the queen with one frame as mentioned in the plan and under new conditions that it makes. This attraction is stronger in some colonies than others. I remember once placing the queen with one frame of brood in a prepared hive, and setting it on old stand. I shook about half of the colony in front; put the rest of them on top with a wire separating-screen between, and gave a small back entrance. The bees practically abandoned the lower for the upper. It was a sight to see them string around to that small back entrance. Imagine the support this colony would have given the queen under the plan in question. If the queen gets little or no support, and is removed from the parent hive a distance of two supers or more, as advised, and she ceases laying, it then resolves into about the same condition as having her caged for the time, and the caging of the queen has been practiced and advocated as swarm prevention. Then in the end the plan means division, and division in any manner has a very marked effect on swarming, which is not questioned.

If the Demaree plan or its modifications (which these all are) has any advantage over the shaken-swarm plan relative to swarm control, the placing of the excluder, an obstruction to the free movement of the queen, and lack of support from her bees on account of attraction above, can lay a pretty strong claim for the difference. Of course, if, finally, division is made, it is an added factor.

Galena, Kan., Jan. 31. J. P. Brumfield.

[The Fowls plan was either so good that it required no discussion, or it was no good at all. We hold that it is good. We would like to know who tried it and with what success.—Ed.]

"Water-soaked" Wax.

Some of my neighbors are having trouble in rendering wax from old black brood-combs. They melt the combs (with water) in five-gallon cans. Part of the wax crumbles and looks like cornmeal, and will not stick together.

Is there any simple way of making dark wax lighter-colored, without using sulphuric acid? I have tried vinegar on a small scale, but it did not seem to have any effect on the color. Perhaps I did not use enough vinegar.

Win. Muth-Rasmussen.

Independence, Cal.

[The wax referred to is water-soaked. Beeswax, when it becomes mixed with water, assumes a crumbly, mealy consistency so that it is difficult to get it back into hard firm beeswax again. You can expel the water by using dry heat—that is, placing this mealy wax in a suitable dish and holding it over a slow fire until it melts. The water and wax will then separate and the wax will be hard.]

Water-soaked wax is a physical mixture of wax and water and not a chemical mixture; that is, the wax itself is not changed except in shape, being in small particles separated by thin films of water. After being kept a long time in the air this water will all evaporate, leaving the wax as a powdery substance bearing little resemblance to beeswax. This, however, can be brought to a firm condition by the dry heat above mentioned.

We do not know of any way that beeswax can be clarified on a small scale without an expenditure of an unwarranted amount of money. You can melt the wax, dip boards in it, peel the thin films of wax off the boards and expose them to the sunlight, and whiten the wax, then melt again and strain; but the additional amount that you could get for the wax in the clarified condition would not begin to pay you for your expense in bleaching. Furthermore, the bleached wax is not quite as ductile as that which is not bleached. We have never been very successful in experimenting with vinegar. Sulphuric acid is all right to carbonize the impurities, but we do not advise the use of this chemical except when one has access to steam and a properly built lead-lined vat or tank, and even then the acid should be used in extremely small quantities. The average person who attempts to clarify small amounts of beeswax with sulphuric acid uses ten, twenty, and sometimes even a hundred times too much acid. The wax is "killed" and almost ruined.—Ed.]

Surely "Penny Wise and Pound Foolish."

Not many beekeepers in Jamaica possess this useful machine. Year after year they extract the wax by boiling the comb and wringing it thru a bag. The result is, they lose about half their wax by this primitive method.

Not many weeks ago I called on a beekeeper, and in conversation he told me it scarcely paid for the trouble to melt up very old comb, as there was very little wax to be got out of it. On asking him what method he used to press the melted comb he said, "By wringing it thru a bag." He had melted up fifty supers of comb (500 frames), and

got only 50 lbs. of wax. I offered him four shillings for the refuse, which he accepted. On taking it home I boiled it with plenty of water and pressed it thru a steam wax-press. Pressing two gallons of the melted comb each time gives the best results. I also find by pouring about a quart of boiling water on the bag containing the melted comb each time it is turned for pressure is important. The boiling water softens the cocoons, and washes out the wax. After I had got thru with the melting and pressing of the refuse, the wax weighed 50 lbs.; at 13½ pence per lb., \$13.50—not a bad day's work. I earned nearly enough to buy friend M., who sold me the refuse, one of these useful machines.

Hydrogen Peroxide to Cure Bee Paralysis.

Last fall my colonies were seriously depleted by the "whatever it is" disease. We were having fine weather, the bees working on asters one day and the next rolled out in front of the hives to die. They went into winter with no brood (October) and few bees, but all wintered. I have heard of others in this vicinity that rolled out thru the winter and died. Just before fruit-bloom we had three cold rainy days, at the end of which I found my bees rolling out over the ground, forming little clusters on dead weeds or sticks, some hopping over the grass, and some spotting or streaking up the front of hives, also the entrance-boards. I fed them—poured on top the frames and bees warm sugar syrup with two to three teaspoonfuls hydrogen peroxide to the pint, and controlled the disease, or think I did. The treatment was repeated two and three and four times a day for two days, and a pint can of the medicated syrup with cloth cover inverted over the frames and surrounded by packing. The third day there was only an occasional hopping bee, and they were busily working on the barberry hedge. Peroxide has been my standby in the poultry department. One teaspoonful poured down one sick hen generally cures her. As to the bees, not only do I not want to change queens because my own bees are more than satisfactory, but the plan doesn't look good to me. One could not be sure that the new queens are immune. Indeed, those colonies of my own suffering the severest last fall, had much the lightest attack this spring, and vice versa.

May G. Alley.

Pine Grove, W. Va., May 1.

[Bee paralysis and Isle of Wight disease seem to resist many kinds of medication. Reports have shown that bee paralysis, or what was like it in this country, has yielded in some cases by sprinkling powdered sulphur on the bees. As sulphur is a mild antiseptic it may have some curative value. In the same way hydrogen peroxide may be used also. As nearly every family keeps it on hand we suggest that it be tried out.—Ed.]

A. I. Root

OUR HOMES

Editor

Love ye your enemies; bless them that curse you; do good to them that hate you, and pray for them which despitefully use you, and persecute you.—MATT. 5:44.

Father, forgive them; for they know not what they do.—LUKE 23:34.

Behold the Lamb of God that taketh away the sin of the world.—JOHN 1:29.

If thine enemy be hungry, give him bread to eat; and if he be thirsty, give him water to drink; for thou shalt heap coals of fire upon his head, and the Lord shall reward thee.—PROV. 25:21, 22; ROM. 12:20.

In our issue for July 1, 1915, I inserted a clipping from the *Sunday-school Times*, headed "Getting Even." That little clipping has been of so much importance to a sinful world that I am sure our friends will excuse me if I give it once more right here:

GETTING EVEN.

To get even with one who has wronged us is to get down as low as he is. The more outrageous his injustice, the lower we shall have to go if we insist upon getting even with him. So "getting even" always leaves us worse off than we were before. If ever one man was unfairly treated by another, it was David, at the hands of jealous, unworthy, infuriated Saul. But when David's chance to get even came, he preferred to stay on the heights. To "revenge" ourselves is to return the sort of thing that was given to us. It is as tho, having been cheated by counterfeit money, we wait for an opportunity to pass some of the counterfeit back to the cheat. No matter what we have suffered, we cannot afford to do that; for then we have been injured twice; and the second injury is far worse than the first. There is a better way of getting even with one who, in order to harm us, has descended to a low level. It is to stay above him in God's company, and by love to bring him up to that level.

My reason for presenting it a second time is because of something that more powerfully illustrates the admonition to return good for evil than anything, so far as I can recall, that has ever come to my attention. It is also a clipping from the *Sunday-school Times* in regard to a great missionary, and reads as follows:

What a great, burly, bewhiskered silent man he is! He will weigh over two hundred and fifty pounds. Once he and his wife were put in the stocks and beaten with the Russian scourge. When the beating was over he was unconscious and his wife was dead. He inquired from what section the Cossacks had come who had beaten him and murdered his wife, and he journeyed to their section; that was five years ago, and he has since baptized eleven hundred of them. And they were converted, too, and gloriously so; for each one of these more than eleven hundred have put their property and lives in jeopardy by professing faith in Christ and by being baptized in his name. Is not this a present-day example of the grace of God that came by the Lord Jesus Christ?—*Baptist World*, Louisville, Ky.

There you have it, friends. If the above is not "getting even" with a vengeance, then I do not know. It is really too bad

that the *Baptist World* did not give the name of this saintlike missionary. He was not only beaten, like God's veteran apostle Paul (and probably left for dead), but his poor wife was killed outright. We have been told the American Indian never forgets an injury. Well, suppose this missionary, after he recovered, had spent five years of his life in killing Cossacks; and suppose he had succeeded in killing, say, eleven hundred. I am quite sure the great wide world would have smiled when it heard of it, and said, "He pretty well balanced the account." But the poor fellow had different ideas of revenge. He first inquired in regard to what section of the Cossacks had done this great injury. Then deliberately, quietly, and prayerfully, he set about getting his revenge—that is, getting what might be called revenge. But his ideas of revenge were along the line of the beautiful texts I have quoted—"Do good to them that hate you; bless them that curse you, and pray for them that despitefully use you." We have heard about heaping coals of fire on one's head; and our mothers and teachers have explained to us that the "coals of fire" represent good deeds. Probably those very Cossacks that committed that atrocious crime were ignorant, like our poor brothers in Mexico, for instance. They did not understand this missionary. They thought that he and his good wife were enemies. Quietly, but with a strong determination in his heart to win them to Christ, he went to work, and, probably to his great surprise, he found these poor people ready to receive God's precious word; and in only five years he baptized eleven hundred. We are not told that he succeeded in laying up treasures on earth; but, oh dear me! what a "heap" of treasure he laid up for himself "in heaven"! Eleven hundred precious souls singing praises and thanksgiving to him for having led them out of heathen darkness into the light of the gospel!

The above has been added to our little tract about the defeat of injustice, etc.; and may God speed the message. Let me digress a little:

A good lot of people, both men and women, when they are getting old like myself (past threescore and ten), are tempted at times to think their work is done—that the great responsibilities of the present age will have to rest on younger shoulders. Did you ever feel that way, my aged friend? Very likely you have. Well, up in Michigan there is a lady (I think she said she is over

eighty years old) who cannot get about very well, but who can distribute tracts, and she has been making excellent use of the little tract I have mentioned—"The Defeat of Injustice." Here are the closing words of one of her letters:

I have thought it best not to watch for fruits, like Jonah; but if I am working the will of my heavenly Father, and it is acceptable to him, if I do not see results or people—yes, people who make a high profession do not seem to approve and encourage, as might be expected of them—I try not to be disheartened. I left the word "discouraged" out of my vocabulary long ago. I do not use the word at all except to tell others to leave it out.

Ypsilanti, Mich. RHODA C. W. DERBYSHIRE.

What do you think of that, friends, young and old? The word "discouraged" is left out of her vocabulary. Is not that an exhibition of faith? Well, after getting several hundred of my tracts, and seeing them bear fruit, she sent me one of her tracts. I think you will read it all when you get a glimpse of the title, and then you will smile as you go on.

WAR ON CHRISTIAN PRINCIPLES.

One of the conditions of the treaty with Mexico, it is said, that in any future war which may break out between the two countries shall be conducted on Christian principles.

Now, we all know that this is an age of progress, and that all sorts of improvements are constantly taking place in all sorts of matters; but war on Christian principles is certainly the latest, and if it be carried out we think it will prove the greatest of them all.

Just imagine it! We think we can see the two armies drawn out in battle array. A fair field is before them, the ranks are formed, the positions are taken, the great guns unlimbered. General Scott is just about to give the order to fire, when an aide comes up and respectfully reminds him that "the war is to be conducted on Christian principles," and that it will not do to fire.

"Very true, very true," says the commander-in-chief, "but what are they? I have read Vauban and Scheiter and Turenne and Cohorn. I have read the lives of the old conquerors, and have studied the campaigns of the greatest soldiers; but I never happened to come across these principles in any work upon the military art. Do you know anything about it, Colonel?"

"No."

"Nor you, Major?"

"Nor I either."

"I really don't know how to begin. I suppose it would not do to shoot. Suppose we send for the Chaplain."

The Chaplain arrives.

"Do you know anything about this fighting on Christian principles?"

"Oh, yes! It is the easiest thing in the world."

"Where are the books?"

"Here."

And the Chaplain takes out the Bible.

"Really," says the General, "we ought to have thought of this before. It is a bad time to commence the study of tactics when the enemy is right before us; but I suppose we are bound by the treaty. What is the first thing, Mr. Chaplain?"

"Thou shalt not kill. Thou shalt love thy neighbor as thyself."

"But these are not neighbors. They are Mexicans."

"The same book tells us, a little further on, that the opportunity to do good to a man makes him one's neighbor."

"Will you go on, Mr. Chaplain?"

"Love your enemies. Do good to them that hate you. Pray for them that spitefully use you. If a man smite you on one cheek, turn to him the other."

"But while we are praying for the Mexicans, they will be firing into us."

"No, they are bound by the treaty also. It works both ways."

"Then what is the use of our arms?"

"This is all provided for in the same book. Beat your swords into plowshares and your spears into pruning-hooks."

"Then I don't see that there is anything for us to do here."

"Nothing, unless you send over and ask Santa Ana if he needs anything in the way of medicines or provisions or clothing. I rather think the treaty requires this of us."

"And I don't know but we ought to send them a few schoolmasters, for I understand that they are shockingly ignorant people."

"But how do you ever know which party conquers in this fighting on Christian principles?"

"That is the great beauty of it. Both sides conquer, and there are never any killed or wounded."

I presume this good woman will furnish you as many as you want of the above, free of charge. If you wish to send her some stamps or something more, I am sure it will be all right, because I think she told me she had but little means.

Let me now give you another illustration from my own experience. It was given in GLEANINGS years ago, but it will be new to most of our readers, probably, of the present day.

At the time of my conversion, something like forty years ago, I was, I am sorry to say, in pretty close touch with several prominent skeptics. After my conversion a difficulty or controversy had arisen between myself and the editor of our county paper. No doubt I was more or less at fault, because I was new in Christian work. He seemed to feel bitter toward me because I deserted their ranks and started to follow, as best I could, our Lord and Savior. I tried in my humble way to return good for evil; but it seemed to provoke him all the more. In fact, in his position as postmaster of our town he succeeded in having GLEANINGS thrown out of the mails—that is, he made such a representation of it at Washington that I received notice it could not be mailed at journal rates. I shall always remember how he looked as I met him on the street one morning. Taking his cigar out of his mouth, and puffing a cloud of smoke up toward the blue sky, he said:

"Mr. Root, I think now you will have to buy a lot of postage-stamps."

There was a twinkle in his eye as he said it. I do not know how it is now; but at that time the postmaster had a percentage

on the number of stamps he sold. I need not take time to tell you that, in answer to my little prayer, "Lord, help!" before it was time for the next issue of our journal to come out, a message came from Washington that GLEANINGS had been reinstated. At different times he tried to do me injury; and when the report came out in the papers that the great yields of honey I had been bragging about were produced by feeding glucose, he, it seemed to me, made it harder for me to prove my innocence of the charge. Things went on in this way for years. As our industry developed, and we were sending so much stuff by mail, in the course of time there was talk of increasing the salary of our Medina postmaster; and as the Department ascertained that our establishment was furnishing the great bulk of the mail business to our town I was appealed to, and I think I was also asked if I would recommend the present postmaster and ask for a corresponding increase in salary. In other words, had the postmaster in the past worked in harmony with our business in sending goods all over the world? At this crisis it was a little humiliating for my old enemy (if I may call him such) to come to me and ask a favor. As nearly as I can remember, his words were something like this:

"Mr. Root, there is no longer any need that you and I should be at swords' points as we have been in the past. If we turn about I can help you and you can help me; and I greatly need this increase in salary; and I assure you I will do the best I can to accommodate you in every way in your great and growing business."

I did not answer right away. Here was a grand opportunity for "paying back" or "getting even." Past things that I had patiently and uncomplainingly suffered came up before me. Satan suggested I should tell the postmaster that I preferred to recommend somebody else for his office. Then, again, that expression of his, "swords' points," came up. These "points" were all on his side, for God knows I had, year in and year out, *tried* to "do good to those that hate you." I do not think it took me very long to decide, however, that here, at last, was a chance to heap some coals of fire. I smiled, and looked him pleasantly and squarely in the face and said something as follows:

"Mr. —, I for one shall be very glad to have pleasanter relations between you and me than they have been in years past."

Then I signed the papers. From that time on there were no more clips in regard to A. I. Root and his fanatical methods;

and my good friend was, I think, a little less bitter toward the Bible and Christianity. Later on, his health failed; and finally there came a message that he had not many hours to live, and he wanted to see me. Imagine my joy and surprise to hear him say he had been reading his Bible, and had accepted his Savior as the Lamb of God that taketh away the sin of the world.

Now, dear friends, please do not think I am boasting when I say that this man was saved, not by what I *said* to him, but by the way in which I had succeeded (in my poor humble way) in illustrating the truths of the gospel I was trying to spread abroad to all men. It was my *action*, the way in which I *deported* myself under fire, that recommended the dear Savior, and not what I had said.

And now in closing let me say to you, dear friends, whose eyes rest on these pages, that you can do a greater work, perhaps, by your acts and daily conduct than by anything you can say. Let the whole world see that you are ready and on the alert to love your enemies and to "do good to them that hate you."

Let me close with still *another* clipping from our good friend Ridgeway, in the *Sunday-school Times*:

There is nothing better to be said of a citizen and neighbor than that he was a good man. Not great, not learned, not able, not rich, but *good*. Greatness falls, learning rusts, ability wanes, riches fly, but goodness goes on forever. The good man is, first of all, a God man. Good and God are words with the same mother. The good man is kindly, generous, helpful, thoughtful. When he speaks and promises, no one asks a writing. Such men are the regular standard output of those manufactories called Sunday-schools.

~~~~~  
"CAST THY BREAD UPON THE WATERS, FOR THOU SHALT FIND IT AFTER MANY DAYS."

The letter given below was one of my "happy surprises," and it brought to mind the beautiful little text I have chosen for the head of this article.

A KIND WORD FROM C. G. TRUMBULL, EDITOR OF THE SUNDAY-SCHOOL TIMES.

*My dear Mr. Root:*—Last week I returned from a western trip, having the privilege of speaking at a dozen meetings in Kansas, Nebraska, and Iowa, on the subject of the Victorious Life—victory by faith in Christ.

On my way home I was breakfasting one morning in a railroad station, and my appetite was appealed to by the mention of an article on the menu served with "strained honey." I ordered it; and as I was eating the honey I wondered idly whether there was any real honey in it, or whether it was simply a manufactured and artificial product, of which we are told there are so many masquerading under natural names these days. It tasted all right; but I was rather inclined to think it was being "put across" on me, and I picked up the little "individual service" bottle containing the honey, and glance-

ed carelessly at the label. I didn't notice the whole label closely, and set the bottle down again.

I enjoyed my honey, whether real or not, however; and a few minutes later I looked at the label again, this time more closely. Imagine my surprise and delight as I saw printed across the bottom of the label, "A. I. Root, Medina, Ohio."

"There's no counterfeit there, if A. I. Root's name is on it," said I to myself; and I felt as tho I had run across an old and a warm friend on my journey. Instantly I recognized that I had before me the real thing, from a man who was a real man because Christ is in his life.

I just wanted to pass on this bit of travel experience to you, and to thank you for having made my breakfast more enjoyable. You have brought honey into my life over and over again by your wonderfully appreciative and encouraging words about the *Sunday School Times*.

With warm and grateful greetings, believe me,

Yours in His faithfulness,

Philadelphia, Pa., May 15. C. G. TRUMBULL.

The above suggests several things—first, that the dining-room menu still persists in saying "strained honey." It has been something like fifty years since I helped to give the world the honey-extractor, which enables us to get the honey out of the combs in a much better and purer form than squeezing or straining it out. Secondly, our good friend Trumbull, with a great lot of other people, does not seem to recognize that our pure-food laws have for several years past pretty much done away with the adulteration of honey as well as other things. There is quite a penalty imposed for adding glucose or any other similar substance to liquid honey, and I believe the law is pretty well enforced. I hardly think a spurious article can be found now in our groceries nor in the drugstores of the United States. No doubt my good friend Trumbull has paid me a higher compliment than I deserve; but I decided to let it go in print because it so well illustrates that any man or woman who persistently tries to be honest and to do right before God and man, year in and year out, will ultimately get the promised reward. The bread cast on the waters will not be lost.

#### SUNDAY'S EVANGELISTIC WORK IN BALTIMORE.

In the Home paper in our issue for Feb. 1 I said nothing would save Baltimore except a visitation of the Holy Spirit, and that I finally knelt down and prayed that the Lord might call Billy Sunday to that terribly wicked city; and I learned afterward that he had already arranged to go there. I have space to give only a brief statement in regard to the result. The Baltimore *American* for April 24 has quite an article in regard to the last day in the great tabernacle. A large number of converts, about 23,000, were gained, which, if

I am correct, exceeds all former records, according to the size of the city. It is a wonderful achievement. It comes pretty close to being one in 25 of the whole population. While he was preaching his closing sermon to a vast audience of the people, another meeting was held, and addressed by Charles A. Windle and Jacob E. Meeker. These two great defenders of the liquor business of course had no end of fault to find in regard to the harm that Sunday's earnest preaching had done to the "booze business." Over a million and a half people listened from first to last to Sunday's preaching in Baltimore. At the farewell sermon 914 came forward.

After the above was in type I found the following in the *American Issue*:

On the closing day of the Billy Sunday campaign in Baltimore, the evangelist talked to 100,000 people, and the leading newspaper of the city the next morning gave 18 columns of space to the tabernacle meeting. On the same Sunday both Windle and Meeker spoke at a meeting in Baltimore to about 2000 people, and the same paper gave the wet meeting a half-column space.

This shows how the people of Baltimore felt about the Sunday meetings in comparison with the meeting held by the wets.

#### LEARNING TO SWIM.

Again and again are we confronted with a newspaper clipping telling of boys and girls being drowned who might easily have saved themselves if they had been able to swim but a little. A person who cannot swim, if thrown into the water where he comes within a foot of reaching a support may drown helplessly because he is unable to move his body just that one foot. In fact, I myself would not be here writing these notes were it not that I had just a little practice in the art of swimming sixty years ago. I was vividly reminded of it by the following from the *Plain Dealer*:

TEACH PUPILS TO SWIM; CHICAGO EDUCATORS URGE COURSE BE ADDED TO CURRICULUM.

CHICAGO, Aug. 13.—Members of the committee on buildings and grounds of the board of education today adopted a resolution recommending the teaching of swimming in every public school.

A special committee, of which Mrs. Ella Flagg Young, superintendent of schools, is chairman, was appointed to work out the practical details of the plan.

It is estimated it will cost the city about \$1,000,000 a year to add swimming to the curriculum in every school. The steamer Eastland disaster led to a consideration of the subject by the committee.

No matter if it does cost a million dollars a year or more to teach our children to swim as well as to read, write, and spell, let the good work go on; and I am especially pleased to note that the capable and talented woman mentioned in the above is to have charge of the matter.

# TEMPERANCE

"BOOZE" ADVERTISEMENTS IN OUR CITY  
DAILIES, ETC.

We clip the following from the *Ohio Farmer* for May 13:

A report just issued by the Bureau of Chemistry, United States Department of Agriculture, covering food-law cases judged since April 20, 1915, lists over 60 patent medicines as misbranded and fraudulent in that their analyses prove that they contain no elements to effect the cures or relief that their labels claim. The list includes baby soothing-syrups, which are pronounced positively dangerous on account of the opiates and alcohol that they contain; and, furthermore, in the words of the government decisions, the label claims are "false and fraudulent in that they are applied to the said articles knowingly, and in reckless and wanton disregard of their truth." This is the season when many people's minds dwell on taking "spring tonics" and "bitters" as relief for the lassitude resulting from diets unsuitable for the warmer weather. True, we do need the tonic to be obtained in the mineral salts of herbs and fruits, but it is far wiser and more effective, and also much cheaper, to get it in fresh green herbs and such fresh fruits as are obtainable now. A daily "mess o' greens"—we had a most appetizing dish of dandelion greens for dinner yesterday—will do you far more good than any of the "bitters," tonics, and nerve remedies advertised so liberally in your local newspaper. Whatever herbal efficiency there is in these is usually so doped with alcohol that the harm done outweighs the good that the herbs alone could do. Therefore it is far better for your health and your purse to take your "yarbs" and your iron, potash, lime, and sulphur first hand and directly in the fresh green vegetables, fruits, eggs, and milk. Spinach, dandelion greens, and raw cabbage are much more effective sources of iron than any beef, wine, and iron compounded in a bottle from the drugstore.

Just a word about dandelions before we take up the matter of liquor advertisements. I am glad to see a good word for dandelions, especially since so many people talk about dandelions as they did a few years ago about sweet clover. Dandelions are not only a splendid erop to plow under to enrich the ground, but they are excellent cow feed. When you find a cow that will not eat dandelions you may make up your mind that her education is lacking, just in the same way you decide the education of an editor is lacking when he gives place in his columns to booze advertisements.

Now in regard to fraudulent medicines. We are informed there is a law against palming off on the public misbranded bottles with an exaggerated statement as to the virtue of the contents; or, worse still, selling something that is not a remedy at all for the trouble specified. And, by the way, it rejoices my heart as I go over the agricultural periodicals sent out from our different states to notice the splendid sentiment coming from the different editors in regard to everything harmful to the inmates of the homes on the farm. May God be

praised for our splendid agricultural periodicals. There are few of any kind nowadays, except our great city dailies, that will accept any sort of booze advertising. In our issue for Feb. 1 I said I had been pained because our neighboring city of Cleveland seemed to be the only large city that did not contain a daily having the courage to say that no more whisky advertisements would be found in their columns. If I am making a mistake, please correct me. It is true, however, that our old *Plain Dealer*, sometimes for a week or ten days, will have no whisky or beer advertising whatever; but just when I begin to rejoice, then comes something like what I saw a few days ago—a booze advertisement that had the cheek to claim their beer was "liquid bread." One of the great dailies, if not the greatest in the large city of New Orleans, has just stepped over on the dry side. See the following from the *American Issue*:

It is announced that the *Times-Picayune*, of New Orleans, which heretofore advertised liquors, is to join the ranks of newspapers which refuse such advertisements.

But here comes something from our beloved Florida that does not call for rejoicing. I clip it also from the *American Issue*:

THE "GREATEST OFFER EVER MADE."

Who says that the liquor-dealer is always lacking in a sense of the eternal fitness of things? In support of the contention that he occasionally is consistent we cite an advertisement which appeared recently in a Florida newspaper (the *East Coast Advocate*, Titusville), in which the "greatest offer ever made" is set forth. This offer consists of a box of 50 cigars, with a claimed value of 7½ cents each, for \$3.48, and with each purchase will be given a premium of one quart of whisky and a revolver. The cigars are evidently a mere incident. But what could be more consistent than a bottle of whisky and a revolver?

When one reads the above he is tempted to wonder if it is possible a periodical could be found *anywhere* whose editor is so far behind the times that he would accept such an advertisement. The bottle of whisky with the cigars *might*, in one sense, be consistent; but why in the world should the revolver be put in? Is it the hope or expectation that, after the purchaser has drunk the whisky, he will shoot his wife or children, and then in his drunken craze use the revolver on himself? Do we need any *more tragedies* along that line than we have already? By the way, is there no law, either in Florida or in the United States that will put a stop to such kind of advertising as well as that sort of gift or prizes offered as premiums? Instead of sending mission-

aries to the heathen, why not open up a crusade to educate some of our country editors?

THE DRUNKEN CHAUFFEUR, THE MAN WHO SOLD HIM THE DRINK, AND THE JOURNAL THAT ADVERTISED THE DRINK.

We clip the following from the *American Issue*:

WHO ARE THE GUILTY PARTIES?

A drunken man in Detroit was driving an automobile and ran over a man, killing him. The driver was arrested, convicted, and sent to the penitentiary for 15 years. The fact that he was drunk when the accident occurred did not save the man from punishment.

The *Ohio State Journal*, commenting on the case editorially, says: "For a man who is drunk to run a car is an offense itself; and when he happens to kill a man, the offense naturally intensifies the crime. If there is anything the law should punish severely, it is where a drunken man undertakes a run an automobile."

But what about the men who made and sold the liquor which made the man drunk and caused the killing? Are these men guiltless?

And what about the newspaper that in its advertising columns urges men to drink? In the same number of the *Ohio State Journal* in which the editorial appears is an advertisement to the effect that a certain brand of liquor is "worthy of a place in the best of society, is good for young and old, and is a good tonic of high value."

In the same paper of the same date another brand of liquor is proclaimed to be a "spring tonic, a delicious drink, and an ideal thirst quencher."

Probably the drunken automobile driver who killed the man had been reading these advertisements.

Is the drunken automobile driver the only guilty party?

What does the *Ohio State Journal* think about it?

I hope the above will be read over and over, not only by drinking men, but by those who vote for drinking men; those who vote wet, and the editors of the periodicals that accept wet advertising.

PROHIBITION DOES NOT CONFISCATE PROPERTY, AFTER ALL.

We take pleasure in clipping the following from the *Methodist Temperance Bulletin*:

SALOONS AND BREWERIES TURN TO LEGITIMATE BUSINESS.

"Hydes," the finest saloon of Seattle, has been remodeled as a tea-room, with beautiful decorations, oriental furnishings, and comfort conveniences. Hundreds of Seattle's leading women are its patrons.

Prohibition does not confiscate property, but merely forbids its misuse.

The Raymann Brewery, of Wheeling, West Virginia, is now the P. O. Raymann Company, engaged in meat packing.

The Uneeda Brewery, of West Virginia, is now a milk-produce company.

The Benwood Brewery (West Virginia) is now a chemical and soap plant.

The Fairmount Brewery (West Virginia) is now an ice and milk products plant.

The Huntington Brewery is now a meat-packing plant.

The Cedar Rapids Brewery is now a yeast-factory.

The Iowa City Brewery is now a creamery and produce company.

The Star Brewing Company, of Washington, Pennsylvania, is now the Capital Paint, Oil, and Varnish Company.

The North Yakima Brewing Company, of Washington, is now a fruit by-products company.

The Salem, Oregon, Brewery, is now making logan-berry juice.

"PREPAREDNESS," NOT AGAINST AN IMAGINARY FOE, BUT AGAINST A REAL ONE.

We learn from the *Patriot Phalanx* that Gen. Nelson A. Miles, in his speech in Washington, D. C., said:

The proper "preparedness" should be, not against an imaginary foe, but against the ever present enemy that is destroying more American men and women and homes than any foreign foe could ever do.

Can't a lot of us say amen to the good old general's declaration?

GOD'S KINGDOM COMING IN SOUTH DAKOTA.

We clip the following from an article in the *New Republic*:

MITCHELL, S. D., April 21.—The greatest dry victory ever won in South Dakota was achieved last Tuesday when a score of towns and cities now wet swung into the dry column, and every dry town remained dry. . . . Three cities not only refused to go back to the saloon system, but increased their dry majorities of a year ago—Aberdeen from 4 to 66; Mitchell from 102 to 240; Rapid City from 43 to 134.

"THE MILD AND UNASSUMING CIGARETTE."

We clip the following from an article in *Plain Dealer*:

ATTENTION, HENRY FORD; AMERICANS THIS YEAR PROBABLY WILL SMOKE 21,000,000,000 CIGARETTES.

NEW YORK, May 11.—Bitter news for the Carrie Nations of this land is contained in a report compiled by the Wall Street *Journal* and made public today. It concerns the mild and unassuming cigarette of which so many harsh words have been said by well-meaning persons.

The report shows that if American smokers continue using cigarettes thru the year at the rate they have for the first three months the total consumption for 1916 will be well over 21,000,000,000.

The increase in consumption for the first three months of 1916 in the United States and Kansas over the same period in 1915 is 1,484,000,000. The total consumption last year was 18,000,000,000.

Our nation is just now making a big war, and, by the way, in many respects a troublesome war, on habit-forming drugs. All things considered, is there a worse "habit-forming drug" at the present time than the cigarette? Let our nation (and every other nation, for that matter) answer. Are we to understand from the above that the *Plain Dealer* considers cigarettes "mild and unassuming"? and also that Ford and Carrie Nation and other people who stand with them on the cigarette business are only half-crazy fanatics?

## BUY THE BEST

Why buy inferior queens when the best can be bought at the same price? You have heard of Dr. C. C. Miller's famous honey-gathering stock. How would YOU like to have a strain of bees like his? You CAN have. LISTEN, and we will tell you how.

We have made arrangements with Dr. Miller to furnish us breeders from his stock that has produced 266 sections weighing 244 pounds. These breeders are FINE. They are pure three-banded Italians, very gentle, and produce fine large daughters. Few people ever have a chance at the best in the world—so grasp this chance while you have it.

*To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.*  
C. C. Miller, Marengo, Ill., March 1, '16.

|                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |   |    |                   |        |         |                   |      |       |                   |      |       |                   |      |       |                   |      |       |

**H. D. MURRY,  
MATHIS, TEXAS**

## BEE-LINE QUEENS      GOLDEN AND THREE-BANDED ITALIANS

From Caraway's prize-winning stock. Every queen purchased of me I will guarantee to give satisfaction. If she does not I will replace her with another queen or refund your money. They are hustlers, long lived, not inclined to build burr-comb, cap their honey white, and are not given to swarming, and are gentle to work with.

My bees and queens are winners of over 100 first premiums in the past eight years. This speaks for itself. If you are going to buy queens you cannot do better than buy the Bee-Line Queens.

Queens are postpaid, and safe arrival is guaranteed to all points in United States and Canada. No diseases of any kind in my apiaries.

State inspector's health certificate with each shipment.

### PRICES FROM MAY 10 TO NOV. 1.

**BREEDERS.**—The cream selected from our entire stock of outyards; nothing better. These breeders, \$5.00 each.

Can furnish bees on Danzenbaker and L. or Hoffman frames.

Above price on bees by pound, nuclei, and colonies does not include queen. You are to select such queen as you wish with the bees, and add the price.

No bees by pound sent out till first of June. Also nuclei and colonies, if wanted before June 1, add 25 cent to price in table.

Breeders, select tested, and tested queens can be sent out as early as weather will permit. Send for testimonials. Orders booked now.

**H. G. Quirin-the-Queen-breeder**  
Bellevue, Ohio

## THREE-BAND ITALIAN QUEENS

They are bred from imported mothers. They are the best for honey-producing purpose; very gentle, not inclined to swarm. If you buy once you will buy always. **GUARANTEE** that all queens will reach you in good condition, to be purely mated, and to give perfect satisfaction. All orders filled at once.

Untested, . . . April 1 to July 1, 1, \$0.75; 6, \$4.25; 12, \$8.00  
 Select Untested, . . . " " " 1, .90; 6, 5.00; 12, 9.00  
 Tested, . . . " " " 1, 1.25; 6, 7.00; 12, 13.00  
 Select tested, . . . " " " 1, 2.00; 6, 11.00; 12, 20.00

L. L. Forehand, Fort Deposit, Alabama

## Italian Queens with a Record of 30 Years

Leininger's strain of Italian bees and queens have been carefully bred for 30 years; for gentleness and honey-gathering qualities are unexcelled; 95 per cent pure mating guaranteed. Queens ready June 1. Untested, each, \$1.00; 6, \$5.00; tested, \$1.50; 6, \$8.00.

Fred S. Leininger & Son, . . Delphos, Ohio

E. A. LEFFINGWELL, ALLEN, MICHIGAN

## PATENTS Practice in Patent Office and Courts Patent Counsel of The A. I. Root Co.

Chas. J. Williamson, McLachlan Building  
WASHINGTON, D. C.

# EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

## The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

**PRICES.**—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

The A. I. Root Company . . . Medina, Ohio

## Queens of MOORE'S STRAIN of Italians

### PRODUCE WORKERS

That fill the super quick  
With honey nice and thick.

They have won a world-wide reputation for honey-gathering, hardiness, gentleness, etc. Untested queens, \$1.00; six, \$5.00; 12, \$9.00. Select untested, \$1.25; six, \$6.00; 12, \$11.00. Safe arrival and satisfaction guaranteed. Circular free.

J. P. MOORE,  
Route 1, MORGAN, KY.

Queen-breeder

N. Forehand, Fort Deposit, Ala.

## Tobacco Habit EASILY CONQUERED

How to do it quickly, agreeably, and without drugs. By Mac-Levy, the eminent expert. Only book of its kind.

A life-lengthening, health-giving, joy-and-contentment-bringing book. Written in delightful, easy style. No sermons. No fads. Get this volume if smoking, chewing, or snuff-taking is hurting you, and if you wish to overcome the habit without relying on will power, drugs, or anything else that is disagreeable and strenuous. Success guaranteed or money refunded.

*Cloth bound, clear type. Price, postpaid, \$1.25, or at all stores where books are sold.*

ALBRO SOCIETY, Inc., 181 Lexington Ave., 270A, New York City

## Where are You Located?

**IN OHIO?**—Then your orders will naturally gravitate to Zanesville, the Bee-supply Capital of the state.

**IN WEST VIRGINIA?**—The large supply-house nearest to most beekeepers in this state is at Zanesville.

**IN WESTERN PENNSYLVANIA?** — You are a next-door neighbor.

**ELSEWHERE.**—Zanesville service will yet commend itself to you as being the best obtainable.

The leading line of bee supplies, unsurpassed shipping facilities, years of experience, and painstaking care in packing and forwarding goods, fair and considerate treatment, all insure a degree of satisfaction that can scarcely be duplicated elsewhere.

If exasperating delays or otherwise unsatisfactory service have been your past experience, give us a chance to demonstrate the superiority of the service we offer.

## MYERS HYDRO-PNEUMATIC PUMPS FOR THE HOME WATER SUPPLY

Every Woman and every member of any family living in the country, small town or village, will enjoy reading our new Catalog, telling all about MYERS HYDRO-PNEUMATIC PUMPS, and how they have brought to the door of every home—yours included—such conveniences as a bath room, toilet, and running water in the kitchen and laundry—water at the turn of a faucet, same as in city residences, wherever and whenever wanted.

MYERS HYDRO-PNEUMATIC PUMPS are made in many styles and sizes for operation by hand, windmill, gasoline engine, or where electric current is available, by motor. These are the pumps that pump air and water into a pressure tank. This compresses the air in tank which acts as a reserve power forcing the water to any point desired. An equipment is easy to install, the upkeep is nominal and the water service excellent.

You are tired carrying water and want to know more about this modern way, and how easily you can now have a successful private water system in your own home. Our Catalog will tell you. Write for it.

351 ORANGEST. F.E. MYERS & BRO. ASHLAND, OHIO.

# WARDELL STRAIN OF ITALIANS

Descendants from the Famous Root \$200 Queen

I was head queen breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

|                 |                                                             |
|-----------------|-------------------------------------------------------------|
| Untested        | during June, \$1.50; in July, August, and September, \$1.00 |
| Select Untested | 1.75                                                        |
| Tested          | 2.50                                                        |
| Select Tested   | 3.50                                                        |

Delivery will begin about June 1. Address all orders to

F. J. Wardell, Uhrichsville, Ohio

Bees, a full pound of the right kind for business, with young laying queens, 1 pkg., \$2.25; 6 pkg., \$12.50; 2-lb. pkg., with queen, \$3.25. Queens, bred for business, untested, each, 75 cts.; 12, \$8.00. Safe arrival in good condition guaranteed. Health certificate with each shipment. Circular free. J. B. HOLLOPETER, queen-breeder, Pentz, Pa.

FOR SALE.—Bright Italian queens at 75 cts. each; \$7.50 per dozen or \$60 per 100. Ready April 15. Safe arrival and satisfaction guaranteed.

W. W. TALLEY, Rt. 4, Greenville, Ala.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, beautiful and gentle. Mated, \$1.00; six, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SONS, Wilcox St., Binghamton, N. Y.

QUEENS.—Improved three-banded Italians, bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$3.00; select, \$1.00; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed.

H. C. CLEMONS, Rt. 3, Williamstown, Ky.

MULLIN'S UNRIVALED ITALIAN QUEENS.—Gentle and prolific, three-banded, and one of the best honey-gathering strains. After May 1 to July 1, untested, \$1.00; \$9.00 per dozen; special rates after July 1. Try one. You will want more.

O. S. MULLIN, Holton, Kan.

Queens now ready. Golden and three-band Italian queens. I shall do my best to fill all orders promptly. If any queen fails to give satisfaction I will replace her free. Untested, 75 cts. each; six for 4.00. Send all orders to

E. A. SIMMONS, Greenville, Ala.

Queens by return mail, or your money back. Guaranteed purely mated three-banded Italians, Northern strain, bred for gentleness, honey-gathering, and wintering. Select untested, \$1.00 each; six for \$5.00. Select tested, \$1.75 each. Write for price on large orders. State inspector's certificate. Satisfaction guaranteed.

J. M. GINGERICH, Kalona, Iowa.

Famous Howe's, Root's, Moore's, Davis' select strain of honey-gatherers, disease-resisting. None better for all purposes. Untested, one, 75 cts.; doz., \$7.50. Select untested, one, \$1.00; doz., \$9.00; ½ doz., \$5.00; tested, \$1.25; doz., \$10.00; select tested, one, \$1.50; ½ doz., \$8.00; extra select, \$2.00. Bees by the pound, \$2.50 with queen. Honey crop short. Will have plenty of bees in June.

H. B. MURRAY, Liberty, N. C.

Carniolan, golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, box 315, Buffalo, Tex.

If you want a queen for that queenless colony, we can send it to you by return mail. Young tested queens, \$1.00, \$12.00 per dozen. Untested, \$1.00; \$9.00 per dozen. We breed the three-band Italians only, and we breed for the best. Our thirty years of queen-rearing proves this. We never had a case of foul brood in our apiaries, and we guarantee every queen sent out by us.

J. W. K. SHAW & Co., Loreauville, La.

Three-banded Italian queens guaranteed to please and to give results; 75 cts. each; 6 for \$4.25; 12 for \$8.00; 100 for \$65.00, in lots to suit; select breeders, \$5.00 each. One-pound swarm with fine queen, \$2.25 each; without queen, \$1.50 each. Write us your wants. We will give you a square deal. We are keeping up well with orders, getting them as we are. June will be the big bee month. Always give your express office when wanting pounds of bees. CURD WALKER, Queen-breeder, Jellico, Tenn.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can therefore supply you with the biggest, strongest nuclei you will be able to find anywhere. Our bees are all on the standard-size Hoffman frames, combs built on full sheets of foundation, and on wired frames. We are now shipping nuclei, and can fill your orders promptly. Bees guaranteed to be free from disease.

HYDE BEE Co., Floresville, Texas.

## HELP WANTED

WANTED.—At once, young man to work with bees. Give age, and wages expected, in first letter.

M. C. SILSBEE, Rt. 3, Cohocton, N. Y.

## SITUATIONS WANTED

WANTED.—Position in apiary; experienced; wages \$50 a month and board.

GEO. A. BALDERSTON, Kennett, Cal.

## Convention Notices

A summer course in beekeeping is being arranged at the Ontario Agricultural College for the week of June 12. It will consist of apiary demonstrations and practice. Day sessions will be conducted in the apiary as far as possible, and four illustrated evening lectures will be given during the week.

Such special subjects as wintering, swarm control, bee diseases, queen-rearing, requeening, and the like will be taken up in turn, and demonstrated by means of the bees and appliances in the apiary. Students will be given practice in the various manipulations under discussion. Instruction will be given by the Provincial Apiarist, assisted by Mr. James Armstrong, Vice-president of the Ontario Beekeepers' Association, and other prominent Ontario beekeepers.

Mr. Frank C. Pellett, State Apiary Inspector of Iowa, has consented to spend a few days of the week in attendance and assist in the instruction. He will also give illustrated evening lectures on "Beekeeping in the Mississippi Valley," and on "Our Back-door Neighbor." The latter subject deals particularly with the economic importance of wild life, including bees and insects. Many years of time have been spent by the speaker in its preparation, single families being under observation for months at a time. Many of the slides made from photographs taken from life by the author in the field were secured with great difficulty. Mr. Pellett is an excellent speaker, and a master of the different subjects which he will discuss.

Judging by the correspondence to hand, the interest in this course will be excellent. There are no tuition fees charged, the only expense being for railroad fare and board while in attendance.

The Wellington County Beekeepers' Association is arranging to hold a field day at the College during the week of the summer course. Beekeepers who find it impossible to attend for the whole week are cordially invited to enjoy the good things of the field day, the exact date of which will be announced later.

Guelph, Can., May 11.

MORLEY PETTIT.

## “The Doolittle Plan”

of working out-Apiaries is fully described in **The Management of Out-Apiaries** by the well-known author, G. M. Doolittle, of New York.

This is the new title of “A Year's Work in an Out-Apiary” by the same author. This is the fourth revision of this work on this topic of management of outyards. If you haven't a copy of former editions you should not fail to get this edition. Price 50c.

Order now from the publishers.

The A. I. Root Co., Medina, O.

# SPECIAL BARGAINS

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

## HIVE-HANDLES.

We have a surplus stock of handhole cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

## OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of eight-frame packed 5 in a package, which we offer to close out as follows: YW 5/8, one story, eight frames, 12 packages, five hives each, at \$8.00.

## NO. 2 OR B GRADE HOFFMAN FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

## METAL SPACERS SLIGHTLY DEFECTIVE.

In making the metal spacers for the metal-spaced frames there are a percentage which come out either sheared a little scant on one side, or with slight breaks in the tin where it is drawn up into the spacing-boss. These are hardly passable as perfect stock, but in actual use they will answer every purpose as a spacer. Rather than throw these into the scrap we will offer them while they last, including nails to nail them on, at 20 cts. per 100; \$1.80 per 1000. Transportation charges extra.

## 1 1/4 H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

## WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1 1/2-inch tire, and solid cast hub holding spokes and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

## SUPERS FOR EXTRACTING OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. l. Medina.

200 D9/10, nailed and painted, with top and bottom starters, none frames in each, new. Sell new for \$1.20; offered at \$6.00 for 10; \$55.00 per 100.

410 D8/10, nailed and some painted two coats, some one coat; 273 not painted. Sell new for 90 cts.; offered at \$5.00 for 10; \$45.00 per 100.

180 8/10 supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first two lots are the 5 1/2-inch supers with hanger cleats and shallow Danz. frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

## ALEXANDER FEEDERS FOR EIGHT-FRAME HIVES.

The Alexander feeder as we now make it is adapted to either eight or ten frame hives. Formerly we made a shorter length for the eight frame than for the ten-frame hive. In cleaning up old stock we find 300 of these eight-frame feeders which we offer, to close out, at half regular prices—viz., 15 cts. each; \$1.35 for 10; \$11.00 per 100; \$30.00 for the lot.

## TIN COMB-BUCKETS.

While these are listed in the catalog in one lot at \$1.50 each, their convenience in carrying comb to the extractor shut up from robbers is not set forth. We have a surplus stock, and offer them, to reduce the number on hand, at \$1.25 each. You can place four Hoffman frames or five non-spaced frames of Langstroth size in each bucket.

## JONES HONEY-KNIVES.

This is a form of honey-knife used largely in Canada, and preferred to the Bingham by those who have tried it. The blade is 1 1/2 inches wide, and a flat V or triangular shape. We had a lot made to supply a call we had, and still have in stock 28 of them. We offer them at 75 cts. each. Mailed as a pound parcel when packed.

## SHIPPING-CASES FOR 12 AND 24 SECTIONS.

When we discontinued listing shipping-cases to hold 12 sections we still had quite a stock of various styles on hand, many of which are still in stock. We have also some of the older styles of cases for 24 sections of various sizes. We offer these various cases to close out at the following bargain prices. Here is an opportunity to lay in a stock of cases preparatory to the honey crop near at hand at very low prices. None of these cases, except as noted, are large enough to take sections with cartons or corrugated liners, except the bottom sheet. 12-lb. 2 or 3 rows cases with 2 and 3 inch glass for the 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, 4x5x1 3/8 sections, packed 50 in a crate at \$4.00 a crate; packed 10 in a crate at 85 cts. a crate. A few crates of cases for 16 sections 4 1/4 x 1 1/4 at \$4.50 per crate of 50 or 95 cts. per crate of 10. A few crates of cases for 24 sections 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, and 4x5x1 3/8 at \$8.00 per crate of 50; \$4.00 per crate of 25, or \$1.70 per crate of 10. The 12-lb. safety cases, which we no longer list with safety cartons, and 2-inch glass for 4 1/4 x 1 1/4, 4 1/4 x 1 1/2, and 4x5x1 3/8 sections, per crate of 10, \$1.20; per crate of 25, \$3.00. Without cartons, but including corrugated liners and glass, \$4.50 per crate of 50.

## NO. 2 OR B GRADE SECTIONS.

We have a surplus stock of B grade sections in all the commonly used sizes and styles, and are behind on orders for No. 1 or A grade in some kinds. To insure prompt shipment it may be advisable to order B grades if you can use that grade. In beeway style the B grade costs 50 cts. per 1000 less than A grade, while in the plain or no-beeway styles the reduction for B grade is 75 cts. per 1000. The loss from unusable sections in B grade is very little more than in the A grade. Try them if you have not done so.

## SWEET-CLOVER SEED.

We have a good supply of very choice hulled white-sweet-clover seed scarified for quick germination, requiring only 10 lbs. per acre for a good stand. We offer this for a short time to reduce stock at \$18.00 per 100 lbs. Now is the right time for sowing with a nurse crop to produce hay or bloom with seed next year. We have also choice hulled yellow which we will sell at \$15.00 per 100 lbs. A thousand pounds of hulled white for shipment direct from Des Moines, Iowa, not scarified, offered at \$15.00 per 100 for prompt acceptance.

FOR SALE.—1910 Model 4-cylinder 30 H. P. REO, run only 15,000 miles, in fine condition. Is of racing type, with gasoline-tank in rear, two-seated, no fenders. Gas lamps, no starter. Tires in good condition. Ideal car for running out to outyards and carrying light loads. \$200.00.

**THE A. I. ROOT COMPANY, MEDINA, OHIO.**

## CONVENTION NOTICES

Field day and basket picnic of the members of the Colorado Honey-producers' Association, at Lindenmeier Park Lake, Fort Collins, Saturday, June 10, 1916. Meeting open to everybody interested in bee culture.

- 9:00 A.M.—Meeting called to order by Pres. Geo. Miller of Littleton.
- 9:15 A.M.—“Best Methods of Improving our Stock of Bees.” Discussion led by Harry Crawford, Broomfield, and Prof. D. W. Spangler, Longmont.
- 9:45 A.M.—Question-box.
- 10:00 A.M.—“The Bee-inspection Law of Colorado, Its Interpretation and Application,” Prof. C. P. Gillette, Agricultural College, Ft. Collins.
- 10:30 A.M.—Demonstration of starting queen-cells by the Doolittle plan, F. G. Rauefuss, Englewood, and F. L. Stone, Denver.
- 11:00 A.M.—“Swarm Control;” 1. In relation to Honey Production; 2. In Making Increase. Discussion led by A. C. Van Galder, Berthoud, and A. Elliott, Timnath.
- 11:30 A.M.—“The Use of Honey in the Home,” Address by Miss Haynes, Department of Domestic Science Extension Work, Agricultural College, Ft. Collins, and Mrs. W. P. Collins, Boulder.
- 12:00 M.—Recess for luncheon. (Visitors are expected to bring lunches, but coffee and lemonade will be provided.)
- 1:30 P.M.—“How Can We Increase the Use of Honey?” B. F. Hastings, Golden, and C. H. Wolfe, Greeley.
- 2:00 P.M.—Visit to the Agricultural College.

Fort Collins is on the Colorado & Southern Railway, and on the Union Pacific. The train service with Denver and northern Colorado points is very good. The roads through northern Colorado are good. This section north of Denver is the garden spot of the state. We suggest to members having automobiles to make the trip in their car, bring their families or beekeeping friends along; let them enjoy the beautiful scenery along the way, and have a good time at Lindenmeier Lake Park. This place is the popular picnic place of that city. It is one mile from town, and street-car runs right up to the gate. There is plenty of shade, a large lake with boats, and every comfort desired. Be sure to come, and induce other beekeepers to join you.

## TRADE NOTES

### BEESWAX LOWER.

Beeswax is being offered us at somewhat lower prices than were being asked sixty days ago. We have sufficient in stock to last us for some months, even with the excellent trade we are having in foundation. We quote, till further notice, 28 cts. cash, 30 in trade, delivered at Medina for good average wax.

### FOUNDATION MACHINE IN OREGON.

We offer a 6 x 2½-inch thin-super foundation-mill at Independence, Oregon, at the bargain price of \$12.00. This is a good second-hand mill sold to a party who died before it was put into use. His widow desires to dispose of it. Who in the Northwest can use it and help themselves to a bargain, and help a widow at the same time?

### SECOND-HAND FOUNDATION MILLS.

We have to offer the following list of foundation machines which have been used but are in fair condition. In many cases they will answer as well as a new machine where you have only a moderate output. Send for sample of foundation from any mill in the list which may interest you.

- No. 0153, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.
- No. 0156, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.
- No. 0165, 2½ x 6 hexagonal extra thin-super mill in fair condition. Price \$10.00.

- No. 0183, 2½ x 6 hexagonal thin-super mill in very good condition. Price \$14.00.
- No. 0211, 2½ x 10 hexagonal light-brood mill in poor condition; rolls quite badly pitted; will make fair foundation. Price \$13.00.
- No. 0230, 2½ x 10 hexagonal medium-brood mill in fair condition. Price \$18.00.
- No. 0233, 2½ x 10 hexagonal medium-brood mill in poor condition; cells bruised. Price \$14.00.
- No. 0234, 2½ x 6 extra thin-super mill in very good condition. Price \$12.00.
- No. 0237, 2½ x 6 thin-super mill in fair condition. Price \$10.00.
- No. 0238, 2½ x 6 thin-super mill in fair condition. Price \$10.00.
- No. 0239, 2½ x 10 medium-brood mill, hexagonal cell, in fair condition. Price \$18.00.
- No. 0242, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0242, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0243, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.
- No. 0244, 2 x 10 round-cell medium-brood mill in good condition. Price \$14.00.
- No. 0245, 2 x 10 hexagonal medium-brood mill in very good condition. Price \$18.00.
- No. 0246, 2½ x 10 hexagonal medium-brood mill in good condition. Price \$20.00.

THE A. I. ROOT COMPANY, Medina, Ohio.

## SPECIAL NOTICES

BY A. I. ROOT

### FATHER, GRANDFATHER, GREAT-GRANDFATHER.

Real manhood, it seems to me, commences when somebody begins to call a man “father.” And when it comes to being called “grandfather” he ought to realize a greater responsibility is resting on his shoulders; and if a kind Providence permits him to live until he is a *great-grandfather*, he should feel, especially if he is in the full enjoyment of his faculties, that there is a still greater reason for devoutly thanking God for having permitted him to live so long. And what I have had to say about fatherhood applies, of course, with as great (or greater) force to motherhood. The above remarks are prompted because on Sunday morning, May 21, Mrs. Root and I could thank God that he had permitted us to see not only our children's children, but were permitted to welcome into this world or ours *one great-granddaughter*, Rebecca Ellen Calvert. At this time, May 27, both mother and baby are doing finely.

Perhaps I should add that the father and mother of this new arrival are Mr. Howard R. Calvert and the daughter of Mrs. H. G. Acklin, mentioned on page 646, Aug. 1, 1915. “Howard” is the eldest of our oldest daughter “Maude,” and Mr. J. T. Calvert, General Manager of The A. I. Root Co.

### “THE GOOD TIME COMING.”

*Mr. A. I. Root*:—I have just read your temperance talks in Feb. 1st GLEANINGS, and am thanking God for the progress that common sense and righteousness are making, and for a few fearless men like you and Billy Sunday who keep constantly fighting the great evils of our country. We will secure a few more recruits, and make a few more charges, and, with the help of God, victory will be ours.

You and I are old, and may not live to see the blessed day; but earth shall glisten in the ray of the good time coming, boys, the good time coming, when the saloon will be a reminiscence of the darker days of the past.

While you have on your war-paint in opposing the saloon, there is another evil that needs the batteries of all righteous people turned upon it, and that is the pool hall. Of itself it is not so formidable an enemy of God; but in dry territory, at least, it is a bureau of evil information where the thoughtless youth can always find some one who can direct him to the boot-legger, the harlot, or the gambling-den. I pray God that they and the saloon may go down together.

D. W. HOLLAND.  
Geuda Springs, Kan., Feb. 14.

| The Swarm, Maeterlinck.....               | 1.40 |
| The Bee-master of Warrilow, Edwards.....  | .57  |
| Lore of the Honeybee.....                 | 2.00 |

Alexander's Writings on Practical Bee Culture. By the late E. W. Alexander, who conducted the largest apiary in the United States. A wonderfully interesting discussion of beekeeping in its broadest phases. Any one can understand it; 35 chapters, 95 pages. Paper bound, 50 cts. postpaid.

The Management of Out-apinaries. By G. M. Doolittle. Packed full of most valuable information ever given to beekeepers. A practical and interesting book by a very successful apiarist. Sale has reached nearly 5000 copies; 60 pages, paper bound, 50 cts. postpaid.

## MISCELLANEOUS HAND-BOOKS.

|                                                                                                                                          |    |
|------------------------------------------------------------------------------------------------------------------------------------------|----|
| A B C of Carp Culture, by Geo. Finley (post-<br>age 5 cts.).....                                                                         | 25 |
| A B C of Potato Culture, by Terry. New edition,<br>revised and enlarged; paper, 50c; cloth, 75c; mail,<br>85 cts. (postage, 7 cts.)..... |    |

This is T. B. Terry's first and most masterly work. It has really made a revolution in potato-growing, and has been reprinted in several foreign languages. By getting the ground in proper condition to grow great crops of clover, and turning this under, Terry succeeded not only in getting *more* potatoes, but even *better* ones, and in producing them at less expense also, than by any plan or system before the time he began his experiments in 1885. This book has already passed thru three editions of many thousands. It not only includes potato-growing in the United States, but in Bermuda, the Island of Jersey, and other warmer parts of the world where "new potatoes" are raised for the express purpose of getting the high prices in the cities during January, February, and March. The book also gives special attention to the different and best methods for preserving and keeping *seed* potatoes in the very best condition to plant in all these different localities.

A B C of Strawberry Culture, by T. B. Terry. New edition, revised and enlarged; paper, 45c; cloth, 68 cts.; by mail, 75 cts.

After Terry's potato-book had obtained such a kind reception from farmers, market-gardeners, and others, he was induced to give his plan of growing strawberries, as he did potatoes, by plowing under great crops of clover, and, like the potato-book, his writings gave a new impetus to strawberry growing; in fact, some of his pupils declare that, aside from the picking, they can grow strawberries almost as cheaply per bushel as potatoes. By following Terry's teachings thousands of people have not only been able to give their families but the whole wide

world better strawberries, and more of them, than they ever saw before.

|                                                                        |     |
|------------------------------------------------------------------------|-----|
| Asparagus Culture (postage 6 cts.).....                                | .40 |
| Alfalfa Culture (postage 6 cts.).....                                  | .40 |
| Barn Plans and Out-buildings.....                                      | .90 |
| Fruit Harvesting, Storing, Marketing, etc. (post-<br>age 10 cts.)..... | .75 |

It has been well said that it is an easier matter to grow stuff than to sell it at a proper price after it is grown; and many men fail, not because they are inexperienced in getting a crop, but because they do not know how to sell their crops to the best advantage. This is the first book of the kind we have had as an aid in selling. It not only tells all about picking, sorting, and packing, and gives all the best methods for storing for one or two days or a longer time. It also tells about evaporating and canning when there is a glut in the market. It discusses fruit packages and commission dealers, and even takes in cold storage. It is a new book of 250 pages, full of illustrations. Publisher's price, \$1.00.

The Lure of the Land; Farming after Fifty..\$1.50

A most valuable book, just out, by Dr. H. W. Wiley, formerly Chief Chemist of the United States. You want this book in order to be able to distinguish real science from popular humbugs if for nothing else. No man at the present day is better prepared, in my opinion, to give us facts than Dr. Wiley, who for so many years held his important office. Price \$1.50 postpaid; or the book and GLEANINGS one year for \$2.00.

Farming with Green Manures, postpaid..... .90

This book was written several years ago; but since competent labor has got to be so expensive and hard to get, many farmers are beginning to find they can turn under various green crops much cheaper than to buy stable manure and haul and spread it—cheaper, in fact, than they can buy fertilizers. This book mentions almost all plants used for plowing under, and gives the value compared with stable manure. Some of the claims seem extravagant, but we are at present getting good crops and keeping up the fertility by a similar treatment, on our ten-acre farm.

Farm, Gardening, and Seed-growing; postage 7c .90

|                                               |        |
|-----------------------------------------------|--------|
| Fuller's Grape Culturist (postage 10c).....   | \$1.15 |
| Garden and Farm Topics, Henderson, postage 5c | .60    |
| Gardening for Pleasure, Henderson, post. 12c  | 1.10   |

While "Gardening for Profit" is written with a view of making gardening *pay*, it touches a good deal on the pleasure part, and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds, without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 246 pages and 134 illustrations. (Retail price \$2.00.)

Gardening for Profit (postage 12c)..... \$1.10

This is a late revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, altho we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts. (Retail price \$2.00.)

Gardening for Young and Old, Harris, postage 8c .90

This is Joseph Harris' best and happiest effort. Altho it goes over the same ground occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing your ground, and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.

|                                                                       |     |
|-----------------------------------------------------------------------|-----|
| Grasses and Clovers, with Notes on Forage<br>Plants (postage 3c)..... | .20 |
|-----------------------------------------------------------------------|-----|

This is by Henry A. Dreer, author of the book "Vegetables under Glass" that has had such a large sale of late. This little book tells how six tons of grass has been grown to the acre, and gives much other valuable matter.

Greenhouse Construction, by Prof. Taft (post-  
age 10c) ..... \$1.15

This book is of recent publication, and is as full and complete in regard to the building of all glass structures as is the next book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.

Greenhouse Management, by Prof Taft (post-  
age 12c) ..... \$1.15

This book is a companion to Greenhouse Construction. It is clear up to the times, contains 400 pages, and a great lot of beautiful half-tone engravings. A large part of it is devoted to growing vegetables under glass, especially Grand Rapids lettuce, as well as fruit and flowers. The publisher's price is \$1.50; but as we bought quite a lot of them we can make a special price as above.

Gregory on Cabbages, paper (postage 5c).... .20  
Gregory on Squashes, paper (postage 5c).... .20  
Gregory on Onions, paper (postage 5c)..... .20

The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.

Handbook for Lumbermen ..... .05  
Home Pork-making; 125 pp., illus., post. 5c. .40

I think it will pay well for everybody who keeps a pig to have this book. It tells all about the care of the pig, with lots of pictures, describing cheap pens, appliances, all about butchering, the latest and most approved short cuts; all about making the pickle, barreling the meat, fixing a smoke-house (from the cheapest barrel up to the most approved arrangement); all about pig-troughs; how to keep them clean with little labor; recipes for cooking pork in every imaginable way, etc. Publisher's price is 50 cts.; ours as above.

How to Make the Garden Pay (postage 15c) \$1.35

By T. Greiner. Those who are interested in hot-beds, cold-frames, cold green-houses, hot-houses, or glass structures of any kind for the growth of plants, cannot afford to be without this book. Publisher's price, \$2.00.

How to Keep Well and Live Long (post. 10c) .90

The above book by T. B. Terry is, in my opinion, destined to relieve more pain, sickness, and death than any other book in the whole world that has ever come to my knowledge. That is pretty strong language, I admit; but since Terry commenced, years ago, to urge the importance of pure air, pure water, and a simple diet of good simple food, in moderate quantities, the whole wide world, doctors included, seems to be gradually falling in with him. Of course other good and wise men commenced a similar crusade for better health long before Terry did; but he seems to have a happy faculty of getting hold of people and keeping their attention. After you once start in with the book you will be pretty sure to read it to the end, and you will ever after be a better and happier man or woman for having read it. We have a special low price for clubbing with GLEANINGS—that is, both for \$1.50. If you have already paid for GLEANINGS a year or more in advance you can have the book for 75 cents postpaid. Since it first came out, only a short time ago, we have sold nearly 1000 copies.

Maple Sugar and the Sugar-bush (post. 3c) .25

Manures: How to Make and How to Use

Them; in paper covers (post. 5c)..... .30

The same in cloth covers (postage 6c)..... .65

Nut Culturist, postpaid ..... \$1.25

Onions for Profit (postage 3c)..... .40

Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with all the author's enthusiasm; and even if one is not particularly interested in the business almost any person who picks up Greiner's books will like to read them thru.

Practical Floriculture, Henderson (post. 8c) \$1.10

Small-fruit Culturist, Fuller ..... .75

Experiments in Farming, by Waldo F. Brown

(postage 2c) ..... .08

This little book ought to be worth its cost for what is said on each of the four different subjects; and

the chapter on cement floors may be worth many dollars to anybody who has to use cement for floors, walks, or anything else. In fact, if you follow the exceedingly plain directions you may save several dollars on one single job; and not only that, get a better cement floor than the average mason will make.

Our Farming, by T. B. Terry (postage 10c) .75

Same, paper cover, postpaid..... .50

In which he tells "how we have made a run-down farm bring both profit and pleasure."

If ordered by express or freight with other goods, 10 cts. less.

Talks on Manure (postage 10c)..... \$1.35

By Joseph Harris. Written in conversational style, which makes it very interesting reading. It covers the subject very completely; contains numerous analyses of manures and comparative tables. The use of technical language is avoided, which makes the book of greatest value to the practical farmer. A book of 366 pages, nicely bound in cloth.

The Dollar Hen (postage 10c)..... .90

The above book will be clubbed with GLEANINGS for one year at \$1.50; or if you have already subscribed a year or more in advance you can have the book postpaid for 75 cts.

My opinion is, that "The Dollar Hen" is not only one of the best books on poultry that we have at the present time, but it is worth nearly as much as a dozen other books. Perhaps this is extreme, but we have very few books that are strictly up-to-date, and still fewer that pitch right into the superstitions and humbugs now scattered all thru our poultry books and journals.

The New Rhubarb Culture (postage 5c)..... .40

Whenever apples are worth a dollar a bushel or more, winter-grown rhubarb should pay big. It does not require an expensive house nor costly appliances. Any sort of cellar where it will not freeze is all right for it; and the small amount of heat necessary to force the rhubarb costs very little. The book is nicely bound in cloth, full of illustrations, mostly photos from real work. 130 pages. Every market-gardener should have this book for the lessons taught indirectly in regard to forcing other crops besides rhubarb. Publisher's price 50c.

Tile Drainage, by W. I. Chamberlain (post. 5c) .45

Fully illustrated, containing everything of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in doing almost anything else; and by following the plan directed in the book, one man will often do as much as two men without this knowledge.

Tomato Culture (postage 5c)..... .35

In three parts. Part first.—By J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South with some remarks by A. I. Root adapting it to the North. Part second.—By D. Cummins, of Conneaut, O., treats of tomato culture especially for canning factories. Part third.—By A. I. Root, treats of plant-growing for market and high-pressure gardening in general.

Winter Care of Horses and Cattle (postage 3c) .25

This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in a book. It has 44 pages and 4 cuts.

What to Do, and How to be Happy while Do-  
ing It (postage 8c)..... .65

The above book by A. I. Root is a compilation of papers published in GLEANINGS IN BEE CULTURE in 1886, '87, '88. It is intended to solve the problem of finding occupation for those scattered over our land out of employment. The suggestions are principally about finding employment about your own homes. The book is mainly upon market-gardening, fruit-culture, poultry-raising, etc. Illustrated, 188 pages; cloth.

Same, paper covers (postage 8c)..... .40

Notice.—Having a large stock of this last book on hand, May 15, 1916, we reduced the price to cloth bound, 25c; paper, 15c postpaid.

THE A. I. ROOT CO., MEDINA, O.

# HONEY - CANS

---

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

---

## Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

---

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

---

## Toepperwein & Mayfield Co.

Nolan and Cherry Sts.

San Antonio, Texas

# The Hooker Crate-opener

---

A high-grade handy tool for prying off lids, pulling large or small nails, hammering, etc.

---

Useful alike to the man of the family and to the housewife who so often needs a handy tool of this kind.

---

Showing how to pull a nail with the slot in the side of the tool.

THE HOOKER CRATE-OPENER is forged from a bar of **fine-quality steel**. ALL IN ONE PIECE.

It is hardened and tempered and is almost indestructible. Gun-metal finish. No wooden handle to split when you begin to pry.

## A Hooker Crate-opener a Premium for only ONE NEW yearly "Gleanings" Subscription

Introduce GLEANINGS to beekeepers in your locality and send us a **new yearly subscription** with remittance of \$1.00, for which you will secure a HOOKER CRATE-OPENER in return for your trouble.

Canadian postage 30 cts. extra.

**OLIVER**  
The Standard Visible Writer

Its record has never been equaled.

Catalog free.

Oliver Typewriter Co.

946 Prospect Avenue, Cleveland, Ohio

You can rent an Oliver three months for \$4.00.

## MYERS JACKS

A Myers Pump, a Myers Jack, and a Gasoline Engine furnish a dependable water supply for the average requirements.

Myers Jacks are easy to connect to any windmill head pump, without disarranging the pump or pipes in any manner. They are neat in design, well proportioned, and sturdily built. The side arms are steel or tough wood and so constructed that the cross-head can be raised or lowered to suit different height pumps. The gears are machine-cut. These are some of the reasons that Myers Jacks are favorites.

Write for circular showing all styles including the new type for operation by electric motor.

F. E. Myers & Bro., Ashland, Ohio

No. 351 Orange Street

### YOUR SUCCESS IN BEEKEEPING DEPENDS ON the kind of bees you keep and how you handle them.

Blanke's 68-page book is not merely a catalog; it is an authoritative expert guide on the kind of apiary supplies that successful beekeepers have proved to be profitable in actual use. Blanke carries the largest stock of bee supplies west of the Mississippi, and can make prompt delivery. Every article carried is perfect fitting. Whether you're a beginner or an expert beekeeper, you ought to get the Blanke Bee Book -- send for it today.

#### Fine Poultry Book also Free

If you keep poultry too, ask us for illustrated poultry book; full of valuable pointers on poultry-raising as well as a catalog of profitable poultry supplies.

**BLANKE MFG. & SUPPLY CO.,** Pioneers in Bee, Poultry, and Dairy Supplies, 207 Washington Ave., ST. LOUIS, MO.

THE FRED W. MUTH CO.

204 Walnut Street

Cincinnati, Ohio

## EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur while in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A postcard will bring it to your address free.

## HONEY GRADING RULES

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL., FEBRUARY 6, 1915.

### COMB HONEY

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades*

- Honey packed in second-hand cases.
- Honey in badly stained or mildewed sections.
- Honey showing signs of granulation.
- Leaking, injured, or patched-up sections.
- Sections containing honey-dew.
- Sections with more than 50 uncapped cells, or a less number of empty cells.
- Sections weighing less than the minimum weight.
- All such honey should be disposed of in the home market.

### EXTRACTED HONEY

This must be thoroughly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each

five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

### STRAINED HONEY

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

- Extracted honey packed in second-hand cans.
- Unripe or fermenting honey weighing less than 12 lbs. per gallon.
- Honey contaminated by excessive use of smoke.
- Honey contaminated by honey-dew.
- Honey not properly strained.

### NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES

*Adopted at Cincinnati, Feb. 1913*

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

#### I. FINISH

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

#### II. COLOR

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

## III. WEIGHT.

1. *Heavy*.—No section designated as heavy to weigh less than fourteen ounces.
2. *Medium*.—No section designated as medium to weigh less than twelve ounces.
3. *Light*.—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F-W-H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

## CULL HONEY

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

## HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

ST. LOUIS.—The demand in this market for comb honey has been very light, and not enough selling to make firm quotations. Extracted honey has been in good demand, and we believe this market is almost cleaned up of last year's stock, and new honey will meet with a good demand. No. 1 bright amber comb honey is bringing \$3.00 per case; No. 2, \$2.50 per case; under grades, less. Southern extracted honey, amber, in barrels brings from 6 to 6½; in cans, 7 to 7½; dark, ½ to 1 ct. per lb. less. Beeswax is firm at 30½ for prime; impure and inferior, less.

R. HARTMANN PRODUCE CO.

St. Louis, June 6.

ALBANY.—Very little honey is moving on this market now. The extracted honey is all sold, and some comb honey unsold. This is the off month for this market. Demand will not begin again until August. Beeswax brings 28 to 30.

Albany, June 5.

H. R. WRIGHT.

CHICAGO.—Very little honey has been sold during the past two or three weeks. Comb honey is selling at 12 to 13 for the white grades, and ambers from 1 to 2 cts. per lb. less. Extracted brings 7 to 8 for the white grades, and 6 to 7 for ambers. Beeswax brings 30 to 32, according to color and cleanliness.

Chicago, June 5.

R. A. BURNETT & Co.

INDIANAPOLIS.—Comb honey as well as extracted is moving very slowly at this time. This, of course, is due to the weather conditions. Comb honey is selling from \$3.50 to \$4.00 per case. Extracted is bringing 9 to 11 cts. We are paying producers 28 cts. cash or 30 in trade for good average wax delivered here.

Indianapolis, June 5.

WALTER S. POWDER.

DENVER.—Local demand for comb honey light with ample supply. We are selling in a jobbing way as follows: No. 1, per case of 24 sections, \$2.93; No. 2, \$2.70. White extracted, 8½ to 8¾; light amber, 8 to 8¼; amber, 7 to 8. We pay 26 cts. per lb. in cash and 28 cts. per lb. in trade for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.  
Denver, Col., June 6.

F. Rauchfuss, Mgr.

ZANESVILLE.—Honey is in pretty good demand, with quotations practically unchanged. Locally stocks, except western, are pretty well cleaned up. With normal weather conditions there will be better than an average crop of white-clover honey in the north-central states. While the market may remain firm for a time, some weakening after, say, thirty days would not be surprising. Comb is selling at \$4.00 a case down, according to quality and quantity. Extracted is in limited demand, with prices 9 to 11. For beeswax, 29 cts. cash, 31 in trade, is offered for good average grades.

Zanesville, June 5.

E. W. PEIRCE.

KANSAS CITY.—There has been no new honey on the market. There are a few cases of honey, No. 1 selling at \$2.75 to \$3.00, and some No. 2 stock selling at \$2.50 to \$2.75. This stock is showing a more or less candied condition. The demand for extracted honey is better. The market seems to be cleaning up quite rapidly, prices ranging from 6 cts. for dark amber to 7½ for real light amber. There is no strictly white extracted honey on the market. Beekeepers report the condition of the bees good, and the outlook is for a good flow of honey.

C. C. CLEMONS PRODUCE CO.

# Queens! Queens! Queens!

We will make a specialty of shipping Queens, Nuclei, and Full Colonies from Florida during the present month. We are breeding from queens that produced a surplus of 300 pounds per colony in a 24-day honey-flow in Florida, and that are unexcelled for prolificness, gentleness, and honey-gathering.

When you order queens from us you get **QUALITY, PURITY, AND HONEY-GATHERERS**. We can fill your orders from our famous Honey-gathering Strain for Queens, Nuclei, and Full Colonies promptly, and guarantee safe delivery and entire satisfaction to you in every respect. Our aim is to give you the best stock on the market at the time you want it. Write for special price on orders of 50 or more. We ask you to give us a trial and let us prove to you that our stock is unexcelled by anything on the market.

## There is Money in Our 3-banded Italian Bees

20 Years of Select Breeding Gives Us Queens of Highest Quality

### Queens for Honey Production - - Queens of Unusual Vitality

Our select colonies used for breeding purposes, larvæ and select drones are those of the highest standard, the choice of over 1000 hustling, honey-producing colonies of pure Italian bees. These select colonies are located at such a distance from all other bees as to assure pure mating, and thus very effective use of our select drones. The larva we use in grafting is as small as can be seen and handled, having just come out of the egg. These are placed in cells which in turn are placed and nourished in strong ten-frame colonies, which, when honey is not coming in sufficiently, are heavily stimulated by feeding. Thus we get cells that produce large, long-lived, and hardy queens, which give workers unexcelled as honey-producers. We use no baby nuclei. All our queens are hatched and reared in strong three and five frame full-depth hives. Thus natural conditions are preserved.

All orders will be filled promptly by return mail or soon. We have no disease of any kind. Satisfaction and safe arrival we guarantee.

|                                                       |                                                    |
|-------------------------------------------------------|----------------------------------------------------|
| Select untested . . . 65 cts. each or \$60.00 per 100 | Tested . . . . . \$1.00 or \$90.00 per 100         |
| Untested . . . . . 50 cts. each or \$45.00 per 100    | Select tested . . . . . \$1.25 or \$115.00 per 100 |

All queens are warranted purely mated. Wings clipped free of charge.

# Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted----

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

## "If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

# NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers --in short, everything the beekeeper requires for the proper conduct of an apiary.

**C. H. W. Weber & Company, Cincinnati, O.**  
2146 Central Avenue

## What do you know about that

We are getting an almost innumerable number of orders to go by parcel post -- a great thing for beekeepers on rural delivery. **BUT REMEMBER** to always include enough in the amount sent to cover the postage required. . . .

For instance, if you are within 150 miles of Syracuse, and need 500 sections, we can mail them for 41c; 250 sections for 21c, and 100 sections for 11c. Foundation in 5-lb. lots, can be mailed for 11c; 2 lbs. for 7c; 1 lb. for 6c. Always figure postage more than foundation weighs. Rates inside of 150 miles once the total weight plus 4.

**F. A. SALISBURY, Syracuse, New York**  
1631 West Genesee St.

# Make This a Lewis Year

While you are starting the year's work--getting your bees ready for business--taking stock of supplies on hand and speculating as to what the season's outcome will be

## Make This Resolution

That you will use LEWIS BEEWARE this year—because it means success insurance to you—because it means beehives and parts made of the best material by skillful workmen—because it means goods accurately and systematically packed—because it means sections made of bright lumber, highly polished, accurately dovetailed, and scientifically grooved.

## Lewis Hives are Built Like Furniture Lewis Sections are the Kind that do not Break in Folding

You will find LEWIS BEEWARE almost at your own door—thirty distributing houses in the United States and foreign countries. If you have not one of our catalogs send for copy at once.

G. B. Lewis Company, Watertown, Wis., U.S.A.  
Exclusive Manufacturers Lewis Beeware

# DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

## Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me.  
A. W. DARBY, Alburg, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

Dadant & Sons, Hamilton, Illinois

NO. 12

## EDITORIAL

Mr. M. W. HARVEY, in this issue, gives some good orthodox advice on the control of swarms at outyards—see page 490.

### Our Cover Picture

THAT the straw skep is not a relic of the past in every country is shown by the picture reproduced on the cover, sent by Hans Matthes. Mr. Hamelberg, in his article, page 481, explains why the straw hive is still used so extensively in Holland.

### Honey as a Food

THE honey salesman should not fail to read very carefully the article by J. H. Heberle in this issue. The German chemists have proven that honey is more easily assimilated by persons of weak digestion than is ordinary cane sugar; and they explain why this is so.

### A Long-time Subscriber

ONE of our subscribers, Mr. J. B. Ratcliffe, Amboy, Minn., sent in his check to cover five years renewal for GLEANINGS, making thirty-eight years of continuous subscription. We wonder how many others there are who have been with us this length of time.

### Drifting

MR. R. F. HOLTERMANN, page 491, has not had the same experience, apparently, with his bees drifting in his big quadruple winter cases that we have had. He suggests that if we have the entrances arranged so they will face all points of the compass there will be no drifting. That is exactly what we did have, yet we had a great deal of drifting. Time and again, colonies that were very strong would become very weak, or one that was very weak became very strong.

We were well pleased with the big winter cases except in this one particular.

### Honey Butterscotch

HERE is a recipe for some good old-fashioned butterscotch. You can't get enough of it, and it won't hurt you for it's nearly all honey.

Boil two cups of honey until it hardens when a little is dropped into some water. Stir the latter part of the time, taking care not to let it burn. Stir in half a cup of melted butter, add  $\frac{3}{4}$  teaspoonful of salt, and flavor with vanilla. Pour on to a cold greased platter, and, when cool, cut into squares and wrap in oiled paper. Wrapping is quite important, as, unless the candy is kept away from the air, it will gather moisture and become sticky.

### How Bees Made a Cherry Crop Possible

MR. E. WHITCOMB, a former president of the National Beekeepers' Association, and one of the prominent beekeepers of Nebraska, reports in the *Independent Farmer* of May 25 how his bees made it possible for him to secure a big crop of cherries when other cherry-growers, without bees, secured none. He says:

We had 300 bearing cherry-trees close to our apiary. During the blooming season there were two days during which our bees worked on these cherry-blossoms profusely. As a result we harvested 300 bushels of cherries when our neighbors two or three miles away, who had no bees, and whose trees bloomed as profusely as did ours, were compelled to come to our orchard for cherries.

PROF. M. B. WAITE, of the United States Department of Agriculture, among other things he has given to the public on the subject of the relation of bees to horticulture, says:

"Out of 2586 blossoms covered with gauze netting, only three apples set fruit. Of these the Baldwin, Spitzenburg, and Fameuse set some fruit. The Baldwin, which is often self-fertilized, gave four times better results when cross-pollinated. Cross-pollinated apples were larger, more highly colored, and better supplied with seed."

## A Remarkable Clover-honey Year in Prospect

NOT in years have the prospects for clover honey over the country generally been so favorable as this year. The U. S. weather maps show that there have been copious rains thruout most of the clover districts. The rains of this season have pushed them forward still more. Unless cold and rainy weather continues thruout the blooming period there will be clover honey this year galore unless—well, wait.

Honey has been yielding well from a good many sources in the southern states. Altho the season was partly a failure in Florida it has been good in Texas. Conditions have been favorable for alfalfa in most of the western districts. The season will not be a failure in California.

## Successful Shipments of Pound Packages of Bees from the South

THE Penn Co., of Penn, Miss., report that they have shipped 1000 different packages of bees without combs, and the loss has been insignificant. W. D. Achord, of Fitzpatrick, Ala., apparently has not had as good results, for he says he has put in claims of over \$500 against the express companies for delays in shipment.

We have been shipping bees from our southern apiary in combless packages to our Medina yard. When the weather is not too hot they arrive in fine condition. But it is evident that the express companies must learn the importance of keeping bees out of the sun, and putting them thru as speedily as possible.

## There are Dollars in it; a Kink in Feeding

THOSE who are making increase will doubtless be interested in the reply to Dr. C. E. Blanchard, in the Heads of Grain department, page 496. In raising queen-bees, at least, we have proven one thing to our satisfaction—that the food supply for a cell-building colony must be continuous and very slow. Any feeder that gives to the bees a large amount of food all at one time, or even a few ounces in a few hours, is not suitable for stimulating. The Boardman one-hole feeder, or any feeder where the supply can be regulated down to a minimum, will produce more bees and more cells and more queens than any other feeder. With it a quart of feed can be made to last for two or three days, depending on the size of the colony. At the present price of

sugar climbing up to 10 cents it pays to have an economical feeder. A feeder like the Alexander, for example, where the bees can empty it in a couple of hours, starts the bees to rushing out of the hives in an uproar, and is quite liable to start robbing. With the Boardman stopped down to one hole there is no excitement, no rushing from the hive, but a continuous supply of food for cell-building, and brood-rearing goes on without a let-up.

Time and time again we have had fine batches of cells destroyed because there would be a few hours when there would not be a continuous supply of feed.

While this is something of a repetition of what we have stated already elsewhere, it is something that will bear repetition until beekeepers grasp the principle, *for there are dollars in it.*

## The Ford Automobile for Out-apiary Work

FOR the first time in our experience we are using the Ford in place of our heavier machine at higher prices. We find the expense of operation about one-third that of the heavier machine. These little Fords of three-fourths ton weight will go where the ton and 1½-ton machines cannot. With their narrow tires they will run in ordinary wagon or buggy ruts, where the tires of the larger machines can scarcely travel. Just recently we put on the rear of our little Ford a light truck body; and we find that, while the little light outfit will not carry as heavy a load as the larger machine, yet it goes so much quicker and at so much less expense that we are using the Ford in place of the heavy truck about nine to one.

## Are the Allies Using Honey in Place of Sugar for their Armies?

A YEAR ago cheap honey from the South was begging a customer; but now the condition is changed. Large amounts of honey are being exported, presumably for the armies of the Allies. The soldier is supposed to have a balanced ration, and sugar is important as one of the foods. When sugar is expensive, why not substitute honey? Sugar has gone up to such a high price that honey is actually cheaper, and is, of course, a better food.

The great nations of the world that are compelled to economize doubtless see this, and the result is that extracted honey will probably be firm during the coming season, even in spite of the prospect of a big crop.

While the great armies of the world are

possibly using honey, the extensive advertising of the A. I. Root Company in placing honey in families where it has never been before is doing its part. Many, some of whom are competitors, are hoping that the Root Company will continue its campaign of advertising honey.

### How European Foul Brood Spreads; a Plausible Explanation

IN this issue, page 479, Mr. Allen Latham, an unusually close and careful observer, has an article that is worth a careful reading—not only on the part of one who has European foul brood but the one who *may* get it, and the latter class is by no means small. His theory, that the spread of the disease may come thru an infected water supply from the fecal discharges of nurse bees from diseased hives, may have something in it. It is very clear that European foul brood does not spread in quite the same way that American does. If Mr. Latham's theory can be proven to be correct, it will help us materially in combating the disease.

That the disease can be held in control, or cured by the introduction of a mild acid in the food supply, does not seem quite so plausible in view of the fact that liberal feeding without medication or a good honey-flow will nearly always check European foul brood, and sometimes cure it. However, the plan is worth trying. Possibly the bacteriologist under Dr. Phillips could determine whether a mild acid is destructive to the *Bacillus pluton* that is the cause of European foul brood.

### Exaggeration in Advertising; a U. S. Supreme Court Decision

EVERY now and then an advertiser, while giving value received, in order to get business will make extravagant claims. Not long ago an advertiser in our columns made claims concerning his queens that we regarded as extravagant and impossible, and we wrote him, requesting that he remove the objectionable feature; but he demurred. We insisted, and he finally complied. We were uncertain at the time whether we had the legal right to withdraw the objectionable sentence; but we came to the conclusion that we would stand damages if necessary.

We now learn that the Supreme Court of the United States has handed down a decision to the effect that an advertiser is guilty of fraud if by exaggerated advertising he secures business, even tho he gives value received. For example, a real-estate agent

may make certain plausible but impossible claims concerning the productiveness of lands he advertises. He makes sales, and the properties are worth the price paid for them. But according to the Supreme Court it is a fraud if that advertiser makes exaggerated claims that are not true, and a fraud order may be issued against him, shutting him out from the mails even tho the price charged is fair.

*The Rural New-Yorker*, in commenting on this decision, says, "It certainly squares with common honesty and decency in business transactions. Too many otherwise perfectly honorable concerns consider they are licensed to make all sorts of unwarrantable claims in their advertising so long as they are giving fair value for the money they received. We are glad to see the Supreme Court put the stamp of dishonesty on unwarranted advertising claims."

We hereby give notice to our advertisers that we shall exercise our discretion in removing objectionable statements — statements which, in our judgment, are calculated to catch customers, even tho those customers receive full value for their money.

### Granulation of Comb Honey; the Results of an Experiment Covering Three Months

WE believe it is a generally recognized fact that honey, either comb or extracted, if subjected to *variable* temperature will granulate more readily than the same honey kept at a constant temperature, either high or low. It has also been proven beyond question that a cold atmosphere is much more conducive for making honey go into a solid state than a warm one.

To demonstrate the first proposition, we made up a case containing a few sections from the West, a few from the middle West, and a few from the East, of clover honey. The lot was put indoors and outdoors every day beginning Feb. 1 until last week. Results: One of the samples granulated solid; the other two remained entirely free from granulation. Contrary to expectations, the two last named did not granulate in spite of the extremes of temperature during the February, March, and April weather almost down to zero at times, and up to 80 or 90 at night. This puzzled us not a little until we remembered that those three lots of honey had been kept prior to that time and continuously at a temperature of 90 F., since the first of November. That high temperature, without any variation, had put the honey in a state where any subsequent

treatment would not be likely to make it granulate. While one of the samples did turn to a solid condition, the other honey remained as liquid as when produced, and was in a fine condition.

This brings out one point that is worth considering. A long-continued temperature of 95 or 96, or even 100, for two or three months, may insure some grades of comb honey against granulation even when subsequent conditions are favorable.

It is a well-known fact that, when *extracted honey* is heated to 130 F., and kept hot for two or three days, it will remain liquid much longer than the same honey if heated to 160, and kept hot for only about an hour. By prolonging the period of a lower warm temperature, almost the same results are secured for comb honey apparently. The lower the temperature down to, say, 70 F., the longer it must be kept at that point to insure against granulation.

Taking these facts into consideration, the comb-honey buyer will seek to keep his honey in a warm or even hot room up to about 100 degrees, and hold it there to prevent early granulation the following summer or fall.

### The Next Edition of the A B C and X Y Z of Bee Culture and the Frenchman who Thought all the World could Parlez-vous

WHEN a certain Frenchman left his native country he supposed that all the rest of the world could *parlez-vous* simply because he could. When the authors of the original A B C book put out the first editions of it they assumed that certain fundamentals in beekeeping were understood by every one; and the result was in some cases they shot a little over the heads of many of their readers; or, as the inimitable Hasty once said, they got the hay so high in the rack that some of the sheep could not reach it.

The new edition takes up the minutest details so that the beginner cannot fail to have a general groundwork of the business before he goes into the general art. For example, no previous edition has had a general article on "brood," altho many of the articles had something to say about it in a general way and considerable about foul brood. The new edition, now on the press, has a chapter on the subject, attempting to define what normal brood is in its different stages; how worker and drone brood may be distinguished, and how the cappings of either can be distinguished from the cap-

pings of comb honey. Of course, the veriest tyro in the business ought to know the difference between capped comb honey and capped brood, and, like the Frenchman, we thought everybody did. But if one has never seen either, how is he to know? The pictorial representation with the legend beneath, taken from our next edition, attempts to make this plain. See page 488, this issue.

### Education and Diplomacy versus the Strong Arm of the Law in Handling Foul Brood

ONE of our Ohio foul-brood inspectors, A. C. Ames, was in to see us the other day. In speaking of the foul-brood situation he remarked, "I have come to the conclusion that we need in Ohio and everywhere else a campaign of education. Foul brood is scattered all over the state. Many beekeepers are careless and indifferent, and so, of course, they eliminate themselves in time, but they leave behind them sources of infection. There are beekeepers of another class who are inclined to defy authority if the strong arm of the law is brought to bear to compel them to clean up. In that case they may or may not make trouble by scattering the disease out of pure revenge." He mentioned one case where one of the best beekeepers in the state is located. This beekeeper keeps his yard free from disease. Not far from one of his yards is a man who harbors disease, and apparently always will have it unless the state compels him to clean up. Said Mr. Beekeeper, "Oh! let him alone. I can keep disease out of my yards as it is; but I couldn't if he deliberately tried to put it there." If the inspector brings the law to bear, the other fellow will naturally infer that his neighbor "squealed" on him.

"One who has foul brood and who would resent compulsion has a powerful weapon," said Mr. Ames, "and diplomacy is far more potent with such fellows than the strong arm of the law, and a good deal safer for beekeepers in the immediate vicinity."

Incidentally Mr. Ames is one who believes we are going at the foul-brood situation in the country wrong end to. He holds that every state should have a campaign of education. This can be done by sending out extension workers who will instruct good beekeepers how to prevent and control disease, as the other fellows will eliminate themselves in the near future. The Ohio chief inspector, Mr. Shaw, hopes in time to get this kind of extension work started. If he does he will have the gratitude of the beekeepers of the state. Speed the day!

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

J. L. BYER, you are quite right, p. 430, in saying that "dysentery (?)" (isn't diarrhea the better word?) can be caused "without any cold weather, and by so short a confinement as five or six days."

I've known bees to spot their surroundings in summer, with no confinement whatever, apparently because badly scared. [The word "diarrhea" is more accurate than "dysentery;" but the latter term is a little smoother, and has become so engrafted into our literature that it seems impossible to make the change.—Ed.]

"FIRST covering the entrance with netting so that the bees would not fly out, the hive was placed in the house cellar," p. 398. Some beginner may understand that to mean that it is all right to have bees fastened in hives in cellar, which would be a mistake. Of course the netting was removed after the bees quieted down.

MRS. ALLEN, p. 428, either you have made a new observation or you haven't observed closely enough. It's the first mention I've seen of bees handling eggs with their antennæ instead of their jaws. [Evidently Mrs. Allen meant "mandibles" instead of "antennæ;" because, so far as we know, the latter are never used for any sort of work in the hive.—Ed.]

IF you have only a small amount of cappings, and want to drain all the honey out of them, here's a kink worth knowing. After letting them drain perhaps a day, put the cappings down cellar to finish draining, and the honey will become thin, and drain to the last drop. You can feed it to the bees, or use it for vinegar. An easier way is to let the bees clean the cappings. Put them in a shallow box, put something under one side of the box so as to make it slanting, and as often as the bees dig the cappings level turn the box around.

A. I. ROOT, in speaking a word in appreciation of the dandelion, p. 463, you might add a word as to the beauty of the flower. One who can look closely at it without admiring it is lacking in appreciation of the beautiful; and a bank thickly studded with the bright blooms is a thing to delight the eye. [A lot of good people in Medina think we scattered dandelion seed; in fact, practically every beekeeper, because his bees pollinate the dandelion blossoms so that all the seeds mature, is accused of the same thing, whether he lives in Medina or else-

where. It is these very people who see anything but beauty in something that requires constant warfare to keep it off a lawn.—Ed.]

R. F. HOLTERMANN, you say, p. 405, that "Colonies have been found with the swarming impulse week after week, altho I continue to break down the cells." That sounds as if you could prevent swarming by continuously killing cells. With me that's the unusual thing. Either the colony gives up starting cells after about the second round, or else it swarms without waiting for cells to be sealed. If I persist in killing, a persistent colony will swarm with an egg in a cell. You say, "If I could have foreseen this I would have shaken . . . as we all know such a colony will not gather the usual amount of surplus honey." By "such a colony" I suppose you mean one kept from swarming by continuously killing cells. Of course such a colony will not equal one that never thinks at all about swarming, but I don't notice such a great letting-up in colonies where cells are killed. At any rate, if I could keep a colony from actually swarming by continuously killing cells, I'd never think of shaking, for I believe shaking would interfere with the crop more than the sulking of swarmy bees, if they can be kept from going on to actual swarming.

"QUEENS dearly love to lay eggs in new comb," p. 437. My observation has shown that bees decidedly prefer old black combs for either eggs or honey; yet several times I've seen the statement that they preferred new comb, so that it is possible that, under some conditions, they do. Who can tell us what the conditions are? I can think of one; and that is, when drone comb is greatly desired and new drone comb is built. In that case I've known eggs to be laid in new comb a long way from the brood-nest. [We have noticed that queens seem to have a liking for new comb, particularly that built from foundation. It is not the newness of the comb or wax, but, rather, the physical condition—the convenience of the shallow cells. We have very often seen a queen take up with a partly drawn comb from foundation, and supposed that the reason for this was one of pure convenience, both for laying the egg and for determining whether the cell is eggless or broodless; for the queen in this neck of the woods always makes an inspection of the cell before she lays the egg. She will turn around unerringly and deposit the egg in the cell inspected.—Ed.]

J. E. Crane

## SIFTINGS

Middlebury, Vt.

I have just opened several hives that had European foul brood last year, and were treated by making queenless for a time. Some were given a young queen at the proper time. The brood in all looks healthy and free from disease.

\* \* \*

That item in editorial, page 302, April 15, containing the experience of E. D. Townsend in advertising, viz., that the advertising that brought best results was in women's journals of national circulation, is well worth remembering.

\* \* \*

I notice that O. L. Woodward reports on page 359, May 1, that European foul brood spread to those colonies immediately adjoining the one first discovered. It looks more and more as tho it spread from nursing bees entering the wrong hive.

\* \* \*

"Florida Sunshine!" Hurrah! A new department in GLEANINGS! This will be particularly enjoyable in that portion of the year when we have little sunshine in our northern skies. I spent nearly two days in Mr. Baldwin's charming home among the pines three years ago, and I believe no better man could be found for this department in all Florida than he.

\* \* \*

A little cloth-covered book of 64 pages has come to my table entitled "The Value of Sweet Clover." It is, I believe, the best-arranged treatise I have seen on this subject. It is by J. F. Sinn, of the Berry Seed Co., Clarinda, Iowa. The price, however, \$1.00, seems quite too high when you can get a well-illustrated bulletin containing even more matter by sending our cents to the International Harvester Co., Chicago.

\* \* \*

That little poem by Mrs. Allen, page 330, is well worth reading—not once nor twice, but many times, until we can catch its meaning in something of its fullness. The subject is one of the smallest objects in which we are interested, and yet we cannot comprehend the mysteries and wonders it holds in its tiny shell. And then to think that there are a thousand things all about us just as wonderful. Surely wealth is not altogether in gold and silver, or notes and bonds, or other material things.

\* \* \*

On page 167, Feb. 15, H. L. Case, F. Greiner, and W. F. Marks recommend past-

ing a label on each comb of honey, stating that "this section of honey (14 oz.) equals in food value 24 oz. of beefsteak, 30 oz. of codfish, 20 eggs, 11.2 oz. cream cheese, 2 quarts of milk," the whole costing \$1.52. Now I have had a very high opinion of the food value of honey; but this beats me. Would it not be better to say, "This section (14 oz.) of honey equals in food value any one of the following"—24 oz. of beefsteak, etc.? or put it as it is in the *American Bee Journal*, "14 oz. of beefsteak or 30 oz. of codfish," etc.

\* \* \*

Our friend Doolittle discusses drouths, page 144, Feb. 15, in an interesting manner, but does not tell us how they can be prevented. Like the poor, they are likely always to be with us. One hundred years ago this very year there was an unusual drouth in this section, with unusual cold, so it is handed down as the cold dry summer of 1816. A good crop of winter wheat matured that kept the people from starvation, and so it has been ever since—seasons of drouth and seasons of unusual moisture. In 1860 we had little rain in this locality until late in July, and stock had to be reduced to one-fourth the usual amount to winter. Almost every colony of bees died, and yet seed time and harvest have not failed, and we seem to get along fairly well.

\* \* \*

I see two editorials in GLEANINGS for May 1, along the line of sweet clover. With the eye of faith the editor sees our country "from the Atlantic to the Pacific, and from the Great Lakes to the Gulf," as a land flowing with milk and honey. He says that badly cured sweet clover fed to cows causes them to give more milk than other hay. The increase in the flow of milk from cows fed on this once despised weed has been noted in these parts, and it is a most important fact. As the country grows older and our cities larger, the demand for milk increases by leaps and bounds. Already the city of New York sends a daily train as far as northern New York, and on down thru Vermont, 350 miles, and loads up with milk packed in ice for the population of the city. Large quantities of milk or cream are used for ice-cream—a modern demand. Large amounts of cream are separated and sent to the cities daily, in addition to the milk. It looks now as tho the value of sweet clover would come quite as much from its ability to increase the flow of milk as the flow of honey.

# BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

While Dr. Miller and others had a time deciding whether queens at a certain stage of their lives "quacked" or "piped," weunses have produced a crop of over 35,000 pounds of bulk comb honey. A difference in locality.

\*\*\*

Rain, rain, rain, during the last several weeks, and pretty general over the greatest part of the southwest, except in the lower Rio Grande Valley. Altho preceded by a long drouthy period there has already been obtained thruout the mesquite sections a good crop of early spring honey from this source. Prospects for our usual honey crop are excellent too.

\*\*\*

While the beekeepers of the North were determining whether their bees would come out of winter quarters successfully, beekeepers of the great Southwest were busy—head over heels—making a honey crop from the mesquite. This began to bloom in March, a month earlier than usual, and yielded an excellent crop of very fine white honey—another matter of locality.

\*\*\*

It is interesting to note the great popularity of the automobile in beekeeping now. The change has come only during the last few years, altho a few beekeepers used them before. We could not get along without one. Our only regret is that we did not procure one several years ago, as we know now, from careful estimation, that we might be several thousand dollars better off if we had.

\*\*\*

Rabbit-spacing of frames as used by the late L. Stachelhausen is still kept up by his widow, Mrs. Stachelhausen, and her son-in-law, Ed. Dietz, who together continue the bee business formerly established by our old veteran "Father of Southern Beekeeping." Folded tin rabbits, notched to hold each plain all-wood shallow frame, are preferred by them to the self-spacing-frame feature. They operate more than 600 colonies.

\*\*\*

By our smoke method, and shaking out the few remaining bees as the supers are jerked off and the hives loaded immediately, it is possible to take off *more than a thousand pounds of honey in half an hour*. The writer holds an actual record of 1140 pounds of honey removed in exactly 28 minutes, a young lawyer friend, then a beekeeper, keeping the time.

"All work and no play makes Jack a dull boy" is an old saying with much truth in it. This applies to beekeepers too, and other folk. It is gratifying to note the change in GLEANINGS, that of devoting more space to the poetical and the comical side of beekeeping instead of giving only the good solid matter. Mrs. Allen and J. H. Donahey are both aiding in this direction by the contributions along their respective tendencies. This "kind of stuff" may not appeal to everybody, but some of us like a change from the ordinary once in a while.

\*\*\*

There has already been trouble in the Texas honey market this early in the year. Certain parties who felt they were not getting their share of the honey trade, consequently cut prices below the market figures. This was followed by others; and, as a result, market prices dropped one cent a pound all around. Such has also an ill effect in that the buyers have become reluctant about handling the product on account of the instability of prices, and so the beekeepers suffer. Shall we ever be able to get together, and, thru organized efforts, save our industry from these ruinous proceedings?

\*\*\*

## PREVENTING GRANULATION OF HONEY.

If every beekeeper would heat the extracted honey to a temperature of about 150 F. before sending it to market, there would be less complaint from dissatisfied customers, and a better sale of honey. Our experience has taught us to pack not a single package of honey, extracted or bulk comb, without first heating the liquid honey that goes into the finished package. While this does not insure against granulation again later, the heating does delay this long enough so that the honey may be sold and used before it might granulate again. This enables us to sell more honey instead of finding stocks of granulated honey on hand that cannot be readily sold off on account of the objection found to it on the part of the customers. There are a few consumers who actually prefer honey in the granulated form; but the great majority believe all honey in this state to be old honey, and not fit to use. Much of the most beautiful white honey this spring has caused trouble of this kind because it showed a great tendency to granulate within a few days after it was extracted. Heating all that we shipped out has prevented us any trouble of this kind, however.

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

At present writing, May 7, the saw palmetto (called also scrub palmetto (*Sabal megacarpa*) is just coming into bloom, and yielding a pound per hive a day in the neighborhood of Eau Gallie East Coast, about fifty miles below here.

It will be in full bloom here by the first or second week in June. Weather has been very dry, but that is no criterion of the yield. The year when the bloom looked the poorest, the yield was the best ever known. From six to eight pounds daily per hive has been reported from this source, and eight or nine is not unknown. This palmetto grows all over the "flatwoods" (the low pine-lands that overflow more or less during the rainy season), also along all water-courses, and on the edges of all heavy hammocks. The latter places are best, for there the bush grows to the height of eight feet or more, and yields best. The stunted sort in the flatwoods does not yield so well. Too much rain during bloom produces a mildew; too great drouth or dryness in the air, too much heat, produces a parched bloom that withers soon. Both conditions are detrimental to nectar secretion. When all conditions are right, however, it yields profusely, and is the finest of table honey. Some think it the very best in the state. It is lemon yellow, thick heavy body, and aromatic both in taste and smell, wonderfully appetizing and delicious. Having had two poor years in succession from this source, it looks as if we might get a yield this year, or, as the vernacular has it, "We belong to have a good bloom."

\* \* \*

"Even an error may give text for a sermon." I confess, when I read "Don't we have good-looking covers?" (Mrs. Allen, page 182) I was ready to shout, "Yes, if they are metal covers;" but further perusal of that department contribution showed me that our poetess was thinking of one kind of covers and I of another. But, all the same, I must give that sermon, even tho a mistake led up to it.

Florida, above all other states, needs metal-roofed covers. For sixteen years I have tried all the kinds of covers ever tried by any mortal man. I have used wooden covers, put together with kerfs, with grooves and tongues, painted joints, etc. I have used tarred-paper covers and roofing-paper covers. I have never yet found a brand that would not leak sometimes, and many of them all the time, some very badly. A bad case of mildew, warping, and decay is the result to the cover that leaks, and

mayhap worse to the colony. As a roof is the most important part of the house, so it is of the hive. If that is poor, the whole is a failure, no matter how good in itself the rest may be. Here the summers are in the rainy season. We may have bright hot sunshine for half a day, and downpouring rains the rest, then steaming heat again. You can imagine how an ordinary roof suffers—even a roof that would pass as a pretty good cover in the North.

I find galvanized iron better than tin. If you paint the former, all the better; if you do not get around to it in time, it suffers little, if any, for a good while—no rust, no warping, no leaks, and last, but not least no blowing off. I used to be annoyed in outyards, or at the home yard, when absent, by the covers going rolling across the yard in some of our summer high winds. Now, with the metal-roofed telescoping covers all is solid, secure, and dry as a powder-horn. I can leave a yard for months, and know that all is absolutely as dry and secure as the heart of the pyramids! "I care not what others may say; but as for me, give me" metal covers or give me none! While I know some advocate, even here, a cheaper cover, sooner or later they will regret it. I nail the metal part down over the telescoping side and ends with one-inch clout nails that clinch easily. I have devised a way of placing the cover over the projecting edge of the sliding leaf in my saw-table, and clinching the nails on the iron table. It takes but a few moments to go over a hive thus. The nails are driven at an angle, so as to enter the sides and ends, not into the board top merely, under the metal, thus welding the whole into almost one piece that can be thrown and banged around endlessly with no danger whatever of breakage. And then, too, these covers can be piled up so neatly, take little room, can be used for piling hives on, act as a seat in the yard, stand firm when so piled, do not rock and slip around as sloping covers do. They are exact and symmetrical, and practical in every way. It seems to me for our climate especially, they are the "last word" in hive-covers. I would strongly advise all who are beginning with bees here, or who may not be entirely satisfied with the sort of covers they are now using, to give these metal-roofed covers a trial, convinced as I am that they will thence use no others. They cost a bit more, but are well worth it. To come back to the starting-point, you can still exclaim, "Don't we have good-looking hive-covers?" for none give a neater look to a yard than these same metal telescoping covers.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Thirty years ago today (May 22, 1916) I hived my first swarm of bees and may be said to have entered the bee business on that day, for I have owned bees ever since. One of the reflections that came to my mind in a most forceful manner was this: "What should be our attitude toward the beginner?" As a matter of justice and fairness toward the amateur there are many things we might say to him that would tend toward discouragement on entering the bee business as an occupation. From my own experience and observation I am ready to give some frank words to the amateur. I do not believe there was ever a more verdant youth than I at the beginning of my beekeeping experience—that is, so far as any knowledge of the bee was concerned. I had sufficient enthusiasm to keep pace with any condition which might arise; but the necessary knowledge was lacking. If, instead of my uncle having given me a lot of second-hand hives, with a little encouragement, he had advised me to get rid of those bees as quickly as possible, and avoid the fever for all time, I should have been financially better off at the end of the first eighteen years. It is not my wish to say that I could not have made a success of the bee business in those years had I had experience. I did not know how, and my time was too much occupied with fruit and potato growing to give the bees the required care. Then, too, I was trying to raise comb honey every year, regardless of the season, with the result that my loss in sections was very heavy, and my output of nice comb honey very small.

Those conditions prevailed until my bees were becoming less and less in numbers, the other farmwork having divided my time in such a manner that the bees were the last to receive attention. It was a dead loss to me, and I thought many times I would give the bees up entirely. But that old feeling of love of nature would assert itself, and I could not resist the fascination of the bees. Now, here is one of the points I wish to make clear. The amateur with the love of nature in his heart, and the bee a part of this devotion to nature, will succeed when the amateur who goes into the business simply as a business asset will fail. It takes a lot of courage to face a series of poor years (and consequently small crops), and the fellow who enjoys the business will hold on when the one who looks only for money will quit.

As a matter of fact I am thoroly of the

opinion that at least 90 per cent of all those who have entered the bee business more or less extensively have failed, and the greater per cent of those remaining have made little more than the amount actually invested. The fact that I with many others had failed in my early efforts to make a financial success of the business does not prove that all was lost. The knowledge of the bees is worth a consideration as a part of one's education, and may in after-years be utilized when circumstances have placed both opportunity and necessity in one's path. I have come under this same chain of circumstances, in that I have for the past twelve years found it both desirable and profitable as well as a source of supreme pleasure, to continue the business. The bee business, in order to support a family in the proper manner, must be carried on in an extensive way or the profits from the good years will not make up for the deficits of the poor ones. So the amateur who has visions of extensive operations and a large bank account must first take into consideration that all is not a bed of roses, and that the dark days must be lighted with the sunshine of the bright days in the form of surplus funds saved from the good years. It would pay any Eastern beekeeper to spend a year in the West with some of the big honey-producers, learning the business. That may sound a bit like a "slam" at the Eastern beekeeper, but it is not intended as such. The fact remains, however, that the ideas of the Western beekeepers are so much bigger and broader that one learns by leaps and bounds when under the influence of the Western spirit. I could return to the East now and make dollars where I was not able to make cents when I came here—not because I had not studied all of the technical terms in beedom, and knew all of the fundamental workings of the bee, but because I have learned better than to try to compel bees to put up nice comb honey when the flow is not sufficient to accomplish the object, when the efforts of the bee could have been turned into a commercial value by having extracting-combs to hold their labors during the slow flow.

The amateur should be given as many of the facts in connection with the ups and downs of the business as possible; then if he wishes to try his skill in the business he does so at his own peril. But the brightest side should appear only with the dark side, for they will both have to be faced sooner or later, and their early acquaintance will make the way less fearful in the end.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

CLIPPING QUEENS' WINGS DETRIMENTAL TO THEIR PROGENY?

"Did you apiarists who advocate clipping the wings of queen bees ever stop to think that such a course might prove detrimental to their offspring, the workers? I should fear that such a course might in time be the means of producing worker bees with weakened or deficient wings, and thus the 'best bees' we are working for might be crippled in wing power."

This is something that was written about quite generally thirty to forty years ago, as at that time natural swarming was the general mode of increase, and with unclipped queens swarms were liable to get away. To obviate this, the clipping of every queen was advocated by beekeepers in all parts of the world. I remember at that time this same question came up and one writer told us that he had worked along that line for forty years with his sheep, clipping the tails from his lambs when they were small in the hope of getting a breed of tailless sheep. In spite of his desires every lamb that was born always had a perfect tail. I know that wonders have been accomplished by way of changing the color of sheep from the black of the original to that of white, and also the character of their wool from coarse to fine, and that of the form of the Southdown with a smooth skin to that of the Merino with its fine wool and folded or wrinkled skin.

It seems to be quite generally assumed that it would be as easy to change the characteristics of the worker bee by the selection of queens and drones as it would be to change the characteristics of other domestic animals by the selection of parents. In the latter case the parents transmit to a greater or less degree their habits, faculties, peculiarities and desires to their progeny, but that can hardly be said in the case of the honeybee, especially when the progeny is a worker. The worker bee presents something along the line of heredity somewhat different from any of our domestic animals. Here is something which our evolutionist friends have not seen fit to tackle. The worker bees are passionately fond of gathering and storing honey and pollen, defending their homes with energy and patriotism as well as performing all the other work that falls to their lot, yet none of their ancestors on either side for untold generations has had either the desire or the ability to defend their home or lay up stores for winter or a rainy day. I am not an evolu-

tionist, but it seems that some of our past theorizing in regard to working for the best bees may have been of little value. Is there not something here that should receive attention in discussing the question of breeding bees up to the highest standard in respect to honey-gathering, wax secretion, white capping of combs, hardiness in wintering, or eliminating disposition to swarm, or weakening the workers' power of flight by clipping queens' wings? He who should undertake to create so great a difference among worker bees in outward appearance as there is in domestic fowls between the monster Brahma and the diminutive bantam would doubtless be considered rash. Then why should he be thought to stand on safer ground when he undertakes to make as great a difference among colonies of bees in respect to desire to swarm as there exists between the Rhode Island Red and the White Leghorn in respect to inclination to incubate? And as the inclination to sit is far from being bred out of the Leghorn, how much less than reckless should he be thought who undertakes to breed out of the honeybee the desire to swarm altogether? Is this not also applicable to the attempt to lengthen the tongue of the worker bee so that one or two one-thousandths of an inch may be added so that the nectar in the red-clover blossoms can be reached? To me it has always seemed that the reaching of the nectar in the red-clover bloom could far more easily be obtained by a crossing of the different clovers thru pollenization or selection of those stalks for seed from roots giving the shortest corolla. If the red clover bloomed here to an extent sufficient for seed I should have tried such a selection years ago. But thru hundreds of very minute worms taking their abode in the red-clover heads just prior to its blooming, few if any corollas appear.

But to return: By a like course of reasoning, as with the poultry, what possible ground for fear can there be that clipping the wing of a queen will weaken the power of the worker progeny to fly? If the fact that for many thousands of years at the very least the queen bee as well as the drone has neither exercised nor had the power to gather honey and pollen from the flowers, has neither destroyed nor weakened the desire and the ability of the worker bee to perform that labor, we may safely dismiss any fears we may have harbored that the clipping of the queen's wing will in any way affect the usefulness of her workers.

# GENERAL CORRESPONDENCE

## PAINT YOUR HIVES EVERY FIVE OR TEN YEARS

BY E. S. MILES

"There are two sides to every question," altho the other side to some questions is rather small. To paint or not to paint is one of these; and not to paint is, in my opinion, decidedly the small side. It is almost universally believed by enterprising and progressive people that painting wooden buildings pays, not only because it adds to the life of the building, but it keeps it in good condition. A well-painted building will shed water in a wet time, and not warp apart in a dry time. Then well-painted, nice-looking buildings are an asset to any place, please the eye, give satisfaction, and are an incentive to enterprise and thrift. But, somebody says, we are talking of painting hives, not buildings. However, the above applies just as well to hives; and, in addition, the hive, standing as it does near the ground, usually with grass around it, in a very damp place in wet weather, is even more in need of protection from the elements. Before we leave the subject of the desirability of painting, whether buildings or hives, let the reader take a trip, in imagination, thru any settled community. Is it not universally true that the buildings of the prosperous, enterprising people are invariably kept well painted? Which is the place containing a tenant, or a poor man struggling to make a start, perhaps, or the booze-fighter or loafer? If it is not the place with old unpainted buildings, porches partly down, perhaps several window-lights replaced with a bunch of rags, then the conditions are different from any I have traveled thru.

Some one says that a hive is different—there is moisture in a hive, which paint will not allow to escape, and that will be bad for the bees. I am not ignorant of the fact that we have two eminent authorities who think bees do enough better in unpainted hives to offset all the advantages of painting and more. With all due respect for them, however, I do not agree. There is a chance that, further east, as the climate is more moist, there might be a difference in favor of unpainted hives; but it would seem that the need for protection would be also greater. But, speaking from my own observation and experience, I know that unpainted hives *here* deteriorate very rapidly. The covers warp badly, the body and floor joints spread and rot. I have had a good many colonies in unpainted hives, having pur-

chased many such, and keeping them from a month or two up to a year in some cases. In addition I kept one colony in an unpainted hive for many years, for the sole purpose of seeing what advantage it was to the bees. I can say positively that I was unable to see any advantage whatever in the unpainted hive. I believe the moisture can be allowed to escape from the hive in more effective ways than thru the walls. I should not want to be confined to that way alone, I am sure; and if I can let it escape in other ways I do not need that way.

If we have made the desirability of painting apparent, let us consider a few points in painting. Painting a hive is similar to painting any woodwork. The hive must be dry, and free from dust and dirt. This is necessary for a lasting job of painting, and especially so on a hive, as they are rather hard on paint. If there are knots or pitchy places they must be painted over with shellac first, and allowed to dry. Any cracks or joints not tight should be filled with putty after the first coat before applying the second. Three coats are necessary on new work for a first-class job, and the paint should be thinned with pure linseed oil for the first coat. I don't save on "elbow grease" in applying it. Rub it in thoroly. Let it dry several days between coats, and be sure it is fairly warm when putting on the second and third coats. I prefer a good grade of ready-mixed paint rather than white lead and oil. I think it sticks better, becomes harder, and, according to my experience, is more lasting. There is a difference in ready-mixed paints, however, and it is advisable to go slow until you know you have a good one.

In repainting hives after being in use five to ten years, more skill is required to get satisfactory results. Some have said that hives may be repainted while in use. The giver of such advice is unskilled in painting. You cannot repaint a hive while it is in use, and yet *do a good job*. Old hives must be thoroly scraped or sandpapered. Any old paint that is loose enough to come off with a good scraper in both hands of a vigorous man *must come off*. Any propolis must either be burned off with a torch or, if not badly daubed, after thoroly scraping, a coat of shellac put on before painting. The bottom-board must be thoroly cleaned and painted on the *bottom* as well as the top.

"That which is worth doing at all is worth doing well" applies especially to painting a hive; for if so painted, and repainted every five to ten years, a hive will never have to be replaced on account of age. A neighbor of mine is now replacing hives that are 12 or 15 years old, as he says they

are too rotten to stand any manipulating. My first hives, purchased 23 years ago, are as sound and tight as ever. I have purchased many unpainted hives not in use 20 years, that I have thrown away because of rotting around the edges so that they were no longer bee-tight.

Dunlap, Iowa.

## WHITE CLOVER AND ITS DISTRIBUTION

BY JOHN H. LOVELL

[The following by John H. Lovell is from the new edition of the "A B C and X Y Z of Bee Culture." We are glad to give it a place in these columns at this time, for we believe the illustrations of this celebrated honey-plant are finer than anything that has ever been reproduced before.—Ed.]

In the central and eastern states no other honey-plant is so universally known as white clover, and white-clover honey is the honey *par excellence*—the honey with which all other honeys are compared. It is a delicious white honey of the finest quality. While not so thick and heavy as goldenrod nor so pronounced in flavor as buckwheat or basswood, it yet possesses the qualities which satisfy the largest number of consumers and fills most perfectly the demand for

a table honey of the highest grade. It is given the preference by most purchasers, and the highest encomium which can be bestowed on any honey is to pronounce it equal to that of white clover. As a confectionery its appearance is most attractive, while for medicinal purposes it is unsurpassed.

In general in America where it is sufficiently abundant white clover usually yields excellent honey harvests, which are not far

White-clover blossom—first stage.

from surpassing all records. In 1913, at Marengo, Illinois, Dr. C. C. Miller obtained from 72 colonies, spring count, 19,186 sections of chiefly white-clover honey, or an average of 266.47 sections per colony. The three best colonies yielded 390, 395, and 402 sections respectively. This phenomenal surplus was largely due to a most favorable season consisting of a succession of hot humid days, altho the strain of bees and the care they received were important factors. The flow began about June 1 and continued until the last of August, the bees then gradually changing to sweet clover and heartsease. During this long even flow there were up to September 1 only two rainy days. At other times the rain came during the night, the weather becoming clear again before the bees were ready to begin work in the morning. In central Kentucky, in 1906, 115

colonies stored 12,000 pounds of white-clover honey and increased to 240 colonies. From the same apiary in the following year the product was 30,000 pounds, while in 1908 drouth reduced the crop to 15,000 pounds.

The flowers of white clover are familiar to every one since the plant finds a congenial habitat in the vicinity of human dwellings. It carpets the lawns, fringes the paths and roads, and is common in the fields and pastures. There are in each head or flower-cluster from 57 to 89 small florets. At first all the florets stand erect, but as the marginal ones are pollinated they cease to secrete nectar and are bent backward and downward against the stem. By preventing useless visits this change in position is beneficial to both flower and insect. When they expand the flowers are white, but they often turn reddish after they are reflexed. The calyx is only three millimeters long, so that not only honeybees, but many other insects are able to reach the nectar. Honeybees also often gather loads of greenish pollen, altho this is not abundant.

#### DISTRIBUTION OF WHITE CLOVER.

White clover is very widely distributed in the north temperate zone of both hemispheres. The factors controlling the secretion of nectar are very imperfectly understood. While in the United States and England it is usually a good honey-plant, in France and Switzerland, in fact, thruout continental Europe, one may travel for several kilometers and not see a bee on it. At Ronen, France, during one day of white-clover bloom a hive on scales actually lost 300 grams in weight. In various localities in the United States it is also reported to be an almost total failure. At Plainfield, N. J., altho the ground is often white with the bloom a good flow is obtained only about once in ten years. One beekeeper says: "As an actual fact, the amount of clover honey is not measured by the quan-

White-clover blossom—second stage.

tity of bloom; for I have seen the fields white with an abundance of it, but only a fair crop. I can remember one year when we had a great scarcity of bloom, and yet we had a good crop of clover honey. I have also seen fields white with clover but no honey." In the southern and extreme western states white clover is of little importance to the beekeeper, not so much because it does not secrete nectar as because it is not sufficiently common. In many districts the climate is too dry. The nectar secretion also varies greatly from day to day according to weather conditions.

White clover is at its maximum as a honey-plant in what is known as the "white-clover belt"—that is, in the blue-grass region of Kentucky, in Ohio, Indiana, Illinois, Missouri, Iowa, southern Minnesota, and southern Wisconsin, Iowa, and southern Illinois being in the heart of the belt. Even here the nectar yield is often very variable. In some years it is enormous. In others no surplus is stored. At Richmond, Kentucky, according to Virgil Weaver, a normal year comes only once in every five years, viz., 1897, 1902, 1906, 1910. Two full crops

obtained in succession are often followed by several years when the yield is less satisfactory. This difference is largely determined by soil and climate. In wet clay ground in regions where the winters are severe the roots may be much broken and drawn out upon the surface, or the plants killed outright by repeated "lifting" caused by the alternate thawing and freezing of the soil. The destructive work of the frost, however, is much lessened by the natural mulch afforded by the dead vegetation found in waste places and in meadows, which have not been cropped too closely. Snow also offers excellent protection, and, when it covers the ground for most of the winter clover suffers little or no damage. Winter-killing from freezing in well-drained sandy soils or in warmer climate is practically unknown.

In Kentucky, Iowa, and the surrounding territory, where there are light soils, it seems to be well established that there will be a very small honey-flow if the preceding season has been very dry. If there is no rain after July 1 the drouth destroys the old plants of feeble vitality, checks the growth of offshoots, prevents the germination of seedlings, and retards the formation of an extensive root system with the result that there are few blossoms and little nectar the following season. This statement does not call for discussion since all herbaceous plants growing in porous sandy soil suffer if there is a large decrease in the normal rainfall. Altho the injury wrought by the drouth does not become apparent until the next season, it should not be attributed to winter-killing, but to the correct cause—the absence of sufficient moisture in the soil. But if there is a good stand of white clover in early spring, a drouth in May or June, if copious rains follow, will only retard the bloom and delay the harvest. I have seen clover parched by drouth in June, says a beekeeper, and not a blossom in sight. Then came a succession of soaking rains, and, presto! bloom and a crop of honey.

White-clover blossom—third stage.

Similar results have been described at London, Canada. An exceptionally dry fall after August 15 was followed by a dry spring until the last of May when a series of warm rains commenced which continued almost daily until about the twentieth of June. The effect was marvelous. July found the fields and roadsides a beautiful mass of white and alsike clover, and the honey crop was the best that memory can recall. A very cold spring may also cause failure, even if there is a normal rainfall. In 1907 in parts of New York the average temperature of April, May, and June was four degrees below the respective means for these months in other years, and there was no white-clover honey.

Cold rainy weather during the honey-flow will both lessen the quantity of nectar and prevent the bees from working on the bloom; for the best results there must be a series of warm humid days. Finally, where white clover has been grown indefinitely in the same fields the soil conditions may become deleterious. Microscopic protozoa may multiply until they destroy a large part of the beneficial bacteria, or the soil may become acid and require a liberal application of lime. Such land is said to be "cloversick." Nearly all of northeastern Ohio and

the major part of Pennsylvania show a deficiency of lime. This is also true of Massachusetts where very little white-clover honey is produced. Progressive farmers are learning that by applying lime they can grow white clover and produce honey to the same extent as did their grandfathers.

There is no more important or interesting subject to the beekeepers of "the white-clover belt" than the life history of white clover and its problems. The plant is propagated both by seeds and runners which root at the nodes and finally become independent stocks. As in the case of the strawberry, a single plant may in a favorable season cover with its runners a circle of ground one or two feet in diameter. If these new plants winter uninjured they will

bloom the following season in the same manner as strawberry-runners. The older plants, as is again true of the strawberry, exhausted by multiplying both sexually and vegetatively, are easily killed by drouth or cold. When the ground is densely covered with an old growth there will be little opportunity for runners to root or seed to germinate; hence there may come years when there are few new plants to bloom.

White clover seeded in the spring will produce, if there is sufficient rain, a heavy crop of bloom in July and a fair amount of seed. Much depends upon locality. Clover raised from seed is more valuable for nectar the second season than during the first, but after that it begins to decline in vigor and to yield less honey.

## EUROPEAN FOUL BROOD; PREVENTION AND CURE

### Why Italians are Practically Immune. A Lemonade Cure

BY ALLEN LATHAM

European foul brood is caused by a germ; but this germ is not spread, as most people think, by its presence in honey, but rather by the bees themselves. Such a statement is difficult to prove, but no other theory, so far as the writer knows, will account for facts observed.

A colony may contract the disease thru contaminated honey, and possibly a great many cases arise thru this cause. If a colony dies of this disease, and is then robbed out, there is little doubt that the robber-colony may contract the disease. But after the disease once gets a footing in an apiary, its spread there is due to other causes.

An inspector once told the writer that, because of the congested condition of his apiary, he would have the time of his life if foul brood once got a footing. In clearer words, he gave me to understand that if one colony got it the adjacent colonies would soon get it, and that it would spread thru the entire apiary. When the disease did come the results were peculiarly contrary. My colonies are in pairs, and the pairs are scarcely two feet apart; but there were comparatively few instances in which both colonies of a pair had the disease, and there was absolutely no indication that the disease had spread by moving from colony to colony. Instead new cases would spring up in entirely different parts of the apiary.

This fact gave rise to the following reasoning: Since the disease does not travel by mixing of bees, nor by robbing, how can it travel? At just this point a happening

brought the explanation. At that time there were three or four cases in the apiary, well under control. For several days the bees had been kept in by cold winds and cloudy weather. The weather cleared in the night, and there came a heavy dew with fog. As the fog in the morning hours cleared, the bees flew by thousands, all eager for water. One could scarcely step on the grass without killing a bee, for they were sucking up the dew at a rate I never observed before. Within a fortnight European foul brood appeared in about a dozen more colonies. I could see but one explanation—namely, in sucking up the dew, the germs of the disease, there from the droppings of nurse-bees, found their way into several colonies.

This conclusion immediately suggested the advisability of sprinkling the grass in the immediate vicinity of the apiary with a weak solution of carbolic acid in order to repel the bees while in search of water. If made to go further in their quest for water, there would be a greatly lessened likelihood that disease germs would be gathered up with the water. I would urge every one this spring who finds an outbreak of this disease in his apiary to practice this control measure and report results.

From this the writer was led to study the spread of the disease in the colony itself. Incidentally he found why Italians are practically immune while blacks are not. At first in a colony only one larva (or at least a very few) is diseased. It is perfectly reasonable to assume that a single germ

may be the cause of the outbreak, and that only one bee can get this single cause. The larva or larvæ die; and, in the case of Italians, are quite likely to be picked up and carried bodily from the hive. The more economical black bee first sucks out the juices of the dead larva and then casts out the skin. These juices are then fed to the other larvæ, and the disease spreads rapidly thru the colony. Thus it follows that the Italian bee individually is no more immune to that germ than is the black. It is fatal to both; but the Italian, thru its different habits, appears to be immune.

One can easily see how the foregoing explanation will account for various aspects offered by this disease, and how it in particular explains the cure wrought by the temporary removal of the queen. It also suggests the possibility of medicinal treatment. If one can feed a mild disinfectant, why cannot the germs in the larval food be rendered innocuous?

The older readers will recall that Alexander of buckwheat-honey fame often stated that the coming of the buckwheat-flow did away with European foul brood. The writer thought that possibly there was some mild acid in buckwheat nectar which killed the germs of that disease. Why, then, not feed some mild acid to the bees? This was tried last summer. Some fifteen colonies were thus treated, and in every case the disease disappeared. Mild and severe cases all went, some quickly, others lingeringly. One week of treatment made a most marked effect in some colonies, while in others three weeks passed before improvement was marked. But they all finally became well, and are today on their old original combs, and, so far as known, perfectly healthy.

The treatment consisted simply of feeding the juice of one lemon daily to each colony. Half a pint or so of thin syrup was made, and the lemon juice stirred in. In other words, a rich lemonade was made and fed to the bees.

One of my strongest colonies became diseased, and in about ten days was so foul that one could smell it six feet from the hive. It was rank, fully thirty per cent of the larvæ being dead and rotting. After seven lemons had been given this colony there was scarcely one per cent of diseased larvæ, and in three weeks the colony was entirely well, and stored three supers of honey, equaling colonies which had not been diseased at all. The queen was not caged at all, and no treatment whatsoever was used except the lemonade.

In marked contrast with this colony was another. To make the case of this one

clear it is well to relate its previous history. In July, 1914, this colony was found diseased in an out-apiary. Its queen was caged. By an oversight nothing more was done to this colony till in October, when by chance it was discovered that the queen was still caged, having been there some eleven weeks. She was liberated, and the colony was brought to the home yard for observation. There were still nearly 8000 bees; and tho they were all at that time old, I decided to try to bring the colony thru the winter, and into condition without assistance. It wintered successfully, thanks to the longevity of Banat bees, for the queen was a grade Banat. Tho very weak in the spring of 1915, the queen soon had brood in two combs, and at first no sign of disease showed. But about the time the disease broke out in other colonies this one again became diseased. The old queen died, never having been very vigorous after her long confinement. Another queen of resistant strain was given the colony. Slowly but surely it began to pick up, but showed no marked gain till the bees of the new queen appeared on the scene. Lemonade was administered for about five weeks. By July the colony was clean, and it even went into the super, tho it stored no finished sections.

In speaking of this treatment with other beekeepers I have been told that it was not the lemonade, but merely the stimulating feeding that did the work. If this be true then so much the better. If we can cure European foul brood merely by the feeding of some six or eight pounds of sugar syrup, it should be generally known. I have not put the matter to a test, but I am satisfied that the lemonade will do it if the syrup alone cannot.

Shaking may be desirable in some cases, especially during a honey-flow when the colony can recover from the shock. But the lemonade treatment is desirable when there is no honey-flow. Colonies too weak to shake can be built up to strength, and a cure wrought by the expenditure of the price of a dozen or so lemons and six pounds of sugar. If one will, at the first appearance of the disease, use the carbolic acid as suggested as a preventive, then treat the diseased colonies with lemonade, he can bring his apiary thru the attack with very little loss.

Much has been said about the danger of the reappearance of the disease when the old combs are still in the hive. In my own experience I have found no tendency to that reappearance, the new cases being about equally divided between colonies which have never had the disease before and colonies

which have been treated without shaking. And as a further argument in the favor of the milder methods of treatment, I will say that the disease has reappeared in colonies which had been shaken the year before in the same proportion as there were strictly new cases. The shaking method is urged upon us on the strength of its certainty as a cure. Personally I believe it would be certain provided there was no disease in the neighborhood by means of which new outbreaks will surely come. So long as the disease is in a neighborhood it is foolish to practice the shaking method; but after the neighborhood is cleaned up, then I would advocate the renewal of all combs. Until the neighborhood is freed of disease, then I

say use the milder methods, inasmuch as they are much cheaper, entailing, as they do, less labor and financial outlay, and yielding as certain results.

It is evident that it would be well to requeen all colonies which have contracted the disease with stock which has shown resisting powers. By this, one can more certainly forestall fresh outbreaks of the disease.

All the foregoing relates to European foul brood. I have not yet been given an opportunity to test curative treatment to a colony infested with American foul brood. Will those who have the opportunity try the lemonade treatment and report?

Norwichtown, Ct.

## NOTES FROM HOLLAND; OUR BEE-HOMES

BY J. H. J. HAMELBERG

Having noticed that black bees prevail in this country, the reader will not be astonished to hear that the bee-home most commonly found in Holland is the old-fashioned straw skep. We have them in all shapes—square, rounded off at the top, conical, round, with a flat head, etc. In some of them, as in the Gravenhorst skep, movable frames can be put; but in most of them the comb-building is left entirely to the fancy of the bees, some sticks being put inside for the support of the combs. A good many skeps now have an opening at the top, covered with a felt stopper for feeding purposes, and for obtaining a few pounds of comb honey in small wooden boxes which are put over this opening in a good season. But the primitive, conical-shaped skep without any improvement is as yet most commonly seen.

These skeps, altho altogether unfit for modern beekeeping, still offer some advantages. Bees winter exceedingly well in them, especially in the so-called thick-walled ones, and in hot weather they keep the bees much cooler than wooden hives, it being hardly possible for the brightest sun to penetrate these straw walls, nearly  $1\frac{1}{2}$  inches thick. Most beekeepers can make these skeps themselves, and, during their leisure hours in winter, they so spend their time, thus saving the outlay for new hives, having the straw for the taking. Besides, no bee-home is handier for migratory beekeeping. A bee-proof cloth is fastened around the bottom with a few nails. In the evening the entrance is closed with a plug of grass, and the skep is ready to be taken any distance. For wintering, the beekeeper, once being sure of a colony having sufficient stores (to

ascertain which he uses a steel bar (Roman balance), or, if he has sufficient experience, he simply lifts the skep), does not take any other precaution than to fill the entrance with some mortar, and, while this is yet soft, bores a hole in it with a stout lead-pencil. Often even this filling with mortar can be dispensed with, when the bees plug up the entrance to a convenient size with propolis. Being always kept under cover (on scaffolds in sheds), skeps will last for years; and, when showing any signs of decay, they can often be repaired with a handful of straw and some binding material, or by plastering them with some adhesive substance, as, for instance, lime mixed with loam. New ones can be bought for about half a dollar apiece.

All these advantages, however, do not make the skep a fit bee-home for the modern beekeeper, and I rejoice to be able to say that hives are coming in use in this country more and more. We have some large apiaries, in which the skep figures only as a curiosity. Some prints of these have appeared in GLEANINGS from time to time. But apiaries in which *hives* figure by way of exception are much more numerous, the best evidence of this being given by our bee-markets at Veenendaal and Bennekom. At the last market at Veenendaal more than 3000 colonies were offered for sale, but not a single hive was to be seen, all the colonies being in skeps.

The fact that there is no standard frame will prove a great hindrance to hives becoming more popular. Many dealers in beekeepers' supplies have their own patent hive, and each of them considers his make the best, of course. Besides, there are yet some German makes on our markets, which

augments the confusion and makes it hard for the less up-to-date beeman to make a choice.

Altho our country is not a large one, there is a perceptible difference in the climatic condition of some parts of it as compared with others, and the bee-flora especially is not the same in all parts of it. Locality, therefore, plays a role with us as well as in the land of the stars and stripes; but it seems that but little attention is paid to this fact by our dealers in beekeepers' supplies. Once their hives and fixtures have given fair results in one locality, they seem to conclude that their system is the best for the whole country. But the beekeeper may find out the contrary to his sorrow. Our beekeepers, not being men of means as a rule, have to stick to the hive first chosen, even if it is not satisfactory; and the worst

of it yet is that when, for some reason or other, a dealer goes out of the market, his hive and fixtures, as a rule, disappear with him, and the beekeeper is put to a strait for obtaining his supplies.

The skep has none of the above disadvantages. It answers as well on the low humid sea-coast as on the inland plains and heather-fields. Against the confusion in the choice of a hive stands the simplicity of the skép; and it stands to reason that, as long as the majority of our beekeepers are not convinced of the advantages of hive-manipulation, the rearing of better queens, etc., the skep will hold its sway in this country. For this reason alone, if for no other, it is to be considered urgently desirable for our government to consider seriously the better instruction of our beekeepers.

Soest, Holland.

## A ROOMY AND CONVENIENT EXTRACTING-HOUSE ON WHEELS

BY EARL C. BIDDICK

My movable extracting-room is 8 feet wide, 16 long, and 6 high. It is screened half way on each side, so that the canvas may be rolled up, making it a cool and comfortable place in which to work.

There are two screen-doors—one where I am standing, and the other on the right

side at the center, so that the honey-supers may be carried in from that side.

The 2 x 8's which rest on the bolsters must be the same width as the bolsters, to prevent it from tipping easily. The 2 x 4's are fastened to the rack with brace-rods, and square irons bolted.

Earl Biddick's extracting-wagon. A framework of 2 x 4 material is built on a 8 x 16-foot platform, and covered with canvas. There is plenty of room for engine, eight-frame extractor, uncapping-box, etc.

The engine and eight-frame extractor are placed in the extreme front end of the room, where they balance well on the wagon. I use two-ton springs for moving the wagon.

A hole is cut in the floor, and a pipe is laid to carry the honey out over the left

front wheel into a tank not over 36 inches high, large enough for a day's run of honey.

One of the main features of this wagon is that, as soon as one arrives at the yard, and blocks the springs, extracting can be commenced without delay.

Meridian, Ida.

## SWARMING PREVENTED BY CONFINING A QUEEN WITH EXCLUDERS

BY J. H. BURNS

Some time ago I described my method of swarm control in GLEANINGS. As I had tried it on only a small scale I was anxious to know if any other beekeeper had used the method in a large way, but I was taken sick shortly after and stopped reading. I intended to experiment further on a larger scale; but as I am still unwell it is not likely that I shall ever be able to do much with bees again; therefore I have decided to describe again briefly the method, together with such alterations as I contemplated trying, in the hope that it may prove useful to some one else. I should be glad to know if this method has ever been tried before, and whether it is as likely to prove effective as my experiments indicate.

The method is a simple one. It consists in inclosing the queen on a brood-frame by covering it on both sides with excluder-zinc. It is better to use a wide-frame; but bulging the zinc in the middle will do. This is done just before the swarming season commences, and before queen-cells are started.

The idea is to cage the queen in the brood-nest, and yet allow the bees free access to her. This, I reason, will prevent formation of queen-cells, and the decreasing brood will induce the colony to give up all notions of swarming. I was able to test it on only a few colonies, but no swarm issued from any of them. Did the decrease in the brood

probably prevent swarming in this case? There is another advantage in decreasing the brood. The useless after-harvest consumers are lessened. Still, a trial with a few hives is not conclusive; but I give the results to the public so that others may reap the benefits if there are any, as I am not able to finish the work myself. Had I been able I would have liked to try caging the queen without using a comb; and I had even contemplated doing without either hunting or caging her majesty. Instead of the ordinary division-board I would have made a tight-fitting one with excluder-zinc. At the beginning of the swarming season remove this division-board from the side, and place in the middle of the hive, spacing the frames over. The queen can now use only four combs, and the brood will diminish a half. Whether this is enough to stop swarming remains to be seen. If not, a six-frame hive could be used, or even a four-frame. In these cases, brood-rearing would have to be provided for in spring by tiering as Dr. Miller and some others do with the eight-frame. Or a large hive with any desired number of these division-boards could be used. But this is all theory. Perhaps this would actually induce swarming by acting the same as contraction; but I think it is well worth a trial.

## AS GLIMPSED THROUGH THE CAMERA

BY H. H. ROOT

A man may be born smart, but he cannot be born with experience. Experience comes by the slow and sure process known to every one. As Josh Billings used to say, "Experience teeches a good skule, but the tuishun comes pretty hi." A man may learn the theory of swimming, and be able to go thru all the motions, but nevertheless he feels as helpless as any other individual when he first finds himself in deep water.

The beginner in beekeeping may understand the theory of beekeeping pretty well; but he is likely to feel himself in rather

deep water the first time he fully realizes that he is the owner of thirty or forty thousand vigorous bees. It is the purpose of the following set of illustrations to tide the beginner over that helpless feeling that comes to every one when he runs up against a problem which the books apparently ignore entirely. I make no apology for this elementary presentation. We were all there once. The older beekeepers, the ones whose hairs of experience are beginning to turn gray, will please skip the four following pages.

Ever since about two days after you sent in your order for the bees, altho you have not owned it even to yourself, you have been sauntering around the railroad station occasionally, so that if by chance the express agent knew anything about a certain package of bees addressed to you he could let you know. As the days have come and gone you have finally begun making some pointed inquiries, then finally you wrote an apologetic letter merely to see if anything had gone wrong in the filling of your order. A few days later you wrote another letter not quite so apologetic, ending up with a few well-chosen words calculated to bring results. Then when you had almost given up seeing the bees you were summoned to the station, and to the station you went, not able to conceal your eagerness.

You examined the shipping-case carefully, as an experienced beekeeper should, and tipped the case over on one side to read the directions. Here you made your first mistake; for, altho it did no harm in this instance, sometimes it is not at all a good plan to roll the case about nor turn it over on its side, especially if the day is hot and the combs are soft.

You start for home the proud possessor of ten or fifteen thousand worker bees and an Italian queen. Your children try to look thru the wire screen to see if they can find the queen. They do not know that the queen would not be fooling around on that wire cloth. You feel a little like running all the way home; but you reflect that it would look better to walk quietly, and then, any way, probably it would be better for the bees not to be jolted any more than they have already been.

Remember that it is not a good plan to locate the hive with the entrance facing a sidewalk, path, driveway, or any other thoroughfare. It may look pretty and all that, and you may like to stand in the path and watch the bees coming and going; but the bees don't like to have people walking in front of their hive, interfering with their line of flight. It makes them cross and irritable. The entrance should face away from any thoroughfare, and nothing should be allowed to obstruct the front of the hive, whether it be a tree, shrub, or even tall grass and weeds.

According to directions, contract the entrance of the hive by putting in an entrance-contracting cleat, which is merely a stick of the proper size to fit the entrance, with a notch cut out on the under side for the bees to pass in and out. Unless you buy a full-size colony it is better to have the entrance quite small at the start. A nucleus does not need a full-size entrance. In fact, so large an opening is a positive disadvantage.

Remove the four screws that hold the top of the shipping-case securely to the side. For goodness' sake, don't pry up the tacks from the edge of the wire cloth and imagine that the bees will leave the combs in the shipping-case and crawl into the empty hive. Just before you take the cover off, blow a very few puffs of smoke lightly across the wire cloth to drive the bees down a little. Never try to stupefy bees with smoke. That is not what the smoke is for. Smoke scares the bees, and their first impulse is to load up with honey, so they run for the combs and eat all they can hold. Under such conditions they are good-natured, like some of the higher types of animals.

The long-anticipated moment has come. Carefully lift out, say, the center comb, and you are quite likely to see on it the large graceful-looking queen. Tho you may never have seen a queen before, you will recognize her instantly when you see her. She does not look blunt and clumsy like a drone, and there is something majestic in the way she moves.

Carefully lower each comb of bees from the shipping-case into a space made for them by removing empty frames of comb foundation from the new hive. Under ordinary conditions it is, perhaps, best to locate the combs of bees close to one side of the hive, and put a division-board, or follower, next to them on the other side. Gradually, as the bees need more room, they can be given an extra frame of comb foundation.

Watching a nucleus develop into a full-size colony is like watching the development of a child. And to realize that you have a force of little workers bringing in pollen and nectar is solid comfort; but do not think for a minute that the bees work for nothing and board themselves. They need some care. Under certain circumstances it may be necessary even to feed them—but that is another story.

This shows an ordinary frame of sealed brood containing both drone and worker, and a few scattering cells of unsealed brood. The drone brood appears at the top and at the lower corners. The cappings are larger, of course, and much more convex, than the ordinary worker. In the case of laying workers and drone-laying queens, there will be found drone brood in worker cells. While no larger than worker brood, it has the characteristic rounding or convex surface that makes it stand out conspicuously. When comb is built from full sheets, of foundation there is not much drone brood; but sometimes, when a colony is determined to rear it, they will enlarge the cells as they did in the case above. The unsealed brood is shown scattered here and there in the open cells, most of it worker, but a little of it is drone. The larvæ lay curled up all very often lay drone eggs. Some of the older brood is hatched out, leaving here and there empty cells which the queen will occupy again with eggs as soon as she comes back from about six days old. In the midst of a heavy honey-flow these cells will be filled with honey. Sealed honey is shown in the upper corners; and the unsealed is shown in the other portion of the hive. The color of the cappings over honey is usually white. Sometimes it is dark and very often is transparent, showing the honey behind. The capping over brood is more fibrous and from a light to a dark brown. It also shows quite clearly the hexagonal shape of the cells. The capping over honey shows this less plainly.

N. B.—This cut and the matter appear in the next edition of The A B C and X Y Z of Bee Culture under the heading of BROOD.

## EFFICIENT PRODUCTION OF EXTRACTED HONEY IN CALIFORNIA

## Conserving the Strength of what is the Equal of a Double Colony

BY G. W. BERCAW

By exhaustive experimenting we have developed the following plan of producing extracted honey on a commercial basis, assuming, of course, that there is a constant flow of nectar suitable at all times, and under normal conditions. This plan, however, might not work successfully in a colder climate; but we have found it is about the only one, so far as we are able to determine, that is efficient in our California climate.

Toward the close of the season, or after the rainy season has begun in autumn, put a full-depth super over the brood-chamber. Do not disturb the brood-chamber during the last extracting. This extra super is to be provided with full-drawn combs, ready to fill with brood, honey, and pollen, as the bees may feel disposed thru the winter months, when it is warm enough for activity, and on toward the spring. Do not put a queen-excluder between the two supers, but allow the bees and queen full access to all portions of the hive, above and below, in order that both supers may be filled as much as possible with brood and honey at the very earliest flow in the spring, which in some localities is as early as February.

Keep a close watch before a heavy flow comes on, as, for instance, in localities where the orange furnishes the flow, or the deciduous fruit-trees. In some instances both of these flows occur at about the same time. About 21 days before the honey-flow put a queen-excluder between these two supers, securing all the brood and stores above it possible, taking each frame out and shaking it in front of the hive to make sure that the queen is below in the brood-chamber. This shaking should be done after the excluder is in place. This gives an extra-strong colony of bees, boiling over, so to speak, with queen below and an excluder between the queen and the upper story.

When the heavy flow comes, these bees will fill the upper story with honey every ten days during the flow, so long as they do not swarm out. The honey may not all be capped within this time; but rest assured nature has taught them when to cap it, and it will be done exactly as nature intended it should—when it is ripe. This will depend upon the weather conditions, and on the rapidity of evaporation, etc. If the work of capping appears slow, and honey seems to be coming in fast, give the bees more room by adding another super above the one already on.

We have given this plan of manipulation a complete and comprehensive test, and find it the best one we know of. Of course, if the colony should cast a swarm it will not store the honey that it would under non-swarming conditions. When putting the excluder between the supers it is a very good plan to examine each comb below, and cut out all drone comb that may show up there. I presume that all beekeepers who take care of their yards work all the drone comb into the extracting-supers, and the worker comb into the brood-chamber. Notwithstanding this, drone comb will be worked into the corners and other vacant places in the brood-chamber, especially during the early spring season. This can be checked somewhat at the time of putting the excluders between, by cutting it out, as much as possible. Sometimes it is a good plan to transfer to the upper story at this time some of the combs that are below, and full sheets of foundation substituted below. This procedure must be left entirely to the judgment of the person working. By close watching one will be able to get a good strong colony of bees at the right time—the whole solution of getting a good honey crop—getting really two colonies of bees crowded into one. Such a colony will soon expand from the lower super into the one above for want of room. The queen must be kept below at all hazards. There is room enough below in the brood-nest to supply young bees; and with sufficient room above, the bees will not crowd the brood-nest so as to cut off the supply of young bees, so essential, of course, to the prosperity and success of the colony as a whole. Of course there will be a good many drones in the super above the excluder, which cannot escape, but they will soon die and fall to the excluder below, where they can readily be brushed aside. They are of but little account at this time, however; but if one desires to have them fly, the hive-cover should be raised a little, when they will soon all escape. These drones are of value, in large yards, where young queens are mating more or less every day.

It is quite true that this plan of manipulation takes a great deal of time if the yards are large and extensive; but what else can you expect if you want a good crop of honey? A beekeeper gets out of his apiary an amount just in proportion to what he puts into it, just the same as a rancher or farmer gets from the soil a crop in propor-

tion to what he puts into it. It means work, work, work. A single day in the early part of the season is worth three a couple of months later on.

This method might not be quite so successful in a country where the season is short and heavy; but here in California our seasons extend over many months, some months more heavy than others; but there is very little time during the year when bees cannot fly, more especially so in the Valley country.

At all events queen-excluders should be used in the production of extracted honey, as it is the only way to be sure of keeping the queen below the extracting-super. And where brood of any age is allowed in the extracting super, clean, wholesome honey cannot be produced. Do not keep excluders on during the winter months. Remove them in the fall, or about the time that the rainy season commences here in California, allowing the bees and the queen full access to the entire hive until the proper time comes the

following spring. When the excluders are again put on, the brood that is in the upper part will all disappear, as before mentioned, in about 21 days at the limit; and as fast as the young bees emerge, these cells will be filled with honey and other stores, thereby giving more capacity and efficiency in the manipulation of each individual colony.

I assume that the bees are of good stock, strong and healthy. They must be requeened every two years at least. It is a good idea to requeen a portion every year. For example, if the yard contains 200 stands of bees, requeen 100 each year. This is equivalent to a full requeening every two years. We think it pays any beekeeper to requeen in this manner. Either raise your own queens or purchase good stock. At all events, keep good strong vigorous stock. We prefer the three-banded Italian or the leather-colored queens in preference to all others, as they seem to be more or less immune to disease—at least this is our observation covering a good many years.

Glendale, Cal.

## CONTROL OF SWARMING IN OUT-APIARIES

### The Science of Keeping all the Bees together and Working in the Supers

BY M. W. HARVEY

Swarming is the fulfillment of a natural impulse of bees, and is governed by certain fixed laws; hence if man is going to control these fixed laws he must use other laws, and be ready when the time comes. I am a comb-honey producer, and do not follow any one fixed law in the control of swarming, so I will give them as used at different times of the season.

We will suppose the main honey-flow is just starting, and we have used every effort to get all colonies up to the same strength during the six weeks previous, and they are now at the swarming-point. The first thing is to get the supers on. There will be no swarming until a week to ten days later. If we are to keep those bees together, and make them work for us we must get busy. My first method is, examine every colony and every comb with brood in for queen-cells. When one is found with cells put a new hive in place of the old one. Find the queen, and place her in the new hive with the comb she was found on, and be sure there are no queen-cells on it nor even stubs, or the bees may start cells again and swarm. Now place the super on the new hive and an empty super on top, if the first super is well started, say half full or better. Shake all bees in front of the new hive.

Now, if increase is desired, take that old hive of brood and place it on top of a medium strong colony that is not doing any super work, with a queen-excluder between. They will finish those queen-cells and they will be as fine cells as any raised by any other method.

In one week to nine days go over this yard again, and this will be the big swarming week. Ten per cent or more will be getting ready to swarm. Now is the time to make all the increase. The swarming fever is on, and we have all the ripe queen-cells we need. If enough increase is not made from what were shaken, and there are cells to spare, divide these old hives of brood.

If no increase is wanted, take the brood and build up weaker colonies or place it back of the new swarm, and each week shake a few bees into the new hive until all is hatched and united again. These will make powerful colonies that may swarm again during the second flow.

This is my favorite method, and surest. It has been condemned by many because it is much work, and therefore a failure. I think I can account for the failure. A lazy man should not attempt to handle more than one apiary with natural swarming. The

man with out-apiaries must know what he can do and how many colonies he can handle in a day. I have taken care of 700 colonies alone, in four yards, thru the swarming season, and handled every brood-comb every seven to nine days—without losing a swarm. I admit it takes lots of hard work, and everything must move like clockwork and without lost motion.

The most failures in this method have been caused by shaking colonies that have never thought of swarming, and that might not swarm during the season. I never shake until I find cells started.

Other failures consist of weakening the old hive of brood so that the brood is chilled, and the new swarm dwindles. A colony to shake should be in the same condition a natural swarm would be. It should be strong, and nearly all the brood should be sealed. When shaking, leave about as many young bees in the hive as a natural swarm would leave. A shaken swarm that has cells nearly or entirely sealed is almost sure to swarm out in 24 hours. The queen in such cases should be clipped or caged so she will not get away.

Another method is to lift the hive from the bottom-board and look for cells on the combs. This is a quick way to get over a lot of colonies. I use it somewhat when I get behind and swarming is getting ahead of me. But I miss some, as it is hard to see cells in a strong colony unless they are on the bottom of the combs.

If no increase is wanted, and there are no weak colonies to build up, I shake in with the swarm all the young bees out of those old hives left back of the shaken swarms the week previous. That gives them a lot of young comb-builders and a big boost, and swarming is done with. I have taken off three finished supers by the time their brood-combs were filled out from one-inch starters.

Those old hives of sealed brood without bees are looked over carefully, and all queen-cells pinched off. I use those hives to shake new swarms on and put on plenty of super room, and then swarming is cured.

Another method which I use mostly in the second flow, when hives are full of honey, and frames are hard to get out, is to raise the hive up from the bottom; and, when queen-cells are formed, cut out all cells, then exchange locations with a weak colony. That ends the swarming in one operation, and shoves the other colony into the supers lively.

Still another method: If I want a moderate increase I shake one colony clean of bees; then the next one found wanting to swarm I put on a new location and place the old hive of brood in its place and give a caged ripe cell.

If the reader will notice, in all of these methods I aim to keep all my bees together, and all strong, at all times, and working in the supers.

## WHY I CLIP THE WINGS OF A QUEEN ON BOTH SIDES

BY R. F. HOLTERMANN

So Dr. C. C. Miller wants to know why I clip the wings on both sides of the queen, p. 345, May 1. The queen appears to me to look very awkward, backing to lay into cells. There may be nothing in this, but she certainly looks like a cripple with one side clipped and the other not. In this matter I followed the advice of the late Wm. McEvoy, and am satisfied with the change.

In my estimation there is a much better way of marking a queen's age. We used to clip the queens before the colonies were taken out of the wintering-cases. This necessitated putting the record on the wintering-case and a transference of this record to the hive when it was removed from the case. This gives extra thought and work at a time when one is in a hurry. So I now follow the idea given to me by my son Ivar. He scrapes the propolis from the top of the top-bar and marks when the queen is clipped. My system of marking the age of the

queen is to put down "Cl/May15/16," if she is found and clipped that day. If she is found *clipped* on that day the top-bar is marked "Cl/May15/16. If she is found clipped, and there is a record that she was found clipped (Cl) the previous year, that means that the queen is nearly three years old.

I prefer this system to having the record on the queen for the queen may be anywhere in the hive; but there is no difficulty in finding it on the top-bar.

While writing in reference to clipping I have come to the conclusion that it *may* not be well to clip the wings too closely, for there must be some circulation thru the wings, and probably the nearer the body the more this is interfered with.

BEES DRIFTING.

The editor of GLEANINGS appears to be under the impression that with the four-colony winter-cases the bees drift. Let me

say that, during the years I have used those cases, I have not one particle of evidence in that direction. There are many conditions which bring about a considerable variation in the strength of colonies that are no evidence of drifting. In the next place, with the entrance in one case facing north and south, and in the next east and west, and the row of cases broken in that way, I do not know of any better way of preventing the drifting of bees.

There is one thing I have noticed; and that is, that the more anxious the bees are

to get out of the hive, and the higher the outside temperature, the more the bees will drift, other things being equal. If bees have been wintered poorly, owing to poor stores or for some other reason, or if they have been hauled in hot weather, as for hauling to buckwheat, they will drift when opened during daylight. I would ask if bees drift when packed four hives in a case, and the entrances changed every second case. Under what conditions will they not drift? I know of no better plan to prevent it.

Brantford, Canada.

## ANOTHER ONSLAUGHT ON AMERICAN FOUL BROOD

BY JOS. J. ANDERSON

On p. 586, July 15, 1916, I outlined some very perplexing experiences with American foul brood.

I make this quotation: "A mile from my two yards is an apiary where I know some foul brood has existed. Have my bees carried the disease from there after being shaken?" The editor comments: "In answer to the last sentence we say, probably, yes. We do not believe the recurrence of foul brood in your yards was due to the fact there was only one shaking instead of two, or that the Baldrige plan was unsafe, altho if one uses it he takes a little risk; but if we had much disease in a yard we would use it; for to destroy good brood in a strong colony is a waste. By the Baldrige plan this is all saved, except what is actually dead or diseased.

"To sum up, it is possible that some of this recurrence was due to the Baldrige plan; but we venture the assertion that 99 per cent, if not all, came from the yard a mile away. We suggest that Mr. Anderson buy out that yard or get his neighbor to treat it. If two shakings are necessary to make sure to cure American foul brood, we are willing to be shown."

With reference to the Baldrige plan, if it is used at all, great care must be used to see that the hive is absolutely bee-tight. No opening anywhere can be tolerated where a single bee can enter the hive. Then instead of the funnel I would suggest the use of the bee-escape tacked over the auger-hole, since I have discovered that bees will enter the hive thru an eight-inch funnel, tho the hole at the end be large enough for only one bee to pass at a time.

Now for a sequel to my former article: July 3, finding the honey-flow nicely started, I proceeded to treat the diseased bees. I shook 103 colonies on this date as follows: First, from each diseased colony I took all

frames that contained no brood, tying the same up in the cellar away from danger of being reached by the bees. Three helpers made it possible to do this in a hurry, tho there was not the least inclination to rob on the part of the bees. The object of removing these frames was to make the work of actual shaking more rapid. While doing this I marked the weak colonies, some twenty in number, on which I intended to tier the brood. Here let me emphasize the fact that, for treatment to be successful, colonies must be very strong in bees, even if it is necessary to double up. I remember at one time treating seven colonies for a neighbor. These were all shaken into two hives, and they made rousing colonies that stored a lot of surplus. This was seven or eight years ago, and no sign of the disease has since shown up in his yard.

I next removed all brood from each colony, inserting one old empty comb. This helps to keep the bees contented, so that they are not as much inclined to swarm out. To avoid shaking out the honey which was coming in heavily, I was forced to brush the bees instead of shaking. I had previously prepared a lot of hive-covers by attaching on the under side several narrow strips of foundation. The process of removing brood, brushing the combs, placing in the old empty comb, and placing on the prepared cover, did not occupy over one minute per colony. It is important that there be sufficient help to remove frames, brush off bees, and tier up the brood with the least possible exposure. Notice that there was no changing of hives at this shaking.

On July 7 I administered the second shaking, proceeding as follows:

A clean hive with full sheets of foundation on wired frames was placed conveniently near each colony to be shaken. The old hive containing bees to be shaken was set

#### SETTLED IN THE SADDLE.

From remote history bees have been known to choose odd places for a home; but it remained till recently for a swarm of bees to "settle" on the saddle of a bicycle. The illustration shows a swarm that took possession of the seat of a bicycle on one of the main business streets of Whittier, Cal., on a recent summer afternoon. The time of day was a busy one, and the usual passing of pedestrians, shoppers, autos, and other vehicles was going on. The bees alighted in front of a confectionery store, and completely covered the seat of the owner's wheel. A curious crowd soon gathered, but kept at a very respectful distance. A beekeeper brought a hive and soon coaxed the little workers into it.

MIL0 HUNT, Whittier, Cal.

about two feet in front of the stand, and the new clean hive set in its place with six frames removed from the middle of the hive. One attendant carefully raised the cover, and another the old comb that had been inserted. One thump on top of the hive-body dislodged all bees, which fell into the hive, and the newly drawn comb was removed by a third attendant from the hive-cover into a covered pail. A few strokes of a Cogshall brush (for no thin honey prevented the shaking of the bees) removed the bees from the old comb, which was placed in a tight box fitted with a cover.

This new wax and the frames were removed to the cellar as fast as the box and pail were filled. Then all bees were dumped into the clean hive, and the cover placed on. I lost a few queens, but not many—not enough to pay for the time and trouble, and risk from exposure in hunting them up.

About 12 days from the first shaking, the weak colonies (now very strong) on which brood had been tiered, were shaken. The combs were all stacked in the cellar. The procedure previously outlined was followed, the second shaking occurring four days after the first. This finished the job, and ought to show satisfactory results. I no-

ticed no recurrence last summer; but I found four cases in the outyards from which diseased bees had been hauled home. This season's inspection will be the test of last season's treatment.

As the editor suggested, I looked after the neighboring apiary a mile away, having the appointment as deputy state inspector, and found a very serious condition, which perhaps accounted for the very unsatisfactory results of my 1914 treatment. Out of 47 colonies I found 25 diseased, most of them fairly reeking. A brother with 17 colonies just over the division fence had 7 colonies out of 17 diseased. All infected colonies were burned, and the ashes buried, and all old hives and old combs on the premises were destroyed in the same way. The strange feature of this experience is that these men who claim to have handled bees for thirty years, and claim to know all about foul brood, did not even know that foul brood existed among their bees until I called on them. I found old infected hives standing open, combs scattered in all directions—an ideal condition for the spread of the disease.

Last season, in the two counties comprising my district I inspected some sixty

one apiaries and over 2800 colonies. Twenty-three apiaries were diseased. Of the 2803 colonies I found 375 diseased, of which 215 were burned and 160 treated. All bees in box hives were transferred to movable-

frame hives. With the work so well under way, and an increased apportionment for this district, we are hopeful of very beneficial results.

Salem, Ida.

## NOTES FROM GERMANY

### Honey; Some Qualities Not Generally Known. Reason why Very High Temperatures Should be Avoided when Liquefying Honey

BY J. A. HEBERLE, B.S.

Honey is not a substance with a constant definite chemical composition, but a very complicated compound varying considerably, because it is derived from a large variety of nectar-secreting blossoms and plants.

Dr. Haenle, in his "Chemistry of Honey," gives as an average for a large number of analyses of pure honey from different parts of Germany the following:

Dextrose, 42 per cent; levulose, 35 per cent; saccharose, 2 per cent, making it a sugar content of 79 per cent, water about 20 per cent; nitrogenous matter 1 per cent; mineral constituents, 0.2 per cent; phosphoric acid, 0.02 per cent.

Of the 79 per cent of sugar content in honey, 77 per cent is in a form that, without any action on the part of the digestive organs, is immediately assimilated and goes into the blood.

Any one who, because of much physical exertion, becomes so tired that he feels completely exhausted, will find that, by taking a spoonful or two of honey direct, or with water or a little bread, in a few minutes he will be relieved of his fatigue: his strength is restored, so that he can again undertake a task that requires much exertion.

Because this sugar in honey is in a form to be assimilated without taxing the digestive organs, Dr. Feehlmann (*Schw. Bztg.*) called it "physiological" sugar.

For the mineral constituents and their importance to the human body, see GLEANINGS, p. 797, 1915.

#### ENZYMES IN HONEY.

In addition to the sugar, mineral matter, ethereal, and albuminous bodies, there is something very important in honey that has received but little attention. Dr. Thoeni said in a lecture (*Schw. Bztg.*) that, years ago, Erlenmeyer and Planta, two eminent investigators, showed that in the preparation of honey from nectar cane sugar was converted into invert sugar, and starch into dextrin and sugar. This change is caused by enzymes or ferments. Anzinger showed later that, besides the ferments which made

the invert sugar called "invertose," and those which change starch into dextrine, and sugar called "diastose," there is still another ferment in the honey called "catalose." This ferment has the power of converting hydrogen peroxide into water and oxygen. Marpmann claims to have found still other enzymatic bodies in honey; but this has not yet been corroborated.

The nature of these ferments is not quite understood. They seem to be bound to the albumen molecules. Only the effect they produce is known, but not how they come into existence—how they are produced. It is only known that they are derived from living cells.

Ferments, for the live process of all plants and animals are of the utmost importance. For instance, in the digestion and nourishing of the body they are indispensable since without them assimilation is not possible. The ferments are very susceptible to heat. Temperatures less than 212 F. injure them; and if the heat continues for a longer period they are destroyed. Because the ferments are derived from living cells, their functions are called biological.

From the importance of these enzymes in the process of digestion and assimilation it is obvious that honey, not only on account of the "physiological" sugar of which it is composed, but also for the presence of these ferments, is far superior to all other sweets, no matter how costly they are nor how pleasant they may be to the palate.

At present it is not possible to produce these ferments in a pure state; besides, their production would be so costly that they could not be added to any of the sweets on the market.

Besides these ferments there is a specific albumen present in honey; but whether this is altered by high temperature is not mentioned.

I have for years recommended to my patrons in liquefying honey not to heat above 122 degrees F., believing that a considerably higher temperature would have an un-

favorable influence on the aromatic principles in honey. Whether I am correct in this I know not.

More investigation seems necessary to determine the influence or the alteration honey undergoes when strongly heated. Dr. John published in the *Muench. Btzg.* a series of experiments and the methods employed on the property of honey to change starch

into fermentable sugar. Common sugar must first undergo a change before it can be fermented. He finds that up to 50 degrees C. the diastase in honey retains its full power to change starch into sugar; but at 55 C. this power is reduced; and at 65 C. (149 F.) this power or property is completely destroyed.

Kempton, Bavaria, Germany.

## THE GRAVITY METHOD OF STRAINING HONEY

BY W. H. CRAWFORD

For ten years I worried with honey-strainers, using several different kinds during that time. In this climate honey dries to thick candy very quickly when spread out and exposed to the air, and on that account honey-strainers clog up so often that they are a nuisance.

Twelve years ago I eliminated strainers from the list of devices used in the production of extracted honey. Tall tanks are provided, the size and quantity depending on the amount of honey to be handled. One tank at a time is filled brimful of the honey just as it is taken from the extractor. The honey is allowed to remain in it at least three days, if possible, by which time gravitation will have completely separated the bits of wax and pollen or propolis from the honey, pushing them clear up to the very top of the tank, where they can be taken off with the hand almost as easily as the peel can be taken from a banana.

The second tank is being filled while the first one is allowed to settle thoroly, and likewise the third tank is filled in the same manner, giving ample time for the honey in each tank to be thoroly separated from all foreign substances that may have been in it at the time when taken from the extractor.

In drawing the honey out of the tanks, care should be taken to leave enough honey in them to stand four inches above the gate, thus preventing bits of any kind, or foam, from being filled out into receptacles.

### A QUICK METHOD OF FILLING PAILS ACCURATELY.

In filling ten-pound pails we first weigh 10 lbs. of honey into a ten-pound pail. This pail is put on a board of any thickness, 7 x 7 inches square, cleated across the grain at one end with a thin cleat, and cleated at the other end with a cleat of just the right thickness to incline the board when placed on a level floor, to the proper angle that will barely cause the honey in the pail to touch the rim on the lower side. Two nails

are driven near the lower edge of the board, which prevent the pail from sliding off.

This board is put beneath the gate and the pails are placed on it to be filled. It is perfectly easy to fill the pails just right with this device, because it is so easy to see just when the honey barely touches the rim at the lowest point.

Any size of pails can be filled the same way by making a board for each size, and by using the same principles as described above.

Being so very handy and cheap, we never think of using any other method of filling pails. Should the weight of the honey change at any time, the board can be easily adjusted so that the proper amount of honey desired will fill the pail so that the required weight of honey just barely touches the rim of the pail on the lower side.

Roswell, N. M.

[The gravity method of clarifying honey, as mentioned by our correspondent, has been tried under all conditions. We do not know who was the first to use it. Some have felt that when the honey is thick and waxy the gravity method is not practicable. However, the thick honey simply means that more time must be allowed—hence more tanks. No doubt there is a limit somewhere after which the honey would require heating in some way.—Ed.]

### No Use in Drawing a Color-line.

I am much interested in the knocks on the goldens. I have a few queens from the best breeders in the United States; but I have one black colony that I got of a farmer that beat all the others last year, and wintered finely. On May 1 it had eight frames of brood, and without feeding or attention since last fall. These bees were wintered outdoors in a double-walled hive, and are very gentle. I realize they are out of date; but as long as they give me the most honey I will stick to the blacks.

A Beginner.

# Heads of Grain From Different Fields

THE BACKLOT BUZZER

*The doctor who patched up the old beetrue hunter wanted to know if they were really wild bees he captured. The patient said the bees weren't especially wild, but the owner of the tree was.*

## June Faith.

Such countless questions darkening our days!  
Such wide-eyed wonders drifting down the ways

Of living and of laughter and of light.  
And thru the weary darkness of the night!  
"Why?" and "Why?" and "Why?" from  
soul on soul,

And "How?" and "Whence?" and "Whither?"  
thru the whole

Unending and unsatisfying cry  
Of climbers on the trail that leads so high.

O shaken souls, and stirred! why strain to  
know

These dim far things when bees are hum-  
ming so?

Let go your strangling questions—this is  
June!

Let go and listen—life is all atune!  
Come hear her birds and bees—why, all my  
lives

Resound with rapture of a million lives  
That flash, ecstatic, thru a few swift hours,  
And live and live and live with all their  
powers!

By fields of clover-bloom wild roses nod.  
Come, climb and sing and leave the rest with  
God.

Nashville, Tenn.

Grace Allen.

## How to Make Increase by Feeding; What Feeder to Use.

My little beeyard is doing finely, having here a number of good days during fruit-bloom, some of which is still on. The strong colonies have brood-chambers full of honey and brood, and supers with baits are now filled with bees doing something, anyway.

What, in your opinion, is the best way for me to increase the coming year to 100 colonies? It is a rather slow process building up from the few I have, 12 colonies now, by stealing a comb now and then from them and ordering packages in the spring from the South.

How, where, and for what price can I buy combs with honey in them, say 200 combs in Hoffman frames, clean and free from any fear of foul brood? If I had these combs I could have 100 colonies by a year from now, and from that on it would be easy. I do not like to buy bees in hives.

Youngstown, O. C. E. Blanchard, M.D.

[It will be perfectly feasible for you to increase your twelve colonies up to a hundred. The writer did this some years ago, or, rather, we took ten colonies, supplied them with laying queens, gave them only frames of foundation, increased up to over 90, and secured a crop of 2000 pounds of honey, but the conditions that year were favorable. They are very favorable this year, and we see no reason why you could not duplicate the feat.

In order to make the increase rapidly, and not waste time, it would be necessary for you to buy untested queens. However, by making a smaller increase, or by running a series of nuclei, you can raise your own queens. You would not need very many nuclei, but simply enough to furnish you young queens as fast as the increase was made, which, of course, would be rather gradual.

The Alexander plan of increase we would consider as good as any; but under your conditions what you will need to do after the honey-flow is over is to divide your colonies up and supply each division with a laying queen to start on at once, because it will be only a waste of time to make a division unless the colony has its own queen.

We would use the Boardman feeder and stop up all the holes except one. Make a syrup of about 50 per cent water, 50 per cent sugar, by weight, and with the holes all stopped up but one, you will be able to make the syrup in the feeder last about 48 hours. A slow feed to the bees after the honey-flow is over is much better for increase and getting brood than a large amount of feed at one time. The ordinary open feeder, like the Doolittle, the Miller, or the Alexander, or even the Simplicity, gives the syrup out rapidly. It excites the bees, they rush out into the air, start more or less robbing, caus-

ing the bees to waste their energy in unnecessary flights to discover where the unusual supply of food is coming from; but the Boardman feeder, on the other hand, when it is regulated down so that the syrup goes to them very gradually, does not cause this excitement, and the bees go on breeding and thus save themselves unnecessary wear and tear in going to the fields.

We don't advise buying combs containing stores. It is very doubtful about your being able to obtain any that would be free from disease, or, rather, there would be the danger, if disease of any kind starts among your bees, you would have your labor almost for naught. Your better way is to use frames filled with foundation, wired of course, and put one of these between two frames of brood during the warm weather; but do not give these frames too fast. You will have to exercise considerable judgment in that you do not spread the brood too much, thus causing some of the brood to chill. There should be a fairly good force of bees to take care of the brood as it hatches out.—Ed.]

**No Trouble from the Spray on the Cover Crops.**

Wesley Foster, Feb. 1, page 96, in the paragraph on spraying and beekeeping, takes too gloomy a view as to the destruction of bees on account of spraying fruit-trees.

I have 22 colonies within a stone's throw of our 40-acre apple-orchard, which we spray very thoroughly three to four times a year, and I assure you that we hardly miss a blossom. We do not ask our hands how much they spray a day, but we ask them how thoroughly they have done their work.

The first spray is usually as soon as the cluster of flowers separates from the bud, and the second spray when the petals of the flowers begin to drop. My bees, in blooming time, naturally go in streams to this orchard, and in three years of spraying I have never found a dead bee in the orchard, and have not seen more dead bees around the entrance to the hives than what will die of old age.

We spray with lime, sulphur, and arsenate of lead. All those orchardists that spray before the bloom begins to drop will find out to their sorrow that it will not do to spray too early, because spraying, when wrongly done, will wash the pollen from the bloom, and such blossoms will not set to mature an apple. They usually fall off when they are about the size of a pea.

As to the killing of bees from the cover crop in this locality about the middle of May, when we spray for the last time, there is hardly any bloom on the ground from which bees could be injured, and one or two rains will usually eliminate the danger of bee-poisoning. It should be the aim of all beekeepers to have such laws passed that orchardists should spray when the cluster first separates and after the bloom begins to fall off; for by that time there are very few

bees that will visit an orchard except in a few instances where a few blossoms will open exceptionally late on a tree, which, however, is not much, and cannot injure bees to any extent.

Bees are absolutely essential in making a fruit crop. We have the only orchard within bee-flight that is sprayed. We have several large orchards which are not sprayed, and we made last year a good half-crop of 1852 barrels, while the other orchards have had an entire failure of Ben Davis apples. Our orchard is entirely Ben Davis, and this is principally due to thoro spraying and my bees.

Strafford, Mo.

T. L. Seharff.

[If you use sulphur in each of your sprays the bees will not be poisoned much, as sulphur is a repellent to insects, including bees. The fact that there was "hardly any bloom" on the cover crop would also protect you.—Ed.]

**Swarming with Clipped Queen, Transferring, etc.**

Dr. C. C. Miller:—1. If I give a queen two hive-bodies for a brood-nest, shall I get as much comb honey from that colony as with one body, or shall I get more?

2. If I elip queens can I let the colonies swarm naturally, and then, about six o'clock in the evening, take out queen and bees and put them in another hive on foundation? I work all day, and get home at 6 o'clock. My wife is not strong enough to move a hive after the bees have swarmed, so has to wait till I get home. What, in your opinion, would

An early swarm. Photographed by W. W. Gardner, Winsted, Ct.

be the best way to handle them? I am afraid I don't know enough about them to make an artificial swarm as I never handled bees before.

3. I have a hive full of crooked combs that were built in Hoffman frames without starters. They are now full of brood, and I want to take them out and get straight combs with full sheets of foundation. How can I manipulate them so as to let the brood all hatch? What is the best way to get the honey out of them? I have no extractor.

4. When is the earliest time I can start nuclei in this locality? I have one colony now which has capped drone-cells.

5. Which do you advise—one or two frame nuclei?

6. If I start a nucleus with one or two frames of bees and brood about the middle of May, is there any possibility of surplus from that colony if it can be helped with brood from another colony? How much help would it need? There is much more I should like to ask, but will try to understand the A B C and X Y Z, and Fifty Years Among the Bees for the rest. I have gotten lots of valuable information from both of those books.

Bert T. Wiemeller.

Indianapolis, Ind.

Dr. Miller replies:

1. You will gain decidedly if, with a strong colony, you allow the queen two stories up to the time of putting on supers, and then reduce to one story. I never experimented much in letting the two stories continue when supers were given; but from the little I did at it I thought I lost rather than gained.

2. Yes, you can do as you propose; but if you can get your wife to aid and abet you, or even some child, you can do a better way. When the swarm issues, catch the clipped queen and cage her; thrust the cage into the entrance of the hive, or else close beside it where it will be in the shade, then in the evening or next morning you can operate to your satisfaction without having to hunt for the queen.

3. Set over the hive an empty hive-body containing a straight comb of brood that you will get from some other colony. Any time after three days, if you find eggs in the upper story you will know that the queen is up, or at least has been up. If you find the queen on one of the frames, set that frame to one side; lift off the upper story; put a queen-excluder on the hive, return the upper story, and then put back the comb with the queen. If you don't find the queen up you must continue looking for her other days until you do find her. Three weeks after putting the queen over the excluder, all the worker-brood in the old hive will be hatched out, when you can set the upper hive down on the bottom-board and take away the old hive. You may drum the bees out of the old hive; or if you are careful you can cut out the combs, bees and all, and brush the bees off the combs at the entrance

of the new hive. It is just possible that the combs are so thoroly built crosswise that you cannot get out any frame. In that case take a hand-saw and cut away any attachments of comb to the sides of the hive. Turn the hive upside down and lift it off the combs, when you will have the latter at your mercy. Some of the combs of honey may be fit for the table. Melt up the rest; and, when cold, lift off the cake of wax.

4. You can do so while dandelion is in full play; but unless you have some special reason for doing so at so early a date, better wait till white clover begins.

5. In general the two-frame, and sometimes the three-frame, are better.

6. Yes, not only a possibility, but a good probability, if you give it a frame of brood by May 25, and then two more brood afterward, giving each of them after an interval of ten days.

### fooling the Robbers.

Last season I discovered a sure cure for robbing; at least the plan did not fail me once during the season. I take two boards four or five feet long, and lay on top of the hive lengthwise, the outer edge of the boards even with the outside edge of the hive. These extend about two feet over the front of the hive. Then I take a piece of old carpet or anything that will reach around the boards, hive and all. With a short board

I press the carpet tight against the sides of the hive and put something under the hive if there is any light showing. This forms a dark passageway of about two feet into the entrance of the hive. The robbers won't enter unless they can see light or some way to dodge out. The bees which belong to the hive will pass thru and into the hive.

Kansas City, Mo.

J. H. Morris.

### Extract Those Partly Filled Sections.

I know not whether any one else has tried it, but I had my blacksmith make me four clamps in order that I might extract from imperfect sections. I tried to get a clamp suitable for the purpose, but without success, so I had a blacksmith make me four—one for each basket in the extractor. They are just long enough to slip over the ends of section-holders with four sections in; and when the thumbscrew was turned down there was no trouble in the extractor, except I had to put a screw-end down in the extractor.

Of course I uncap after the sections are clamped in the holder.

To extract honey from unfinished sections I had the blacksmith make me four clamps from a 1/4-inch iron rod, as per sketch. Sections are placed in the section-holder, a clamp fastened over the top of the holder by means of the thumbscrew. After uncapping where required, the clamped section-

holder was then placed in the extractor with the thumbscrew down to avoid coming in contact with the upper part of the extractor while in operation. I found this little device satisfactory in every way, and take pleasure in passing the idea on to any beekeeper to whom it may be useful.

W. L. Palframan.

Niagara on the Lake, Ont.

**The Super-spring Fixes It.**

Doolittle says, p. 796, that if the super is the least bit too broad for the mass of sections "we have a space to be filled with propolis, very much at the expense of the appearance of the sections when ready for market." Does he mean if there are curved lines? If all lines are straight, will not the super-springs prevent any open space for propolis anywhere in the breadth except around the springs themselves outside of the last fence? What is a super-spring for?

Steven T. Byington.

Ballard Vale, Mass., Oct. 14.

[Doolittle evidently meant that if the super was too large the sections would be only loosely in contact, with the result that bee-glue would be chinked in between the spaces. Usually it is advisable to have the super large enough to admit wedges and a follower-board or springs—preferably the last named. When the sections are closely squeezed together there will not be much bee-glue deposited between the contact edges, for the simple reason there is no room for it. The very purpose of super-spring wedges or thumbscrews is to minimize accumulations of propolis.—Ed.]

Is *Melilotus indica* a good honey-plant?  
Marion, N. C. W. B. Bailey.

[*Melilotus indica* is a honey-plant, but an annual sweet clover, used largely for a cover crop in orchards. It grows readily, but is not as good a honey-plant as *Melilotus officinalis* or *Melilotus alba*.—Ed.]

**Limitations of Express Shipments of Bees.**

Having no foul-brood law and no inspector in this state, would I be allowed to sell pound packages of bees? I note Massachusetts will not allow shipments into that state; but how about New York, Pennsylvania, and Ontario?

From what you know, which do you consider the best counties in Indiana for keeping bees? Is there any good location in the southern part of the state? L. H. Robey.

Worthington, W. V., May 10.

[There is no reason why you could not ship bees in pound packages anywhere except in Massachusetts, and even there you can ship them providing you get permission or have them inspected on arrival; but the trouble is, bees in pound packages cannot stand it to be held until they could be inspected, and we do not know how it would be possible to determine whether they had disease in such packages.

We could not advise you as to the best locality in Indiana; but we would advise you to write to Geo. S. Demuth, care of Bureau of Entomology, Washington, D. C. He was formerly inspector of Indiana, and we think he knows the state very thoroly.—Ed.]

**Why Queens Hatch without Wings.**

I am sending you a sample queen, a virgin, hatched out today, and she has no wings. Half of the queens I have reared this spring have been deformed in this way. I never saw as many crippled young queens in my life, and I don't see what is the cause of it unless it is the cool weather.

Roanoke, Va., May 27. Henry S. Bohon.

[When bees or queens hatch without wings the trouble can usually be traced to too much heat or too much cold at a period when the wings are forming. Sometimes the moth-worm has something to do with it; but in your case we should infer that the bees had withdrawn from the place where the young queen was confined in the cell, and she became chilled during a period of her growth, with the result that her wings failed to develop. An examination of the cage seems to show that she is also defective in her legs. We believe you will probably find quite a difference after warm weather comes on, and especially if you have your cells reared in very strong colonies in double-walled hives. We do not use single-walled hives for the building of our cells. We have two-story powerful colonies in double-walled hives.—Ed.]

**A Correction**

Allow me to correct some errors which crept into your editorial of May 1 entitled "Our Foreign Exchanges." First, you have made an error of names. It is not Ulrich Gubler who has died, but Ulrich Kramer, as you will see by referring to *Gleanings* for 1915. The former is the retired editor of the *Bulletin d'Apiculture pour la Suisse Romande*, and is very much alive. At least

we have a letter from him dated December 28, and we hope nothing has happened to him since. The latter, Mr. Kramer, was president of the Eastern Switzerland Beekeepers' Association.

The three Italian bee journals are still appearing regularly, and several of the French, tho the latter are less regular. Among them we should name the *Revue Francaise d'Apiculture*, published in Marseilles, and the *Abeille Bourguignonne*, published in Joigny. The Swiss "Bulletin" has not missed a number. Several of the German magazines have also continued regularly, tho there is no telling how soon they may have to suspend.

Some Russian bee journals are also coming, and I have on my desk a publication sent out from Tiflis, describing the Caucasian bees and giving a map in three colors, to show the distribution, between the Black Sea and the Caspian Sea, of the Caucasian gray bee and the Persian bee or bee of Lenkaron, with a delineation of the districts in which the two breeds are mixed.

So, in spite of the wholesale massacres caused by the olden-time spirit of conquest, civilization is asserting itself in the countries at war. We trust that, after a while, they may be so sick of fighting that a general disarmament will ensue. Enough wealth has probably been destroyed to feed the entire world for a year or more. Famines may ultimately result.

Of course, the second quotation you make is not from *L'Apiculteur*, published in Paris, but from the *Bulletin*, of Switzerland, and the words are correctly credited to good old friend Gubler. But Mr. Gubler never wrote a line for *L'Apiculteur*.

Hamilton, Ill.

C. P. Dadant.

[Thanks, friend D., for your friendly corrections.—Ed.]

### Bees and Bullets

A few days ago a man who lives near one of my outyards phoned me that a large giant cactus which stood in one of his fields had fallen down, and that a swarm of bees in it was making things so hot for him that he was unable to plow near it, much to his discomfort and annoyance. He concluded that, since the cactus was so near my bees, and that mine were the only ones in the country for some distance, they must be one of my escaped flock, and that I ought, therefore, to come up and take them away. Knowing that a friend near an outyard is a priceless jewel to a beekeeper I immediately went up, more to please him than to get the bees, and found them truly fighting mad. Calming them with a few puffs of smoke I found they had taken up entirely within the cactus, and had got there thru a very small hole in one side. Taking my ax I chopped away the fleshy parts, and there they were in a nice, dry, snug home about two feet long and one foot in diameter. I then broke away the skeleton parts and soon hived them.

I then wondered how they could have got in there and what had originally made the hole. Some birds may pierce the thorns and thiek flesh that covers the skeleton work within, but they always choose to do it at the more tender top, and therefore there must be some other cause. My investigation, however, soon dispelled all doubts, as, imbedded in the wall just opposite the entrance, was a bullet with its nose in the right direction. This told the story. Some one had, perhaps carelessly, shot into the cactus years before, and, contrary to the general rule of wantonness, had actually made a home for a nice swarm of bees.

Phoenix, Ariz.

L. J. Holzworth.

### Putting Fresh Bees where Others have Died.

I received a fine queen last year, but foul brood got in the hive and all died. There have not been any bees in the hive since last December. Would it be safe to put new bees in the hive with the old combs?

Las Vegas, Nev.

Philip Steinman.

[It would hardly be safe to put any fresh bees in a hive where bees had died of foul brood; but are you sure they died of that disease? We are sending you our little book, "Diseases of Bees," and suggest that you look it over very carefully, especially the symptoms of American and European foul brood. If you find scales in the combs of dead larvæ it is probably American foul brood, and it certainly would not be safe to introduce any other bees into the hive; but if they died of dysentery or from exposure to cold weather you could put in a half-pound of bees and make a very nice start.—Ed.]

### Don't Get the Wrong Colored Paper.

The article by Frank Coverdale, April 1, page 284, is of great value; but his reference to litmus paper might confuse a great many. There are two colors of litmus paper—blue and pink. The blue is for testing soil or water for acid, and the pink is for testing for alkali.

Poplar Bluff, Mo.

H. W. Peterson.

### A Love Limerick.

A foolish young lover named Vawter  
Fell in love with a beekeeper's daughter.  
When his heart he had flung  
At her feet, he was "stung"  
And went away breathing out slaughter.

Then came another and sought her  
With jewels and gold, and he bought her;  
But his love she had not,  
And she never forgot  
The unhappy lesson it taught her.

For into a passion he wrought her  
By drawing the marriage ties tauter;  
So she got a divorce,  
With a pension, of course,  
And left him with jeering and laughter.  
Æsop.

A. I. Root

## OUR HOMES

Editor

Come with us; let us lay wait for blood; let us lurk privily for the innocent without cause; let us swallow them up alive as the grave; and whole, as they that go down into the pit.—PROV. 1:11, 12.

We have made lies our refuge, and under falsehood have we hid ourselves.—ISAIAH 28:15.

The letter below explains itself:

*Mr. Root:*—I am sending you an article which I took from the *Fra*. I should like to see it denied in your Home department. WALTER E. WRIGHT.  
Ellwood City, Pa., May 29.

I presume our readers are aware, or at least most of them are, that both the whisky party and the temperance people are sending out large-sized sheets about once a week to post the people in regard to this matter of wet and dry, giving statistics as to what is the result in states that have voted dry, etc. As Kansas has been held up before the nation as an example of the beneficent results of prohibition, The National Wholesale Liquor-dealers' Association has "got busy" in hunting up everything that could be said against prohibition in Kansas. Sometimes their statements have a grain of truth to start with; and the statements that they make may be true; but their explanation of the facts given is misleading. Here is an illustration:

"Kansas closed 220 schools in 1913."

The above was given on the sheet our friend inclosed. Now, I have not looked the matter up, but I presume Kansas has been in the forefront in consolidating her country schools, just as we are now doing here in Ohio. But within two miles of where I am now sitting, the old schoolhouse where I learned my A B C's has been moved away, and is now used as a barn. Are we to understand that this means that the juveniles in that neighborhood have fewer and poorer school advantages than they had 70 years ago? Not by any means. An electric railway runs close to the spot where that old schoolhouse stood; and the pupils, not only from that neighborhood but along the electric line, attend the fully equipped and up-to-date schools here in Medina. Think of using that as an argument against prohibition!

Some years ago Elbert Hubbard gave us so many good things in his *Fra* magazine that we subscribed for it. But shortly afterward he said so many things that were so shocking and so irreverent and blasphemous that we could not consent to have it come any longer. My stenographer says the *Fra*, like the *Philistine*, seems to oppose all moral reforms. Well, our brother sends us two pages; and these two pages seem to be

crammed so full of false statements about Kansas, and bitter denunciation of temperance and temperance people, that I could only wonder that anybody of decency could tolerate it in the average home. Here is a sample:

After thirty-five years of trial, prohibition with all the trimmings has given Kansas an enormous rate of divorces granted wives for cruelty and drunkenness; an unusually high and increasing rate of pauperism; school systems ranking only twenty-ninth in efficiency; an extremely high and increasing rate of insanity, and almost the lowest church population in the Union. Kansas closed 220 schools during 1913. The 1915 census shows a population decrease of 18,404 since 1910.

I am surprised to find that there is a magazine in the United States that would give space in its reading-columns to anything so much in line with the sheet that is being sent out by the Liquor Dealers' Association. I have one of the latter in my hand, bearing no date, but headed "Serial 22." The heading of the sheet is as follows:

NINETEEN STATES ARE "DRY" (?), BUT ABOUT 10,000,000 MORE GALLONS WERE USED LAST YEAR THAN EVER BEFORE.\*

Uncle Sam is drinking more whisky today than at any time since he was born. The nation drinks more whisky as a result of prohibition. Four dead, one is dying. Six other youths of Plainview, Texas, are seriously ill. Drank hair tonic. Seventeen sons of prominent families swallowed stuff when they could not get liquor in a dry town; a barber was a victim.

It is evident from the above heading that the liquor party are hard up in their efforts to find fault with prohibition. Because some boys drank some hair tonic and were killed, they quote it as the result of not having a legalized saloon where they could quench their thirst.

In regard to the statement that ten million more gallons of whisky was used in one year as a result of prohibition, one is led to smile. If prohibition really results in an increase in the amount of liquor used, why in the world does not this liquor dealers' association turn in and help us, tooth and nail? I have not the figures at hand, but I am quite sure the consumption of liquors of all kinds is on the decrease. Brewers are making assignments, and quitting the business. Great stocks of liquor are accumulating, and nobody seems to know what is going to be done with them unless we use them for running automobiles.

\* In regard to the above ten million gallons, I think I have seen it stated somewhere that more whisky is being used as a result of cutting off the beer and the ruin of the breweries. The whisky, on account of its smaller bulk, can be easily kept out of sight; but notwithstanding the above explanation I am quite sure we have honest statistics to the contrary in regard to whisky.

In regard to Kansas, I clip from the *American Issue* for May 27 the following:

## PROSPERITY STATISTICS.

|                                                     | Missouri  | Kansas     |
|-----------------------------------------------------|-----------|------------|
| Age of states (years) . . . . .                     | 95        | 55         |
| Population . . . . .                                | 3,300,000 | 1,690,000  |
| Saloons . . . . .                                   | 4,000     |            |
| Per capita expenditure for liquor \$                | 24.00     | \$ 1.48    |
| Criminals to 3000 population .                      | 10        | 1          |
| Bank deposits per capita . . . .                    | \$ 20.00  | \$ 140.00  |
| Assessed property valuation<br>per capita . . . . . | \$300.00  | \$ 1700.00 |
| Automobiles to every 100<br>farmers . . . . .       | 1         | 20         |

In Kansas there are 131 towns of 1000 population which own electric-light plants, water and sewer systems, splendid sidewalks and public schools, without a single cent of revenue from the liquor traffic. In Missouri there are scores of towns of from 1000 to 4000 population with open saloons paying a high license, where they have no electric-light plants, no water or sewerage, and poor sidewalks.

In the panic of 1907, Missouri, with all her big banks, was unable to send one penny to the East. Kansas banks sent \$50,000,000.

Kansas spends \$38,000,000 less per year for intoxicants than does Missouri. This explains the prosperity of Kansas.

Please notice in Missouri there is only one farmer out of a hundred who has an automobile, while in Kansas one farmer out of five has one; and I think that, if you will look into their homes and over their farms, you will find everything in proportion.

Now, our good brother who writes the letter at the opening of this article wants to know *who* tells the truth. And this brings up something that I have long wanted to talk about. Who are most likely to tell the truth\*—the liquor party who have no other motive in this fight than to increase their sales, and make *more money*? Does not the text I have chosen from Isaiah fit them pretty closely if not exactly?

We have made lies our refuge, and under falsehood have we hid ourselves.

They make a feeble pretense of wanting to benefit humanity. As the temperance papers have had much to say in regard to the suffering wives of intemperate men, the liquor party gives a letter that purports to come from a suffering wife. She does not exactly say that prohibition brought about all her troubles and destitution, but they try to make it appear that way. Here is the wife's (?) letter:

\* Let us pause right here, friends, and take a square look at the matter. Shall we believe these weekly sheets sent out by the liquor party—a party that made and kept Ohio wet simply because the slum voters of the great city of Cincinnati overwhelmed us? Shall we let them rule the whole state of Ohio in opposition to the schools and churches, and the Christian people? Shall this slum element, perhaps half drunk when they vote, be believed, and their words be accepted as truth in opposition to the devout Christians who make it their daily prayer as given in that beautiful Psalm, "Search me, O God, and know my heart; try me, and know my thoughts, and see if there be any wicked way in me, and lead me in the way everlasting!"

## A WIFE'S PLEA.

The entire state of Tennessee is "dry"—that is, unadulterated liquor cannot be sold openly. But bad whisky and other injurious substitutes may be obtained in "blind tigers."

The following is a letter from a heartbroken wife to the *Memphis Press*:

*Editor the Press*:—Why don't the administration close the dives in the city? Why don't they stop the sales of whisky? You can get it in restaurants, all you want. Gambling is going on in every corner, and the police know it. The chief knows it.

My home is wrecked, and my life is ruined. My husband has drunk until he has lost his mind and left his home and wife without one bite to eat, or one cent to buy anything with—running after those gambling-hells and rotten whisky.

Will the good people of this town stand for it? My husband was one of the best men in the world until this blind-tiger business started.

For God's sake, close these gambling-hells and blind tigers.

From a wife who has suffered and is today without a dollar.

Here is a clipping, also from the *American Issue* that bears on the subject:

## MAKING IT HOT FOR THE CRIMINAL LIQUOR INTERESTS.

Last week special deputies acting under direction of the Attorney General, raided places in Girard, Ala., where liquor had been stored by bootleggers with a view to distributing it thruout Alabama and neighboring states. Girard is just across the river from Columbus, Ga., and offered natural advantages for the importation of contraband whisky.

The first day's raid netted the officers' liquor seizures to the value of \$265,000; the second day \$109,000, and the third day \$100,000.

The Governor of the state sent a company of militia from Opelika to guard the liquor which the officers put in storehouses for safe keeping. An attempt was made by the liquor interests to enjoin the state from removing the liquor, but Chancellor Lewis refused the injunction.

Just think of it, friends—toward half a million dollars' worth of liquors confiscated! No wonder it requires the militia to protect it; and the question comes up as to what is going to be done with all this confiscated liquor. Won't we be obliged to get it in shape so we can use it in our automobiles in place of gasoline, which is now going up so fast?

Now, in closing let me illustrate the point I am trying to make by an incident that happened years ago.

A beekeepers' convention was held somewhere in the West in conjunction with a state fair. Our good friend E. Whitecomb, of Nebraska, was one of the managers of the state fair. Back in those old days they had booths for selling beer, running in full blast at the state fair. Kegs of beer were exposed right out in daylight with great blocks of melting ice resting on them so as to give the multitude a "cool drink." As Mr. Whitecomb was one of the managers I went to him and remonstrated. He replied something as follows, so far as I can remember:

"Mr. Root, we try to be fair, and take a

medium course on all these questions where there are so many differences of opinion. It is true we have given the saloon-keepers the privilege of having a stand to sell beer; and to be fair about it we gave also the W. C. T. U. and the Anti-saloon League the privilege of selling or giving away their literature. We think it best to let the people see *both* sides. Now, in view of the fact that we get quite a lot of money from the beer-stand, and not a cent from you temperance people, we think *you* surely ought not to complain."

Several temperance and Christian people were with me when I made my plea; and as our good friend Whitcomb was very busy, the matter was dropped right there; and ever since that time I have wondered that so many good people should get the idea into their heads, or let it get into their heads, that the liquor party is on *one* side of a debated question, and that the Anti-saloon League is on the *other* side, taking it for granted, without giving it a thought, that both sides were after the money that was in it. I think the world is getting past this notion, however; and before I forget it I wish to mention that, shortly after that state fair, friend Whitcomb was soundly converted, and he came out in print right on the pages of GLEANINGS, announcing his stand for the Lord Jesus Christ and for temperance, and for everything else that benefits humanity. I notice that he is still holding to the faith, and writing articles in the *Independent Farmer* for the benefit of humanity. The wets are after the dollars and dimes and nickels. They seldom have the cheek to *claim* that they are after anything else. The temperance people are giving their money, year in and year out, with but little hope of getting any of it back here on earth; and notwithstanding the discouragements and misrepresentations, and notwithstanding the falsehoods (that it seems impossible to refute as fast as they are uttered by the enemy), we are still holding our faith and courage.

Perhaps I might mention the fact that the A. I. Root Co. has, in times past, given something like \$25,000 to the Anti-saloon League with but little expectation that we should ever get it back—at least in *dollars and cents*. But we still have faith enough to keep on, because we believe the promise that "bread cast on the waters" shall (perhaps long years afterward) bring its reward; and while it may be true, as I said above, that we shall never get a return of treasure here on earth, we shall get something a thousand times better—"treasure laid up in heaven."

"WAR ON CHRISTIAN PRINCIPLES."

Whosoever shall smite thee on the right cheek, turn to him the other also.—MATT. 5:39.

Just after my article in the June 1st issue, entitled "Getting Even," and "War on Christian Principles," I saw an account in a daily paper of two prominent men, both of whom, I believe, occupy high offices, and are well known to the world. It seems that, by some mistake, each one of the two had engaged a certain section in a Pullman car. Of course it was a mistake, as such mistakes will sometimes happen. Instead of showing a gentlemanly and Christianlike spirit, each one demanded what he paid for, and each had a receipt for the same. After a wordy fight, one slapped the other on the face, and was afterward sued for \$25,000. After an expensive lawsuit the plaintiff got a verdict of 25 *hundred* dollars. Now comes the question, "Is it possible that neither of these two prominent persons has ever heard of turning the other cheek also? Or is it true that the war spirit has so permeated the whole wide world that two prominent men—men occupying high places in the state of Ohio, and perhaps in the nation, seemed to be entirely ignorant of the fact that citizenship, to say nothing of Christianity, demands that we behave ourselves in a gentlemanly and Christianlike way, especially in the presence of the traveling public?"

Years ago, when traveling thru the Black Hills of South Dakota, something similar happened. Two men had the documents to show that they had paid for a certain section in a crowded Pullman car. The porter could not help them, and so they sent for the conductor. The conductor was new at the business, but did everything in his power to quiet the tumult. He offered each one of the belligerents another berth near by; but both declared in substance that he had paid for that particular section, and *was going to have it*, no matter *what* it cost. They were evidently men of means and of education; but the two kept up their jangling until toward midnight. As my berth was close by I could not get to sleep. I myself tried my hand as peacemaker, but it seemed to make them worse. I do not know how it *finally* ended. I became pretty well acquainted with the Pullman conductor, and I really pitied him with my whole heart. Now, here is the saddest part of it: By mere chance I ran across this same conductor several weeks afterward. I told him I hoped he had not had any similar experience since the incident I mentioned. His reply was, "Why, Mr. Root, I have had the same thing over and over again, and even *worse* 'rackets' than the one you saw."

The above would indicate that the Pull-

man-car management ought to have some better system in order to avoid such mishaps; and still more important—yes, vastly more important—we ought to have the apostles of the Lord Jesus Christ scattered like the salt in the parable all thru business and thru the great traveling thoroughfares, to urge all mankind, little and great, to be ready to turn the other cheek also before getting into quarrels over the merest trifles like the one I have described. What an easy thing it would be in such cases to show forth a Christian spirit to all about us and say, "My good friend, stay where you are. Do

not be worried a bit. No doubt the management will give me another section or berth just as good!"

Now, friends, to come right down to the practical point, how many of you whose eyes rest on these pages will hold yourselves in readiness to show forth a Christlike spirit just as soon as an opportunity occurs, especially when it occurs where there are crowds of lookers-on ready to take sides? Are we who profess to be followers of the lowly Nazarine ready to show forth to the world the grander beauties of "war on Christian principles"?

---

## HIGH-PRESSURE GARDENING

OUR GARDENING AND FARM PERIODICALS.

I have already expressed the thought that it cheers my heart to run over hastily the beautiful farm periodicals from the different states—not only for their intelligent teachings in the line of agriculture, but their high moral tone. I have yet to find a genuine farm paper on the wet side. Of course there occasionally comes out a "make-believe," put out by the wets.

Now just a word about tilling the soil. Here is something from the *Kansas Farmer* for May 27, on the outside cover; and it is such good sound sense I think it will pay you to read it over and over.

Tillage is plowing, harrowing, dragging, disking—anything done to stir the soil, either before or after the planting of the crop.

The principles of good tillage are practically the same for all conditions:

1. Stirring the soil breaks it up. The smaller the particles of soil the greater the area the root hairs or "mouths" of the plant have to "graze" on. Good tillage gives the crop more soil surface on which to feed without increasing your taxes.

2. When fresh vegetable matter is present, stirring the soil tends to make more plant food available. The organic matter is brought into closer touch with the mineral particles of the soil, and plant food is set free by chemical action as the vegetable matter rots down.

3. Air is as necessary for the roots of plants as for the leaves. Plants die if there is no air in the soil. Tillage aerates the soil, supplying oxygen, which is used directly by the soil organisms, and nitrogen, which is used by legumes by means of the nitrogen-gathering bacteria which live on their roots.

4. Tillage tends to regulate the water supply in the soil. Well-tilled soil absorbs rain more rapidly than does a hard soil, and permits a freer circulation of moisture brought up from below by capillary action, such as occurs in a lamp-wick. Like a sponge, it takes water more quickly and stays moist longer than does soil that is packed hard.

5. Tillage kills weeds.

Briefly summed up, then, we till to make a home for the growing plant, to set free plant food, to aerate the soil, to get and use moisture, and to kill weeds.—CARL VROOMAN.

And here is a new periodical from away off in San Francisco. On the beautiful bright illuminated cover we read: "Little Lands in America." Our older readers will remember, perhaps, that years ago I had a series of articles headed "How to support a family on one-fourth of an acre." Of course the quarter-acre was to be mostly covered with glass. The same thing is now incorporated in a chapter or two in our tomato-book. Well, just below the heading of this little magazine we read: "A national magazine edited by William E. Smythe. Devoted to the most valuable of all arts as revealed in the prophetic vision of Abraham Lincoln—the art of deriving a comfortable subsistence from the smallest area of soil."

The above is a revelation to me. If Abraham Lincoln did give us that beautiful thought about getting a living on a little plot of ground, say out in the back yard, I shall have still more reverence and respect for his memory than ever before.

Just below the above there is a picture of a honeybee, and under it the legend "The honeybee earns \$400 a year in your back yard." The first article in the journal for April is headed "What do you know about bees?" It is quite well illustrated. The price of the magazine is \$1.00. The address is 504 Sharon Building, San Francisco.

By the way, "A little land and a comfortable living" is now receiving additional emphasis from the boys' and girls' clubs. The girls especially, of the whole United States (or at least nearly so), are now striving to see who can make the most money on one-fourth or even one-sixth of an acre. I need not copy the reports here, because our various periodicals are full of them. Not only have wonderful results

been achieved by girls in their teens, but several girls under fifteen have done wonders. I think I saw in one of our periodicals a picture of a girl only thirteen years old who had made something like forty dollars in growing and canning tomatoes on only a sixth of an acre.\* Now, you need not say these stories were all "made up," for you can see it done in almost every progressive neighborhood; and if you live in a city, by taking a little pains you may see what is being done in a similar line in the boys' and girls' gardens on vacant spots of ground. The owner of the ground usually not only lets it to poor people free of charge, but plows and cultivates it so it will be in good shape for gardening, and sometimes furnishes manure and fertilizers. If a man has a piece of real estate in a growing city, it is nothing strange if it should transpire that he gets a better price for it when it is covered with vegetables and flowers than if it is left to grow up to unsightly weeds. May God bless the boys and girls who are in love with modern agriculture; and may the modern agriculture ultimately lead them to get in love with the great Father above who gave us this beautiful world with its wonderful possibilities along the line of agriculture.

I have given you pictures during the winter of my Florida garden; and some of you may wonder what I am doing here in Medina on this last day of May. Well, I have not done very much as yet, because the ground has been too wet to work; and in our Medina clay soil that means quite a little more than it does down in Florida, where one can always get to work two or three hours after the heaviest kind of rain-storm. I have peas up that are doing very well; but my sweet corn, planted at the same time, has, a great part of it, rotted in consequence of the cold and wet. The Golden Bantam, as heretofore, stands bad weather very much better than the other varieties.

A year ago I spoke to you about a hand cultivator to be run by a motor. There are several such machines now on the market; but they cost about \$150, and weigh pretty well toward 500 pounds. I have got hold of something that, for an old man like myself, I think is better than a motor cultivator. In fact, it is very much simpler. It is a little hand cultivator that I just bought of Sears, Roebuck & Co. It weighs only 20

\* I find the following in *Farming Business* for June 5:

Olza Chick, of Ferguson, Ky., was awarded the first prize in the Canning Clubs of the state. In the summer of 1915 she raised 5944 pounds of tomatoes on one-tenth of an acre, and canned 1075 cans of tomatoes alone. Her work netted her \$121.

pounds, and it cost only \$1.95. It not only pleases me because of its lightness, but the tools that go with it are such hard-polished steel that the result is, the tool is almost as smooth as glass. It slides into the dirt, even if it is damp, and the dirt slides off from it. This is a wonderful improvement. I might have thought of it long ago, for the reason that my favorite implement in gardening is a large-sized enameled spoon. This spoon is always clean because it is so easy to rub off the soil when you are thru cultivating or when you are done using it. I prefer my big spoon to any kind of trowel. In stirring the soil around a plant, or in lifting little plants from the seed-bed to be put out in the garden, the spoon is about the handiest tool I ever got hold of. If I lay it down and forget where I left it, I am like a fish out of water, as the expression goes.

A word more about the cultivator. I have been using hand cultivators that cost four or five dollars. But this little light cheap cultivator I have mentioned is for me away ahead of any of them. Of course it has no arrangement for sowing seeds, etc., and I do not believe I like a combined tool. I like to have every tool made for a particular purpose with as few loose attachments as possible to get lost and require time in changing and adjusting.

Perhaps you wonder why I do not say a word about the maple sugar I mentioned last year, as a "substitute" for an electric or gasoline motor. Well, the maple sugar does not always answer just right. Perhaps when one is taking strong muscular exercise day by day he can stand a fair amount of sugar; but where one has to spend a good portion of his time sitting in the office, as I am now while dictating this, he had better be careful about *too much* sweet; and *no* sweet (nor anything else, for that matter) between meals.

#### THE STRIPED SQUASH AND MELON BUG.

*Mr. Root.*—I was quite interested last year in the discussions and remedies to prevent the devastation of the striped vine-bug. This may not be just the proper name for it, but I think you will understand the fellow I mean. At that time, I thought of writing you; but fearing it would be too late to be of benefit for that year, I decided to wait till the early spring, and I feel sure the remedy that I here offer is a success under any and all conditions. It is not my own invention, neither have I any interest in either of the ingredients used, which consist of air-slacked lime and either coal oil or turpentine, the lime to be moistened with the liquid till it is highly scented, and then sprinkled or sifted on the hills. When scattered over the vines where bugs are thick on them it seems that each individual bug tries to be the first to clear the premises to get away from it. I have used both the oil and turpentine, and see little difference in results. This is what the R. M. Kellogg people use for their melons, I have been told, and that is the way I found its virtues.

I told you last winter when visiting you at Bra-dentown about their melon crops; and from my window as I write, just across, are their cold-frames filled with pint berry-boxes set solid, and two to three melon-plants now up in each box, some starting the second leaves. I was over at noon to investigate for this report, and took measurements of their beds. I find there is 18,024 square feet under glass, and all solidly filled with the small boxes with plants and seeds, as a few of the latter are not up yet. These boxes are to be transferred to hill spaces in the field at the proper time. Their fields are marked off one way eight feet, and the cross four feet; then in placing the plant boxes each alternate four-foot mark is missed in opposite rows, so that in cultivating it makes rows one way four feet apart and eight the other. This plant is only a part of their fields for this year. Bugs do not respect their plants above their neighbors, so they would not use a remedy that is not a sure thing. The lime is a benefit to the plant life in the land. They now have 120 acres under overhead irrigation, and working this dry weather. As you spoke of so doing, you had better come over and see them this summer.

Three Rivers, Mich., May 11. M. L. BREWER.

My good friend Brewer, I have used kerosene on sawdust, and at first I thought it was going to do the business; but after a while the bugs became so greedy, at least here in Medina, that they did not pay much attention to it. Then I tried strong tobacco dust, and that did very well until we had a rain. I finally saved my plants, but it was only by eternal vigilance. I have in mind this Kellogg institution; but here in Medina, at this date, June 3, we have been having such abundant rains that I cannot even get out to try my new Ford automobile.

#### PRICKLY PEAR IN AUSTRALIA.

Mr. Root.—For about a year I have been a subscriber of GLEANINGS. I always read it carefully from one end to the other, and never get tired of it. You must not think I am a great beekeeper, for I am only starting; but, beekeeper or not, and even if it cost me my last penny, I must have GLEANINGS. But now for the reason of this letter:

Yesterday I received GLEANINGS for June 15, and on page 515 I read something about the food value of the prickly pear. You must know that I am a Dutchman, and left my own country five years ago. When I came here I had some money and took up some land—the piece where I live now. That land was infested with prickly pear; but I thought it was possible to clean that rubbish off. You should know that I have to clean the pear or I lose my land. But after five years I have cleaned only about 30 acres out of 130. We lived as carefully as possible; but, all the same, I lost every penny I had on that stuff; and so it is, not only with me but with all my neighbors; and not only my surrounding people are suffering, but hundreds and hundreds of selectors who took up prickly-pear land. Some acres cost up to \$75 to \$100 for the first cleaning. The next year that same acre will be like a wheatfield, so thick is the young pear coming up again from seed. In a word, the prickly pear is the pest of Queensland.

I would not have stopped here at all had not an American, Mr. Roberts, come here to Queensland with a new invention to clean pear with a gas. I managed to buy an outfit for gas, and that is doing good work. The densest pear can be treated now for \$3.60 an acre, so that is a blessing.

This letter is to give a warning to people about prickly pear. It is believed here generally that the pear is practically good for nothing. It grows anywhere and everywhere on good and bad soil, in the sun and in the shade, with rain and without rain, even on rocks and on some stumps and trees. Birds, cows, wallabys, kangaroos—in fact, all animals that eat the fruit, spread the seed, and so, notwithstanding the fact that thousands of acres are cleaned every year the pear in Queensland is increasing at the rate of one million acres a year.

There is an agricultural bank here from the government for helping the new settler on the land with some money to carry him over the first few difficult years. But that bank decided a few months ago not to lend a penny to prickly-pear selectors, so frightened is even the government at this pest. They have lost too heavily on prickly-pear selections; therefore my question, "Must we not give warning to other countries, or are we all mistaken, and is pear a valuable plant? Then, again, is it paying to make prickly pear into fodder? Of course this has much to do with prices of land and wages. Land runs here from about \$10 to \$50 an acre, and wages are about \$2.00 a day.

Perhaps you will be so kind as to give this a thought; and if you think it is a pest, please tell your own folks through your paper; and if you think it can be made into paying fodder, please let me so kind as to write me.

I hope you will excuse me for my broken English; but you must remember it is not my own language.

W. MERTENS.

Gayndah, Queensland, Australia.

Many thanks, my good friend, for your kind letter. No doubt the variety of prickly pear you have is a nuisance; but my impression is that the spineless cactus we have here, and which is selling as high as several dollars a leaf, is quite a different thing from your prickly pear. I have gone over all of your letter most carefully, but do not find a word in regard to the spineless variety. The spineless now growing in my garden is perhaps a foot wide and a couple of feet long—no spines whatever; in fact, you might give them to the baby to play with, and it has been abundantly demonstrated that cows, horses, sheep, pigs, and even poultry, eat them with avidity. It must be your variety is different from the new kinds we have here, or that your soil is in some way peculiar.

After you eradicate this wild prickly pear, could you not grow the spineless kind? Has anything of that sort been tried so far as you know? I should be glad to hear from you further.

#### SPINELESS CACTUS IN OREGON.

In regard to the spineless cactus, I got some years ago. I paid a big price for them. I took the best of care of them, and expected wonders; but in return they only dragged along for a year or two, and finally died. I think it is too wet and cold here.

You know Burbank sold out to a company, and they tried to get me to take shares; but I wanted to see what the thing was worth before investing money in it. While they may do all right in a warm dry climate I am satisfied they are not a success in this part of the country.

Laurel, Ore., Dec. 2.

**BREEDERS.**—The cream selected from our entire stock of outyards; nothing better. These breeders, \$5.00 each.

Can furnish bees on Danzenbaker and L. or Hoffman frames.

Above price on bees by pound, nuclei, and colonies does not include queen. You are to select such queen as you wish with the bees, and add the price.

No bees by pound sent out till first of June. Also nuclei and colonies, if wanted before June 1, add 25 per cent to price in table.

Breeders, select tested, and tested queens can be sent out as early as weather will permit.

Send for testimonials. Orders booked now.

## 55c-- Golden and 3-banded Italian Queens -- 55c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested (1), 55 cts.; 12 or more, 50 cts. each. 1 lb. bees, \$1.25; 2 lbs., \$2.00; 1-fr. nucleus, \$1.25; 2-fr., \$2.25, Full colony 8-fr., \$6.00; 10-fr., \$7.00. No queens at these prices.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

*To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.*

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested, \$1.00; 12 for \$10.00; Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

**THE STOVER APIARIES, MAYHEW, MISSISSIPPI**

## WARDELL STRAIN OF ITALIANS

Descendants from the Famous Root \$200 Queen

I was head queen breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

## ITALIAN QUEENS

Three-banded

From June 1 to November 1

Only 75 cts. each; 6, \$4.00; 12, \$7.50; tested, \$1.00; 6, \$5.00; 12, \$9.00; of an exceptionally vigorous and long-lived strain of bees. They are gentle, prolific, and the best of honey-gatherers. Send for my free circular and price list.

JOHN G. MILLER, CORPUS CHRISTI, TEXAS  
723 South Carrizo Street

### Italian Queens with a Record of 30 Years

Leininger's strain of Italian bees and queens have been carefully bred for 30 years; for gentleness and honey-gathering qualities are unexcelled; 95 per cent pure mating guaranteed. Queens ready June 1. Untested, each, \$1.00; 6, \$5.00; tested, \$1.50; 6, \$8.00.

Fred S. Leininger & Son, Delphos, Ohio

### Italian Queens --- Three-banded

We have bred queens over 25 years, and have hundreds of customers who will testify to the quality of our queens. We haven't any disease among our bees and never have had. Our prices are as follows: Untested queens, \$1.00 each; \$10.00 per dozen. Tested, \$1.25 each; \$12.00 per dozen. Select tested, \$2.00 each; \$20.00 per dozen. Breeding queens, \$5.00 each. Special prices on large orders. Our customers must be pleased. Safe arrival guaranteed. Send check with orders to

J. W. Taylor & Son, Beeville, Bee Co., Texas  
Prices on nuclei on request.

### THREE-BAND ITALIAN QUEENS

They are bred from imported mothers. They are the best for honey-producing purpose; very gentle, not inclined to swarm. If you buy once you will buy always. GUARANTEE that all queens will reach you in good condition, to be purely mated, and to give perfect satisfaction. All orders filled at once. Untested, . . . April 1 to July 1, 1, \$0.65; 6, \$3.75; 12, \$7.25  
Select Untested, " " 1, .90; 6, 5.00; 12, 9.00  
Tested, " " 1, 1.25; 6, 7.00; 12, 13.00  
Select tested, " " 1, 2.00; 6, 11.00; 12, 20.00

L. L. Forehand, Fort Deposit, Alabama

### Italian Queens . . . . .

Untested during June \$1.00 each, 6 for \$5.00, 12 for \$9.00. After July 1, 75 cts. each in any quantity. Satisfaction in all cases or money refunded.

L. H. Robey, Worthington, W. Va.

### ITALIAN QUEENS, NORTHERN BRED

are surely most hardy for Canada and northern States. Try one. Untested, \$1.00; select tested, \$1.50. List free. Plans "How to Introduce Queens, and Increase," 25 cts.

E. E. MOTT, Glenwood, Mich.

### BEE SUPPLIES

Send your name for new 1916 catalog.  
Dept. T. CLEMONS BEE SUPPLY CO.,  
128 Grand Avenue, Kansas City, Mo.

# EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

## The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

Indianola Apiary offers bees and queens for sale for 1916 as follows: Tested queens, \$1.25; untested, 75 cts.; 1 lb. of bees, \$1.00; one-frame nucleus, \$1.25. Add price of queen if wanted. J. W. SHERMAN, Valdosta, Ga.

Phelps' Golden Italian Queens combine the qualities you want. They are great honey-gatherers, beautiful and gentle. Mated, \$1.00; six, \$5.00; tested, \$3.00; breeders, \$5.00 and \$10.00. C. W. PHELPS & SONS, Wilcox St., Binghamton, N. Y.

ITALIAN QUEENS.—For the balance of the season we will sell untested queens at 60 cts. each or \$6.50 per dozen; tested, \$1.00 each or 6 for \$5.00. Safe arrival and reasonable satisfaction. Address W. J. FOREHAND, Ft. Deposit, Ala.

QUEENS.—Improved three-banded Italians, bred for business, June 1 to Nov. 15, untested queens, 75 cts. each; dozen, \$8.00; select, \$1.00; dozen, \$10.00; tested queens, \$1.25 each; dozen, \$12.00. Safe arrival and satisfaction guaranteed. H. C. CLEMONS, Rt. 3, Williamstown, Ky.

Queens now ready. Golden and three-band Italian queens. I shall do my best to fill all orders promptly. If any queen fails to give satisfaction I will replace her free. Untested, 75 cts. each; six for \$4.00. Send all orders to E. A. SIMMONS, Greenville, Ala.

Queens by return mail, or your money back. Guaranteed purely mated three-banded Italians, Northern strain, bred for gentleness, honey-gathering, and wintering. Select untested, \$1.00 each; six for \$5.00. Select tested, \$1.75 each. Write for price on large orders. State inspector's certificate. Satisfaction guaranteed. J. M. GINGERICH, Kalona, Iowa.

Famous Howe's, Root's, Moore's, Davis' select strain of honey-gatherers, disease-resisting. None better for all purposes. Untested, one, 75 cts.; doz., \$7.50. Select untested, one, \$1.00; doz., \$9.00; ½ doz., \$5.00; tested, \$1.25; doz., \$10.00; select tested one, \$1.50; ½ doz., \$8.00; extra select, \$2.00. Bees by the pound, \$2.50 with queen. Honey crop short. Will have plenty of bees in June. H. B. MURRAY, Liberty, N. C.

Rhode Island Northern-bred Italian queens, \$1. Circle. O. E. TULIP, Arlington, R. I.

Well-bred bees and queens. Hives and supplies. J. H. M. COOK, 70 Cortlandt St., New York.

QUEENS THAT COUNT.—See our Adv. elsewhere in this issue. GEO. W. PHILLIPS, Lebanon, Ohio.

Fine Italian queens by return mail. Select golden and three-banded, lined to select drones. Hardy, prolific honey-gatherers. Single queen, \$1.00; 2 queens, \$1.75; 3 queens, \$2.50; 12 queens, \$9.00. Six or more at dozen rates. No disease. Safe arrival. I positively guarantee every queen to give reasonable satisfaction. CHAS. M. DARROW, Star Route, Milan, Mo.

ITALIAN QUEENS, Northern-bred, Three-banded, Highest Grade, Select Untested, Guaranteed. Queen and drone mothers are chosen from more than 600 colonies noted for honey production, hardiness, prolificness, gentleness, and perfect markings. Price, one, 80 cts.; 12, \$8.00; 100, \$55.00. Also bees by the pound. Send for circular. J. H. HAUGHEY, Berrien Springs, Mich.

Hollopeter's strain of three-banded Italian bees and queens now ready. Bees, a full pound of the right kind for business, with young laying queens, 1 pkg., \$2.25; 6 pkg., \$12.50; 2-lb. pkg., with queen, \$3.25. Queens, bred for business, untested, each, 75 cts.; 12, \$8.00. Safe arrival in good condition guaranteed. Health certificate with each shipment. Circular free. J. B. HOLLOPETER, queen-breeder, Pentz, Pa.

If you want a queen for that queenless colony, we can send it to you by return mail. Young tester<sup>s</sup> queens, \$1.00, \$12.00 per dozen. Untested, \$1.00; \$9.00 per dozen. We breed the three-band Italians only, and we breed for the best. Our thirty years of queen-rearing proves this. We never had a case of foul brood in our apiaries, and we guarantee every queen sent out by us. J. W. K. SHAW & Co., Loreauville, La.

Carniolan, golden, and three-banded Italian queens. Tested, \$1.00 each; 6, \$5.40; untested, 75 cts. each; 6, \$4.20. Bees, 1 lb., \$1.25; 2 lbs., \$2.25. Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS.. I. N. BANKSTON, box 315, Buffalo, Tex.

Three-banded Italian queens guaranteed to please and to give results; 75 cts. each; 6 for \$4.25; 12 for \$8.00; 100 for \$65.00, in lots to suit; select breeders, \$5.00 each. One-pound swarm with fine queen, \$2.25 each; without queen, \$1.50 each. Write us your wants. We will give you a square deal. We are keeping up well with orders, getting them as we are. June will be the big bee month. Always give your express office when wanting pounds of bees. CURD WALKER, Queen-breeder, Jellico, Tenn.

LEATHER-COLORED ITALIANS.—Large, vigorous, three-band Italian queens that have proven that they can stand a severe winter, last winter being a test for them. For size, beauty, gentleness, and honey-gathering qualities they will surprise you. If you have foul brood, try them. It will be half the fight. All queens are guaranteed for a period of one year from date received. If they fail to please you, you get your money back. Prices: 1, \$1.00; 6, \$5.00; 12, \$9.00. No foul brood in my apiary nor near me. W. D. SELLERS, 242 Pine St., Lancaster, Pa.

FOR SALE.—Three-banded Italian bees. Three-frame nuclei with queen, \$3.00; without queen, \$2.25. We have more bees than we can manage, and can therefore supply you with the biggest, strongest nuclei you will be able to find anywhere. Our bees are all on the standard-size Hoffman frames, combs built on full sheets of foundation, and on wired frames. We are now shipping nuclei, and can fill your orders promptly. Bees guaranteed to be free from disease. HYDE BEE CO., Floresville, Tex.

ITALIAN QUEENS.—Golden or leather colored; 75 cts. each; \$4.25 for 6; \$8.00 per doz. Tested, \$1.50. NORDLING APIARIES, Button Willow, Kern Co., Cal.

See our large advertisement elsewhere. Why pay more when you can get from us better queens for less money? We guarantee our queens to be as good as any produced North, South, East, or West. Try them. M. C. BERRY & Co., Hayneville, Ala.

FOR SALE.—Three-banded Italian queens and bees from the best honey-gathering strains obtainable. Untested queen, 75 cts.; 6, \$4.25; 12, \$8.00; tested queens, \$1.25; 6, \$7.00; 12, \$12.00. For select queens add 25 cts. each to the above prices. For queens in quantity lots, or bees by the pound, write for prices. ROBT. B. SPICER, Rt. 181, Wharton, N.J.

TENNESSEE-BRED QUEENS! My three-band strain that has given such universal satisfaction for over 40 years. Orders filled promptly or money returned by first mail. 1000 nuclei in use. Tested, in June, \$1.75; untested, \$1.00; in July, \$1.50 and 75 cts. Postal brings circular. JOHN M. DAVIS, Spring Hill, Tenn.

## POULTRY

FOR SALE.—Fourteen thorobred Sicilian Buttercup hens and one rooster. First \$20 takes the lot. L. S. GRIGGS, 711 Avon St., Flint, Mich.

## HELP WANTED

WANTED.—A single man to work 140 colonies of bees on shares; one with experience, and steady; good locality. J. J. WALKER, Rt. 5, Ogdensburg, N.Y.

MAN WANTED.—At once to work with bees. State age, experience, and wages. Three or four months' work. Address THE ROCKY MOUNTAIN BEE CO., Forsyth, Mont.

## CONVENTION NOTICES

A field meet for the beekeepers of Southeastern Iowa will be held at the queen-rearing yard of J. I. Danielson, Fairfield, Iowa, July 27. All are urged to come.

### EASTERN MASSACHUSETTS CONVENTION.

The regular monthly and annual meeting for election of officers, for the season, of the Eastern Massachusetts Society of Beekeepers, the original Massachusetts society, was held at room 15 Old South Building, Boston, on Saturday April 1, 1916.

The speaker of the day was Miss Dorothy Quincy Wright, of Lowell, who gave us an interesting talk on "Planning the season's work—efficiency methods applied to beekeeping."

The new president, who was unanimously elected, is Prof. Gladstone H. Cale, of the Essex County Agricultural School, at Hawthorne, Mass., who, upon taking the chair, thanked the members for the honor, and pledged his best efforts for the carrying-out of the work of the society.

Mr. Thomas J. Hawkins, 4 Emery St., Everett, the former president, was chosen secretary, and the Board of Directors are Rev. T. J. Horner, of Attleboro, Mass., chairman; Mrs. Susan M. Howard, of Stoneham, and Mr. Benjamin P. Sands, 1051 Old South Building, Boston.

THOMAS J. HAWKINS, Sec-treas.

The field meet of the Chicago-Northwestern Beekeepers' Association will be held at the home of W. W. Faulkner, 3000 N. Cicero Ave., Chicago, Ill., July 15, 1916.

Many things combine to make this an ideal place for a meeting of beekeepers. Besides being entertained by one of the most hospitable families in Illinois, we shall meet Mr. Faulkner, Sr., who is probably the oldest and one of the most successful bee-

keepers in the United States. Mr. Faulkner, Sr., is in his 100th year, and was born among the bees in Scotland. The family recently sold a large portion of their bee-range for over \$260,000. They still retain the buildings and ten acres of the best part of the farm, worth another \$50,000. The house stands on a ridge that was once the shore of Lake Chicago, which at one time covered the entire site of the present city. It can be reached by trolley from anywhere in the city for a five-cent fare. A basket dinner will be served by the queens that do not swarm, which we hope will attract enough drones to furnish an intellectual feast as well.

Chicago, Ill., June 6.

C. O. SMITH.

## TRADE NOTES

SECOND-HAND FOUNDATION-MILL IN LOS ANGELES, CAL., FOR SALE.

We have for sale at our Los Angeles branch a 12-inch medium-broad mill in fair condition, with some defaced cells, but in good enough condition for years of service for a beekeeper who makes his own foundation. We offer the mill for \$15.00.

SWEET-CLOVER SEED.

We have several bargains to offer in sweet-clover seed. If interested, write us, stating the quantity you can use and the variety you prefer, and we will quote you and submit sample. We have some stock at Des Moines, Iowa, and Chicago, Ill., as well as Medina, and will quote bargain price to close out stock.

BUCKWHEAT FOR SEED.

The time is here for seeding buckwheat for a honey crop. We have here at Medina a limited supply of both Japanese and silverhull, which we offer at \$2.75 per 100 lbs., bag included, subject to previous sale. We can also furnish at the same price, and subject to sale, the Japanese variety from Ashland, Mo.

NO. 2 OR B GRADE SECTIONS.

Our surplus stock of B grade sections in the regular size,  $4\frac{1}{4} \times 1\frac{1}{2}$ , two beeway, is reduced to normal proportions. The new lumber on which we are now working is of excellent quality, and produces only a small proportion of B grade. We still have a good stock of B grade in plain sections of regular pattern; and as these are supplied this year at a reduction of 75 cts. per 1000 below A grade, they should be well worth using at this rate.

THE A. I. ROOT COMPANY, Medina, Ohio.

## SPECIAL NOTICES

BY A. I. ROOT

GOOD BOOKS AT A GREAT BARGAIN.

Most of these books are old, but not all of them. They are offered at a bargain because they have accumulated, and do not seem to sell at the regular prices. First we have "Love: the Supreme Gift; or, the Greatest Thing in the World," by Henry Drummond. Some years ago this little book of 32 pages had a great sale, and created quite a stir in the world. The price was 10 cents. As we have 250 copies on hand, you may have one or more of them free of charge if you will send a stamp to pay the postage.

"The Revised Version of the New Testament." This was gotten out in 1881, when the New Version first appeared. It is a very pretty little book, printed with large type so old people can read it easily. It sold readily for 10 cents; present price 5 cents postpaid. We have about 300 copies.

In 1881, by request we made selections from the Home Papers, which had then been running for some six years. The original price was 10 cents. We have about 300 copies left, which you can have postpaid for 5 cents each. The book contains 48 pages, and includes gardening, poultry, and suggestions like those in several others of our books about what to do when out of work, and, first and last, more particularly, the kingdom of God and his righteousness. We have about 300 copies left, which we will furnish at 5 cents each as long as they last.

The next one is "Poultry for Pleasure and Poultry for Profit." This is a very pretty little poultry-

book with an illuminated cover. It has 48 pages and some very good illustrations. The price was 25 cents. We have some 20 copies left; and while they last you may have them postpaid for 10 cents. This little book ought to make any boy or girl happy who is getting interested in poultry.

"Silk and the Silkworm"—also 25 cents. It has 30 pages, illustrated. It will be sent by mail for 10 cents. We have 28 copies.

"Merrybanks and His Neighbor." This is a book of 210 pages, fully illustrated. This book is like our larger one ("What to do," etc.), written with the view of telling idle people what they may do to earn a living right around home. Nearly all the events mentioned in it are actual occurrences, but they were put in story form by A. I. Root over thirty years ago. The price was 25 cents; but you may now have it postpaid for 10 cents.

Here is another book—"The Story of Art Smith." I have made mention of it once or twice already. The book took such a hold on me that I could scarcely eat or sleep until I had finished it. The principal moral of the book is the account of how this boy, Art Smith, persevered and finally overcame more obstacles, accidents, and discouragements (mainly thru a lack of means) than any man or boy I ever heard of. The disappointments and disasters, it seems to me, would have set almost any other boy crazy; but, like Edison, he stuck to his hobby of making a flying-machine that would *actually fly*, until he finally conquered. The last I heard of him he was making flights in Japan. The boy had (and perhaps has yet) a praying mother. I hope the good woman is still alive. The price of the book is 25 cents; but as we have something like 80 copies left out of 100 we now offer it postpaid for only 10 cents.

"Injurious Insects of Michigan," by Prof. A. J. Cook. This book was first put out in 1874; and while improvements have been made in the way of insecticides, I believe this work of Prof. Cook stands with perhaps few exceptions as perfectly orthodox up to the present time. If I am correct, our good friend Cook was one of the pioneers in introducing the arsenite sprays for the destruction of the codling moth. The book contains 48 pages, and is abundantly illustrated. As we have 38 copies yet on hand we reduce the price, 25 cents, to only a nickel, for which we will send the book postpaid. It ought to be worth that amount to go over the early work of such an interesting writer as our old friend, who has done so much, not only for beekeepers but for the world at large.

Besides the books mentioned we have "What to Do, and How to be Happy While Doing it." This was a 50-cent book, bound in cloth; paper, 35 cts. We now offer it, bound in cloth, for 25 cents, and in paper for 15 cents. See A. I. Root's Special Notice, GLEANINGS for May 15.

We have also about 12 copies of the "New Agriculture," mentioned on the page referred to. This is really a valuable \$2.00 book, which we now offer for only 75 cts., because it is old. As long as the present copies last we will mail the book postpaid at the latter price.

THE 1915 YEAR-BOOK OF THE UNITED STATES BREWERS' ASSOCIATION.

The above is the title of a large book of 360 pages. It is put out by the United States Brewers' Association, and is gotten up without regard to cost, for the sole purpose of defending the brewing business. It is quite evident that they have spared no expense, and have employed the most able attorneys and men of all callings to help them to prove that the temperance wave is a mistake and a misrepresentation. It is not worth while to go over the arguments they present. It is quite evident, however, that they have, with much commendable study, looked up every "hook and crook" that would enable them to contradict or counteract the effect of the facts that temperance periodicals and temperance people are giving to the world. I will close this brief notice of the book by calling attention to a self-evident fact. The Anti-saloon League, our churches, our schools, our Endeavor societies, Sunday-schools, etc., are laboring for the sole purpose of protecting humanity, especially the boys and girls and the babies of the whole wide world. The brewers, on the contrary, are laboring and spending their millions for the "sole purpose" of holding their customers and keeping their breweries running so they can get more money from the unwary and unsuspecting.

# SPECIAL BARGAINS

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

## HIVE-HANDLES.

We have a surplus stock of handhole cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

## OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of eight-frame packed 5 in a package, which we offer to close out as follows: YW 5/8, one story, eight frames, 12 packages, five hives each, at \$8.00.

## NO. 2 OR B GRADE HOFFMAN FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

## 1 3/4 H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

## WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1 1/2-inch tire, and solid cast hub holding spokes and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

## SUPERS FOR EXTRACTING OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. b. Medina.

200 D9/10, nailed and painted, with top and bottom starters, nine frames in each, new. Sell new for \$1.20; offered at \$6.00 for 10; \$55.00 per 100.  
180 8/10 supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first two lots are the 5/8-inch supers with hanger cleats and shallow Danz. frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

## ALEXANDER FEEDERS FOR EIGHT-FRAME HIVES.

The Alexander feeder as we now make it is adapted to either eight or ten frame hives. Formerly we made a shorter length for the eight frame than for the ten-frame hive. In cleaning up old stock we find 300 of these eight-frame feeders which we offer, to close out, at half regular price—viz., 15 cts. each; \$1.35 for 10; \$11.00 per 100; \$30.00 for the lot.

## TIN COMB-BUCKETS.

While these are listed in the catalog in one line at \$1.50 each, their convenience in carrying combs to the extractor shut up from robbers is not set forth. We have a surplus stock, and offer them, to reduce the number on hand, at \$1.25 each. You can place four Hoffman frames or five non-spaced frames of Langstroth size in each bucket.

## JONES HONEY-KNIVES.

This is a form of honey-knife used largely in Canada, and preferred to the Bingham by those who have tried it. The blade is 1 1/2 inches wide, and a flat V or triangular shape. We had a lot made to supply a call we had, and still have in stock 28 of them. We offer them at 75 cts. each. Mailed as a pound parcel when packed.

## TUMBLERS HOLDING 6 1/2 OZ., 40 DOZ. TO BARREL.

Having a surplus stock of honey-tumblers packed 40 dozen to barrel, including tin tops and wax-packed liners, we offer them for a short time, to reduce stock, at \$6.00 per barrel, or \$5.70 in 5-barrel lots, shipped direct from Medina.

## SHIPPING-CASES FOR 12 AND 24 SECTIONS.

When we discontinued listing shipping-cases to hold 12 sections we still had quite a stock of various styles on hand, many of which are still in stock. We have also some of the older styles of cases for 24 sections of various sizes. We offer these various cases to close out at the following bargain prices. Here is an opportunity to lay in a stock of cases preparatory to the honey crop near at hand at very low prices. None of these cases, except as noted, are large enough to take sections with cartons or corrugated liners, except the bottom sheet. 12-lb. 2 or 3 row cases with 2 and 3 inch glass for the 4 1/4 x 1 3/8, 4 1/4 x 1 1/2, 4 x 5 x 1 3/8 sections, packed 50 in a crate at \$4.00 a crate; packed 10 in a crate at 85 cts. a crate. A few crates of cases for 16 sections 4 1/4 x 1 1/2 at \$4.50 per crate of 50 or 95 cts. per crate of 10. A few crates of cases for 24 sections 4 1/4 x 1 1/2, and 4 1/4 x 1 1/2, and 4 x 5 x 1 3/8 at \$8.00 per crate of 50; \$4.00 per crate of 25, or \$1.70 per crate of 10. The 12-lb. safety cases, which we no longer list with safety cartons, and 2-inch glass for 4 1/4 x 1 1/2, 4 1/4 x 1 1/2; and 4 x 5 x 1 3/8 sections, per crate of 10, \$1.20; per crate of 25, \$3.00. Without cartons, but including corrugated liners and glass, \$4.50 per crate of 50.

## NO. 2 OR B GRADE SECTIONS.

We have a surplus stock of B grade sections in all the commonly used sizes and styles, and are behind on orders for No. 1 or A grade in some kinds. To insure prompt shipment it may be advisable to order B grades if you can use that grade. In beeway style the B grade costs 50 cts. per 1000 less than A grade, while in the plain or no-beeway styles the reduction for B grade is 75 cts. per 1000. The loss from unusable sections in B grade is very little more than in the A grade. Try them if you have not done so.

## TOBACCO DUST FOR KILLING INSECTS.

Fine tobacco dust is used for dusting on lettuce and other plants for killing the insects, as well as for fertilizer. We have two kinds of dust—the very fine, from ground stems, which we offer at 20 cts. for 10 lbs.; \$1.50 per 100 lbs., or a case of about 400 lbs. at \$1.00 per 100 lbs. We can supply, also, a much coarser dust from leaves, which is much stronger, at 50 cts. per 10 lbs., \$3.50 per 100 lbs.

FOR SALE.—1910 Model 4-cylinder 30 H. P. Reo, run only 15,000 miles, in fine condition. Is of racing type, with gasoline tank in rear, two-seated, no fenders. Gas lamps, no starter. Tires in good condition. Ideal car for running out to outyards and carrying light loads. \$200.00.

**THE A. I. ROOT COMPANY, MEDINA, OHIO.**

# Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

## The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's  
Decision

## Where are You Located?

**IN OHIO?**—Then your orders will naturally gravitate to Zanesville, the Bee-supply Capital of the state.

**IN WEST VIRGINIA?**—The large supply-house nearest to most beekeepers in this state is at Zanesville.

**IN WESTERN PENNSYLVANIA?** — You are a next-door neighbor.

**ELSEWHERE?**—Zanesville service will yet commend itself to you as being the best obtainable.

The leading line of bee supplies, unsurpassed shipping facilities, years of experience, and painstaking care in packing and forwarding goods, fair and considerate treatment, all insure a degree of satisfaction that can scarcely be duplicated elsewhere.

If exasperating delays or otherwise unsatisfactory service have been your past experience, give us a chance to demonstrate the superiority of the service we offer.

Ask for our free illustrated catalog.

# HONEY - CANS

---

We have made especial efforts this season to supply our patrons with cans and cases of the finest quality, and we have now in our warehouse a complete stock ready for immediate shipment to you.

There is much satisfaction in knowing that there is a dependable source of supply so near to all Texas Beekeepers, and others in the great Southwest. Experience has taught us to anticipate properly the needs of our patrons, and we have as yet failed to fall down at a critical time. Sometimes we feel that it is not wise for Beekeepers to trust entirely to the supply house for eleventh-hour assistance, but we concentrate our energies, nevertheless, on complete preparation, and when you are ready we are. Write us for prices.

---

## Weed's New Process Comb Foundation

We have made extensive improvements in our comb-foundation factory this season at a great expense, and are now operating day and night under the supervision of a man direct from the A. I. Root Company, who has had many years of experience in the manufacture of this product. When placing your order with us you are assured of receiving Comb Foundation of unexcelled quality.

---

A full line of Root's Beekeepers' Supplies on hand at all times ready for immediate shipment.

# BEEKEEPING

By Dr. E. F. PHILLIPS

---

One of the best bee-books that has been written in this decade.

Regular price \$2.00; or clubbed with "Gleanings in Bee Culture," one year, for \$2.50; or with our "A B C and X Y Z of Bee Culture," \$3.50.

Canadian Postage, 30c extra; Foreign Postage, 60c extra

---

One would naturally suppose that its author, a scientific man—a trained entomologist, and one who is constantly associated with some of the best scientists of the Government—would turn out a book that would be so technically scientific that it would be beyond the reach of the average beekeeper. This is not the case. While it is scientific, it is couched in such language and style that the average reader can easily understand it. But when we say it is scientific, we might, without further qualification, convey the impression that it is not also practical. As a matter of fact, the book is intensely so, because Dr. Phillips has traveled all over the United States, mingling with the best beemen in the country, and he has had, during several years back, one of the best beekeepers in the country, Mr. George S. Demuth, as his first assistant.

---

The A. I. Root Company, Medina, Ohio

# Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same.

| June and July                  |                                                                   | August and later              |  |
|--------------------------------|-------------------------------------------------------------------|-------------------------------|--|
| Untested Queens . . . . .      | 1 for 60 cts.; 12 for \$ 7.00                                     | 1 for 55 cts.; 12 for \$ 6.00 |  |
| Tested Queens . . . . .        | 1 for \$1.05; 12 for \$12.00                                      | 1 for \$1.00; 12 for \$10.75  |  |
| Select Tested Queens . . . . . | 1 for \$1.75; 12 for \$19.25                                      | 1 for \$1.65; 12 for \$18.00  |  |
| Very best queens for breeding, | \$3.00. 1 lb. bees in package, \$1.25; 2 lbs. in package, \$2.00. |                               |  |

Add price of queen. If any of our untested queens should prove to be mated we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

## EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A postcard will bring it to your address free.

Red Catalog, postpaid.

Dealers Everywhere.

"Simplified Beekeeping," postpaid.

### HONEY GRADING RULES

#### GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

**Extra Fancy.**—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

**Fancy.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

**No. 1.**—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

**No. 2.**—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following:

Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY 6, 1915.

#### COMB HONEY.

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped, except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 12½ oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uni-

form color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case."

*Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.  
Honey in badly stained or mildewed sections.  
Honey showing signs of granulation.  
Leaking, injured, or patched-up sections.  
Sections containing honey-dew.  
Sections with more than 50 uncapped cells, or a less number of empty cells.  
Sections weighing less than the minimum weight.  
All such honey should be disposed of in the home market.

#### EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

#### STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.  
Unripe or fermenting honey weighing less than 12 lbs. per gallon.  
Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.  
Honey not properly strained.

#### NATIONAL BEEKEEPERS' ASSOCIATION GRADING-RULES Adopted at Cincinnati, Feb. 1913

Sections of comb honey are to be graded: First, as to finish; second, as to color of honey; and third, as to weight. The sections of honey in any given case are to be so nearly alike in these three respects that any section shall be representative of the contents of the case.

#### I. FINISH.

1. *Extra Fancy.*—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side.

2. *Fancy.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than six unsealed cells on either side, exclusive of the outside row.

3. *No. 1.*—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain, comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row.

4. *No. 2.*—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than 60 unsealed cells exclusive of the row adjacent to the box.

#### II. COLOR.

On the basis of color of the honey, comb honey is to be classified as: first, white; second, light amber; third, amber; and fourth, dark.

#### III. WEIGHT.

1. *Heavy.*—No section designated as heavy to weigh less than fourteen ounces.

2. *Medium.*—No section designated as medium to weigh less than twelve ounces.

3. *Light.*—No section designated as light to weigh less than ten ounces.

In describing honey three words or symbols are to be used, the first being descriptive of the finish, the second of color, and the third of weight. As for example: Fancy, white, heavy (F.W.H); No. 1, amber, medium (1-A-M), etc. In this way any of the possible combinations of finish, color, and weight can be briefly described.

#### CULL HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour, or "weeping" honey; sections with comb projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than ten ounces.

# WARDELL STRAIN OF ITALIANS

Descendants from the Famous Root \$200 Queen

I was head queen breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

JULY 1, 1916

## HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

NEW YORK.—The old crop of comb honey is now pretty well cleaned up with the exception of some off quality—odds and ends for which there is practically no demand. New crop from the South is now beginning to arrive, and No. 1 white stock is selling around 14 cts., in some instances 15, while off grades sell accordingly—lower as to quality. We have nothing new to report as to the market on extracted. There is a fair demand, at unchanged prices, with liberal supplies. Beeswax is steady at 30 to 31.

New York, June 19. HILDRETH & SEGELKEN.

ST. LOUIS.—The demand for honey in this market has been very light the past two or three weeks, especially comb honey. No new honey has arrived here. We are selling in a jobbing way No. 1 bright amber comb honey at \$2.75 to \$3.00 per case; No. 2 from \$2.50 to \$2.75 per case, under grades less. Southern amber extracted honey, in barrels from 6 to 6½; in 60-lb. cans, from 6½ to 7½; dark, ½ to 1 ct. per lb. less. Beeswax is quoted at 30 for prime; impure and inferior, less.

R. HARTMANN PRODUCE CO.

St. Louis, June 21.

KANSAS CITY.—The honey market remains about the same. There is very little old honey left on this market, and so far this season we have seen no new honey. We believe that the new honey, when it comes in, will sell at about \$3.50 to \$3.75 per case. Extracted honey is cleaning up very rapidly; and while prices are no higher, there is a considerably firmer feeling to the market. Prices range from 6 cents a pound for dark amber to 7 for lighter honey. There is no white extracted on this market.

C. C. CLEMONS PRODUCE CO.

Kansas City, June 17.

ZANESVILLE.—There is no particular change in the honey situation here, the demand being about normal for the season, and prices practically unaltered. In a small way best white comb brings around \$4.00 a case. Some western sells for \$3.75. Jobbers are allowed usual trade discount. Extracted is in limited demand at prices as heretofore, 9 to 10 cts. for best white; darker grades correspondingly less. For good clean beeswax we pay producers 28 cts. cash, 30 trade, and invite shipments on this basis.

Zanesville, June 17.

E. W. PEIRCE.

DENVER.—We have nothing to offer in comb honey at the present time. We are selling extracted honey in a jobbing way as follows: White, 8½ to 8¾ cts. per lb.; light amber, 8 to 8¼ per lb., and amber, 7 to 8 per lb. We pay 26 cts. per lb. in cash and 28 in trade for clean, average yellow beeswax delivered here.

THE COLORADO HONEY PRODUCERS' ASSOCIATION,  
Denver, June 19. F. RAUCHFUSS, Mgr.

## ITALIAN THREE-BAND BEES

For the rest of the season I recommend my three-frame nuclei for building colonies. Prices the same as in June 1st issue. Cheap as I can furnish northern bees.

E. A. LEFFINGWELL,

ALLEN, MICHIGAN

## BANKING BY MAIL AT 4%

### Do Not Take Risks

Deposit your money in this bank where you will be sure it is in absolute safety. Our conservative policy, honorable management, large capital and surplus, and strict state supervision assure security for every dollar.

Moreover, you receive four per cent interest, compounded twice a year.

Deposits may be sent by mail in the shape of check, draft, money order or the currency by registered mail.

One dollar opens an account.

## THE SAVINGS DEPOSIT BANK CO. MEDINA, OHIO

KNIVES

Barker Mfg. Co.  
Box 117 David City, Nebr.

# Quality Quickly

There's the reason why we maintain two western branches and warehouses. The convenience of lower freight and prompter shipments, coupled with the excellence of our bee supplies, have been realized by western honey-producers.

It is unnecessary to talk here about the type of supplies carried in stock at these two distributing points.

## The Proof of Quality

Our exhibit at the Panama-California Exposition was awarded a grand prize and a gold medal.

This is California's  
Decision

245 Mission Street

We have moved. Office and warehouse in the same building.  
Write for catalog and send us your list of wants.

# Woodman's Section-fixer

A combined section-press and foundation-fastener of pressed-steel construction. It folds the section, and puts in top and bottom starters at one handling, saving a great amount of labor. Hundreds of them in use. The sale this year has increased wonderfully, and they give perfect satisfaction in every case when properly operated. Dadant & Sons say, "The sale on Woodman section-fixers now far exceeds all others."

With top and bottom starters the comb is attached to all four sides, a requirement to grade fancy. Increase the value of your crop this season by this method. The best and most successful producers such as Dr. Miller use top and bottom starters. Their honey would ship across the continent without breaking down, even if only half completed.

Price \$2.50 without lamp. With lamp, \$2.75.

Weight, 5 lbs.; postage extra.

Adjustable to any standard size of section. Send for special circular with large illustrations.

**A. G. Woodman Co.**  
Grand Rapids, Mich.

## For New England

Beekeepers, we have everything you need in the way of supplies. Remember we are in the shipping center of New England. Let me send you a new catalog.

# Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

## Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted----

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

# "If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.  
873 Massachusetts Avenue

# NOW IS THE TIME

To order your supplies, and thus have every thing in readiness for the spring.

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, slipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

**C. H. W. Weber & Company, Cincinnati, O.**  
2146 Central Avenue

## What do you know about that

We are getting an almost innumerable number of orders to go by parcel post --- a great thing for beekeepers on rural delivery. **BUT REMEMBER** to always include enough in the amount sent to cover the postage required. . . .

For instance, if you are within 150 miles of Syracuse, and need 500 sections, we can mail them for 41c; 250 sections for 21c, and 100 sections for 11c. Foundation in 5-lb. lots, can be mailed for 11c; 2 lbs. for 7c; 1 lb. for 6c. Always figure postage more than foundation weights. Rates inside of 150 miles once the total weight plus 4.

**F. A. SALISBURY, Syracuse, New York**  
1631 West Genesee St.

# Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

**WHY IS THIS TRUE?** BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who "has been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis Sections in a season, and has not found one section in the whole lot that was not perfect? Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

**INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.**

**G. B. Lewis Company, Watertown, Wisconsin**

Catalog on request giving nearest distributor.

# DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

## Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me.

A. W. DARBY, Alburg, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

NO. 13

## EDITORIAL

### The Demand for Bees and Queens

THE demand for queens this year has been the greatest ever known. Large numbers of queen-breeders — more so than usual — are swamped with orders. The demand for bees also, especially in combless packages, has been very great; and the bee-supply manufacturers, so far as we know, have had a harvest of orders. The idea of preparedness seems to be in the minds of beekeepers everywhere, because there never was a year when there was a prospect of a larger yield of honey. Notwithstanding all this, there may yet be an entire failure of clover.

### Stings that Leave no Sore Spots

THE sage of Marengo is always bright and breezy; and he has a way of differing sharply with an opponent that does not leave a sting nor a sore spot. Witness, for example, his rejoinder to R. F. Holtermann in *Straws* for this issue.

The editor of *GLEANINGS* has had a good many "scraps" with Dr. Miller, both in private and in public. Some of his private letters are as good as a circus. We rather enjoy drawing his fire; because (to change the figure) his is the kind of fire that doesn't scorch. We hope, therefore, that Mr. Holtermann will draw some more fire. Go after him, Mr. H.; but look out that you do not get the worst of it, even if he is '86.

### Getting Free Advertising in Local Newspapers

DR. A. J. BONNEY, in this issue, has an article which will well bear careful reading. The newspapers are looking for good "dope" to publish. Dr. Bonney has prepared a series of striking paragraphs that tell the truth about bees and honey. If the beekeeper will seek to give his local newspapers paragraphs like these he will bring his business before the public in a way that will not cost him a single penny. This is the year to advertise honey if there ever was such a year. If the clover crop is go-

ing to be large, advertise; if it is going to be short, advertise anyway, and make the price in keeping with other food products. Everything is going to be up because it is war times if there ever were war times. All the great nations of the world are now having big and little wars, and at this writing it looks as if our dear Uncle Samuel would get involved with his neighbor on the south.

### The Meanest Colony to Introduce a Laying Queen to

A COLONY that has been queenless for a week or ten days, has built cells, and possibly hatched a virgin, is about the meanest proposition to introduce a queen to that we have. If the virgin is not lost in mating, the fact cannot be known definitely until a frame of brood is put in the hive, and cells started. An expert can tell by the behavior of the bees. If a laying queen is to be introduced to a colony that may or may not have a virgin, she will not stand much show if the virgin is present; and if the virgin is a young one, or inside of a cell, the bees may take things into their own hands, and kill the laying queen. About all one can do is to give such colony a cell, if they do not already have one, and always a frame of brood if it can be spared from some other colony. The beginner should understand there is a large amount of risk in trying to introduce a laying queen to a colony that has been queenless for a week or ten days.

### Beekeeper-Berrygrower, Here is Your Chance

THERE are many inexpensive ways of calling attention to honey. A number of very good suggestions are given in this special number on the subject. Here is another plan which we feel sure is practical and well worth trying. Mr. Frank Rauffuss, of Denver, gives the details in the following letter:

We are herewith sending you a little slip, 2½ x 6 inches. The plan for using this is to

get beekeepers who are also berry-growers to insert one of these in the bottom of each box of berries they pack, so the housewife will come across it when she empties the box and can try out the suggestion of using honey in place of sugar for sweetening berries.

HAVE YOU EVER SWEETENED BERRIES  
WITH HONEY?  
IF YOU HAVE NOT, TRY IT TODAY.  
IT IS DELICIOUS.

We hope that this will be the means of inducing some people to use a mild-flavored honey for the above said purpose. Furthermore, we expect the beekeepers who are berry-growers to get the other berry-growers to utilize these strips also.

It is surprising how few people use honey on strawberries, for instance. We prefer it to sugar on any kind of berries, however, for it blends so well with the fruit-juices that the flavor is far better than that of berries sweetened with granulated sugar.

### Bees Exonerated

A GOOD many beekeepers are bothered every year by berry and grape growers complaining about the bees, and insisting that the bees "bite" the fruit and suck the juices. The trouble is that people who make such complaints do not read bee-journals and do not know that what they are claiming is an impossibility.

Our attention has just been called to a paragraph in the *Indianapolis News*, taken from the *Scientific American*. We hope that this paragraph may receive considerable publicity over the country. We fear, however, that it will not be as widely copied as the some sensational claim were made against our friends the bees. Newspapers, as a rule, are never quite so happy as when they are showing up somebody or something. Our hats are off to the *Indianapolis News* for having the good judgment to copy something really worth while.

An agricultural society of Florence, Italy, has recently carried out a thoro investigation of the alleged injury of fruit by bees, and has completely exonerated the latter. Bees are unable to perforate the skin of fruit, and it is only incidentally that they suck the juices of fruits injured by other natural causes. The damage sometimes attributed to these insects is due to poultry, wild birds, wind and hail, and even more frequently to hornets, wasps, vine-moths, and other insects. Instead of being harmful to orchards and vineyards, bees perform the useful service of effecting the cross-pollination of flowers, and hence the setting of fruit, as well as the desiccation of damaged fruits (especially grapes) by sucking the

juice and pulp and thus preventing fermentation and rot extending to sound individuals. The orchards and vineyards frequented by bees give the most constant crops.—*Scientific American*.

We suggest that beekeepers get their local papers to publish this clipping, giving credit not to GLEANINGS IN BEE CULTURE, but to the *Scientific American*, in order that the reader may not get the mistaken idea that he is reading a biased statement. There is no time when this clipping could be used so effectively as right now.

### Clover Prospects Weighed in the Balance; On a Tiptop of Expectancy

ACCORDING to all reports from all over the country, clover—white, alsike, red, and sweet—was never more abundant than this year. The fields are white with it. We have gone over portions of northern Ohio in an automobile—localities that never showed white clover before, and found they are showing quite a large profusion of it. Some fields look as if they were covered with snow.

But the all-absorbing question with the beekeeper is, "Will this clover yield honey? and how much?"

Bees in our part of the country are barely making a living and rearing brood. Colonies have to be watched very carefully to see that they do not starve. The conditions are much the same as last year—rain, rain, and chilly weather, interspersed now and then with sunshine and a little warm weather. But no sooner does the nectar begin to come in than it rains again.

Last year there was an enormous crop of clover honey in spite of these rains; but it came a month or six weeks late. History may repeat itself this year. If settled warm weather should come on, there would probably be a clover flow the like of which was never seen before.

But why does not clover yield on occasional warm days? One of our neighbors, Adam Leister, a local beekeeper, and a splendid farmer, offers this explanation: Rains and cool weather have made a rank growth of the clover plants, including the blossoms; in fact, all kinds of grasses and clovers are growing so rank that lawns have to be mowed almost every other day. Well, this rank growth has absorbed all the strength of the clovers so there is nothing left to develop nectar in the blossoms. It used to be an axiom, and it is a pretty good one today, that, when farmers begin to complain of drouth, honey begins to yield. In other words, it is impossible to grow a

rank growth of clovers and get nectar at the same time. As soon as the rain stops and the weather turns hot, the growth of the clover plant stops and nectar begins to yield.

The United States weather maps, one of which reaches us every day, show that this rainy weather is practically universal thruout the clover regions of the United States. It spreads from the Dakotas to Maine, from Maine to the southern states, and from there to the Rockies. Texas has had an unusual amount of wet weather for that state, and it has certainly been a honey year for the Lone Star State.

If this cool rainy weather should continue another month there may not be much if any clover honey; but the probabilities are that it will change soon; and when it does, if not too late, there will doubtless be a big crop of clover honey thruout the United States. We have the plants this year—thousands of acres of them—and we have the moisture in the soil and in the air; and now the thing we earnestly hope for is a good old-fashioned drouth, for no drouth now could stop the flow of clover nectar.

Our Rocky Mountain beekeepers probably will not feel so very badly if the cold weather of the East continues; for their crop, on account of snow in the mountains, is reasonably assured. California will have more honey than early indications seemed to show.

The price of honey this coming season will depend somewhat on how much clover honey is secured in the eastern states. The whole beekeeping world, on account of this, stands on tiptoe awaiting the events of the next few days.

*Later.*—Sunshine and a clear sky have come. Will it continue? We are "tiptoed" clear up high.

Beekeepers are requested to send in postal-card reports.

### Some Pointers on Advertising Honey; Shall a Producer Retail His Own Honey?

It is apparently easier for the average individual to produce an article than to let the prospective purchaser know he has something he wants to buy at a profit to the producer.

One reason for advertising any merchandise is to help the prospective purchaser realize that we have the particular article he wants. The various methods outlined in this issue in the articles on honey advertising which have been effective in increasing sales are well worth careful study. How-

ever, the plan which is best in one locality may not be best for another.

The local beekeeper has the advantage over outside advertisers, as he knows the peculiarities of the people of his own locality, and can also appeal to local pride. The most important factor is to have an article *worth* advertising, and at the same time offer it for sale in a form to meet local needs best.

We have long been of the opinion that beekeepers who specialized on the larger packages, five-pound pails and up, were making the most money, and they are certainly creating a larger demand. The grocer will handle the larger packages when the beekeeper is back of the goods, as suggested by Mr. Frank Kittinger, this issue, page 533. It costs practically as much to sell the 10-cent size as the \$1.00 package; but mark this: *To enjoy the co-operation of your grocer you must protect him by not underselling.*

All advertising should be of a character to inspire confidence of consumer, also the dealer, not only in the goods advertised, but in the man back of the goods. Your advertising is capitalizing your character.

Exhibits as described by Mr. Burton N. Gates and several others are one of the best means of publicity and one of the cheapest. The opportunity for personal contact can not be overestimated, and we consider it one of the cheapest means of effective advertising. Articles and statements tending to create interest in bees in general, interesting facts suggesting the honey industry, and the publishing of honey cooking recipes gradually build up public sentiment in favor of honey, creating the desire that results in the purchase.

If more beekeepers displayed attractive signs it would not only help their business but the industry in general. Billboard advertising in cities is expensive; but you have the opportunity at no expense, aside from the sign; and if you live on a main road invest in the best sign you can afford. Utilizing your location in this way will make you slick up a little, improving general appearances; and Ruth C. Gifford's suggestions, page 537, regarding appearances can not be overlooked, and will apply to your plant as well as the goods you sell.

The idea suggested by John R. Pomeroy, page 542, and others, would be a long step in the right direction, and in our opinion beekeepers would be wise in adopting a uniform sticker, **EAT HONEY.**

The beekeeper has another problem to solve: In these days of high cost of labor, the increased cost of doing business must

be considered. GLEANINGS has always advocated development of the home market; but not every one is in a position to do this. Some would be losing money to attempt to sell locally. One expressed the situation in this way: I prefer to keep more bees, produce more honey, sell to the large buyer, using the time required to sell my crop locally in getting ready for next season.

These are personal problems to be decided before the question of local advertising is considered. If your decision places you in this class, eliminating local advertising, we believe the real beekeeper's fraternity spirit will keep you alive to every opportunity to scatter the doctrine, EAT HONEY, that, if persisted in, will gradually erase honey from the luxury column and place it where it belongs—among the staples.

Keep everlastingly at it.

### Our Advertising Number

WHEN we were first asked to get out a special number on the subject of advertising honey we wondered whether it would be possible to secure enough good live material. We are rather proud of the array of material that we are enabled to present in this number.

In *The Independent* for November 8, 1915, appeared an editorial, "The Advertiser as a Public Benefactor." Those who have access to this particular copy would do well to look it up and read the editorial from beginning to end. It is worth while. We wish that we could take the space to quote it all. We quote herewith only the first and the last two paragraphs.

A great deal is said about the value of advertising to the salesman, but very little about its value to the buyer. Yet it is obvious upon reflection that such an expensive piece of machinery as the modern system of advertising could not be maintained unless its benefits were mutual. It takes two to make a bargain, and this new method of bargaining, this new channel of communication between producer and consumer, must be giving satisfaction to both, altho the said party of the second part rarely realizes how greatly to his advantage it is. The common saying, "It pays to advertise," has a wider meaning than it is generally credited with. Advertising, on the whole, pays all those concerned. Advertising pays the advertiser in case the money is wisely expended. Advertising pays the periodical, we are happy to say. Advertising pays the purchaser, for it puts him in the proud position of being sought instead of the seeker.

The use of prepared cereal foods is a veritable revolution in the dietary of the nation. Say five million dollars has been

spent in accomplishing it, could the result have been attained as quickly or more cheaply by any other means? How long without advertising would it have taken to develop and make known to everybody the automobile and the hand camera, the player-piano and the phonograph, the office utilities, the toilet accessories, and all the thousand "Yankee notions" that make our life so pleasant and complete?

No: advertising is not "one of the economic wastes of competition," as it is sometimes called. It is on the whole well worth what it costs to the community, and it is hard to see how the world can ever get along without it. Even if competition be some time eliminated, advertising of some kind will have to be kept up unless the race is to stagnate. Progress consists in the creation of new wants; happiness, in the satisfaction of them. So both progress and happiness are facilitated by the efforts of the advertiser. He is not a producer; no, and neither is lubricating oil a fuel for the engine, but it is quite as indispensable as coal. The advertiser should not be regarded as a parasite upon industry, as an extravagance to be some time eliminated in the interests of economy of distribution. He is more likely to be regarded in the future as a person of greater importance than at present, for the training of the public in new habits and the introduction of new utilities will become more necessary as science and invention become more active. When his real value to the community as an accelerator of civilization becomes recognized, historians will rank the discovery of advertising as an epoch-making event and not less important than the discovery of America.

The reason that so many people do not use honey is that they never think of it. They must be made to think of it before they will take the trouble to buy it. Conservative but continuous advertising in local papers is one of the best forms of keeping honey before the people. There are many other inexpensive ways of securing publicity for honey. As several of the writers in this number point out, a neat sign in front of an apiary on a well-traveled road calling attention to the fact that honey may be purchased within gives surprising results. Between Medina and Cleveland, on the main road, lives a beekeeper who hit upon the ingenious plan of locating a hive in a conspicuous position by the roadside. The hive was enameled white, and on each side was painted the one word "Honey" in a brilliant cherry red. The result of this silent salesman was gratifying. The honey on hand was sold in short order, and at a good price. The picture on our cover for this issue shows the hive on the bank where it could be seen for nearly half a mile each way.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

G. M. DOOLITTLE is just right in his advocacy of drawn comb in sections, when rightly used, p. 320. It might be added that in years of failure I've had such bait combs filled thruout the apiary, while not a drop was stored in sections filled with foundation, in the same super.

WHEN putting foundation in brood-frames the first time, the wedge and sawkerfs are fine; but if ever you want to put in foundation the second time the grooves are a nuisance. Perhaps the best thing then is to fill them with wax or paraffin. [It is not often that comb foundation is put in such frames the second time.—ED.]

SPEAKING of white clover, John H. Lovell says, p. 477, "Honeybees also often gather loads of greenish pollen, altho this is not abundant." If that came from almost any other authority, I should say, "You've been careless in observing, my friend." As it is, I wonder if Illinois is not different from New England. Here I don't think Prof. Lovell would call it greenish, but brown; and it is stored in greater abundance than any other pollen, altho the pellets brought in are never so very large. [It is doubtful whether the color of pollen from white clover in Illinois is different from that of Maine. The matter in question has not been printed in the book, and we are investigating.—ED.]

R. F. HOLTERMANN, I'm not on speaking terms with any man that clips both wings without any better reason than you give, p. 491. You say there is a better way to mark a queen's age—on a top-bar. Isn't it much better still to have it in a book? But what has that to do with the question in hand? I never kept track of a queen's age by clipping, and I think very few do. The only reason I find for your clipping both wings is that when only one side is clipped the queen appears "to look very awkward—like a cripple." If a shark should bite off one of my legs, I don't believe I'd say, "Please bite off the other leg, Mr. Shark, so I won't look so much like a cripple." If looks is the only thing, why not clip only the larger wing on one side? Then at a hasty glance you can't tell her from an unclipped queen.

WHATEVER may be best for the beekeeper on a large scale; for the man with only a few colonies the best thing is to send away his combs to be melted up by those who

make a business of melting combs—so much simpler and easier, and in most cases cheaper. [Sending combs across the country to be melted up by one who makes a business of doing such work is fraught with some danger. We prefer that our customers do not send us such combs on account of possible germs of foul brood. If there is anything that scares us it is to see our bees working on a mess of old combs whose history is unknown.

It is, nevertheless, true that the average beekeeper will not get as much wax out of his old combs as some one who is prepared to do the work. But if he will figure in that he, not "Jones, pays the freight" or express, he may not be making very much after all.—ED.]

H. H. ROOR, after reading last Straw, p. 427, with your foot-note appended, I said: "If all that I don't know about queen-rearing is put along with what Huber Root and Mell Pritchard do know about it, it would make quite a book." For one thing, we don't know, when bees are rearing a queen, how long it takes to feed a larva. At least I don't from my own observations, and I'm a little suspicious that you and your fellow-conspirator are taking the testimony of others rather than your own observations. You say 6 days, and 15 to 17 days from the egg to the perfect queen. The orthodox time for full development, 55 years ago, was 17 to 18 days. See *American Bee Journal*, 1861, p. 199. Later it came down to 16 days, and later still to 15. As 6 days was, I think, the time given for feeding originally, I think you will find that needs cutting down too. In Cowan's Guide Book it is cut down to 5 days. In A B C and X Y Z it is given as 6 days (page 82, 1913 edition); but in a part written later, p. 166, we are told the larva is sealed "after about 5 days." Rather than to have any hard feelings between us I'm willing to arbitrate, with the bees as judges, Mell Pritchard to report their decision. Till then I stand by the statement that it is sometimes less than 5 days from the time the larva leaves the egg till it is sealed, but never more. Just by way of appendix, let me say that I don't believe any good queen ever took 17 days for development, altho under sufficiently poor conditions 18 days or more may be needed. [Mr. Pritchard is going to make some careful tests this season, and he will keep a record of the average elapsed time in some thousands of queens. More anon.—ED.]

Grace Allen

## THE DIXIE BEE

Nashville, Tenn.

In connection with the article, "Nix on the Solar," page 445, June 1, I wonder what a straw vote would show.

\* \* \*

I wonder how long drones will be tolerated in a super. Some frames of brood that we raised contained considerable drone brood (I do hope Mr. Scholl won't read this), and the big burly fellows had hatched out, and were in a crowd just over the excluder when we next opened the hive. Suppose we hadn't opened it—would the workers have allowed them to remain up there until the edict was issued against drones in general? And would they live that long?

\* \* \*

Rain and cool weather have kept the bees of this section in their hives for days at a time, with a truly wonderful clover bloom all around just waiting for its nectar to be gathered in. (But, no; that's the pity; it really doesn't wait at all. As soon as it is thru blooming, it stops, whether the bees have taken the nectar out or not.) One prominent beekeeper recently wrote, "This cold weather and rain has spoiled the best honey-flow I ever had." But even at that, his crop will run into tons; so, in spite of our own sympathy, increased by our own little disappointment at seeing our modest hopes fade, we could only smile when some one said, "Well, I wouldn't mind having a spoiled crop like that every year." You see, we're going to have a good crop in spite of the weather; but if we had had clear days and sunshine, what a story we might have had to tell!

\* \* \*

Talk about advertising, I have just been interrupted by a ring of the front door-bell, and a youth who detained me only long enough to say, "Good for one cake of — soap," while he handed me a printed sheet with a coupon attached bearing the capitalized legend, "FREE SOAP COUPON," also instructions and descriptive detail. Housekeepers in this city have been fairly "pestered" one time and another by various ambitious firms who have chosen this house-to-house method of advertising. Often some inducement is offered—a measuring-cup, I recall, by the cottolene people—to persuade us to put in an order (thru our own grocers) before some specified date, or a coupon is presented for part payment. For a while two or three baking-powders kept my door-bell ringing almost constantly. The soap and scouring-powder people are

working Nashville now on this coupon basis. You see it's the housekeepers that buy the baking-powders and the cottolene and soap. And it's the housekeepers who buy the honey too, I'm thinking.

\* \* \*

## FOR BEGINNERS.

If you have not been allowing swarming, and yet want some increase, you may have started nuclei with two or three frames of brood and some honey from big, strong, crowded colonies that needed room. But do be sure to watch over them. They will quite surely need to be fed after the honey-flow, if not before, to develop into sufficient strength to be worth anything, even wintering. I have seen nuclei started in July and August, and left to depend on their own efforts till fall, when they were given enough syrup to go over winter. But tho they pulled thru till spring all right, and started building up, they failed to get strong enough to take advantage of clover when it came. As soon as the flow was on, hive conditions developed rather similar to those described by Mr. Chadwick on page 388, May 15. The bees plunged right into nectar-gathering; but, not being strong enough for super work, they filled up the brood-chamber and soon the queens were honey-bound. It does not pay to have these weak colonies about the yard; so be sure, when you start increase, to give them such good care that they will have a chance to amount to something.

\* \* \*

## In Clover Time.

Across the hills of spring we drove  
And down the lanes between,  
Before the breath of summertime  
Had dusted up the green.  
And, oh the sudden, dizzy sense  
Of worlds blown all abloom,  
With every breeze coquettishly  
Flirting some perfume!

The delicate wild roses blew  
Faint sweets from every spray  
Where old rail fences ran zigzag  
In their bewildered way.  
And, oh the honeysuckle scent  
Afloat from first to last,  
So winy and intoxicant  
It swayed us as we passed!

But best of all, aye, best of all,  
Was clover by the road—  
And in the field—and up the hills—  
For everywhere it showed;  
And everywhere its breath was sweet,  
And everywhere a bee  
Was swaying, raptured, at its tip  
And humming merrily!

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Mr. Crane says, page 328, May 1, in speaking of out-apiaries for comb honey: "Much of one's success will depend on doing everything when it should be done." Is not that the case in managing for any kind of honey, Bro. Crane?

\*\*\*

Mr. L. E. Webb, of Morgantown, N. C., says his bees gather sourwood honey from a mountain location that is two and a half miles distant at the nearest point, and as far as five miles distant. Mr. Webb must have obtained his stock from some of those long-winded stout-winged fellows west of the Rockies.

\*\*\*

Allen Latham says, page 362, May 1, that one year he produced a honey crop which netted him over \$60 per day for time actually on the job. This leads me to reflect that I have known beekeepers who have doubled that amount per day for time actually put in, but which does not say by any means that several additional days could not have been put in at a like remuneration, by doing, as Bro. Crane says, "the right thing at the right time."

\*\*\*

I am in receipt of a copy of the report of the state bee inspector of Iowa, for which I am indebted to Inspector Frank C. Pellett. What a contrast indeed to the way things are carried on in this state! Mr. Pellett's report, consisting of seventy pages, neatly bound in cloth, is brimful of things that must interest Iowa beekeepers, with much information valuable to any of us. This man Pellett seems to be one who does things, and would be an asset at the head of such a department in California. There is no question but that we are falling behind in the inspection line—far behind many other states. Our inspection is divided into county units that are more or less subject to political influence, and our state association is as full of wire-pulling as an egg is of meat. And, sad to state, we seem to be going to stay where we are, which I believe would be just as well as to have some men at the head of the state department who have been slated for the place. If we had a man like Mr. Pellett, what a boon to our industry it would be!

\*\*\*

## COLD-WATER PAINT FOR HIVES.

The editor, on page 343, May 1, has virtually recommended a paint which, if I am

correct, is called "powdr" or cold-water paint, it being mixed with water instead of oil, and is much cheaper to apply the first coat. But is it cheaper in the long run? I have had it under my personal observation this season with the purpose in view of deciding its value as a hive paint. I cannot say, however, that I have been altogether pleased with the results of its use. In the first place, it is a wood protector and not a preserver. On any surface where its application can protect all of the exposed parts of wood it will work very well, but in no other places. The outside coating is simply all there is to it. After it is applied the water evaporates and leaves a cement-like crust on the wood. But, unlike oil paints, where the surface is not entirely free from moisture it has no penetrating or preserving power, and leaves the wood open to the elements of the weather to such an extent that season-cracking is not stopped, while the same wood with oil paints applied, and the oil penetrating into the wood, would preserve and prevent the cracking. When a beekeeper goes down into his pocket to pay for lid material which calls for a board 17 inches wide, and of clear redwood, he is naturally a little "peevd" when he finds that his paint experiments have caused some very wide rents in those beautiful one-piece lids. Then do you wonder that a fellow-beekeeper hastens to admonish all to go a bit slow on the proposition? Try it out a little for yourself and see if I am right. Meanwhile let me recommend to you good white lead and pure raw linseed oil as being the very best white paint you can find. For dark colors there is nothing better than red paint commonly used for roofs, called "prince metallie." Hives should not be painted dark colors in this region, as the sun's rays are too strong, causing more intense heat.

[Cold-water paint is certainly better than no paint at all. A large percentage of beekeepers don't paint their hives. The hot sun checks the wood because the dark color of the weather-stained wood draws the heat, and the combs inside are sometimes melted down. "Powdrpaint," if white, would overcome the difficulty. Of course, no water paint can be equal to an oil paint; but look at the difference in cost, and think how swarming is increased because the hives are too hot! There are many places where there is no shade. Oil paint is expensive. Why not use water paint or cement paint? —Ed.]

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

CALLED BY ANOTHER NAME.

The ability of locally applied names of plants and shrubs and trees to mislead the best intentions is almost startling. Several years ago a beeman from northern Florida or southern Georgia said to me, "We count on the holly for our surest yield of early honey." When I tried to identify it, whether our white holly of this section, whether it was an allied species, or what, I could glean nothing from his meager description and vague terms. Later on, another beeman from further north in Georgia said about the same thing, substantially, but he used the word "gallberry." Three or four summers ago I was impressed with the value of a modest-looking shrub that grew not over two or three feet high along the water-courses, and near the hammocks of even the pine lands near here—the value, that is, as a bridge between the cessation of the citrus honey and the opening of the palmetto honey-flow. On identification the latter shrub proved to be the *inkberry* (*Ilex glabra*), and as such I always spoke of it; it is thus called in Small (Flora of the South-eastern U. S.) and in Baerecke (Ferns and Flowering Plants, Atlantic Section, Middle Florida); so also in Chapman (Flora of the S. E. United States). All called the plant I knew "the *inkberry*." Not one of them mentioned "gallberry," nor *once* quoted it as even a local name for any plant or shrub. I was surprised and not a little puzzled—for all beemen from the Carolinas to the Keys seemed to know of gallberry and its value for the bees, tho none knew *inkberry*. At last the mystery has been solved. The two are identical—*inkberry* and *gallberry*! Did you ever? And not one of the named authorities mentions *gallberry*, and not a local beeman nor any one I ever conversed with knew of or used the name *inkberry*! Such a complete divergence of terms I have never before known. But at last the fox is run to earth, and has been captured. Henceforth I shall speak to our friend the *inkberry* and call him familiarly by the old term, the common term, "gallberry." It reminds me of the difficulty I had in identifying the four tupelos of the northwest section, the so-called "white tupelo," the "black tupelo," the "black gum," and the "water gum," tho the local beemen call them generally the black and the white tupelos.

THE PROSPECTS FROM THE MANGROVE.

At this time the buds of the mangrove (black mangrove, *Avicennia nitida*) are

opening, and look fair for a good crop; but one never can do more than make a guess about the mangrove. It never lacks for water, drouth never affects it, for it grows on the islands and shores of land that is always moist from the salt water of the tides. It never fails to bloom profusely. But that is all we can be sure of. Vigorous growth and profusion of bloom avail nothing unless the weather conditions are perfect; nor does any one know what these conditions are that make perfection of weather conditions for the mangrove. With the palmetto, beemen can observe that excessive drouth during blooming time, or excessive rain, will lessen the flow of nectar from that source. With the mangrove it is all conjecture. We know it yielded monstrously (no other word will suit it) before the big freeze of 1894; since that time it has been steadily coming into larger and larger proportions and size, gaining some of its old-time appearance, tho none of the shrubs can yet be called really trees in the vicinity of Hawks Park and New Smyrna, the old Mecca of beemen when mangrove gave such unheard-of yields. It has not yet, however, come back into its old-time secretion of nectar. Whether it will ever do so, remains for time to determine. Beemen hope that it may—naturally so. The yield seems better on the mainland, but the quality seems a little better on the Keys off the southeast coast. This honey is light in color, tho not quite so light as pure orange. It is not quite so good in flavor as palmetto or orange. It candies easily and hard, almost as firm as white-clover honey. The fact that it grows only across bodies of water entails a considerable loss of the flying bees across the salt water to the mangrove-fields. I have seen, on windy days, hundreds of bees swimming only to drown on the water between the islands and the mainland—bees that had been unable to combat the high winds with heavy loads of honey. When mangrove yields well a bee can gather a load from a single blossom, and then leave some. This is no fairy tale, but actual fact. It is probably most often the old bees that perish thus—old bees whose wings are frayed and wasted. The cabbage palmetto (*Sabal palmetto*) blooms right along with the mangrove in point of time; but on the higher land—the islands that are above tide-water, and on the hammock lands that are not submerged by salt water. It is a picturesque sight to stand on one of the shell mounds that characterize the East Coast and look for miles over a green sea of mangrove

on the seaside, and sight along miles of towering cabbage palmettoes on the mainland side. It does seem that no number of bees could ever cull all the blossoms that must open along the Indian River when mangrove and cabbage palmetto are both in bloom. The honey is thus always mixed, never pure or separate. But each is a light honey, which is fortunate, or else the light would inevitably be spoiled by the dark. The blend is a good honey.

#### THE "HONEY" METHOD OF INTRODUCING.

Whenever I hear a beeman telling a new or retelling an old method of introducing queens I always "sit up and take notice." I do more. I begin to ask him questions. And the first question is, "Will it introduce a virgin queen?" If he says yes, then you may be sure I always try the method at the first opportunity. When the Miller method of using smoke was being agitated, of course that method had a good trial in my apiaries. And while I did succeed in introducing virgins to nuclei occasionally (tho seldom to full colonies) the one troublesome but essential feature of that method, viz., the necessity of having not more than a one-story hive, made it almost impossible for me to use it when I wished to do most of my introducing, for that is right in the midst of the orange-honey flow, when hives are often three stories high. To take off the two supers, reduce to one story, and then smoke the bees almost to suffocation, and do it all with the supers piled up alongside, waiting till the queen was in made it of little practical use to me, tho it is a useful thing to know, and have on hand for occasion. Not long ago my good friend Mr. F. M. Baldwin, now of Sanford, said to me, "Did you ever try the honey method?" When I said no, he said further that he had obtained almost uniform success with it, and that Mr. Clute, also of Sanford, used it almost altogether, with uniform success. Well, after such testimony I tried the method. Tho I had heard of it before, I had been rather afraid to daub the queen all over and pour her into a hive, especially if she was a valuable one; but I took the first opportunity, and tried it on a rather inferior tho laying queen. All worked well. Inside of a day she was laying. I then tried it on a more valuable queen with the same result, laying inside of a day. Then I went it one better, and put it to the ultimate test. I found a frame of fine virgins, just hatched, and put one into each of three hives, dequeening them at the same operation. All three were accepted and mated all right. Then I tried it on a colony that had been

queenless for a week and had capped cells. I did not even remove the cells. The next day but one I looked into the hive, and was surprised to note the cells still there. Of course I gave the virgin up for lost. I was just placing the hive back in position when I noted the virgin running briskly over one edge of the comb, dodging under the bottom-bars. She looked as vigorous as any queen need to. While I could not account for the presence still of the capped cells, yet the introduction of the virgin was an assured fact. I next tried it on colonies that were dequeened at the operation, but introducing virgins two or three days old that had been caged in queenless colonies ever since being hatched. I have yet to report the first failure. The method seems sure. It is easy; and, tho a little fussy, if you call pouring a bit of honey over the combs fussy, still it is *far* less bother, and takes less time than any other method that I have ever tried—even the smoke method; and instead of being painful to the inmates of the hive it is pleasant and soothing, for there is about half a teaspoonful of honey poured in at the operation, the queen being soused well into the cup beforehand, and all poured together into the top of the hives. Watch till you see her rolling over and over down among the frames in a sticky mass of sweetness, and your heart will fail you at first; but when you see that same queen laying the next day, and looking as bright and clean as if she had had a fresh-water bath, your fears will never recur. I shall continue to give this method severe testing; and if it works as well as it appears so far to do I shall be mightily obliged to my good friend who called my attention anew to an old device. I should like to have others try it and report.

#### ANSWERING INQUIRIES.

For several weeks I have been deluged with letters of inquiry regarding honey conditions in Florida, and possibilities for bee-keeping here. Most of the letters contained no stamps for reply. I will take this opportunity to state that I cannot promise to answer *all* letters, even when they do contain stamps, nor many of them, at times of special work with the bees; but those that seem to contain questions that are apt, pertinent to statewide conditions, or right to the point on some special location, I will try to answer in this department in so far, at least, as I can. In this way a wider circle will be reached, the replies will be put on record, and when, in a few weeks or months, the same inquiries are made again (as they surely will be), I can simply refer them to GLEANINGS, such and such a date.

# NOTES FROM CANADA

J. L. Byer, Markham, Ont.

While we have no crop of honey yet, and are not sure of having any, in view of the fact that all food products are rapidly advancing in price, naturally we might expect to see honey selling higher than usual as well. I have just received a circular with price list, from one of the largest honey-pail manufacturers, and the price on tinware has made an amazing jump. No doubt the consumer, as usual in about all such cases, will have to bear a share of the increased cost of production, as the beekeeper, in addition to having to pay so much more for supplies, will also have to pay a higher price for all the necessities of life that he has to buy.

\* \* \*

We have already mentioned the fact that Ontario is pretty well deluged—at least this is the case in the two counties in which we have bees. Clover is up to the knees already, with bloom scarcely showing. Farmers say the alsike will be too rank to leave for seed; so if they cut it for hay the heavy rains will prove to be a drawback to the beekeeper. White clover is correspondingly of vigorous growth; and while here in York Co. we usually depend little on this source of nectar, this year it may prove to be quite a factor, as it is unusually plentiful. If weather gets fine soon, thousands of acres of buckwheat will go in, as a great acreage is lying idle at date of writing. Buckwheat is a minor crop with us as a rule; but with prices of sugar looming high, naturally a big acreage of buckwheat looks good for a chance for cheap winter stores.

\* \* \*

At this date, June 10th, some clover is coming into bloom, but not enough to make a showing in the hives, even if the weather were fine. It has rained almost continuously for about two weeks; in fact, with the exception of one week of fine weather, that has been pretty much the story all spring. That one fine week was the salvation of our bees, as they were about starving previous to that time. Honey came in with a rush from dandelion and fruit-bloom during the seven fine days, and enough was stored to carry the bees safely to clover bloom. While bees are not as uniformly strong as in some other years, wherever young queens are in evidence, and stores were in plenty, it is surprising how colonies have built up in spite of almost continuously wet weather.

Yes, we are expecting some honey—that is, if Jupiter Pluvius steps aside for a while and allows the sun to perform the work usually looked for in June and July.

\* \* \*

In Notes for June 1 regarding cost of sugar I mentioned the price as \$9.00 per 100 pounds. That price, by the way, is about the retail figure prevailing at this date, \$8.26 being the actual figure wholesale now. Indications are that it will go higher; and I have just been reading an article in which the fruit-growers are afraid that the high price of sugar will seriously interfere with the marketing of their product. While, in common with others, beekeepers will regret to see the great masses of the people compelled to pay a high price for an article of such universal use as sugar, yet they need have no fear that high sugar will in any way hamper the sale of honey, as the contrary is apt to be the case.

\* \* \*

The *Beekeeper* for June says that a great number of pound packages have been lost during the latter week of May, or thereabout. From private information I learn that the loss has been very heavy. Express companies have been blamed in most cases; but I am sure that the customers are often responsible for loss. Shippers should be sure that bees will be promptly cleared at customs or loss is bound to follow. Personally we have received two experimental shipments from the South, and both lots arrived in good order. Neither consignment was held up for an hour, as we had arrangements made for clearance. While both lots arrived in good condition so far as the bees were concerned, there was a vast difference in other ways. The first lot had queens inside with the bees, or, rather, the queen was in a cage inside of the package, but with the cage so provisioned that queens were about liberated when the bees arrived. Every queen in this case was all right. The latter shipment had queens in cages attached to the outside of packages; and of all the queens I have ever introduced, this lot certainly proved my Waterloo. Nearly half of the queens were lost; and from the fact that three that were finally accepted did not lay for about ten days, I was led to believe that a lot of virgins were sent during the rush of the very busy season. More later on this subject, as it is one in which many are interested at present.

# BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

Rain has fallen in the Arkansas Valley of Colorado; and while the weather still is cool for the season thruout the Rocky Mountain region, bees are building up fairly well, and we are hoping for a fair crop. Idaho has some hard freezes, and bees did not winter very well; but no doubt the usual amount of honey will be ready for shipment as the season ends. Apiaries in Boulder County vary very much in strength. Some are building up strong, while others are short of bees, and the queens have not got down to regular systematic work. The solid frames of brood, so necessary to rapid building, are lacking in many colonies.

• • •

## A SERIOUS LOSS FROM FIRE.

Mr. D. C. Polhemus, Colorado's most extensive beekeeper, suffered a severe loss recently in the burning of his warehouse. The total loss is about twelve thousand dollars with but \$3100 insurance. The building was full of supplies, extracting combs, and honey. Mr. Polhemus injured his foot at the time, but wrote me that it would soon be well. The heaviest loss and the hardest to recoup is the extracting combs. As the entire equipment for two thousand colonies was stored in the building, beekeepers can realize and sympathize with Mr. Polhemus and son Edgar in their great loss.

## PICNIC OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION AT FORT COLLINS.

On June 10 the annual picnic of the Colorado Honey-producers' Association was held in Fort Collins, at Lindenmeier Lake Park. Mr. and Mrs. Wm. Lindenmeier, Jr., were royal host and hostess to the 125 picnicers. Coffee and lemonade were furnished by the Fort Collins beekeepers, and the lunches were spread on the tables provided under the trees on the lake front.

The program began at about ten o'clock, with a discussion of the best methods of improving our stock of bees. The valuable point is to rear your own queens from the best you can select in your own apiary. Some advocated the purchase of breeders from the best queen-rearers.

Frank G. Rauchfuss demonstrated the starting of queen-cells artificially by the Doolittle method. His father, Herman

Rauchfuss, elucidated further along the same line. The speed necessary to do good work was well brought out. The strength of a colony to build the cells was an important feature that was not omitted.

Prof. C. P. Gillette, State Entomologist, gave a talk on "The Bee Inspection Law of Colorado," and some pointers on need of greater care in handling diseased apiaries. Beekeepers have not been careful enough in handling the disease, nor following the law closely enough in regard to moving bees.

It began raining before Prof. Gillette finished, and the crowd adjourned to the dancing pavilion, where the morning program was completed. The afternoon program was taken up largely with discussion of uses of honey in the home. Miss Miriam Haynes, of the Department of Domestic Science Extension work, of the Agricultural College, was the principal speaker, and she spoke of the very practical ways in which honey may be used in place of sugar, when sugar is so much higher in price than is pure honey. The use of honey in hospitals and sick rooms, she said, is rapidly being extended, as honey has been found to be so nearly a predigested food.

Mr. C. H. Wolfe, of Greeley, emphasized the need for beekeepers using their local papers in advertising honey, and told of his success in selling his own crop in this way. Mr. Wolfe is a live wire, and he puts enthusiasm in whatever he undertakes.

A feature mentioned by Mr. Rauchfuss was the use of little labels printed and placed in berry-crates. The wording suggested on the slips distributed was, "Have you ever sweetened berries with honey? If you have not, try it today. It is delicious." It is proposed that these slips be furnished by the thousand to the fruit-grower beekeeper at a nominal charge. [See editorial.—Ed.]

At the conclusion of the program most of the picnicers took an auto ride thru the Agricultural grounds. There were about twenty-five auto loads of beemen with their wives and children, who left for their respective homes at about four o'clock.

Dr. H. T. French, Director of Extension; Prof. C. P. Gillette, Director of the Experiment Station; Dr. George H. Glover, head of the Veterinary School; George H. List, Deputy State Entomologist, and Miss Miriam Haynes attended the picnic from the Agricultural College.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

FEEDING BACK TO COMPLETE SECTIONS.

"It now looks as if I would have a large number of unfinished sections at the close of the white-honey harvest. Because of the shortness of the season and the light honey-flow in this locality, only now and then a colony has completed even one super of sections, thus leaving the most of those worked for section honey with two or three supers of sections from one-fourth to three-fourths filled. Under these circumstances it seems as tho it would pay to mass all of the three-fourths-full sections on certain strong colonies, extract the honey from the rest of the sections, and feed for the completion of those massed nearly full."

This is something about which quite a little was written in the latter part of the last century; and while quite a few claimed to make a success of such feeding, occasionally the plan was reported a failure. It was claimed that those who failed did not have the right kind of bees, the colonies fed were not strong enough, the amount of brood and space given in the brood-chamber was not right, or else the honey fed back was not thin enough.

There is quite a difference in the character of the bees, even in the same apiary and of the same race. Some cap their honey with a smoothness and whiteness that is captivating to the eye, and store with energy and activity, even quite a distance from their queen and brood. Others have a disposition to cling to the brood-chamber, to crowd it with honey, and, when that affords no more room, to cease labor rather than overcome the disinclination to pass beyond the limits of the brood-nest into the surplus apartment above. In selecting bees to be employed for feeding back, no point is more important than that those should be chosen that enter the supers willingly. Hybrids of the German and Italian varieties are considered to be the best for the purpose of finishing up partly filled sections by feeding back extracted honey.

Then the character of the queen has quite an important bearing. The point here is that the queen should be prolific. Unless she is so, the colony will not have the numerical strength, and, what is more important, as fast as the brood emerges, the bees will crowd the cells with the feed.

The season also has much to do with this matter. That must be early—the earlier the

better after the white-honey harvest begins to wane. In selecting this time we gain in two ways—first, we avoid as far as possible the disposition of the bees to store honey in the brood-chamber—a disposition which increases as the season wanes; and, second, we secure the great advantage of having the work done during the hottest weather, during which alone bees produce wax and build comb most economically. The opportune time is the interim between the white-clover-basswood season and the late honey season.

For obvious reasons the brood-chamber should be small, because, otherwise, an opportunity is furnished for a large amount of brood, the value of which beyond a certain limit cannot be great, altho it would cost a large amount of the honey fed; and any honey, if stored in the brood-combs, is of less value than it was before. The capacity of five Langstroth frames is what I have used, and consider that better than either four or six. These five combs should be filled with brood as far as possible, and the remaining part of the hive made up of dummies or frames of sealed honey.

The further the comb in the sections is worked out, and the more honey they contain when they are given to the bees to be completed, the greater will be the relative profit. Providing the bees with sections containing comb well worked out and quite well filled with honey, such as are usually plentiful at the close of the early honey harvest is more important than any of the other points in securing the highest success in this feeding-back business. The combs are in condition for the process of filling to proceed at once, and comparatively little wax needs to be produced, so that the work is greatly hastened and the consumption of honey saved in every direction. The honey, also, in such sections, which is unsalable in that condition, is doubled in value by the completion of the sections. Indeed, without the motive of bringing such sections to a salable condition, feeding back would be of doubtful advantage.

For the purpose of feeding back, the extracted honey used should be thinned to near the thickness of nectar as it comes from the flowers; for if honey as thick as that which comes from sealed cells is used the bee will be slow in taking it, especially if the weather is a little cool. By thoroly incorporating with such honey one-half its own weight of water the bees will handle it more rapidly.

# How about Honey for a Side Line?

BY RUSSELL WILMOT

So many things had been suggested for side lines that Tim Smithers was ready to declare there was nothing new under the sun. Tim was wrong, and, being a big man and a successful one, he was ready to acknowledge it. It is only the little two by fours who "never make a mistake, and then only for variety's sake!"

Tim was wondering on this particular early spring morning just what he could feature that the other fellow hadn't thought about, when a woman all out of breath hurried into his store and asked him in a peculiarly wheedling manner if he wouldn't *please* tell her where she could buy some nice honey, either strained or in the comb. She went on to explain that she had been in thirteen stores and had not been able to

right place this time. Seven is called the lucky number, and this is the fourteenth place, so it is doubly lucky."

The woman added, as she took the honey, that her small boy was sick and would not be comforted until she made him one of her famous honey cakes.

Tim Smithers winked four times again, turned the toothpick around to its original position, and reflected silently that this woman certainly had given him the hunch he was looking for. What he said aloud was simply this:

"Isn't that queer? We are planning to sell honey cake at our soda-fountain luncheonette—large, nice, square, luscious pieces of it. Wonder if your recipe is like mine?"

The customer assured him that hers was something extra fine, having been in the family for a number of years. She didn't offer to reveal what it was; but that didn't discourage Tim. He knew, if worse came to worst, the partner of his joys and sorrows, the renowned Mrs. Smithers, who was an excellent cook, could originate a honey cake that would surely equal any old moth-eaten recipe anybody might be able to trot out.

A reasonable amount of well-directed advertising reminded two-thirds of the women in Smithereen how good honey and hot biscuits were, how fine honey is on griddle cakes, how healthful a sweet for the children, and how nourishing as well. Tim soon found he hadn't bought nearly enough honey to supply his demand; but he soon corrected that mistake.

In the meantime his good wife had evolved several honey delicacies which brought every single man, every boarding-house victim, every small boy with a nickel, and every hungry school student to his counters. This is the way some of the good things were made.

locate what she wanted. It was either all dried up, mussy looking, or the people declared they didn't keep honey. Tim winked four times, turned the toothpick in his mouth around the other end to, scratched his head, and broke into a beaming smile.

"Well," he said at last as he placed the honey on the counter, "you've come to the

## HONEYBEE CAKE.

Cream together one and a half cupfuls of strained honey and four-fifths of a cupful of butter. Have two whole eggs thoroly beaten and mixed with half a cupful of rich sweet milk; also sift three cupfuls of flour with two level tablespoonfuls of baking-powder, a teaspoonful of salt, one teaspoonful of cinnamon, three-fourths of a teaspoonful of allspice, and one-fourth of a teaspoonful of cloves. Add alternately to the honey and butter mixture a little of the egg and milk wetting, then a little of the flour combination.

When all the wetting and all the flour have been used, fold in three-fourths of a cupful of raisins and three-fourths of a cupful of well-washed currants. The fruit, of course, must be well floured first. Turn the dough into well-greased individual patty pans. Bake in a moderate oven until well done.

## HONEY PUDDING.

Wash one cupful of rice and put in a deep baking-dish with one quart of milk, one teaspoonful of salt, the grated rind of one lemon, and one ounce of shredded lemon peel. Add eight tablespoonfuls of honey. Bake in a moderate oven, stirring frequently during the first hour. During the last hour do not disturb. Serve with thick cream.

## HONEY FILLING FOR LAYER CAKE.

Cook half a cupful of honey and half a cupful of granulated sugar with two tablespoonfuls of hot water until it spins a thread. Remove from the fire and beat in the stiffly whipped white of an egg. Keep on beating until the mixture cools. Use between layers and on top.

## HONEY BABIES.

Bring one pound of strained honey and one-fourth pound of butter to the boiling-point. Let it cool for half an hour, then beat in half a teaspoonful of cinnamon, one-fourth teaspoonful of ground cloves, one-fourth teaspoonful of allspice, the grated rind of one lemon, and one-fourth pound of chopped almonds. Sift one pound of flour with two level teaspoonfuls of baking-powder. Combine with the honey mixture and let it stand an hour. Roll out one-half or three-fourths of an inch thick, and cut into square or round cakes. Bake.

## COLLEGE ICE HONEY DRESSING.

To one pint each of pineapple syrup, orange juice, and strained honey, add one level cupful of shredded cocoanut and one cupful of shredded walnut meats.

## APRICOT HONEY.

To one cup of apricot pulp add one cup of honey and one cup of heavy cream. Drain canned apricots of their syrup, run thru a sieve, beat the cream, add the honey, and, lastly, fold in the apricot pulp. Serve as a top dressing for fancy ice-cream dishes.

## STRAWBERRY HONEY.

To each cup of strawberries mashed and beaten, add half a cup of strained honey. Fold in the beaten white of one egg or four tablespoonfuls of marshmallow whip.

## LEMON HONEY.

Cream three ounces of butter. Beat in one cup of honey and add the well-beaten yolks of three eggs. Stir in one-third of a cup of boiling water, and cook over boiling water until the mixture thickens. Remove from the range, and beat. Add three tablespoonfuls of lemon juice and three of orange juice.

Auburn, N. Y.

## REMARKABLE DISPLAY OF HONEY BY THE CONNECTICUT BEE-KEEPERS' ASSOCIATION, HARTFORD FAIR, SEPTEMBER 6-11, 1915

BY BURTON N. GATES,

*Associate Professor of Beekeeping, Massachusetts Agricultural College, Amherst, Mass.*

As usual, the Connecticut Beekeepers' Association has made large exhibits at the Hartford Fair. In 1915, however, this exhibit was more attractive than usual. From eight to ten tons of honey, it was estimated, were exhibited. The Beekeepers' Association is exceedingly fortunate in having about \$500 available for premiums—\$200 from the fair company and \$300 from the state. The exhibit was largely competitive, altho there were numerous displays which were put up most attractively, but not for competition. The illustrations include some of these exhibits.

Besides the exhibition of honeybees, wax, apicultural implements, and honey cookery, there were concessions where honey, honey sandwiches, and honey fizz were sold. It was estimated that some five tons of honey were thus disposed of; that from 1000 to 1200 sandwiches were consumed on the grounds. As a new delicacy for the visitors at the fair, it was attempted to sell granulated honey in crisp ice-cream cones of the smallest size. The management, however, told the writer that these were probably too sweet to please the purchaser, and that the project was not particularly successful.

General view of honey exhibit, Hartford (Conn.) fair, Sept. 6, 1915.

The display of bees was found more extensive than usual. There were sixty colonies, each a single-frame nucleus, with the queen, workers, and drones, together with brood, pollen, and honey. In displaying

bees it is a great advantage to utilize merely the nucleus rather than a full colony, which was the older method of exhibiting. The nucleus, moreover, should not be too largely populated. In this way the individual

W. K. Rockwell's display of honey, Hartford Fair.

The prize comb honey, Hartford Fair.

bees could be more distinctly traced and the queen more readily found. Mr. A. W. Yates, who is superintendent of the bee and honey exhibit, strongly advocates a uniform glass nucleus hive which shall be utilized by each exhibitor. This adds to the attractiveness of the display, and facilitates in comparisons and judging.

Beeswax to the extent of 100 pounds or more was also exhibited.

Among the numerous calls in the premium schedule was that for a display illustrative of queen-rearing methods. The first premium was won by Mr. Yates, and is pictured on next page.

Of the competitive displays, Inspector W. D. Wright, of Altamont, N. Y., was the judge. Below is a list of prize-winners, and above is the photograph of the pile of premium comb honey.

It cannot be too strongly advocated, as an attraction which will draw crowds, espe-

cially to the concessioners who have honey for sale, to have a demonstrational cage in which live bees are from time to time handled. Nothing is probably more sensational on the fairgrounds. The writer has frequently heard remarks that these demonstrations eclipse the snake charmer in the fakir row. The public, not knowing too much about bees, is always amazed at the non-concern of the demonstrator in the cage. Mysticism seems to protect the operator. If he is a teacher he will, of course, lecture as he demonstrates to the public, explaining how he manipulates the bees, and, incidentally but strongly, instruct in the value of honey as a food.

The beekeepers of Connecticut are indebted to Mr. Yates for his untiring efforts in promoting beekeeping interests. One of his maxims is, "Let the bees draw the crowd." This is entirely practicable. Its magnetism may be judged by the numerous offhand remarks of spectators. As the crowd drifts along the fairgrounds it may commonly be heard, "Oh, see the bees!" Then a group will turn into the display building where they observe a hundred or more lined up and waiting for honey sandwiches at the sandwich-booths, or a group anxiously awaiting their turn for honey fizz. Impelled by the interest of others, more fall in line. Thus it continues for hours.

Exhibit of beekeepers' appliances, Hartford Fair.

A. W. Yates' exhibit of queen-rearing appliances.

In commenting upon the success of the exhibition this year, Mr. Yates said it was the best and most satisfactory year in their history. Each concessioner had had good business, and had disposed of large quantities of honey. Moreover, the best of feeling had existed between competitors and the visitors.

It is a little surprising that more states do not bend their efforts toward a large honey exhibit, at least in one place in each state. It cannot be expected that the first year will reap the benefits which are resultant of several years of displays. From year to year the beekeeping exhibit at a fair becomes more and more a fixture. People hunt for it, in anticipation of seeing the bees or buying honey. Many a person goes to the fair purposely to secure a certain brand or kind of honey which he knows he

can get there. The writer most urgently suggests, for the consideration of beekeepers' societies, that they plan definitely at their forthcoming winter meetings for a beekeeping display at their prominent agricultural fairs next fall:

The winners at the fair were:

|                             | Premiums won |   |          | Value of |
|-----------------------------|--------------|---|----------|----------|
|                             | 1            | 2 | 3 awards |          |
| William Bristol, Meriden... | 0            | 2 | 0        | \$16.00  |
| C. H. Clark, Cobalt.....    | 2            | 1 | 2        | 39.00    |
| H. W. Coley, Westport...    | 2            | 0 | 2        | 33.00    |
| A. E. Crandell, Berlin ...  | 0            | 0 | 1        | 6.00     |
| J. T. Cullen, Derby .....   | 0            | 1 | 0        | 8.00     |
| William Ehouse, Bridgeport  | 0            | 2 | 1        | 17.00    |
| J. G. Griswold, Hartford .. | 2            | 0 | 4        | 39.00    |
| Allen Latham, Norwichtown   | 3            | 2 | 0        | 46.00    |
| A. W. Yates, Hartford....   | 6            | 6 | 0        | 163.00   |
| W. E. Rockwell, Bloomfield  | 3            | 2 | 5        | 98.00    |
|                             |              |   |          | \$466.00 |

In the culinary department there were but three entries—Mrs. A. W. Yates, Hartford, winning about one-third; Mrs. W. E. Rockwell, Bloomfield, and Mrs. L. W. Adams, winning the rest of the \$35.00 offered in this class. This department is, however, much appreciated by the beekeepers, and interests the public. It is of importance in all honey exhibits.

Amherst, Mass.

## INEXPENSIVE BUT EFFECTIVE ADVERTISING

BY FRANK KITTINGER

The accompanying picture of my honey sign, which is in front of my home apiary, is a means of disposing of quite a quantity of honey. My apiary is located within view along one of the main auto roads between Racine and Milwaukee, where on some days hundreds of autos pass. Quite a few tourists see the sign and stop for honey. I intend having a sign somewhat similar to this at each of my outyards where I have honey for sale.

I also dispose of quite a quantity of honey thru the country stores.

We put up a two-pound can and five and ten pound friction-top pails for retail trade. When I first tried to get country storekeepers to handle my honey they thought they couldn't sell the two larger-sized packages, so that the first order was for more of

the small size than either of the two larger sizes. In nearly every case after the first order, winning about one-third; Mrs. W. E. Rockwell, Bloomfield, and Mrs. L. W. Adams, winning the rest of the \$35.00 offered in this class. This department is, however, much appreciated by the beekeepers, and interests the public. It is of importance in all honey exhibits.

As an inducement for the stores to give my honey a trial I offered to put it in on condition that they give it proper display, and if it didn't sell I would take it back. As yet I have had to take back but very little where it has been properly displayed. I find that honey is something that will not sell readily if set behind a counter out of sight. It must be out where customers can see it.

I do not do any canvassing in the territory where the stores sell. The price is the same to consumers whether they get the honey at the stores or at my apiary. I run

The sign that did the business.

a small advertisement in one of our local papers, to keep my name before the people and let them know I am in the business.

#### HONEY.

Eat Kittinger's Honey. Phone 9333-L.

We put out nothing but a well-ripened grade of light extracted honey for our retail trade. Honey that is honey will give satisfaction, and help to advertise one's business. There is no use trying to work up a trade on honey of inferior quality.

Franksville, Wis.

[When Mr. Kittinger, of Franksville, Wis., hung out his sign, "Pure Honey for Sale," on the tree in front of his home, he not only succeeded in selling a lot of honey but in breaking into publicity on a national scale. The Cleveland Advertising Club, the Rotary Club, and the wholesale merchants board of the Chamber of Commerce, of Cleveland, were lunching together at Hotel

Statler one noon listening to a lecture by Frank Lovejoy, of the University of Wisconsin, on a survey of a Wisconsin county. The occasion was "Farm Market Day." Suddenly Lovejoy threw on the screen a picture of Kittinger's apiary and his advertising scheme. The speaker commented upon the value of the yard and the progressive salesmanship of its owner as indicating in general that farmers are waking up to modern business methods.

This "Farm Market Day" is being staged before advertising clubs and commercial organizations in all the large cities of the eastern half of the country by a group of thirty-five publishers of farm papers, headed by E. T. Meredith, of Des Moines, and about fifteen successful business men from small towns of the middle West. Their aim is to convince city people that the farmer is the biggest single buyer the manufacturer and wholesaler can find, and to show that he is as much a business man as they.—ED.]

## PUTTING BEES INTO THE MOVIES

BY ERNEST A. DENCH,  
*Vice-president Photo-play Authors' League of America.*

The motion-picture producer has no use whatever for the comedy of words. It must contain deeds full of mirth-provoking possibilities, and he has no doubts on this score when he introduces bees.

A well-known situation, with numerous variations, is to have the villain sitting in

the park. A bee lands on his forehead, and a close view is introduced to show the grimace he pulls. He flicks the bee off, only to have it land on the heroine's nose a little distance away. He, of course, gets in bad at once.

Another situation, always sure for a

laugh, is a character who keeps others at bay by threatening to release a hive if they advance on him. These stunts are comparatively easy for the director to put over, tho not so pleasant for the players who have to carry them out.

Not all films offer pure entertainment. The motion-picture producers, like the popular magazines, often put out a pleasing combination of entertainment and education. These educational films, so called, deal with all conceivable subjects; but were you to ask the motion-picture producer the most difficult kind of film to take he would inform you that they are studies of insect life.

All a magazine writer has to do is to interview a bee-farmer and obtain a few still photographs, perhaps already at his command. The film producer, however, in order to secure a convincing picture, must cover his subject in actual reality. He is accustomed to temperamental actors, but finds that bees will not stand for any rehearsals, and often refuse to act in the way required of them.

A producer about to take a film of bee-life will read up a book on the subject and prepare a scenario therefrom. This will probably take several months to produce, and yet at the most will yield only sufficient negative to occupy the screen ten minutes.

A motion-picture photographer of my acquaintance, who makes a specialty of educational work, told me that the hardest task he has ever been up against was filming a swarm of bees in action. He started by establishing a real apiary in the studio yard. Some incidents he obtained with comparative ease; but whenever he wanted to "catch" the bees in action they swarmed around him as soon as he began operations, so was compelled to beat a hasty retreat in the interests of safety first. He had the patience of a saint, and deserved to succeed.

The one and only cinematographer who has achieved a reputation for bee-films is J. C. Bee Mason. He has produced four motion pictures of the honeybee, the royalties from which have netted him \$10,000. In the true way of a pioneer, Mr. Mason had many set-backs before he succeeded, and is now quite hardened to stings.

The normal speed for the taking of pictures is sixteen to the second. Some time ago Morsieur Lucien Bull desired to show the movements of a bee's wings, and had to resort to his electric spark. Had he not done so the results would have proven as indistinct as an electric fan in motion. To accomplish his aim he set free a bee from the contrivance attached to his camera, which attained a speed of two hundred

pictures per second. The bee, however, was such a hustler in regaining its balance that only twenty pictures were necessary to record the stunt—the only time it has been accomplished.

## THE SILENT SALESMAN

BY ED SWENSON

I find that a sign that tells what I have to sell is a great help to me in selling my season's crop of honey. I live on a well-traveled road right in the edge of town, and I find that this sign brings me many sales that would otherwise slip by.

The silent salesman.

If the goods are satisfactory, my customers tell their neighbors, who will also come to the place where they see the sign, as that is the mark the neighbors tell them to go by in finding the place. The sign should be about 4 rods from the road, so people can read it without stopping. But remember that, in order to work up a business, you must produce the best, as quality will be remembered long after the price is forgotten.

Spring Valley, Minn.

[See editorial.—ED.]

Exhibit of J. A. and Charles Kinzie, at the Riverside County (Cal.) Fair.

## HONEY AND HONEY COOKING FEATURED AT A COUNTY FAIR

BY MRS. J. A. KINZIE

My husband, J. A. Kinzie, and his brother, Charles Kinzie, had an exhibit last fall at the Riverside County fair. This was the first time that either of them had exhibited anything at a fair, but they received many compliments and a special premium badge for a good display.

Eighty-two dollars in premiums were offered this year; and out of the fifteen entries J. A. Kinzie received six first and four second premiums, and Charles Kinzie received four firsts and six seconds. This they were proud of, considering that two other beekeepers had entries there who had exhibited before.

Another thing they were pleased with was the interest shown toward the bee industry

by the visitors. The two men were busily engaged nearly every moment explaining things and answering questions.

It was beneficial for the exhibitors as well, for a number of well-known beekeepers discussed various points of the business with them. The head florist of the Glenwood Mission Inn was pleased with the display of honey-producing plants, and gave the botanical names of each plant. I sent to the Root Company for their cook-book and made a few articles to exhibit to show that honey can be used instead of sugar or molasses in cooked goods. Many people were surprised to know this. We feel that we did some good in arousing the interest of the people in honey as a food.

Arlington, Cal.

## A NATIONAL "HONEY WEEK"

BY LEWIS L. WINSHIP

My idea, which at present is nothing but an idea, will require the co-operation of beekeepers all over the country to make it a success. It is nothing more nor less than to establish a national honey week—store-windows all over the country to be given over to the display of honey. I would suggest that it be managed by the National Beekeepers' Association, and that all state

associations be asked to participate, as well as individual beekeepers. It could be managed similar to the "oyster weeks" and "coffee weeks" now in successful operation.

The first year this might not be a decided success, for it would take time; but with proper co-operation could it help but be one in the end? The easiest way to raise money for this undertaking would be to ask bee-

keepers to donate to this cause what they usually spend for advertising. Printing would be cheaper in large quantities; and, really, what is there to advertising in any form but printing? If the money held out, would it not be a good plan to get up a design for a window display similar to what was used for last year's coffee week? My plan would be to have individual beekeepers ask their grocer and other grocers in their city to put a display of honey in their windows for the week. Perhaps the grocer would not be handling honey at the time, but one could loan him enough in attractive packages to make a display, and let him settle for what he sells. Nine times out of ten he would become a regular customer when he sees how great his profits and sales were on honey. Attractive stickers would have to be furnished for beekeepers to put on their envelopes, stationery, etc. These would not necessarily have to be free, and I think that beekeepers would be glad to pay the post price per hundred for them.

A campaign of this size would be nothing for a large private concern; but to the average beekeeper it looks like a great task. Why should it be such a great undertaking

when we have the whole beekeeping fraternity to help? What beekeepers need is closer co-operation and efficiency. When a large private firm goes wrong they call in "the efficiency expert;" when a beekeeper goes wrong he throws down his smoker and quits. This should not be, and we shall never accomplish anything until we learn to stick together thru thick and thin, thru fat years and lean ones. If this is true in other things, it is also true in advertising, and we can accomplish a lot by sticking together.

When your brother beekeeper makes a sale of honey to an old customer of yours, don't say that you never will speak to him again. Ferret out the reason, and see whether cheaper honey, superior honey, or advertising did the stunt. When you find out, remedy the fault. Advertise if you want business; or if he is selling honey cheaper, find out if it isn't cheaper honey.

What we beekeepers want is big business, and we must create a sentiment in favor of honey to sell it. My idea of a *national* honey week is only an outline, and I hope I shall not have to leave it to posterity to see it exemplified.

Springville, N. Y.

---

## APPEARANCE THE MOST IMPORTANT ADVERTISEMENT

BY RUTH C. GIFFORD

Honey, more than any other food, is sold by its appearance. People are in the habit of eating the other foods, and will buy them even when they are unattractive. But if the honey is a little unattractive they say, "Well, I guess I won't take any honey today. I can get along without it." How often I have heard that remark! And is there anything more discouraging?

On the other hand, even if a customer has not thought of buying any, when he sees some nice clean-looking honey he says, "My! but that is beautiful honey. I want some of that."

My father, who handles most of the honey locally, on a single trip often sells as much as six cases (whole case to a family) to people who never bought it before. The people say, "Oh! it looks so nice I can't resist it;" and its only advertisement is appearance.

Several years ago my honey did not sell well. In fact, it did not sell at all. I tried to make it as attractive as I would have wanted it if I had been the buyer. The care started at the time the honey was taken from the hives. Every section had to have all the cells sealed except the row next to the wood. Of course I liked it sealed too,

but that is not always possible. Not a single section containing unsealed honey (except in outside row) was ever offered for sale. The damage done to the trade, and the difficulty in selling unsealed honey, is almost unbelievable—unless you have had experience.

Then every speck of the propolis was cleaned from the outside, the edges, and the inside of the sections. The need of this work, in spite of the fact that it is often mentioned, cannot be too strongly emphasized. People call propolis and surplus wax dirt. The person who is selling the honey can talk himself deaf and dumb in explaining propolis, and the customer will turn right around and call it *dirt*. Cleaning the sections is hard work; but in this locality I have the choice of cleaning them or not selling them. It also keeps my trade. People often say, "I began to think you were not coming this fall. Two men have been here and their honey was cheaper than yours; but I waited for you. Their honey was *dirty*."

The final thing needed to help my honey was an attractive package. Cases holding twelve sections proved to be the most popular for family use. These were stained a

dark blue on the outside with indigo. That kept finger-prints out of sight; and, most important of all, the sections showed up beautifully white against the dark-blue cases. Another thing to be considered was that the cases could be used several times. If the outsides were soiled they were cleaned with a damp cloth. Then another coat of indigo made them look as good as new.

When the honey was to be exposed, as in stores, and for the fancy trade, each section was neatly wrapped in glazed paper and labeled.

In a nutshell, here for the average bee-keeper is the secret of successfully advertising honey. Good honey in well-sealed honest sections; scrupulous cleanliness, and attractive packages.

North East, Md.

## BULK COMB HONEY IN CLEAN GLASS JARS

BY E. B. AULT

I am sending a picture of my display at my former home, San Marcos. It was exhibited at the Hays County fair. In the lower left-hand corner I had a frame of brood with a fine queen on it that I valued at \$50.00. In the showcase I had a printed card reading, "Can you find the \$50 queen?" It attracted lots of attention.

We used clear-glass quart and half-gallon jars with golden tops, to pack the nice bulk comb in. The comb was cut into strips that reached from bottom to top, and the jars were filled with extracted honey.

We also had bulk comb in pails on the lower shelves, but it does not show in the picture.

My wife and I did all the work, even painting all the signs.

We filled a number of bottles with bees-wax; and when cold I broke the bottles, leaving the wax in attractive shapes. I also had a 70-lb. cake with a United States flag sticking in it. An exhibit of this kind costs very little, and yet it sold all my surplus honey the same week.

Calallen, Tex.

E. B. Ault's exhibit of bulk comb honey in fruit-jars at the San Marcos (Texas) fair.

An exhibit of many kinds of fruit and berries canned and preserved in honey. Note.—The apples shown on the table in front belonged to another exhibit.

## EXHIBITING HONEY PRESERVES OF MANY KINDS

BY G. A. KOGER

The picture above shows my exhibit of honey and fruit canned with honey at the Gem State fair, Oct. 5 to 8, at Boise, Idaho. I had the following fruits and preserves put up with honey only—no sugar:

Peaches, pears, blackberries, black and red raspberries, logan berries, gooseberries, tomatoes, cherries, strawberries, peach and pear preserves, and jonathan-apple jelly. Every one was much interested in this part of the exhibit.

The list of awards in the bee and honey department is as follows:

Best five cases comb honey: John Bliss, Ustick, 1, \$15.00; E. F. Atwater Co., Meridian, 2, \$10.00.

Best twelve jars extracted honey: G. A. Koger, Meridian, 1, \$15.00; E. F. Atwater Co., 2, \$10.00.

Best display extracted honey: G. A. Koger, 1, \$10.00; E. F. Atwater Co., 2, \$5.00.

Best cake beeswax, G. A. Koger, 1, \$6.00; E. F. Atwater Co., 2, \$3.00.

Best display apiary products: G. A. Koger, 1, \$15.00; E. F. Atwater Co., 2, \$10.00.

Best single-comb nucleus three-banded Italian bees: G. A. Koger, 1, \$10.00; E. F. Atwater Co., 1, \$10.00.

Best single-comb nucleus Carniolan bees: E. F. Atwater Co., 1, \$10.00.

Best single-comb nucleus Caucasian bees, E. F. Atwater Co., \$10.00.

## AN EXHIBIT SHOULD SHOW MORE THAN HONEY ALONE

BY J. P. LUCAS

If every beekeeper would try his best to make a good exhibit at the fairs the attention of the people would be called to honey in an effective way, and they would be more apt to use it. It is necessary to go further

than setting up a long row of jars of honey. Next year I shall try to get a premium offered for the best display of food cooked with honey, and of canned fruit. I also expect to have a collection of different kinds

J. P. Lucas' exhibit at the Kansas State Fair. Mr. Lucas, for several years, has featured fruit canned with honey. Some of the jars were filled in 1911, and the fruit is still keeping well.

of honey produced from different honey-plants. The more we can adopt these new ideas the more we get out of the old rut.

The illustration shows my exhibit at the State Fair at Hutchinson last fall. My space was about thirty feet in length; and if it had not been so far from my home I should have made a larger exhibit. As it was, my bees and fruit in the glass hive convinced many people that bees cannot destroy fruit.

In the center of the exhibit I had all my different kinds of honey labeled according to the source. Just below this was the fruit put up with honey in 1911. I have made canned fruit a feature every year, and have had some of it on exhibition every time. It is keeping well, and I have convinced a good many of the value of honey for canning. By request I had the recipes printed.

Topeka, Kan.

## RIGHT AND WRONG WAY OF ADVERTISING HONEY

BY JOHN W. LOVE

Advertise first in your local newspapers. Your own town and county are likely to prove easiest developed of all markets because of low transportation costs and your own position in the community. Too many overlook possibilities in advertising right at home.

After that, use papers in neighboring towns and then the city dailies, depending on your capital and selling plan. Farm

papers are probably not as suitable for reaching the honey-buying public as the newspapers and general magazines.

Keep at it. If possible advertise at least once every week to keep the demand steady. An occasional advertisement is likely to be the most expensive in the long run.

In writing your advertisements, make plain in your headline what you have to sell. Such headings as "For Sale," "Notice,"

and "To the Public" are too general. The exclamation-point has no place in an advertisement. Avoid in headlines such smart-Aleckisms as "Don't Read This."

**FOR SALE**

Good pure honey made by our own bees.  
Choice comb and extracted.  
Will sell cheap.

**ALEX. McPHERSON**  
R. D. 7

Head too general and matter uninteresting.

It is well to insist on having your advertisement set up in good style. Avoid heavy borders and glaring "boldface" type. The style of the type should be consistent throughout—that is, don't have the printer use one kind of type for the heading and three or four others in the body of the advertisement. People are likely to realize such an advertisement is not in good taste without knowing exactly why.

Avoid having too many display lines. After the heading, it is well to follow up with a paragraph or two on honey rather than a number of short fragments one above another. The second of the "horrible ex-

**PURE HONEY!**

60-lb. can, \$6.60

**Wm. ARNETT**  
Ganges, O.

Poorly set up. The various type styles give bad effect. Honey will not retail in such large packages.

amples" on this page illustrates the point, while in the first the sentences are not complete.

It should hardly be necessary to say, keep everything else than honey out of the

advertisement. If you have eggs or hogs to sell, advertise them in another place.

Change your advertisement frequently. A change will attract attention, give pleasing variety, and cost nothing extra. It is not infrequent to find the faults of such examples as the two on this page perpetuated thru issue after issue of a paper.

Generally it is best to name the price of your product in the advertisement. Even the people who are interested often forget to inquire for prices, and the effect of the publicity is lost. If the figures are given they can order at once.

Honey-producers who sell to the retail trade thru the grocery stores or direct to the consumer find that honey must be put up in small containers. The average family would have no use for a sixty-pound can of honey, even if father could raise the money. A one-pound jar is not the smallest size which can profitably be put up, honey-distributers have found. By making the larger quantities a little cheaper in price per pound, their sale is encouraged.

Try to have your own advertisements read as naturally as tho you were talking to a friend about honey. When you sit down to write a selling talk, imagine yourself earnestly arguing honey with a prospective customer. Naturalness goes a long way in publicity. Being natural creates confidence. The writer who attempts unusual effects without long training is likely to make his readers suspect that he is trying to "put one over." Even so, clearness in thought is usually the mark of highest skill.

In pointing out the characteristics of honey, appeal to the love of children, one of the most universal of human feelings. Make it stand out so plainly that any one can grasp the meaning. What is good for youngsters ought to be good for grownups.

Perhaps the reason honey is so often regarded as a table luxury is that honey-producers themselves often fall into the habit of looking at it in the same way. To get the public out of this rut, compare honey with other foods from the standpoint of price as well as appetite.

## INSPIRING TEACHERS WHO WILL INSPIRE BOYS

BY C. S. RHEA

Realizing the desire of the rural population, especially the young boys of the country schools, to drift to the cities, the superintendent of public schools of Hart County set apart Sept. 10, 1915, as "farm day," and required the teachers to carry their schools to some farm near by, which was

used to instruct the children on "better farming," and to arouse an interest in farming. The superintendent visited all the schools of the county that day, with a company of Hart County high-school professors, and the editors of the *Evening Post* and *Farm and Family*, both of Louisville,

Demonstrating bees to a bunch of high-school teachers.

Ky. Mr. James Speed, editor of *Farm and Family*, gave a talk on sweet clover. Then I invited them to visit my apiary. After being with me about fifteen minutes they went on to the next school.

Mr. Speed was very much interested in my scales, which consists of a steel shaft resting on a pivot fastened to a tree, with a hive on one end and a weight on the other. The shaft has 1-lb. notches on it,

which enables me to keep tab on my apiary. A tin bucket with a brick in it answers for a weight. The scales may be seen just beyond the extractor, in the picture.

The small hives in the foreground are my queen-mating nuclei. They have a division in the center, with an entrance at each end. I use full-sized Hoffman frames. I can leave my queens in them all the season if I don't have a demand for them.

Horse Cave, Ky.

## POSTER-STAMP IDEA FOR INCITING THE HONEY APPETITE

BY JOHN R. POMEROY

I think if Walter S. Ponder has had difficulty in getting some one to pay attention to his letters before, he has struck a chord in the Feb. 15th issue, page 151, that ought to stir every beekeeper who is interested in getting a better market and better prices for his products. I am in the advertising business, and I have been cudgeling my brain for some solution to the question of raising money for advertising honey, and I must confess this scheme of Mr. Ponder's looks good to me.

While I agree with him that the clover head does not make an especially pleasing picture for this purpose, still I would not be in favor of a non-honey-producing flower for an engraving of the kind. Suppose we offer a premium to GLEANINGS' readers for suggestions. We ought to get something pretty good somewhere among all this gray matter. For that matter, nearly all the large engraving houses will now furnish sketches for poster stamps as well as make up the finished plates to work from. By all

means let's give it a trial, anyhow. There is not a beekeeper in the country who could not use a hundred stamps to advantage, and I know of several in this country who could use thousands. It would certainly mean a tremendous boost for the honey business. The money to be derived from these stamps

would, of course, be used to start a national advertising campaign along the line of "cream of wheat" and others, and afterward some kind of plan might be devised to get each producer to contribute according to the amount he was benefited. What do you say, honey-men?

Gladwin, Mich.

## SOME OF MY ADVERTISING SCHEMES

BY DR. A. F. BONNEY

If the beekeeper with a moderate number of colonies wishes to save in advertising he must first get in with one or more papers near his home town, and send them "news"—local stuff which the editors will be glad to pay for with three dollars' worth of advertising in preference to giving up a dollar cash. In season I advertise, using short snappy items. For a sample: "I am now taking off some very fine white-clover honey, and you would better engage yours. It will not last long." This is enough for once. I try to change weekly, and one or two lines is enough, for everybody will read one line while but few will pay attention to twenty.

It will, of course, do no harm if, in the height of the honey season, you use a good-sized space for a standing advertisement, say a space two columns wide and five to ten inches deep, and a cut of some kind will add materially to the drawing power of the advertisement—say a cut of a large bee or a skep. Do not try to put a history of beekeeping into this space. A simple statement that you have some good, clean, pure honey for sale will be enough unless you see fit to print a price list. I hardly approve of that, however, unless you deliver the honey personally or by mail. The average purchaser of any kind of goods dearly loves to have them delivered—anything from a spool of thread to a diningroom set.

All this is contingent on being able to furnish news to the papers; and to do that, all you will need do is to see the editor. You may not have the "gift" of writing, nor do you need it.

Here are a few samples of the matter I get into the papers to advertise honey. In these I do not mention my own goods, for I am the nearest honey-producer; and if, when people want honey, they will not respond to former and current advertising, my time has been wasted.

"A curious experiment. Take a loaf of home-made bread. Cut from it a slice. Cover one side with good fresh butter, and on that put a thick layer of honey. Give it to the first child that comes along. The in-

stant assimilation of the compound by the kid is the joke."

"A queen-bee weighs a matter of ten grains, and \$1 is an average price for her. At that rate a thousand-pound steer would sell for \$717,000."

"A queen-bee does actually nothing but lay eggs, and will deposit from 1000 to 3000 per day. I am trying to study out some plan by which I can cross the bee and a hen. Think of 3000 eggs a day for three months at present prices."

"A colony of bees often produces a surplus of 200 pounds of honey per year, which, at only ten cents a pound, means \$20. Honey often sells for 20 cents a pound."

"American honey is the best in the world, and is, generally, sent to all parts of the world. A matter of \$25,000,000 worth is produced annually—three times the salmon and double the orange sales, and the output is increasing rapidly."

"When a queen-bee is less than two weeks old she goes out on her wedding-trip; returning, she never again leaves the hive except to accompany (not lead) the departing swarm."

Any one with a knack for writing can get up an unlimited number of such paragraphs, and almost any newspaper man will gladly print them, as they are interesting facts. There is no objection to using the above for the good of the beekeeping world.

I have kept some track of the advertising I have done in four papers for the past year for the store and the honey; and at four lines to the paper per week and 5 cents per line, it totals a money value of about \$40.

In addition to this I have something to advertise—"Bonney Honey" on every envelope I send out, if nothing more than the little red sticker, "Eat Bonney Honey." From May until I am sold out in the winter I use a price list, as I do a considerable mail-order business.

Some beekeepers objected to the little red sticker, "Eat Honey," when I offered it to the beekeeping world. The logic of events

has proven them wrong, for they are now sold by the millions, and the demand is increasing, I am informed.

The suggestion has been made that we beekeepers put out a writing-tablet with a honey advertisement on the cover. The first question that arises is: "Who will pay for printing the covers?" In our store we sell a writing-tablet 6 x 9 inches in size, 1 $\frac{5}{8}$  inches thick, weighing 1 $\frac{1}{4}$  pounds, for five cents, and make 20 per cent profit. It has a red cover on which is printed "I am it."

What could be put on the cover that would convey any message of value to children under fourteen years? and out of an assortment of twenty makes of tablets how could we induce the child to buy any particular make?

Like the little red sticker, "Eat Honey," scriptural quotations regarding honey, and

literature regarding the food value of honey, there is an element of good in the idea; but the only way to use it will be to induce some manufacturer of tablets to get out a natural-history series of tablets with pertinent paragraphs about bees and honey, if it is possible to do so.

The tablets cannot be sold by dealers in beekeepers' supplies, for children do not go there. Drugstores, bookstores, and general stores are where such things are most sold and must be kept. I do not know how many school children there are in this county, but there are thousands.

Personally I think a sign on a building, "Eat Honey," where the children can see it daily, would do as much good as a few writing-tablets scattered about the county. However, advertise, and keep eternally at it.

Buckgrove, Ia.

## CHEAP ADVERTISING

BY TARLTON-RAYMENT

When we are of an analytical turn of mind and probe into some of the weaknesses on the business side of apiculture, the first thing that arrests our attention is the negligence of many apiarists regarding the value of their stationery as a means of advertisement. Some may suggest that we attach far too much importance to mere scraps of paper; but from our viewpoint the subject is well worthy of more earnest thought than is usually bestowed upon it. To enter upon a disquisition as to the value of judicious advertising would be to labor the point unnecessarily; but since striking, well-printed stationery (labels of all kinds are included in the category) may be the means of securing some beneficial publicity, not to provide it is to throw away foolishly that which more astute managers spend huge sums to secure.

Of course there are thousands of keen bee-farmers who fully realize the advantages to be thus gained, and who incur considerable expense; but I am honestly of the opinion that the average "honey-grubber" is far and away too careless. I frequently receive communications that give anything but a good impression of the writer's business—usually a cheap plain envelope destitute of any attempt to keep the sender's business before the recipient. The same criticism can be directed at the writing-paper.

The printing of gaudy, bombastic claims, and hyperbole, is ill advised at any time; but a well-set-up head, especially a neat

pictorial one, nowise detracts from the businesslike appearance of the epistle.

A large number show a predilection for a "cut" depicting a queen-bee. However, such a picture conveys but little to the outsider: and, if of small size, often passes quite unnoticed. On the contrary, a neat etching of the apiary may be made to exhibit notable esthetic judgment on the part of the owner, and, as such, arrests attention and evokes admiration. The latter are the prime requisites in all successful advertising schemes.

Some make use of a "catchy" word or phrase, very successfully, tho of course the benefit that follows is not then due to any artistic appeal but to the whimsical or other presentation. Some few refrain from printing anything other than a bald announcement of name and address, arguing that such a course is undignified. Many would suggest a hesitancy on the apiarist's part to acknowledge the source of his livelihood. From time immemorial apiculture has claimed among its devotees men of high attainments. Then why should not we, humble "grubbers of honey," extol the wonders of the bee? All the foregoing remarks apply with equal force to bill-heads, menus, labels, etc.

In the every-day conduct of our business we are particularly careful to see that all correspondence and goods are despatched with a tradesmanlike finish. Shall we be pardoned if we suggest that a streak of the artistic in our composition is, perhaps, re-

sponsible for our insistence on this point? We not only utilize a half-tone etching for all our paper and labels, but we also make use of play on a registered word. The envelopes read:

From T. RAYMEN,  
Breeder of Queenly  
Queens.  
"Queenlea" Apiaries,  
Briagolong.

It is not rare for us to receive mail from overseas inscribed simply with our name and that of the apiaries, such is the value of a novel word.

All our honey packages have labels that reach right around the tins; and when they are standing in a shop or on a wharf or at a station they make a splendid advertisement. We have repeatedly booked orders from people quite unknown to us personally, but who had noticed our honey *en route* to other districts.

As examples of what we consider effective designs I am forwarding an original drawing of a post card advertising or boosting

Post card for use in selling honey. Designed by T. Rayment, Briagolong, Victoria, Australia.

honey. Of course, all bee-farmers are not draftsmen, so we are sending this one along because there is a call for such an article in GLEANINGS—p. 167, Feb. 15. With your permission, Mr. Editor, we should like to enter it for the gold-medal, prize card, hearty approval, or whatever it is, Messrs. H. L. Case, F. Greiner, and W. F. Marks award for good post cards.

Briagolong, Vic., Australia.

## BULK COMB HONEY IN GLASS TO ATTRACT SALE

BY D. W. MILLAR

I use the accompanying pictures of bulk comb honey in glass in advertising my honey. I have found that honey in this

form will sell even to people who do not like honey nor advise its use. At the same time, honey in glass without comb, and at a

Bulk comb honey in glass is attractive.

lower price, will not sell. Of course, later on those who get to using honey and acquire the habit so that they become regular customers buy the plain extracted honey in gallons and even larger cans.

This honey is from the *campanilla blanca*. I have adopted the three-ounce, the half-pound, and the one-pound jars. Situated as I am, larger sizes show too much breakage, both on the empties shipped here and on the full jars which I ship out.

Holquin, Cuba.

Campanilla blossoms and a sample of what the bees get from them.

## PHOTOGRAPHIC POST CARDS TO SELL HONEY

BY GEORGE H. ELSKAMP

Last year I took off 3000 sections and about 1000 lbs. extracted honey from twenty colonies, spring count. My queens are

Practically every colony also had a super not finished.

Maurice, Iowa.

Copy of one of the illustrated post cards that George H. Elskamp, of Maurice, Ia., uses to help sell his crop.

nearly all leather-colored Italians, but quite a number are mismated. One colony had its 12 supers in all; another colony that was preparing to swarm I divided, and it had 18 supers and one hive-body between them.

[Mr. Elskamp uses post-card views of his apiary, bees, etc., with appropriate inscriptions for helping sell his honey. The 4000 lbs., mostly comb honey, from 20 colonies, spring count, is not a bad record!—Ed.]

## AN EXHIBIT THAT PAID

BY M. H. HILL

I have been a beekeeper for 20 years, and there is no branch of the business that I take more pleasure or pride in than the marketing of a crop of honey, coming in personal touch with customers, either retailers or consumers.

At the present time I have charge of oil property and beekeeping is a side line. In this I have been handicapped in meeting customers and having a chance to talk honey. The opportunity presented itself last fall, when our first county fair was held at

Dewey. Knowing in advance the dates the fair was to be held I obtained consent from my employers to have my vacation at this time, and, assisted by my wife, we prepared 1000 lbs. of our crop for this exhibit. Most of my honey is put up in the bulk as recommended by Mr. Louis Scholl; and I wish to say, in thanks to Mr. Scholl, that putting up bulk honey has always been a success with me.

Even in Northern Wisconsin, where I began the practice, I always marketed my No. 2 section honey this way, obtaining the same price as received for No. 1 section honey; but in Oklahoma conditions are more favorable for putting honey on the market in bulk. Putting up honey in glass containers in an attractive shape is no piker's job, and no one should attempt it without having proper utensils for doing the work.

The managers of the fair allowed me to sell honey the last afternoon of the fair.

1000 pounds of bulk comb honey exhibited by M. H. Hill at the Washington County (Okla.) Fair. Mr. Hill made his exhibit educational in that he showed every stage in honey production—the full combs in observatory hives of bees, uncapping, extracting, clarifying, and bottling.

My exhibit sold in a few hours, and the advertising this exhibit gave me well repaid me for the effort. The sales at this one fair, and the advertising it gave me, made it possible for me to own a five-passenger Overland touring-car.

Dewey, Okla.

## HOW THE BEE HELPS FEED THE WORLD

BY B. KEEP

The January number of the Geographic Magazine is devoted almost entirely to a most interesting and liberally illustrated article entitled "How the World is Fed." It is not possible in a limited space to review this exceedingly instructive article in detail, but as beekeepers we are specially interested in the following, which is copied in full:

### "The Industrious Bee."

Nowhere else in the world is the majesty of small things more strikingly revealed than in the story of the production of honey in the United States. That great decennial interrogation-mark which marches every ten years thru the homes of the American people, and asks them a thousand and one questions, has ascertained for us that the bees of the country annually produce twenty-seven thousand tons of honey. That means fifty-four million pounds! Truly the busy little bee must improve each shining hour to give to the American people fifty-four million pounds of honey, in addition to providing

for its own needs. The number of trips from hive to flower, and from flower to hive, with their tiny loads of honey-making materials that the bees must have taken to bring us these fifty-four million pounds of honey defies estimate; but they afford us an inspiring lesson of what the faithful doing of small things may accomplish."

Note the sentiment of the closing lines.

When the time shall arrive that beekeeping is the business of specialists on a large scale, these figures will begin to appear small by comparison.

What is really to be desired is not more beekeepers but better beekeepers, as has been so often said; and the only hope seems to be in keeping bees on a larger scale by most advanced methods.

New Jersey.

[The census figures are very conservative. Reliable estimates show that the total amount of honey produced—including both comb and extracted—is not far from 200 million pounds.—Ed.]

# Heads of Grain from Different Fields

THE BACKLOT BUZZER

BY J. H. DONAHEY

*Henry Appleblossom has a new patent pending. He has an imitation honey that is nearly as good as the real thing; and, by ginger, it costs only three times as much to make it.*

## Bees Creatures of Habit.

It would seem that there are more influences than at first appear which are given effect by the placing of supers above a colony of bees. During a generous honey-flow many things may be done which, under other conditions, would not be at all advisable.

"Ample superage" is recommended to lessen swarming, and it usually seems to have that effect, be it more or less. But to secure the best result in that direction, supers must be put on considerably in advance of any sign of swarming. Then if outside temperatures should be rather low (usually at night) this large empty space above is very likely to hamper brood-rearing and active "building up," and the bees come to regard that space as something which they "have to put up with," very much as we would regard a vacant upper story in our house which we would come in time to regard as not belonging to us.

If the farmer has great barns, and an immense hay crop, he just goes ahead storing hay into those barns, and does not worry about their bigness; but in ordinary or lean circumstances he is likely to calcu-

late where he can stow to the best advantage what he has, and it is safe to say it won't be scattered or stowed in some far corner.

In regard to their housekeeping, bees appear to acquire habits somewhat like human beings. This colony goes and comes via the right end of the hive-entrance, that colony from the left; this one establishes its brood-nest on the left, while the next has it on the right side of the brood-chamber. One colony is possessed to gum up the rabbets, while another gums up the bottom-board; this one stores honey in the outside frame, while that one stores pollen there. Naturally, when the flow becomes generous, the bees, having acquired the habit, continue to store in the brood-chamber until "it's standing room only." It is scarcely necessary to point to the result of this in diminished brood toward the end of the season, when extensive brood-rearing is most desirable to provide young bees for winter.

The moral of all this is that we should first decide whether then it is profitable to rely upon excessive supering to discourage swarming, or to treat that as a separate problem, and add supers but little in advance of present need, whereby no habit of storing in the brood-chamber is induced. From the 1914 season's experience as here suggested, the writer is inclined to be strongly in favor of the last proposition.

To sum up, let us say excessive supering seems to have much the same effect as insufficient supering—the bees in one case storing below from choice (and habit), and in the other case from necessity—the happy medium being most desirable in order to get surplus stores where wanted.

Lynhurst, N. J.

## The Percentage of Mismatched Queens Received from Breeders.

I gave this matter up years ago. After spending a considerable amount in stamps, and wasting a lot of energy in a futile endeavor to secure something like uniformity, after appealing to bee-journals and experts for assistance, I found that I was simply traveling around in circles. In the absence of a fixed standard, breeders can pass off almost anything upon their customers with comparative impunity. There are, of course, breeders who are reliable, who have brought their stock to a high standard, as bees go, and who are conscientious in their business dealings; but a great many are those who have simply failed as honey-producers, and turned their attention to queen-rearing. These, having neither the requisite training nor a location where pure mating is possible, are, by glowing advertisements, distributing an inferior strain of bees thru an already non-uniform stock.

Los Angeles, Cal.

Arthur Williams.

### Are Moldy Combs where Bees have Died Fit to Use Again?

Of 30 hives from last fall I have at present only 11, all in good order. The 20 that are dead I cleaned out today and both hives and combs are very moldy, due to the moisture of the adhering bees. The frames are nearly all of the old V shape, and I wish to discard them. Is the moldy comb still fit to be used to make into new foundation?

Some of the frames are Hoffman, with wires and good comb. What can I do to get the bees out of the cells? Do you think that these frames could be used again, even tho they are somewhat moldy?

R. A. Dehmel, M.D.

South Germantown, Wis.

[The combs you refer to can be used over again. The fact that they are a little moldy, or contain dead bees in the cells, will do no harm. The bees will clean them out, dead bees and all, very readily, and use them over again. Of course, any combs that are crooked and otherwise undesirable should be melted up.—Ed.]

### How to Transfer from a Log.

While cutting logs in the woods we cut a bee-tree. They were in a limb about two feet in diameter, and about 50 ft. from the ground. We cut a block off about 6 ft. long; stopped up the hole with mud, and hauled it home. Now the puzzle is to get the bees into a hive. We were in hopes of getting a swarm; but as none has left so far we should like to have the bees that are in the log. If you could suggest any way it would be greatly appreciated.

Youngstown, O.

Paul Walters.

[We should treat this log gum exactly as tho it were a box hive, and transfer by the Heddon method. You will have to pound a little longer and a little harder because the trunk of the tree, being thicker, is a little harder to get the bees out of; but if you persist we think you can do it without much trouble. It will not be profitable, at any rate, to keep the bees in the log, for you will not be able to get any honey from them—that is, fit for table use.—Ed.]

### How to Handle Combs after Extracting.

E. S. Miles' article, p. 721, Sept. 1, touches on a very interesting and important subject. How would it suit Mr. Miles to bore, say, an inch hole in his escape-boards and fit it with a tin slide which could be operated from outside the hive, and then, when extracting, leave the escape-boards in place and in the evening return the wet supers and open the slide? When the bees have cleaned up, close the slide and remove when the super is empty. Of course it does not do to leave escapes too long on hives or they may be stuck up by the bees. Personally I don't favor any plan which involves a general mix-up of the wet combs for fear of spread-

ing disease if such should get a footing unknown to the apiarist. By this plan the bees clean their own combs. It may be a bit slow, and mean having a lot of escape-boards; but is not that better than risking spreading foul brood all thru the apiary before one is aware of its presence?

J. H. Todd.

Renwick, Blenheim, Marlborough, N. Z.

### Two and Three Eggs to the Cell; What is the Trouble?

I hived two swarms of hybrids on their old stands, moved both hives (parent colonies) away yesterday several hundred feet. One swarm had issued Thursday, the other last Monday. This morning both queens were dead, and one hive had over 150 dead bees before it.

I purchased three untested Italian queens late last summer, one being O. K., very prolific, and swarmed. The second one was also very prolific, and I have now two supers on and no sign of swarming, but I now find two or three eggs in a cell. The third one did poorly after I put her in, altho she had quite a few bees at the opening of spring. But they dwindled down so till there wasn't a pint in the hive, and then I discovered many cells with two or three eggs and quite a few with four or five. There were no laying workers, for I found both queens and killed the one in the weak colony, and then found no more eggs. But then I found the other one doing the same thing.

C. A. Colell.

Lincoln City, Del., June 5.

[In the case of the two hybrid swarms it is evident that the bees became more or less mixed, with the result that there was some fighting in the uniting. The fact that there were so many dead bees in front of one of the hives would indicate that there was something of this trouble. Why both queens should be dead we can't understand, unless one or more of the virgins went forth with the swarms. In that case the virgins would destroy the old queen. Virgins are usually not hatched when the swarm issues. The probabilities are that you would find young virgin queens in both the hybrid colonies, and laying by this time.

We assume that the three untested Italian queens referred to in the next paragraph have nothing to do with the two hybrid swarms.

The fact that their colonies are not swarming may be a good indication, but the further fact that you find two and three eggs in a cell indicates perhaps that the old queens have turned drone layers, or it may indicate that honey has been coming in, and the queens cramped for room so they are laying two and three eggs in a cell. This does not very often happen, however. The intimation that all three of the colonies have two and three eggs in a cell rather indicates either laying workers or drone-laying queens, but it is a little remarkable that all three

colonies should be afflicted with the same trouble. Without looking into the hives we are not able to offer you any satisfactory explanation.—Ed.]

**Hive Indicator.**

The illustration represents the cover of my eight-frame hive divided into three two-frame nuclei for queen-rearing. You will notice that all records for dates can be kept by using two small nails—one for the month and the other for the day. The pointer indicates conditions; O, queenless; C, cell; V, virgin; S, saw, but not laying; L, laying. I use a small brick as soon as laying begins, so I can see at a glance where my laying queens are, clear across the yard. The bricks I use are 2 x 4 x 7/8, made of cement; and I use them exclusively on full colonies when requeening.

Correction: Instead of E for eggs it would be better to have C for cell.  
 Forest, Ont. I. Langstroth.

**Requeening for Paralysis.**

I want to give my plan of getting rid of bee paralysis. This disease got in my bees from queens that I bought. I hated to kill these fine queens, but soon two-thirds of my colonies were affected. At this time about half of them were black. I tried several plans, but it kept coming back. I finally found a plan that eradicated the trouble, and I am willing for others to try it.

Kill the queen, and eight days afterward cut out all the queen-cells that have been started, and provide eggs from a queen that has never had paralysis. Let the bees raise

their own queen in the hive right with the sick bees. They will not swarm out, even if they have a dozen cells. This plan gets rid of the trouble, and it will not return.

I have some colonies that have never shown the least sign of paralysis, altho bees from colonies all around were dying. It is these colonies that I get the eggs from for breeding.

No doubt some queen-breeders do not pay enough attention to this matter. They are careful to breed from stock that does not become diseased. Colonies headed by such queens will live right in the midst of these and not show the least sign of it.

Mathews, Ala. M. S. Nordan.

**The Liability of Express Companies in the Shipment of Bees.**

If I sell to John Doe, Canada, swarms of live bees with queens, f. o. b. Fitzpatrick, Ala., and I deliver them to express company, get their receipt for the same and mail it to John Doe in Canada, and there is unwarranted delay, is the express company liable if bees are dead? In 1915 and 1914 like shipments were delivered in three days and four hours to same party after leaving here. This year the bees were on the road from 8 to 16 days, and were dead, or nearly so, when delivered. The question is, Should John Doe pay me for bees I sent him, and he, John Doe, look to express company for value of bees not delivered alive? Or should I not look to John Doe for price of bees, and express company pay me? I refer you to my ad. in Gleanings. Fitzpatrick, Ala. W. D. Achord.

[An express company comes under the laws and is a common carrier. While it may receive goods, issuing a receipt which does not agree to land the article received at destination at any specific time, yet there is reason in all things, and the express companies, thru the operation and contracts with the railroads over which they operate, maintain published schedules.

Shipments are based a great many times on these schedules, expecting (aside from the acts of God), goods to reach destination at least within a reasonable number of hours of their schedule time.

From points, for instance, within the territory in which we are located, termed the central states, there is no point within the United States and a greater part of Canada that schedules do not show that shipments may be reached not to exceed seven days; schedules for the Pacific Coast in about five days, these figures allowing a little time for unavoidable misconnections. From points within the state of Alabama to any point in the territory of Ontario, Canada, allowing for above delays, excepting acts of God, shipments should be delivered in not to exceed five days.

Shipments from such points, especially in the case of perishable live stock or live bees, 8 to 16 days would be considered a basis for claim in the eyes of the law, excepting

causes for delay on account of the acts of God.

The fact that the receipt given by the express company or any common carrier does not specify any specific date of delivery does not relieve the carrier when its employees are grossly negligent in the handling of shipment, thus causing these delays. Usually the common carrier will settle claims of this nature where they have no good reason for such delays. They are wise to the fact that the courts would not sustain them.

Generally speaking, we would consider four to ten days' time taken over and above what is termed a carrier's schedule is basis for claim and can be collected.

In the case above cited your customer would be the one to make the claim on the express company, and the customer pay you for the bees; but it is getting to be more and more the custom to make the claim in behalf of the customer because the shipper knows the procedure better.—Ed.]

**A Double Hive-bottom.**

For three years I have used fifty double bottom-boards of my own design, as shown in the illustration. At first I expected the bees would build combs between the two floors, but have had no trouble along this line. I made these principally for convenience in moving during hot weather for a buckwheat honey-flow, but I like them so well that I intend making two or three hundred more, altho I do not expect to do as much moving in the future as I have in the past.

The lower floor is solid, while the upper one, which is really the floor of the hive, is movable so that it can be shifted up or down as needed for ventilation, or, if required, it can be taken out altogether. There are two openings in this upper floor  $\frac{3}{8}$  of an inch

even and pull the floor ahead so there is about a one-inch opening at the back besides. This gives abundance of ventilation, which goes a long way toward discouraging swarming.

The movable slide controls the size of the entrance outside the vestibule; and when moving I can replace this slide with a screen.

Smithville, Ont.

Lewis Minor.

**Can a Colony Clean up American Foul Brood?**

Have you ever heard of bees cleaning up American foul brood? A case has come to my attention that I should like to have your opinion on.

About three weeks ago I found two cases of American foul brood in a neighbor's apiary. One was bad and weak, so he killed it. The other he started to transfer, but noticed that the bees were cutting out some of the cells containing the diseased brood. He then let it go and called my attention to it. Sure enough, they had cut some out—usually destroying the walls connecting at least two adjoining cells. The colony is in fine condition, and the first heavy honey-flow is on.

There is no doubt as to its being American foul brood, tho I had a hard time convincing the owner of it after they had started cleaning up. Even now he wants an expert's opinion on it. My own opinion is that he took a splinter and mused up the diseased brood, enlarging or even breaking the cell. Could this account for it? or is it that they are very strong and making an attempt of their own?

Ramona, Cal., May 18. C. A. Quincey.

[While a vigorous strain of Italians will help clean up European foul brood, it is very seldom that they can handle American without assistance from the owner. Usually it is required to remove all infected material, either by removing the frames entirely or by cutting out pieces of the comb in the frames and substituting foundation instead. Occasionally a very powerful colony will clean out even American foul brood; but there is always danger that the disease will reappear again in a year or two. We always think it advisable, whenever the disease is found in any set of combs, to melt up all the combs even if only one or two cells appear. We have never known of a time yet when a strong colony cleaned out American foul brood, but what, if that colony was left long enough with the same set of combs, the disease would reappear again in one or two years hence, so it is well to err on the safe side.—Ed.]

**European Foul Brood in San Diego Co., Cal.; Apicultural Nomenclature.**

Many bees here in San Diego Co. are dying from European foul brood. I can't understand why one swarm of bees should be called a colony or the cells on foundation called "drawn." My bees build white cells on dark foundation. Am I too particular?

Potrero, Cal.

Geo. W. Riker.

wide, running from front to back. These may be covered with a strip of tin or roofing paper if desired. Thru these openings the bees can go down to a feeder shoved in between the two floors. They will take syrup from a feeder located in this bottom quite late in the fall.

In the swarming season I lower the upper floor in front so that the bees have about a 3-inch entrance. I also leave the two slots

[According to the latest dictionary, a colony is a collection of bees at rest, and keeping house in the hive. A swarm is a collection of bees that has issued from the parent colony, and is usually called a swarm as long as it is in the air or on a tree, and for a few days after it is hived. The old colony is called the parent colony, and the new one is called a swarm until it gets down to its regular housekeeping duties. Then it is called a colony.]

Cells that are built from foundation are often spoken of as "drawn." Where the foundation is very heavy, and there is a large amount of wax in the cell walls, the cells themselves may be drawn—that is, the bees use only the wax in the foundation. As a general rule, drawn comb from foundation is made up of wax taken from the foundation itself, and wax added thereto from other sources. If honey is coming in freely, the wax used to complete the cells may be the virgin scales taken from the under side of the wax-pockets of the bees themselves. These will be white like the paper on which this is printed. It will, therefore, transpire as in your case that the tops of the cells will be whiter than the foundation on which they are built.

Very often the bees take their tributes of wax from other combs. In that case the top of the cells will take on the color of the combs next to them. Comb-honey producers always have to take this into account; and this is one reason why the comb-honey supers are entirely separate and apart from the brood-nest containing darker combs. In the olden days, when we had wide frames containing sections, they were placed first in the brood-nest, and the cappings of those sections would often be as dark as the comb next to them. The solution of the problem, then, was to produce comb honey, not in the brood-nest, because of its discolorations from brood-combs, but in the super or upper story; and the practice is now all but universal.—Ed.]

#### A Good Place to Begin Advertising

My home is in Grand Rapids, Mich., but I spent the winter here at Hammond, a town of about 4000 inhabitants. I started out one morning to find some honey for table use. I went first to the largest grocery in town. On inquiry they said they were quite sure they had some. The clerk found a fruit-jar of honey—price 30 cts. for a pint-can. He took the top off to show up the goods; but, to his astonishment, he found it granulated. He said, "I don't know what ails it, or what makes it look that way; but if you want a can I think I can find one that is all right."

I told him the granulated honey didn't scare me. The next grocery had some honey in tall bottles holding about 4 oz. There was no comb honey at either place.

The next grocery had no extracted honey, but six one-pound sections piled one above

the other lying down flatwise. He said if I wanted that he would surprise me on the price of it, and make it 10 cts. each. It was dark and light mixed; had lain in the dust I don't know how long, and most of the honey had leaked out.

After all that has been said and done thru the bee-journals I didn't suppose there was a town of this size with practically no honey in sight. E. S. Dart.

Hammond, La., Jan. 17.

#### Penny Wise and Pound Foolish to Let Comb Honey in Groceries Granulate.

In the discussion on increasing honey sales I do not think enough stress is put on the customer's loss thru buying candied honey. This year my honey was all sold by Feb. 1. I usually have it the whole year round. One of our family the last of March saw in a first-class grocery in Boston what seemed to be a fine section, and he purchased it for 25 cts. When he reached home it was candied solid, and moths had worked all around the wood. If I know anything about honey it must have been at least two years old. Such a sale as that queers the customer from buying any more honey for a long while.

A section of mine that I have just found has one side sealed and the other side full but not capped over. This was exposed to the New England winter with all its fluctuations without granulation. Any honey that I put in the stores I watch, and at the first symptom of granulation I exchange. You may say it would be impossible for a large producer to do this; but that does not affect the loss of customers by such sales. It is just the same as selling rotten fruit. A man who does that soon comes to his finish.

Woburn, Mass.

E. C. Newell.

#### \$575 in Premiums at the Michigan State Fair.

At the last meeting of the Michigan Beekeepers' Association a committee consisting of A. G. Woodman, E. D. Townsend, and Ira D. Bartlett, was appointed to draft rules and regulations to be used by the Michigan State Fair. As superintendent of the bee department I am pleased to state that the fair authorities have adopted the recommendation, and I am enclosing a copy for publication.

If the maximum amount of premiums is won by beekeepers it will amount to \$575 as against \$132 offered last year.

The fair authorities have ruled that no honey, wax, or supplies will be allowed to be sold prior to the last day of the fair. This rule has not been lived up to in the past, but will be strictly adhered to this year. There will be a further announcement made later, and all beekeepers in Michigan and adjoining states are urged to exhibit.

Detroit, Mich., May 2. E. B. Tyrrell.

[The complete recommendation and premium list appears in Convention Notices, this issue.—Ed.]

A. I. Root

## OUR HOMES

Editor

Know ye not that your body is the temple of the Holy Ghost which is in you?—I. COR. 6:9.

Whatever a man soweth, that shall he also reap.—GAL. 6:7.

I the Lord thy God am a jealous God, visiting the iniquity of the fathers upon the children unto the third and fourth generation of them that hate me.—EX. 20:5.

Our older readers will remember that when GLEANINGS was first started I commenced a good-natured "war on Christian principles." Almost as soon as I became interested in bee culture somebody told me the only way to handle bees successfully was with smoke; and a little later somebody said that tobacco smoke was ever so much better than any other kind of smoke; and pretty soon a young man said he was going to learn to smoke so that he could always have it handy to use on bees. I protested then and there, and then went right to work to make a better bee-smoker than the world had ever used. I have told the story several times, but I will simply go over it briefly.

Well, I told this young man that if he would promise not to use tobacco I would make him a present of a bee-smoker. I think there were then about half a dozen men and boys present, and they put a joke up on me. Another young man said, "Can I have a smoker too on the same terms?"

I assented. Then finally the whole crowd took it up, and I replied something as follows:

"Yes, friends, each one of you may have a fifty-cent smoker free of charge if you will give up the use of tobacco and give me a promise that I can print in GLEANINGS that, when you use it again in any form, smoking or chewing, you will pay me back my fifty cents."

As a matter of course the names of those who made the pledge were printed in the journal, with an explanation. In due time my pledges came from all over the United States, not only from the men and boys, but from several ministers of the gospel, and from quite a few women. The names of all these people, amounting to quite a little over 1000, are given in our back numbers. Just a few paid back the fifty cents.

Now, altho all this happened about forty years ago, I hardly think there has been a year since that I have not had some stranger grasp my hand and tell me what he owed me for having given up the use of tobacco. When I visited H. A. March, away up in Puget Sound, I saw on the mantelpiece a bright new Simplicity smoker, and he informed me it was the one I gave him, years

before, for breaking off tobacco. He said he had never used the smoker, but kept it up there in plain sight as a daily reminder of what he owed his old friend A. I. Root. He told me the story something as follows:

"Mr. Root, when I got that smoker I was having a nervous breakdown. My hand shook so much that I could hardly write a letter. The doctors did not seem able to help me. When I saw what you said about tobacco I grasped the idea as a drowning man grasps at a straw. Now look here. Can you hold your hand any steadier than that?"

Then he held his hand up before my face. I replied, "To be sure, I cannot, for yours is as steady as a piece of cast iron."

Let us now come down to the present day. A month ago I received the following letter:

*Dear Mr. Root:*—Knowing how you feel on the subject of excessive use of tobacco, we are sending you a copy of the new book by Prof. Mac Levy, which we believe will be very interesting to you. Even if you are busy, we hope you will try to take a half-hour to look thru this volume. It is being endorsed by eminent educators and physicians. There is actually a need for such a volume, considering the tremendous amount of damage that is being done by tobacco at the present time.

New York, May 9.

F. K. THOMPSON,

Secretary Albro Society.

I found the book referred to beside the letter, and gave it a rather hasty going-over; but I get so many books to review besides looking over the great mass of agricultural periodicals, that it is next to impossible to read any book clear thru. After giving the book as much attention as I could find time for I answered the letter as follows:

Many thanks for the tobacco book. Thirty or forty years ago we sent out and gave away several hundred books discouraging the use of tobacco. With the present fight against strong drink, our Antisaloon League had thought best to let up a little on tobacco, altho we are still waging war on cigarettes, giving away the book put out by Ford, Edison, and others.

By the way, I was a little surprised—perhaps I should say pained—to notice the author has little or nothing to say about the help that Christianity gives one to break off any bad habit. I did notice one suggestion—that if a man was going to succeed he was to stop swearing. That's well and good; but in view of the great work that Billy Sunday is doing in the way of reformation from strong drink and tobacco, should there not be a little more recognition of divine help?

I heartily endorse the instruction you give, and, by the way, will not such a course help greatly in overcoming any other bad habit—all sorts of "dope," for instance? May God bless and prosper you in the great undertaking.

By the way, just one thing more occurs to me: The matter came up some time ago as to whether our Ohio Experiment Station should teach our Ohio boys how to grow tobacco. I said: "God forbid;"

but Director Thorne, when the matter was presented to him, said he entirely agreed with me, but added something like this: "While three-fourths of my colleagues in the Experiment Station are users of tobacco, what is one to do?"

Medina, O., May 16.

A. I. ROOT.

Very soon after the above, came the following answer from the author of the book:

*My dear Mr. Root:*—I am personally answering your letter of the 16th, because it is so exceedingly interesting to me.

With reference to the fact that little is stated in my book, "Tobacco Habit Easily Conquered," about the help that Christianity gives in breaking off a bad habit, I will say that it was my natural desire to deal strongly with this subject, but I found it necessary to condense most of my thoughts in that line to the "Dictum of Dictums," which you will find on page 95 of my book. The publishers felt that it would be necessary for me to refrain from going into the religious element to any extent in the first edition of the volume. Their rule was based on the same theory that would probably hold you from speaking much about religion when writing an article upon bee culture. Do you see the point? Nevertheless, I know that you will agree that the trend of my work is invariably toward *that which is good*.

In training persons to apply themselves to the resources of nature to take care of themselves generally, and to observe the spirit of doing good to others, I am teaching Christianity. Do you not think so, Bro. Root?

Of course, you can quote from my book as much as you like. Accept this letter as full permission.

I wish I had an opportunity to talk with you about the real seriousness of the tobacco curse. The whole world is coming under its thralldom. The tobacco industries are piling up immense fortunes by poisoning people with nicotine. The appendix in my book is up-to-date, yet it gives but a small part of the great amount of information that is existent. American missionaries in China, for instance, write that in making laws against opium the Chinese have allowed cigarettes to invade their country. In consequence of this, cigarettes are being used by nearly every man, woman, and child to a far more serious extent than was ever done with opium. The effect upon the Chinese is even worse than was the case with opium. Here in America the sales of cigarettes have increased to an extent that seems incredible. During the first three months of this year the increase over the corresponding three months of 1915 was 1,481,000,000.

In about ten years there is bound to be a terrific reckoning; but in the meantime the tobacco companies are bribing newspapers and legislatures, and everything else, to enable them to promote the sale of tobacco. They have even gone so far as to try to prevent the sale of my little volume by threatening to remove their cigarette advertisements from newspapers that publish the advertisements of my book.

You ask me in your letter of the 16th whether my system for overcoming tobacco addiction could be made to apply to other kinds of narcotic drugs. The rules would need to be modified somewhat for either alcohol or for opium and its derivatives.

In the case of alcohol it is necessary to deal with the so-called "periodical" condition; and, moreover, it is necessary to consider the cases of those persons who are killing themselves with alcohol, but who do not have even the self-respect to wish to be freed from the slavery of it. You see their minds are poisoned. I claim that a large number of such persons can be weaned away from their desire for alcoholic drinks if certain rules are followed. I have been working upon a book for some time past, and will communicate with you about it later on.

I am very much interested in what you write about the Ohio Experiment Station teaching boys how to grow tobacco. I tell you, Bro. Root, the curse has such a strong hold upon the public that only an avalanche of some kind is likely to upset it.

I am working upon an ingeniously devised law which will compel physicians and other officials to report to the State Board of Health all cases of insanity, heart disease, hardening of the arteries, cancer, and other serious disorders wherein tobacco has been the main cause. I do not see how the opposition of the tobacco lobby can succeed when we undertake to get such a bill on the statute books of a state. Our explanation will be that, in view of the many arguments respecting the harmfulness as well as the harmlessness of tobacco, it will be manifestly fair for the state to obtain statistics of its own with a view to such future action as may be deemed advisable. The result of getting such a law upon the statute books would be to load the State Board of Health in each state with a vast amount of important facts proving that tobacco is a dangerous poison. After getting such facts on record in the various states, the next move would be to have stronger laws enacted. It is likely, also, that something could be done with the Federal government.

I wish you would kindly put me on your mailing-list, and I shall be glad to reciprocate with a view of co-operating with you more fully. There is some talk about putting my work in a cheaper form, so that it can be circulated inexpensively.

I shall be delighted to hear from you at your convenience.

New York, May 18.

M. MAC LEVY,  
President Albro Society, Inc.

You may be sure that, on receipt of the above, I was delighted to find the following on page 95:

If you have a religious belief (and I sincerely hope you have) here is the most valuable Dictum of all:

Pray to God daily for whatever aid you may feel in need of, to help you in the simple task of following the rules in this book to a victory over the tobacco addiction.

That God will answer these prayers is certain.

When you are free from the awful thralldom—filled with the exuberance of good health, a clear mind, and the true joys of life—add a few words to your daily prayer that God shall show others the way to longer life and contentment, particularly that he shall stay our boys from ever acquiring the tobacco habit.

The above makes the book all right, and I take great pleasure in making other extracts from different pages as follows:

This book just "had to come." My conscience wouldn't allow me to put off writing it any longer.

Tobacco is used in five different forms—cigarette, snuff, chewing tobacco, pipe, and cigar. I rate their degree of harmfulness to the individual in the order named.

Without discussing the ultra-scientific reasons pro and con bearing on the fact, it is generally accepted that the average cigarette-user consumes more nicotine than any other tobacco addict. One who inhales the smoke is a deeper addict than one who doesn't, but both are "in the trenches."

A TALK TO THE BOY WHO SMOKES.

It was at the beach. A number of boys were lathing. They were having great fun.

Three of the boys, in a spirit of bravado, started

to swim to a point of land. It looked simple and easy. But they had been warned of danger and told not to be so foolish as to take such a risk—for Death had caught others there and was still lurking for new victims.

The boys, in their mistaken desire to be manly, and heedless of the danger, kept on. At a place where the sea appeared no rougher than elsewhere, the lads suddenly felt that they were losing control of their feet.

For the first time in their lives they encountered that danger known as an undertow. Experienced sea bathers know of it and they avoid the places where it is liable to exist. These lads, however, did not understand what was wrong. At first they fought to control themselves and to swim to the shore—only a few rods.

They were unable to hold against the terrible and mysterious foe. The undertow caught them and sucked them under the surface of the water, as if a horrible octopus had drawn them into its ugly maw.

Excited observers saw that something was amiss. Two strong swimmers jumped into a boat, pulled sturdily and attempted to save the lives of those boys. One of them was dragged from the water nearly drowned. He recovered afterward. *The other two lads were drowned.*

Think of the agony of the parents and friends! Two boys who were finding life full of good things and who were growing into fine manhood, became victims of the cruel enemy that was concealed beneath the innocent-looking surface of the sea. Two lives were thrown away. You will agree that the affair was horrible. *A tragedy without excuse.*

This brings me to the point where I can tell you about another danger which exists all around you. I mean the cigarette habit.

You learned it for the fun of the thing, probably in the spirit of "don't take a dare." You thought it would be manly to know how to smoke. You saw other boys doing it.

In the appendix to the book there is a large amount of matter in regard to cigarettes, and the effect of tobacco on the coming generations. I select only one of them. As you will notice, it bears on the point made in our last text.

As a matter of fact, the number of conceptions in smokers' families exceeded the number in the other class, but the loss by still births and miscarriages was twice as great—which fact is in line with Dr. Lichty's inductions from the United States census figures.

Additional tables of figures give the information that wives of tobacco users suffered, in excessive numbers, abscesses as well as abortions.

From the above you will notice that the one who deliberately decides to use tobacco not only impairs his own usefulness here in this world, but he bequeaths to his unborn children a handicap that may follow them more or less all their life.

I found a printed slip inside of the book which reads as follows:

#### TOBACCO HABIT.

The mother or wife who has a loved one addicted to smoking, chewing, or snuff-taking, will be delighted to know that a book has been published which should convince any man that his health and efficiency will be greatly improved, and his life lengthened, if he gives up the use of tobacco. This book is entitled "Tobacco Habit Easily Conquered." It tells how

to overcome the addiction, without drugs, quickly and pleasantly. Those interested should write to Albro Society, 181 Lexington Ave., New York. This volume is bound to bring happiness to many homes. It is a handsome book of 155 pages; price \$1.25.

In closing, let me mention just two or three illustrations from what I have seen of tobacco during the past forty years. My own father smoked until his health broke down so he was about to give up his business. Somebody told him to try giving up tobacco, and I am sorry to say the advice did not come from the family physician. Now, my father was quite stubborn and contrary; and when somebody suggested that he could not get along without his pipe even if he should try to, he showed his "Root spunk." But he did give it up, and in just a few weeks he began to flesh up and look happy, and the people joked him about growing young instead of growing old. He lived about twenty-five years after that breakdown. Once more:

Our family doctor, E. G. Hard, of Medina, gradually failed in health, and was finally confined to his bed. A council of able doctors, one or more from the great city of Cleveland, came to his bedside, but could not tell what ailed him. He was told he had but a few days to live. Not long afterward I met him on the street. Of course I started to see him out looking bright and fairly well. Before I could express my astonishment the doctor said something as follows:

"Mr. Root, I owe you an apology."

I was more perplexed than ever; then he added:

"You wonder to see me up and around, and of course you want to know what miracle brought me back from death's door. Well, the upshot of it all is I took the advice you have been giving me for years, and stopped one of my bad habits."

"Why, doctor," said I, "what 'bad habit' do you mean?"

"Yes, Mr. Root, the confession I have to make to you is that I smoked pretty much all the time while in bed. It was the only thing that gave me any relief from my pain. When the doctors failed to find out what the trouble was, it occurred to me that I might try giving up tobacco. I did so, and here I am."

"Why, doctor, do you mean to tell me it was the use of tobacco that dragged you down by slow degrees to death's door, as you call it?"

"Yes, Mr. Root, it was tobacco and nothing else."

The good doctor lived for several years after that.

Now, in order to be strictly truthful

something else must be added to the above. You would suppose, of course, after the above confession, and with renewed health and strength, the doctor would never touch tobacco again. The above is well known, or I would not publish it; but some time afterward a woman said that Dr. Hard was again smoking. I told her she must be mistaken—it could not be. When I overhauled the doctor he said he smoked only a little—only once in a while.

I mention this matter in order to illustrate how loath Satan is to lose his clutches when he once gets a man in his grasp. One more instance:

A prominent member of our church had brief periods of blindness. The doctors could not help him; but when he cut out tobacco all of those bad symptoms disappeared. He told about it in prayer-meeting, and gave it as a warning to the younger ones. Well, somebody told me that this man was again using tobacco, and he gave as an explanation that he smoked a little when he called to see his old father. He said it did his father much good to sit down and have a friendly smoke with him. Once more:

A certain druggist with whom I have been well acquainted pretty much all of my life was taken with nervous prostration. He was not able to do business nor anything else. In fact, it made his life a burden. His father-in-law, with whom I was also well acquainted, was a physician. Now consider how difficult it is for a physician to advise a patient to give up the use of tobacco when he himself is using it. But notwithstanding this, this doctor advised his son-in-law to give up cigars, or at least reduce the number, for he was then smoking at least 25 a day. I think he was in the habit of smoking more than he realized. With a bright and smiling face he came to me and told me about it. He knew how I had all my life been opposed to the use of tobacco. As soon as he stopped the use of cigars, all the trouble vanished; and altho many years have passed since then he is now strong and well.

You will notice in one of the extracts I have made, something about the cigarette habit. I do not think any dealer in Medina sells cigarettes; but the boys of our juvenile schools are getting them in some way. Perhaps that notice about getting the names of boys, page 442, will help to explain. Well, reader, how do you suppose these boys found a place out of sight to smoke cigarettes? They got a board loose on the end of the shed nearest the schoolhouse, and went into the horse-shed belonging to the Congregational church to do their smoking.

We found a lot of cigarette papers scattered all over in one corner, out of sight, and our good pastor surprised four schoolboys when they were smoking. Is the Great American Tobacco Co. really bigger than the United States, thus to defy and trample under foot not only our state laws but the laws of the nation? I think the above will give you some vivid illustrations of that beautiful Bible text, "Whatsoever a man soweth, that shall he also reap."

While the matter is up before us let us consider the following, which I clip from the *New York Times* for May 28, 1916:

SAYS GEN. F. D. GRANT WAS CANCER VICTIM; DR. ABBE BLAMES TOBACCO HABIT, INHERITED FROM FATHER, FOR FATAL THROAT AFFECTION; BOTH CONSTANT SMOKERS; SURGEON TELLS OF EXCESSIVE INDULGENCE AND SAYS HABIT IS TRANSMITTED TO OFFSPRING.

The real cause of the death of General Frederick Dent Grant at the Hotel Buckingham on April 11, 1912, was made public yesterday for the first time. He died of cancer of the throat superinduced by the excessive use of tobacco. His father, General Ulysses S. Grant, died from the same cause, and the malignant growth was attributed to the same agency.

The facts regarding the death of the younger Grant are contained in the following paragraph from an article by Dr. Robert Abbé, senior surgeon to St. Luke's hospital (who was with him when he died), on "The Legacy of the Intemperate Use of Tobacco," which appeared in yesterday's issue of *The Medical Record*:

"I could not help reminding him (a patient) that one of our great national heroes smoked incessantly, as every one knew, and suffered and died from the consequence of disease of his throat. His distinguished son, also heroic figure in our army, adopted the same habit, smoked equally incessantly, and suffered and died of the same terrible consequence. This is a heavy price to pay for the intemperate indulgence of such a throat-irritating and unnatural habit."

I close this paper on the tobacco habit with the following:

PROMOTION ONLY FOR THOSE WHO NEITHER DRINK NOR SMOKE.

We clip the following from the *Sunday-school Times*:

SCHWAB'S REPLY.

..Let each man prove his own work. General Wheeler was talking with Mr. Schwab, head of the great steel combine, and we asked him, "Is it true that in these big corporations, other things being equal, the man is promoted who neither drinks nor smokes?" Mr. Schwab answered that that was the invariable rule in dealing with two or three hundred thousand employees under him. "When two men," he said, "Men equal in skill, preference is given to the abstainer and non-smoker.—From *The Christian Herald*. Sent by J. A. Clark, Greetland, Halifax, England.

The above is a surprise to me in two ways. First, that we have in our land an institution that employs the enormous number of between 200,000 and 300,000 men. Second, that our great factories, railroad companies, and other institutions have begun to comprehend not only that a drinking

man should not be promoted, but that the man who smokes is to be discredited as well. Now, I should like to know whether this means the man who smokes during working hours or the man who smokes only while on duty. I do not believe that there are any

at present among our two or three hundred employees who smoke during working hours; but it pains me to see how many *young* men as well as old knock the ashes out of their pipes when they come up to the office door to mark their time.

---

## HIGH-PRESSURE GARDENING

### HAND CULTIVATORS—SOMETHING NEW.

When I spoke about hand cultivators on page 505, June 15, I had not noticed the advertisement in our issue for May 1, page 13 of the advertising department, of the Barker machine. I humbly beg pardon, not only of the manufacturers of the machine but of our readers as well, for failing to scan *our own* advertising pages a little more closely. I have now been using one of the little Barker machines for three or four days, and it almost seems to me that this is going to bring about a revolution in gardening without the use of horse power. Not only here in the North, but clear down in Florida there are thousands of people who hesitate about going to the expense of a horse for market gardening.

A year ago I spoke of the need of a gas or electric motor to supply power, especially for the use of young boys or old men like myself. The advertisement I have referred to makes this statement: "A boy with a Barker beats ten men with hoes." This sounds pretty strong; but where your garden is free from stones, clods, and trash, a smart boy might come pretty near the above. The picture of the machine explains it. Those ten steel blades chop up the weeds in advance of the steel scuffle-hoe that follows. Where the ground is just right, say just after a rain, even here in our Medina stubborn clay soil you can run the machine as fast as you can walk; and the ground looks, after the machine has gone over it, almost as if it had been passed thru a sieve.

Another very important matter, you can run this little machine closer to all sorts of stuff, say that which is just coming up, or larger, than any other tool I ever got hold of. Most cultivators will throw chunks of dirt on the plants, perhaps knock them over, and, if a rain comes shortly after, they are very much injured. This tool can be tipped so as to run close to the plants without doing them any injury or disturbing the roots, and at the same time cut off or chop up every weed. It also knocks the dirt from the roots of the weed so there is but little tendency for it to take root and start again.

We are often told that the weeds should be killed before they come to daylight—that is, before they have time to start and get above ground. And this is very good instruction. But what are you going to do when it rains as it has been doing here in Medina so far this year (as well as last), so it is only now and then you can get on the ground with either plow or cultivator? After the weeds once get up, say two or three inches high, the only remedy I have ever known is a sharp hoe. But this little machine beats a hoe with a vengeance. But you will have trouble if your ground is stony, especially where there are stones about the size of a hen's egg. They will get between the two blades of the scuffle-hoe, and then the machine will stop suddenly. Cornstalk stubble that was not plowed under, or the roots of docks, etc., also make trouble.

Now, I think I have made an improvement in the use of the machine already—at least the manufacturers of the machine have not mentioned it so far as I know. I was so anxious to try it here in our garden that I started out before the garden was sufficiently dry. The consequence was, the steel blades and the iron wheels that hold them were soon covered with clay that dried on; and our clay is of such a tenacious nature that when it dries on anything one will almost need a hammer to make it let go. After cleaning the blades and other parts a few times so they would do good work I got the oil-can and greased the thing all over. Then I rubbed off the oil and mud until the metals were clean, and gave it another coat of oil. Since then the machine has kept clear from the accumulation of clay very much better, and I think the blades will ultimately get scoured bright and smooth.

There are three sizes of the machine—6, 8½, and 11 inches. Mine is the 8½ size. Where your garden stuff is planted wide enough apart to permit using a horse, you want to make about three trips in each row. First, go clear up to the plants on the right side and then on the left, and then down through the middle; but if you can go as fast as you can walk comfortably, it does

net take very long to put your whole ground in beautiful condition. If your corn and other stuff is planted in hills, instead of drills, there is little that needs to be done with a hoe. Perhaps I might add that I paid \$6.20 for my machine, the same as other people pay, so that you may not imagine that I get anything free for having given the machine this write-up. I think it is going to prove a boon indeed, especially to old people like myself who work in the garden.

"IN THE SWEAT OF THY FACE SHALT THOU  
EAT BREAD."

Last, but by no means least, let me say that for some time back I felt that my strength was gradually failing—not particularly when I was at work in the garden, but when I undertook to read the letters piled up on my desk, and especially to read as I ought to read the books and papers and clippings that the many kind friends are sending to me. I tried to work in the garden, but some way my strength did not seem to hold out. In fact, running the cultivator I have previously mentioned, especially when the ground was rather wet, seemed to be almost too much hard work. After I got this new machine I have been describing I was so much pleased with its workings that I did not stop, even when I *was* tired. Rain was coming again, and I wanted to do all possible before it was again wet. Pretty soon I was in a profuse perspiration. In fact, the sweat was dripping from the end of my nose. I hung my cap on a post and went up and down the rows bareheaded; and pretty soon I struck what the boys call the "second wind." Our older readers will remember my mention of it in speaking of climbing Mount Wilson, in California. That text in the Bible, "He paweth in the valley and rejoiceth in his strength," occurred to me. Instead of becoming tired out I began to draw in great breaths of the beautiful fresh air, and did not feel tired a bit. I nearly finished the whole garden before dinnertime. I ate a hearty dinner, and then took a good long nap, and then was ready for more "gardening." The next day the muscles of my arms were sore; but I took another "dose" of the new cultivator until I was once more dripping with sweat; and now my aches and pains are all gone, and I feel as if I were getting a new lease of life. In fact, I had been praying over the matter of my health, and my prayer was answered.

By the way, I think I should mention right here that a few weeks ago I was thoroughly examined by the medical examiner belonging to a life-insurance company. You see it is quite "interesting" for the life-

insurance companies to have an old man like myself live as long as possible, and, accordingly, he makes examinations without any fees on my part. He gave me some disinterested advice. Well, after I had had a good long talk with this up-to-date doctor he said something as follows:

"Mr. Root, about all the fault I can find with you is that you are 76 years old."

After the doctor and I had had this good long "visit" I happened to mention that I was conducting a health department in our journal; and later on I submitted to him the article on page 1001, Dec. 1, 1915, and I asked him to give his opinion in regard to the soundness of my teaching. He replied later that the best evidence of the soundness of my teachings is the fact that I have lived to be 76 and still keep my strength and the use of my faculties to such an unusual degree.

Well, now, friends, here is the moral to my long story. I was suffering because I had not been getting *sufficient* exercise so as to sweat profusely thru the pores of my body. Of course the enthusiasm awakened by the use of that new cultivator had something to do with it. Several times I urged my good friend T. B. Terry to take even *more* exercise every day right out in the open air, winter and summer; and in accordance with the latter I urged him to take a trip down to Florida, where he could be outdoors in his shirtsleeves every day in the year. The last time I talked with him he claimed that the air in his room (with his ventilating and "humidifying" arrangements) during the wintertime was as pure as it was outdoors. But I did not quite agree with him.

As the insurance doctor bade me goodby he said something like this:

"Mr. Root, if a kind Providence should permit me to live to be 76 years old, and to retain my bodily strength and the use of my faculties as you seem to have, I shall be devoutly thankful."

Just one thing more:

The doctor mentioned asked me about my meals. I told him that for the last five years or more my supper was grapefruit and apples, with a little cheese. He replied very emphatically, "That is just the *very best thing for you*; and if a lot of other old men would stop eating three square meals a day, especially after they give up hard work, a great lot of them would live longer, and enjoy life far better."

IRISH POTATOES 70 CENTS A PECK.

Here we are again, friends, this last week in June, with potatoes at 70 cents a peck, or \$2.80 a bushel. I have for several sum-

mers back urged that Irish potatoes could be grown by starting them under glass here in the North at a big profit; and several times the reply has been, "Oh! this is an exceptional season." But for several years there has been a period between old potatoes and new ones when the retail price on the market was from 60 to 75 cents a peck. I have not grown them under glass here in Ohio, because we do not reach here until about May 1.

I spoke last season about the Early Six Weeks potato, stating that it was free from scab, and more free from blight than any of our other varieties. We not only had beautiful Six Weeks potatoes all thru the summer and fall, but I shipped a barrel down to Florida, and we had them to use pretty much all winter. For some reason they did not sprout so I could plant them until so late that only a few were fit to dig when we left there the middle of April. At the end of a letter to my "long-time friend" A. T. Cook, of Hyde Park, N. Y., I wrote as follows:

I am greatly surprised to know that your season is so much ahead of ours here in Ohio. I have not seen a potato here in our part of the state above ground as yet. I planted some Early Six Weeks nearly two weeks ago, but not a potato up yet.

Medina, O., May 25.

A. I. ROOT.

Below is his reply:

MY EARLY SIX WEEKS POTATOES.

I commenced using them on my table June 8. They are super-delicious. I dug some today, June 17. They are nice and big. Two weighed 12 ounces.

This has been one of the latest, wettest, and most backward seasons I have ever seen, or the potatoes would have been ready to use several weeks earlier. They were planted in the open ground about April 8. I think there never was another potato of such high table quality as the true Early Six Weeks, and they are the best keepers I ever grew.

Hyde Park, N. Y., June 17.

A. T. COOK.

I quite agree with what he says about the Six Weeks being not only a high quality but a splendid keeper. Hyde Park, N. Y., is further east and north than Medina; but by taking pains this Six Weeks potato could easily be grown in Ohio during an average season so as to be put on the market in June. As proof of this, Mrs. Root says a woman in our neighborhood told her about the middle of June that she had early potatoes in bloom planted in the open ground outdoors. Very much can be accomplished in getting early potatoes by having a sandy or gravelly soil sloping to the south, fully exposed to the sun, but sheltered from the west and northwest chilling winds.

A GLIMPSE OF OUR FLORIDA GARDEN.

I think I have already explained that I wrote to our Florida Experiment Station,

asking what crop they would advise during the summer time after taking off potatoes in the spring. Here in the North, we should use clover; but as it does not seem to stand the heat and heavy rains of Florida summers, Prof. Rolfs advised corn and velvet beans, and I took pains to inoculate the beans with the nitrogen bacteria. Below is a brief report of how my experiment is turning out.

Your garden looks fine. I have not seen anything else in Florida to equal it, and nothing in the North to excel it. The ears of corn are beyond my reach, and the velvet beans are immense.

Bradentown, Fla., June 2. C. L. HARRISON.

FLORIDA REAL-ESTATE SPECULATORS — TWO SIDES TO THE MATTER.

Both winter and summer I am having a lot of inquiries in regard to investing in real estate in Florida; and my invariable answer is that no one should think of investing a copper in Florida lands without making a trip and looking things over and getting facts from old residents in the vicinity. Notwithstanding, thousands upon thousands of dollars are being invested in lands which the purchaser has never seen, and many times in lands they never will see; and I am glad to note that most real-estate agents nowadays request people to come and look over the premises before buying. I also have frequent inquiries in regard to certain real-estate companies, especially if they are located in Manatee Co., where our Florida home is. Well, I almost always turn these letters over to my neighbor, E. B. Rood, who deals in real estate aside from his business of truck gardening. One question comes up often, like this:

"Mr. Root, can you find out if these men are responsible? and will they do all they agree to do?"

Now, it gladdens my heart to have Mr. Rood reply frequently something as follows:

"Yes, Mr. Root, I know these parties, or at least I know something about them; and my opinion is that they will do what they agree to do."

With the above preface let me report to you an incident. Some time last winter, just after Mrs. Root and I had finished our dinner, a man arrived in an automobile, taking out with him a couple of heavy valises. He said he had read our journal for years, had purchased supplies of the A. I. Root Co., and had long felt that it would be a great pleasure to meet A. I. Root face to face, etc. Before taking him over the ground, as I usually do, I said I supposed of course he had been to dinner. When he

admitted that he had not, I asked Mrs. Root to prepare something hurriedly while I showed him the garden and the chickens. While he was eating, among other things I asked him how much they charged for bringing him in an auto down to our place. He replied, "Not anything. I told them I wanted to purchase a little piece of land in your vicinity, and they said there would be no charge."

When I expressed some surprise he stopped his dinner to reach his hand in his side pocket, and said:

"Why, look here, Mr. Root; I got a free pass from Tampa. Here are passes over this new east and west railroad."

When I expressed further surprise, and asked him why they gave him this free transportation, he said he was talking of buying some land of a certain company out on the new road. Just here I interposed something as follows:

"Why, my good friend, if I understand you, you have got these passes by representing that you wish or intend to purchase of a company out on this new road, and yet you tell me the garage people sent you down here free, with the understanding that you wanted to buy in this neighborhood."

He stopped eating for a minute, evidently seeing he was caught; but very soon he recovered and replied:

"Mr. Root, this is a free country; and a man can purchase wherever he pleases."

The above seemed to be his version of "personal liberty"—just about the kind of personal liberty the liquor people so constantly harp on.

While the man was finishing his dinner it suddenly occurred to me that he would be going over to neighbor Rood's and getting Mr. Rood to show him the real estate around our neighborhood with *his* automobile. I asked to be excused for a moment to look after some business. The business was to slip over to Mr. Rood's and inform him in regard to the "complexion" of our visitor. Mr. Rood said he had had some experience with that sort of chap, and that I might be sure he would not waste time on him.

After this man had finished I told him to leave his valises with us while he went over to talk with Mr. Rood about the property in our vicinity, and then I went on with my work. Pretty soon Mrs. Root came and told me our new visitor had started on foot back to town with his two heavy valises, and she wanted me to hurry up and overtake him with the auto because of his heavy load. You may think, friends, I was a little unchristianlike when I said, "No, let him travel." She further informed me that he

came in somewhat excited and demanded his valises. When she told him I had put them out in the auto-house he rushed out and put off on foot as described.

"Did he not thank you for the pains you took to get him up his dinner?"

"Not a word of thanks; and he seemed put out because you had set his stuff out in the auto-house."

I do not know but he expected his old traps would be deposited in our best room, and that he would be invited to stay a week, making our home his headquarters. If so, he made a mistake.

I have mentioned the above because I have for some time felt sure the real-estate men—at least many of them—have been unduly censured. I know of two or three cases where they have paid the money back because a customer became discouraged or got the blues, when they had been a good deal out of pocket besides the loss of time. Of course the above is no excuse for unreliable make-believe real-estate agencies, etc.

---

#### "GOD'S KINGDOM COMING."

We clip the following from the *Cleveland Plain Dealer*:

DULUTH VOTES DRY; CITY GIVES PROHIBITION 400 MAJORITY; 15,000 BALLOTTED.

DULUTH, Minn., June 20.—Complete returns on yesterday's wet and dry vote in Duluth show about 400 majority for the dries, out of a total vote of approximately 15,000.

Under the terms of the initiative ordinance, thus adopted, no more saloon licenses will be granted in this city to run after July 1, 1917. Those now existing will be canceled as they expire.

Duluth is said to be the largest city to vote dry by local option.

---

#### LEPROSY A MENACE, EVEN IN THE UNITED STATES.

The following is clipped from the *Daily Commercial* of Three Rivers, Mich.:

Recent investigations show that in South America the conditions are becoming alarming. Absolutely no precaution is taken. Brazil alone has 750,000 cases.

In one village of 1500, one-third of the population were lepers. In this particular village every male leper able to work was employed at making cigars, most of which were shipped to the United States.

It is estimated that there are between five hundred and one thousand cases in the United States. As only eighteen states have laws requiring cases of leprosy to be reported it is hard to get statistics. At present there are two state asylums, one in Massachusetts with ten inmates, and one in Louisiana with one hundred.

Please note what is said in the above about cigars from South America. How about "cutting out" *all cigars*? What about the class of people who usually make cigars?-

# POULTRY DEPARTMENT

## A BACKYARDER'S DREAM.

Several years ago the farmer who had been shipping us eggs wrote to say his hens were on a strike, and he could not send us any more eggs until spring. This was to us an annoying state of affairs, for the bacon-and-eggs-for-breakfast habit was firmly fixed in our home. We held a council of war—wife and I—and resolved to produce our own eggs, tho at that time we knew about as much about hens as the average beekeeper does of integral calculus or the Sanskrit language.

I knew how to incubate bacteria, and could care for chicken pox in the children, so why could I not learn the ins and outs of hens? Then, too, I am always spoiling to be making something with tools and working with my hands at some outdoor task. This is my gymnasium work, and it pays me so well in health benefit that I could well afford to lose money in my outdoor hobbies. Of course, as wife says, my hands do not always look as nice and feel as soft as a doctor's should, perhaps, but I am not of the soft-handed class; and unless I work physically I am not happy or well.

The henhouse was built—a lean-to at the side of my garage, 9 by 18 feet, with a large lot behind for a range. A part of my garden lot has trees; and about these a space of 30 by 70 feet was fenced for the young stock.

My original flock was 12 hens and two cocks bought from a neighbor at one dollar each; a choice strain of White Wyandottes, the hens from a well-known breeder of the fowl who wins many prizes in the shows, and the cocks from a distant breeder famous in poultry circles as a prize-taker with this breed of hens. I considered it a good bargain, and offered to me only because my neighbor had sold his place and had to dispose of his birds because of no place to keep them.

I bought two incubators, and made some fireless brooders. We began hatching early in order to learn the work and be prepared for failures. I sent also for several settings of eggs from well-known concerns offering this breed, hoping to mix in the best blood I could find in making my stock as strong and nearly right as possible.

I will not detail the various experiments and costly mistakes we made the first year. I will not tell how we tried Runner ducks and White Leghorns; how the rats killed some of our flocks, or about the several troubles we had with white diarrhea, sore eyes, etc. It would make too long a story.

The book-keeping department of the enterprise was carefully attended to, and the end of the first year showed that the hens had paid for their own feed, paid for the plant, and we went into winter quarters with a flock of 120 fine birds, carefully selected from some 400 that were hatched.

The hens and pullets were again culled down to about 60 by selling all not laying by the first of January. This has been my rule for the several years I have conducted the hen-plant on our back yard. I have culled, first, for shape and appearance, health, vigor, etc.; and, second, for winter-laying tendency.

The second year, I discarded the smaller indoor fireless brooders for a colony brooder built in the large sunny room of our basement where the furnace keeps the temperature at 70, and the heater run by natural gas does the rest of the heating. This eliminates the many units. I have, since this plan was used, one unit, except at breeding time, for the grown stock and one unit for the young chicks. Such a plan greatly reduces the time required for the work.

The second year the books showed a profit of \$157.50, and we went into winter with a few more than 100 birds.

As soon as people knew of what fine success I was having with this strain of White Wyandottes many wanted settings of eggs. We also sold a good many day-old chicks locally, tho making no effort to sell by mail. We never tried for show prizes, merely striving to build up a strain of winter layers that any backyarder might establish a paying plant right at home and have plenty of eggs when they are hard to find of good quality, and in price from 40 to 60 cents a dozen.

The third year the books showed the net to be over \$350, besides we had built another henhouse 16 by 18 feet at the rear of the garage. The buildings are made of tile, and are warm, well ventilated, and dry. I feed mostly commercial "scratch" and dry mash of bran, corn meal, and meat scrap, with plenty of green stuff, using in winter sprouted oats, beets, small potatoes, and cull apples. I am near large greenhouses, and easily get lettuce, cabbage, and celery scrap for the labor of gathering it.

The new house will enable us to run a 200-hen plant; and with a little advertising effort, and still further care in breeding this strain for winter laying, I feel sure that from this on we may easily make \$500 a year from the hobby—such as we call it—that was started somewhat in spite because a farmer failed us in supplying eggs. Hens will pay in winter, and I have proved this. I admit it may take years to breed the flock to a winter-laying status, and I confess one must give them intelligent care as to feed, warmth, exercise, etc.

Any back yard with a flock of fifty hens, attended as I have cared for mine, can from the eggs and meat buy all the feed, and have a profit that will go a long way toward reducing the cost of living. I can show any one willing to work a little with the hands, and use a little of that so-called gumption, how it may be done.

They may talk about the American eagle, or the birds of paradise, the beautiful pheasant, the strutting turkey—of the peacock with his wonderful tail; but the real bird—the one that gets my admiration and respect—is the faithful winter-laying White Wyandotte hen. Her song is sweeter to me than any fabled nightingale, and her fruit—she is known by her fruit.

So it was not a dream, after all.

Youngstown, O.

DR. C. E. BLANCHARD.

There are two expressions in the above letter that hit my case exactly. 1. "I am always spoiling to be making something with tools, and working with my hands at some outdoor task." Again, "Unless I work physically I am not happy or well." In regard to the soft hands, and always looking and feeling nice, it is not many days since Mrs. Root gave me a regular overhauling because of my dirty hands. She said I would have to get a good stiff brush and some soap, and get the black dirt out from around my finger-nails, etc. I think I did something of the kind; but before the day was over I got hold of a choice plant that had to be set out carefully; and our best soil, even in Florida (that is, where I have doctored it year after year so as to get it in shape to make things grow) gets in and around the finger-nails when you get right down into the dirt, and so it takes a great deal of scrubbing to get it out. A

good deal has been said about chickens and gardens in the saving of expense; but where anybody goes at it—man, woman, or child—in the way the good doctor tells about in the above, it will surely pay in the way of better health, better eggs, and a profit besides.

THEY LAID IN SPIKE OF THE SWEET POTATOES.

In the Poultry Department, March 1, you mention sweet potatoes as being the cause of the hens suspending their laying. I have fed my hens sweet potatoes, boiled and mixed with bran, for their winter breakfast for some years, and had eggs to sell all winter. Of course I never fed them all they would eat. Some folks will tell you that to feed your hens peas will stop their laying; yet my daughter fed hers nothing but peas this past winter, and had just as many eggs. Of course they had free range.

MRS. AUGUSTA TREMPER.

Linden, Texas.

THE RECENT MILK WAR IN CHICAGO, AND SOME OTHER THINGS.

I clip the following from the *Rural New-Yorker*:

The question confronts us "What are we going to do to avoid such conflicts in the future?" That we are held in better repute than heretofore is sure; but whether we can get a living price for our milk is the question. All over this country, milk is the one food that is sold below its real value as food. Compare it with any food you please, and it is, considering its food value, sold cheaper. We have left the marketing of our milk to others, only to find that its food value is not known, and that not a dollar has been spent by these distributors to inform the people of the vital force contained in this, almost the only uncooked food we have today. That the food elements of milk have vital qualities in the maintenance of life and growth is beyond question, and yet the city of Chicago consumes \$20 per capita of liquors to \$5.75 of milk. Our milk merchants, who should have been telling this story, have failed, and we find our market less than one-third what it should be. They have had but one thought, and that has been to fatten on profit. They have had invested less than \$25,000,000 in their plants, and have employed but 4000 men to do their work, while we have had more than \$250,000,000 invested in production, and employed 40,000 to make the milk and feed. They have sold the milk in Chicago at eight cents per quart and five cents per pint, and paid us on an average for the year three cents per quart. Can we longer stand such service, or must we undertake the marketing of our product?

There are three points made in the above than I wish to consider. "Almost the only uncooked food we have today." I did not think of it till just now; but milk certainly is, as a rule, uncooked food, and I suppose our readers all know there has been first and last a good deal of talk and perhaps a good deal of truth in the importance of making one's diet, or at least to a great extent, on uncooked food. At least one good-sized book, and perhaps several books, have been devoted to the matter. Well, honey is also, as a rule, uncooked food, and both milk and honey have the sanction of

Holy Writ. "Butter and honey shall he eat, that he may know to refuse the evil, and choose the good."

The second point made in the above is that beer and other liquors cost on an average \$20 per capita in Chicago, while milk costs only \$5.75. May God help Chicago if this is indeed true; and I think we may rejoice to know that just now milk is rapidly taking the place of beer. Great factories and railroad companies are taking measures to have their employees drink milk instead of beer.

Last, but not least, we are told that in Chicago, where the consumer pays from 8 to 10 cents per quart, the producers, the farming people, get now, or have been getting, only *three cents* per quart. If this recent war should end in giving the hard-working farmer (who works, not only eight hours a day, but close on to *twice* that much) more than he is now getting, we shall all rejoice. The men, women, and children who devote their lives to the production of pure, clean, wholesome food for mankind should have good pay; and anything that can be done to shorten the distance and the difference in prices between producer and consumer is real *missionary* work. We expect that staple articles of food are sold, as a rule, on a very small margin of profit. Of course, it costs something to handle milk, keep it pure and clean and unadulterated, and handle it quickly. But I am sure there is no need of a profit on it of 200 or 300 per cent.

In our Florida home we pay 10 cents a quart, and the money goes directly to the producer. He gets the whole of the 10 cents. He not only gives us the nicest Jersey milk I ever tasted, but he gives such good measure we would willingly pay him more than 10 cents if he would take it. Perhaps I might mention the fact that this good neighbor is E. B. Rood, the strawberry man. He keeps a fine grade of Jerseys which furnish manure for his strawberry-beds, and enables him to furnish his customers both milk and strawberries. He used to furnish *honey* also; but he has now turned the honey business over to another good neighbor, Mr. A. E. Ault.

THOSE PICTURES ON PAGES 485, 486, 487.

Perhaps some of the friends who read GLEANINGS may like to know "who is who" in the pictures mentioned above. Well, it is the family belonging to "Blue Eyes." Mr. Arthur L. Boyden, her husband, is coming from the express office, and their three children, Ralph, Helen, and Wynne, are accompanying him. On page 487 we get a glimpse also of Allen I. Root, Ernest's youngest—the "A. I. R." of the future, kind Providence permitting. I might remark that Wynne Boyden, sixteen years old, and a little taller than his father, is now teaching his grandpa how to run his new automobile.—A. I. R.

Nuclei, per frame, \$1.25; two-frame, \$2.25; eight-frame hive, \$6.50; ten-frame hive, \$7.00. Write for price on large orders. Everything guaranteed to reach you in good order. No disease here. Cash must accompany your order. Please mention GLEANINGS. I. N. BANKSTON, box 315, Buffalo, Tex.

**HELP WANTED**

WANTED.—Experienced young man in apiary work; good character, and active. Address P. O. Box 40, Altamont, N. Y. 22260

MAN WANTED.—At once to work with bees. State age, experience, and wages. Three or four months' work. Address THE ROCKY MOUNTAIN BEE CO., Forsyth, Mont.

**SITUATIONS WANTED**

WANTED.—Position in apiary; 15 years' experience; capable of managing large apiary; \$50 per month and board.

CLINTON VAN PELT, Charlestown, Ind.

**Convention Notices**

The annual field day meeting of the Idaho-Oregon Honey-producers' Association will be held at Parma, Idaho, July 12, on the premises of Gottfried Lohrli. We are arranging with Governor Alexander to attend this meeting, also to have all members who are foul-brood inspectors in attendance so we may give him some real information on the subject.

P. S. FARREL, Secretary.

New Plymouth, Ida., June 20.

**NOTICE OF FIELD MEETING.**

The Chicago Northwestern Beekeepers' Association will hold a field meeting at the apiary of W. W. Faulkner, 3000 North Cicero Ave., Chicago, July 15. Everybody will bring lunch-baskets and have dinner together, picnic style. There will be demonstrations of treating foul brood as well as various other demonstrations showing up-to-date methods of handling bees.  
JOHN C. BULL, Sec.

Valparaiso, Ind.

**A SUMMER MEETING OF BEEKEEPERS.**

In accordance with the action of the beekeepers at the summer meeting held at Hamilton, Ill., last year, the committee appointed has arranged for another meeting to be held at Dubuque, Iowa, Aug. 1 and 2. It is to be hoped that a permanent organization of the beekeepers of the upper Mississippi Valley may be effected, and that these valuable meetings may be continued. The Commercial Club of Dubuque has promised royal entertainment for all who attend. The meetings will be held in the beautiful Union Park, one of the beauty spots along the Mississippi. If the weather is inclement the meetings will be held in the park pavilion.

These meetings are of vital importance to beekeepers, as they help to attract public attention to the use of honey in addition to the value of information gained by the personal contact of successful honey-producers. Dubuque is a city of several thousand population, and a honey market that has hardly been touched. If more city meetings were held so as to bring the use of honey before the general public at home it would not be long before the demand for honey would be doubled.

Every beekeeper who can possibly make arrangements to attend this meeting will gain much of value besides having a royal good time. Bring your wives and families, and help make this one of the best meetings ever held.

N. E. FRANCE,  
A. L. KILDOW,  
C. E. BARTHOLOMEW,  
Committee.

**\$575 IN PREMIUMS AT THE MICHIGAN STATE FAIR.**

Entries in this department close.....  
 All exhibits in this department must be in place by.....  
 Each exhibitor at the time of filing entries will be required to take out an exhibitor's ticket, costing.....

Exhibits in this department must be the product of the bees owned or controlled by the exhibitor.

All bees must be shown in observatory hives so as to be seen on at least two sides, and should not be so crowded with bees but that the queen can be easily found. They must be plainly labeled, and not allowed to fly during exhibition hours.

Exhibits of all kinds of implements, new inventions, and beekeepers' supplies are invited, for which space will be provided. No charge for space will be made for exhibits in this department.

In judging this exhibit the following score of points will be used:

|                              |                       |

Leather-colored Italian bees and queen, in single-frame nucleus observatory hive: 1st, \$5.00; 2d, \$3.00; 3d, \$2.00.

Carniolan bees and queen in single-frame nucleus observatory hive: 1st, \$5.00; 2d, \$3.00; 3d, \$2.00.

Caucasian bees and queen, in single-frame nucleus observatory hive: 1st, \$5.00; 2d, \$3.00; 3d, \$2.00.

Full-colony and full-size observatory hive, showing different parts and appliances of hive, most attractive: 1st, \$10.00; 2d, \$7.00; 3d, \$5.00; 4th, \$3.00.

Sweepstakes, largest, best, most interesting, attractive, and instructive exhibit in this department, all things to be considered: 1st, \$25.00; 2d, \$12.00; 3d, \$8.00; 4th, \$5.00.

E. D. Townsend has been appointed judge of the bee and honey exhibit.

**TRADE NOTES**

**BIG ADVANCE IN HONEY-EXTRACTORS.**

In figuring out the cost of extractors under new conditions, with our late cost-finding system, we find that our prices have been altogether too low to cover all the improvements which have been incorporated in recent years, and we are obliged to make a radical advance on all sizes in order to get a fair return for money expended in labor and material. Our revised list prices on all sizes listed in the catalog are as follows:

|                         |                     |
|-------------------------|---------------------|
| No. 4B Novice...\$13.00 | ROOT AUTOMATIC.     |
| No. 5B Novice... 13.00  | No. 15BF..... 20.00 |
| No. 54B Novice... 20.00 | No. 17BR..... 21.00 |
| No. 84B Novice... 24.00 | No. 18BR..... 23.00 |
| No. 15B Cowan... 17.00  | No. 20BR..... 24.00 |
| No. 17B Cowan... 18.00  | No. 25BF..... 44.00 |
| No. 18B Cowan... 19.00  | No. 27BF..... 45.00 |
| No. 20B Cowan... 20.00  | No. 30BF..... 51.00 |
| No. 25B Root... 36.00   | No. 37B..... 52.00  |
| No. 27B Root... 42.00   | No. 40B..... 55.00  |
| No. 30B Root... 48.00   | No. 47B..... 60.00  |
| No. 7B Novice... 14.00  | No. 37BF..... 55.00 |
| No. 10B Novice... 14.00 | No. 40BF..... 58.00 |
| No. 74B Novice... 22.00 | No. 47BF..... 63.00 |

These prices take effect at once, and prices from our California offices will be the same with freight added, figuring 3½ cents a pound on the weight as listed in the catalog.

**ADVANCE IN PRICE OF WIRE NAILS.**

In the first table of prices on wire nails as listed page 21 of catalog the new prices are:

2d fine, 12 cts. lb., \$1.10 for 10 lbs.; \$6.50 per keg.  
 3d fine, 11 cts. lb.; \$1.00 for 10 lbs.; \$6.15 per keg.  
 1¼-in. lining, 11 cts. lb.; \$1.10 for 10 lbs.; \$6.50 per keg.

All other sizes, 10 cts. lb.; 90 cts. for 10 lbs., and an advance of \$1.50 per keg added to present list.

To the fine flat-head nails in second table add 5 cts. per pound, \$3.00 per keg.

End-space staples, 20 cts. per lb.  
 Crate staples, 20 cts. per lb.

**HONEY-TANKS AND OTHER METAL GOODS.**

The honey-tanks listed in our catalog are advanced 15 to 25 per cent. Oil and gasoline stoves are raised 50 cts. each. Dadant uncapping-can is raised to \$10.00; German wax-press to \$14.00; Townsend uncapping-box to \$18.00; 1½ H. P. Busy Bee engine to \$36.00 with prospect that it will go to \$40.00 before long.

**COMB-HONEY CARTONS AND LABELS.**

The stock for cartons costs now more than double what we paid eight months ago when present prices were figured, so that we must make a further advance of 75 cts. per 1000, or \$1.50 added to present list price.

Paper of all kinds, and ink, have advanced to such an extent that on all orders for labels and other printing we must advance 20 to 30 per cent over the prices now listed. New lists will be issued shortly.

**FURTHER ADVANCES BECAUSE OF INCREASED COST.**

The two-wheeled cart listed at \$10.00 is raised to \$12.50, and without box to \$10.50. Daisy wheelbarrow is raised to \$4.50; the Coggs hall bee-brush is raised to 20 cts.; No. 1 bee-veil is now priced at \$1.00; No. 2 bee-veil is now priced at 70 cts.; No. 3 bee-veil is now priced at 60 cts.; Alexander bee-veil priced at 70 cts.; Hatch wax-press at \$7.00.

**BEEWAX MARKET LOWER.**

We have had an unusual number of offerings of beeswax from beekeepers as well as dealers for this season of the year, and have an unusually large stock on hand. For several years before the war there was a shortage of wax at this season of the year, and prices reached their highest level in May and June. Till further notice we quote 27 cts. cash, 29 trade, delivered at Medina for average wax.

THE A. I. ROOF CO., Medina, Ohio.

**Special Notice by A. I. Root**

THE BARKER WEEDER, MULCHER, AND CULTIVATOR.

The little tool I have written up so fully in this issue will be found pictured in our advertising pages. There is one part of it not shown in the advertisement; and that is, the three cultivator teeth on the opposite side of the scuffle-hoe shown in the cut. These teeth are keen and sharp-pointed, and on a curve, so that they cut into the soil with less force than anything I have ever gotten hold of. After having used the tool a week or more since my write-up, I am still of the opinion that it is going to make a revolution in gardening—especially in the line of hand cultivators.

**PRINTING FOR BEEKEEPERS.**—Noteheads, envelopes, cards, tags, etc. 1000 of either, \$2.15; 500, \$1.30; 250, 95c. Fine stock and cuts used. Lowest prices in the United States. Complete line of samples and price list free.

RENNECAMP PRINTING CO., McKees Rocks, Pa.

**GOLDEN ITALIAN QUEENS**

Bred from a strain of great honey-gatherers; gentle and prolific. Untested, one, 75 cts.; six, \$4.25; 12, \$8.00; 50, \$32.50; 100, \$60.00. All orders promptly filled and safe arrival guaranteed.

L. J. Pfeiffer, R. F. D. 15, Los Gatos, California

**50c -- Golden and 3-banded Italian Queens -- 50c**

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested, one, 50 cts.; 100, \$45.00. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. 1 lb. bees, \$1.25; 2 lbs., \$2.00; 1-fr. nucleus, \$1.25; 2-fr., \$2.25, Full colony 8-fr., \$6.00; 10-fr., \$7.00. No queens at these prices.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

*To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.*  
C. C. Miller, Marengo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested, \$1.00; 12 for \$10.00; Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00.

Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

**THE STOVER APIARIES, MAYHEW, MISSISSIPPI**

**By All Means Buy a Good Veil**

Muth's Ideal Bee-veil, postpaid 75c;  
with other goods, 70c.

OLD COMB AND CAPPINGS rendered into wax with our hydraulic wax-press. Perfect work. We buy your wax at highest market price. Write us.

Cincinnati, Ohio

# SPECIAL BARGAINS

In rearranging our stock we find a number of items no longer listed in our catalog, which some of our readers may be glad to get at the bargain prices at which we offer them to reduce stock or close out entirely. We list a number of these specials on this page, and may add others later as these are disposed of.

## HIVE-HANDLES.

We have a surplus stock of handhole cleats such as we formerly included with all dovetailed hives, and which have been listed at 75 cts. for 100, and will dispose of them to those who want them at 25 cts. per 100; \$2.00 per 1000.

## OLD-STYLE DOVETAILED CHAFF HIVES WITH BOTTOM TO NAIL FAST.

Of these old-style chaff hives we have a number of eight-frame packed 5 in a package, which we offer to close out as follows: YW 5/8, one story, eight frames, 12 packages, five hives each, at \$8.00.

## NO. 2 OR B GRADE THICK-TOP STAPLE-SPACE FRAMES.

In culling over the material cut into Hoffman frames, we find pieces with slight defects which we do not want to put into perfect stock, but which are usable, and too good to throw into the furnace for fuel. We have accumulated some stock of such frames, which are packed 100 in a box, and offer them at \$2.25 per 100; \$10.00 per 500. These are a bargain at the price, to one who is not too particular as to what he uses.

## 1 3/4 H. P. SIXTY-SPEED ENGINE.

We have in stock two of the engines we formerly listed as sixty speed before adopting the Busy Bee engine. These are mounted on wheels, and have a counter shaft by means of which 60 different speeds can be obtained by the various changes of pulley sizes on the counter. This engine sold for \$60.00. We offer these to close out at \$45.00 each.

## WHEELBARROW WHEELS.

We have a number of extra steel wheels for wheelbarrows, which we offer at a special price of \$1.25 each, or, including a pair of springs with bearings, for \$2.00. These wheels are 20 inches in diameter, with 1 1/2-inch tire, and solid cast hub holding spokes and axle in place. These wheels regularly sell at \$1.75, and springs at 50 cts. each.

## SUPERS FOR EXTRACTING OR CHUNK HONEY.

We are offering, while they last, the following bargains in nailed supers for extracted honey. Some have been slightly used, and are in good condition. Prices f. o. b. Medina.

100 D9/10, nailed and painted, with top and bottom starters, nine frames in each, new. Sell new for \$1.20; offered at \$6.00 for 10; \$55.00 per 100.

100 8/10 supers, no paint. Sell new for 85 cts.; offered at \$4.50 per 10; \$40.00 per 100.

The first lots are the 5 1/2-inch supers with hanger cleats and shallow Danz. frames. The last lot are the same depth supers with shallow Hoffman frames hanging in rabbeted ends. Either style may be used for extracting or divisible brood-chambers. The price at which we offer them all nailed up is much below the regular price of same shipped in flat.

## ALEXANDER FEEDERS FOR EIGHT-FRAME HIVES.

The Alexander feeder as we now make it is adapted to either eight or ten frame hives. Formerly we made a shorter length for the eight frame than for

the ten frame hive. In cleaning up old stock we find 21 of these eight-frame feeders which we offer, to close out, at half regular price—viz., 15 cts. each; \$1.35 for 10.

## TIN COMB-BUCKETS.

While these are listed in the catalog in one line at \$1.50 each, their convenience in carrying combs to the extractor shut up from robbers is not set forth. We have a surplus stock, and offer them, to reduce the number on hand, at \$1.25 each. You can place four Hoffman frames or five non-spaced frames of Langstroth size in each bucket.

## JONES HONEY-KNIVES.

This is a form of honey-knife used largely in Canada, and preferred to the Bingham by those who have tried it. The blade is 1 1/2 inches wide, and a flat V or triangular shape. We had a lot made to supply a call we had, and still have in stock 28 of them. We offer them at 75 cts. each. Mailed as a pound parcel when packed.

## TUMBLERS HOLDING 6 1/2 OZ., 40 DOZ. TO BARREL.

Having a surplus stock of honey-tumblers packed 40 dozen to barrel, including tin tops and wax-packed liners, we offer them for a short time, to reduce stock, at \$6.00 per barrel, or \$5.70 in 5-barrel lots, shipped direct from Medina.

## SHIPPING-CASES FOR 12 AND 24 SECTIONS.

When we discontinued listing shipping-cases to hold 12 sections we still had quite a stock of various styles on hand, many of which are still in stock. We have also some of the older styles of cases for 24 sections of various sizes. We offer these various cases to close out at the following bargain prices. Here is an opportunity to lay in a stock of cases preparatory to the honey crop near at hand at very low prices. None of these cases, except as noted, are large enough to take sections with cartons or corrugated liners, except the bottom sheet. 12-lb. 2 or 3 row cases with 2 and 3 inch glass for the 4 1/4 x 1 1/2, 4 1/4 x 1 1/2, 4 x 5 x 1 3/8 sections, packed 50 in a crate at \$4.00 a crate; packed 10 in a crate at 35 cts. a crate. A few crates of cases for 16 sections 4 1/4 x 1 1/2 at \$4.50 per crate of 50 or 95 cts. per crate of 10. A few crates of cases for 24 sections 4 1/4 x 1 1/2, and 4 1/4 x 1 1/2, at \$8.00 per crate of 50; \$4.00 per crate of 25, or \$1.70 per crate of 10. The 12-lb. safety cases, which we no longer list with safety cartons, and 2-inch glass for 4 1/4 x 1 1/2, 4 1/4 x 1 1/2; and 4 x 5 x 1 3/8 sections, per crate of 10, \$1.20; per crate of 25, \$3.00. Without cartons, but including corrugated liners and glass, \$4.50 per crate of 50.

## SHIPPING CASES NAILED READY FOR FILLING.

In repacking large quantities of comb honey we accumulate a number of empty shipping-cases which we cannot use for one reason or another. These are in good condition for use again, and are offered at the following bargain prices, each lot subject to previous sale: 390 11 3/8-inch four-row with 2-inch glass, just right for 24 sections 4 1/4 x 1 1/2; offered at 10 cts. each, lots of 100 or over; 9 carriers of 8 cases each, double-tier cases for 24 sections 4 1/4 x 1 1/2, offered at \$1.25 per carrier; 57 cases, 9 1/2 in. wide by 18 1/2 long, 5 1/2 deep, with 2-inch glass, offered at 10 cts. each; 100 cases, 10 1/2 x 18 1/4 x 5 1/2 deep, with 2-in. glass running the short way, offered at 10 cts. each; 100 cases, 10 1/2 x 18 1/4 x 4 3/8 in. deep, with 2-in. glass the short way, offered at 10 cts. each.

# Mental Demons Are They Holding You Back?

Does a host of mental demons bar your path to success? Do you feel yourself incapable to meet important situations? Do you lack the power to make people recognize you—to make others see things *your way*—to compel people to listen to you? Are you weak in a crisis?

Most men have the brains and the ambition to do big things—but a weak personality—a lack of self-confidence—timidness—poor vocabulary—unreliable memory—“stage fright”—hazy, unorganized ideas—*ineffective speech*—are holding them back from the success they deserve.

## RESULTS!

“Your Course is a most valuable training to anyone who desires to be able to speak in public without embarrassment.”

—C. C. HOFFPAUIR, Att’y, Texas.  
“Not only has it enabled me to speak in public in a way that is most gratifying to me, but it has helped me in business as well.”

—G. M. COSSITT, Banker, Illinois.  
“It has given me greater confidence in my own ability, a better memory, a more polished vocabulary, and a stronger personality.”

—W. L. WILDER, Mgr., Chicago.  
“Your Course is a splendid training for the salesman or sales manager, and I heartily recommend it.”

—O. F. BOURGEOIS, Pres., Chicago.  
“A fascinating and practical training that overcomes one of the common weaknesses of business men—inability to express themselves.”

—GUY H. SHARPER, Banker, Idaho.  
We have hundreds of similar testimonials in our files from men in every walk of life. Send the Coupon today. You owe it to yourself to find out what this Course will do for you.

Send the coupon below at once and let us tell you how you can drive these mental demons away forever—how *you* can occupy a place among men who do things—how *you* can learn to express your ideas forcefully and convincingly—how *you* can acquire a powerful, magnetic personality—how *you* can develop a strong dominating will—how you can become a powerful, public speaker. Our new scientific Course in

## Effective Public Speaking and Mental Development

will quickly train you to speak forcefully and convincingly in public

- talk before your club or lodge
- address board meetings
- propose and respond to toasts
- tell entertaining stories
- make after-dinner speeches
- converse effectively
- write better letters
- sell more goods

# Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same

|                                |                                                                  |                               |
|--------------------------------|------------------------------------------------------------------|-------------------------------|
|                                | June and July                                                    | August and later              |
| Untested Queens . . . . .      | 1 for 60 cts.; 12 for \$ 7.00                                    | 1 for 55 cts.; 12 for \$ 6.00 |
| Tested Queens . . . . .        | 1 for \$1.05; 12 for \$12.00                                     | 1 for \$1.00; 12 for \$10.75  |
| Select Tested Queens . . . . . | 1 for \$1.75; 12 for \$19.25                                     | 1 for \$1.65; 12 for \$18.00  |
| Very best queens for breeding, | \$3.00. 1 lb bees in package, \$1.25; 2 lbs. in package, \$2.00. |                               |

Add price of queen. If any of our untested queens should prove to be mated we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

**W. D. ACHORD, FITZPATRICK, ALABAMA**

## EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

## The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

**The A. I. Root Company . . . Medina, Ohio**

# Gleanings in Bee Culture

# THE BUSY BEE

1 1/2 H. P. Gasoline Engine

A faithful worker and first assistant to the Bee-keeper. Will operate extractor, pump, grindstone, washing machine, etc.

The A. I. Root Co. endorse this engine. Ask them.

**GILSON MFG. CO.**

1000 Park St., Port Washington, Wis.

## “Our Bees are Gentle”

Nope, you won't get stung if you buy our queens. Our queens are very prolific. Bees swarm but little, and are of a beautiful light leather color. Our queen booklet, telling how to rear the finest queens, is free for the asking. Queens to October 1, one, \$1.00; six, \$5.00; 12, \$9.00. Bees by the pound to Sept. 1, 1/4 lb., \$1.00; 1 lb., \$1.25; 2 lbs., \$2.00; 3 lbs. \$2.50. Safe arrival and satisfaction guaranteed.

JAY SMITH, 1159 DeWolfe St., Vincennes, Ind.

## GET THIS BOOK

Galloway's wonderful book of bargains; describes fully and prices Galloway Cream Separators, Manure Spreaders, Gasoline Engines, Farm Tractors. Saves 1-3 to 1-2 on prices usually asked. Also lists and prices farm implements, fencing, auto supplies; everything for farm and household.

HAROLD SOMERS, 150 DeKalb Ave., Brooklyn, N. Y.

## “Best” Hand Lantern

A powerful portable lamp, giving a 300 candle power pure white light. Just what the farmer, dairyman, stockman, etc. needs. Safe—Reliable—Economical—Absolutely Rain, Storm and Bug proof. Burns either gasoline or kerosene. Light in weight. Agents wanted. Big Profits. Write for Catalog.

**THE BEST LIGHT CO.**  
306 E. 5th St., Canton, O.

## EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A postcard will bring it to your address free.

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT CO., MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz. Cases must average not less than 20 lbs. net.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,  
FEBRUARY 6, 1915.

#### COMB HONEY.

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.  
Honey in badly stained or mildewed sections.  
Honey showing signs of granulation.  
Leaking, injured, or patched-up sections.  
Sections containing honey-dew.  
Sections with more than 50 uncapped cells, or a less number of empty cells.  
Sections weighing less than the minimum weight.  
All such honey should be disposed of in the home market.

#### EXTRACTED HONEY.

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

#### STRAINED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.  
Unripe or fermenting honey weighing less than 12 lbs. per gallon.  
Honey contaminated by excessive use of smoke.  
Honey contaminated by honey-dew.  
Honey not properly strained.

# Queens! Queens! Queens!

We will make a specialty of shipping Queens, Nuclei, and Full Colonies from Florida during the present month. We are breeding from queens that produced a surplus of 300 pounds per colony in a 24-day honey-flow in Florida, and that are unexcelled for prolificness, gentleness, and honey-gathering.

When you order queens from us you get **QUALITY, PURITY, AND HONEY-GATHERERS**. We can fill your orders from our famous Honey-gathering Strain for Queens, Nuclei, and Full Colonies promptly, and guarantee safe delivery and entire satisfaction to you in every respect. Our aim is to give you the best stock on the market at the time you want it. Write for special price on orders of 50 or more. We ask you to give us a trial and let us prove to you that our stock is unexcelled by anything on the market.

## Make More Profit by Reducing Cost of Production

Comb-honey producers can put up their sections complete in less than half the time with a **RAUCHFUSS COMBINED SECTION-PRESS AND FOUNDATION-FASTENER**. Now used by hundreds of Western beekeepers who would not think to be without it any more.

**IT IS GUARANTEED TO DO MORE AND BETTER WORK THAN ANY OTHER DEVICE ON THE MARKET.** Your money back if not entirely satisfactory. Made for 4 1/4 x 4 1/4 and also 4 x 5 sections.

**PRICE \$3.00, COMPLETE WITH LAMP AND TREADLE, DELIVERED POSTPAID ANYWHERE IN THE UNITED STATES.** Write for 68-page illustrated catalog of the best bee-supplies made.

**THE COLORADO HONEY-PRODUCERS' ASSOCIATION, 1424 Market Street Denver, Colorado.**

## WARDELL STRAIN OF ITALIANS

Descendents from the Famous Root \$200 Queen

I was head queen breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

# W. H. Laws Talking Queens

We have taken care of every queen order the present season, altho more than 2000 queens were mailed from the Laws yards in past 60 days, but in order not to get swamped we had to withdraw our ad. from GLEANINGS.

We are well supplied with queens, both tested and untested, also as fine a lot of breeders as possible to produce. Any of these can go out by return mail. Samples of live bees from my breeding queens will be mailed free to prospective buyers on request.

The time is approaching when every beekeeper should see that his colonies are supplied with strong young queens for another season. To do this you will need a first-class breeding queen now, or make your arrangements with me for queens to be introduced near the close of your honey-flow.

Prices as follows: Untested, each, 75 cts.; 12, \$8.00; 100, \$60.00. Tested, each, \$1.00; 12 for \$10.00; 100 for \$75.00. Breeding queens, \$5.00 each; six for \$25.00.

W. H. Laws, Beeville, Texas

# The Eyes, Ears, and Mouth are Near Together

To see birds, hear their  
music, and taste honey  
are a happy trio.

## ITALIAN QUEENS

Untested, 75 cents each  
Tested, \$1.00 each.  
Satisfaction in all cases or money refunded.  
Been breeding queens for 25 years, and we know how.

L. H. Robey, Worthington, W. Va.

## HONEY MARKETS

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

CHICAGO.—There has been very little movement in honey at any time during the past two weeks. Prices are without change for the lack of sales on which to establish a new basis. The bulk of the comb is selling at about 13 cts. per lb.; extracted, 7 to 8. Beeswax brings from 30 to 32.  
Chicago, July 3. R. A. BURNETT & Co.

KANSAS CITY.—The honey market has been very slow on account of the great amount of native honey that is coming to market. The price ranges around \$3.50 for the best white-clover honey, 24 sections to the case. Extracted honey is a little slow, price ranging from 6 cts. to 8 cts., according to quality.  
C. C. CLEMONS PRODUCE CO.  
Kansas City, July 7.

ST. LOUIS.—The demand in this market for comb honey has been very light lately. Some new extracted honey has arrived, but receipts have so far been light. No. 1 bright amber comb honey is bringing from \$2.50 to \$3.00; No. 2 from \$2.50 to \$2.75; No. 1 southern extracted amber in barrels from 5½ to 6; in cans from 6 to 7, according to quality; dark from ½ to 1 ct. per lb. less. Beeswax is quoted at 29½ for pure; impure and inferior, less.  
St. Louis, July 3. R. HARTMANN PRODUCE CO.

I am paying in Cuba for honey from 44 to 45 cts. per gallon.  
ADOLFO MARZOL.  
Matanzas, Cuba, June 27.

# Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

Root's Goods mean Real Preparedness.

We sell them in Michigan. Send for catalog. Beeswax wanted---

M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.

## "If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

Walter S. Pouder, Indianapolis, Ind.

873 Massachusetts Avenue

# New Bingham Bee Smoker

Patented

Nearly forty years on the market and the standard in this and many foreign countries. It is the all-important tool of the most extensive honey-producers of the world. For sale direct or by all dealers in beekeepers' supplies.

- Smoke Engine, 4-inch stove . . . 28 oz. \$1.25
- Doctor, 3½-inch stove . . . . . 26 oz. .85
- Two larger sizes in copper extra . . . . . .50
- Conqueror, 3-inch stove . . . . . 23 oz. .75

# NOW IS THE TIME

To order your shipping cases and thus have every thing in readiness for marketing your honey ...

We carry a full line of Root's Goods at all times, and are always prepared to fill any and all orders on short notice.

Hives, supers, frames, sections, comb foundation, section-presses, foundation-fasteners, queen-excluders, queen and drone traps, swarm-catchers, feeders, honey and wax extractors, capping-melters, honey-knives, honey-tanks, honey-packages, shipping-cases, bee-escapes, bee-veils, bee-gloves, bee-brushes, smokers—in short, everything the beekeeper requires for the proper conduct of an apiary.

C. H. W. Weber & Company, Cincinnati, O.

2146 Central Avenue

## What do you know about that

We are getting an almost innumerable number of orders to go by parcel post --- a great thing for beekeepers on rural delivery. BUT REMEMBER to always include enough in the amount sent to cover the postage required. . . .

For instance, if you are within 150 miles of Syracuse, and need 500 sections, we can mail them for 41c; 250 sections for 21c, and 100 sections for 11c. Foundation in 5-lb. lots, can be mailed for 11c; 2 lbs. for 7c; 1 lb. for 6c. Always figure postage more than foundation weighs. Rates inside of 150 miles once the total weight plus 4.

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

# Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

**WHY IS THIS TRUE?** BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who "has been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis Sections in a season, and has not found one section in the whole lot that was not perfect? Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

**INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.**

**G. B. Lewis Company, Watertown, Wisconsin**

Catalog on request giving nearest distributor.

## DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

### Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me. A. W. DARBY, Alburt, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

## EDITORIAL

### Reports Asked for

OUR subscribers and all others interested are requested to send in postal-card reports, consisting of not more than one or two sentences, on what the honey-crop conditions are. Do not make the reports long, as we cannot tabulate them. Report good, bad, and indifferent conditions. We want the truth, but be sure not to take more than two sentences.

We ought to have a report from every subscriber; that is, to enable us to determine the amount of honey and probable prices.

### Summer Field Meet in Tennessee

THE following letter, just received from Secretary J. M. Buchanan, of Franklin, Tenn., will explain. It will be noted that E. R. Root, who is busy on the new edition of the A B C and X Y Z of Bee Culture, is on the program. He has made no definite promise that he will be present, but is making an extra effort to go.

Mr. Root:—You may announce that the Tennessee beekeepers will hold summer field meetings as follows: Nashville, Aug. 9, at the home of Mrs. Grace Allen, 4409 Charlotte Ave.; Hollow Rock, Aug. 10, at the apiary of L. E. Smith; Memphis, Aug. 11, at the Tri-state fairgrounds. Meetings to begin at 10 a.m.

There will be no formal program, but short talks will be given on pertinent subjects by Dr. Phillips, Frank C. Pellett, E. R. Root, Dr. J. S. Ward, J. M. Buchanan, Ben G. Davis, and perhaps others.

J. M. Buchanan.

Franklin, Tenn., July 5.

### The Federal Net-weight Law on Local Sales

A CONSTANT and ever recurring question that comes up is this, and has been answered: "Is it necessary for me to mark the net weight on my sections of honey if I sell only in my own locality?" There is only one answer to this question, and that is, *no*.

But in view of the fact that honey produced by John Jones may be sold by Jim Brown in another state, it is always wise to play safe and mark every section with its minimum net weight in accordance with the federal law.

### White Clover vs. Alsike

As mentioned elsewhere in this department, white clover is not yielding as heavily as alsike. While it is generally recognized that the latter is a better honey-plant per acre, yet for some reason this year white clover is not yielding quite in proportion to the amount of bloom in sight. We find a dozen bees on alsike where we find one on white clover. As the haying season is at its height, and alsike is being cut away, it is possible that the hot weather we are now having will stimulate the white clover so that it will make up for the cutting of the alsike. The rank growth of both clovers because of the heavy rains in the early part of the season may have a favorable effect upon alsike and unfavorable upon white clover. A little later on we shall be able to determine how much effect this had.

### The Case of the Beekeepers versus the Smelter Companies in Canada Continued till October

ON page 215, and again on page 257, we stated that the beekeepers in the vicinity of Smithville, Ontario, had brought suit against a large smelting concern for alleged damage to the bees. In the case that was settled in Salt Lake Valley, Utah, a few years ago, by the smelter company paying \$60,000 to the beekeepers, the complaint was filed that the smelter fumes killed the bees and spoiled the vegetation on which the bees work. The Ontario beekeepers are claiming damages on the same grounds. That both sides may get a little more evidence, the case has been again continued until October, and in the mean time bee-

keepers in Utah, Colorado, and elsewhere, where the smelter fumes are said to have ruined or are ruining the beekeeping industry, are asked to communicate with Louis Minor, Smithville, Ontario, Canada, who seems to be handling the case for the beekeepers.

Of course, it goes without saying that the smelter people will endeavor to show that the loss of bees was due to some other cause than the fumes. Indeed, their attorney has written to us asking for particulars regarding bee paralysis and Isle of Wight disease. The presumption is that the defense will endeavor to show that the decimation of bees is due to one or the other of these two diseases. But they will have to show, also, of course, that it is in the locality.

The fact that the big smelters of the West settled with the beekeepers in the sum of \$60,000 would seem to indicate that the Salt Lake Valley smelters acknowledged the damage rather than fight it out in the courts.

This case in Ontario will be a hard-fought one, as both sides are preparing for a big battle. GLEANINGS will be glad to give its readers the benefit of any developments that may come up, with a summary of the proceedings, and the final verdict if any.

### Honey-crop Conditions and Prices

A CAREFUL survey of the United States government weather maps, showing the weather conditions and the amount of precipitation thruout the clover belt of the country, and the reading of reports as they come in from subscribers all over the country, indicates that a crop of clover honey is probably assured. How large this crop will be it is a little too early to estimate. This is the way reports are coming every day, "Bumper crop of clover honey;" "heaviest flow in years;" "best ever;" "seems like old times;" "the oldest inhabitant never saw a white-clover crop at all comparable to that which exists around here this year," etc. In fact, we have not seen an unfavorable report from any of the clover districts. There is yet from ten days to two or three weeks of bloom in sight. Many report one super filled, and bees at work in others. The flow from clover is a little slow, but steady when weather conditions are at all favorable. The excessive rains, according to the aforesaid government maps, have let up, and in their stead we have hot weather with occasional thunder-showers—just enough to keep the clovers in good condition and to stimulate new bloom.

There is a possibility and even probability that 1916 will go down as one of the biggest years for the production of clover honey that we have ever had.

Two or three years ago we had come to believe that the natural lime in the soil had become exhausted, and that there would never be as large a yield of clover honey as there had been in the old-fashioned days; but the heavy precipitation last year and the early part of this year would seem to indicate that the scarcity of clovers in districts was due not so much to lack of lime as to insufficient moisture in the soil. Abundant rains have put clovers back to their old prominence, and reports everywhere say the fields are white.

We had a call from Mr. R. F. Holtermann, of Brantford, Ontario, Canada, the largest honey-producer in Canada, and one of the largest in the United States. Said he, "If you think you fellows on your side of the line have good clover you ought to come over on our side."

While naturally conservative he believes he is going to have a good crop. Some of his very best colonies have two 12-frame supers of extracting-combs filled already, and he estimates that there is two weeks of clover still in sight.

Reports are rather meager and scattering for Colorado; but early in the season it was reported that there had been sufficient snow in the mountains to insure a crop of alfalfa. Prospects are good in Nevada and Idaho, and there will probably be as much of northern-grown alfalfa as formerly. But in New Mexico and Arizona, and southern California, the yield of alfalfa has suddenly slumped, particularly in Imperial Valley, where the beekeepers are somewhat discouraged over the situation. There has been from a light to a fair yield of mountain-sage, but probably not enough to supply the general demand. In northern and central California the yield has been fair.

The season has been exceptionally good in Texas, and is starting up a little in some of the southern states. Conditions in the early part of the season in Florida were unfavorable, but are improving according to a late report from the southern part of the state.

### PRICES.

This is a rather dangerous subject, as it is impossible at present to give any idea how prices will rule this year. They will probably be easier than last year in spite of the sharp advance of sugar. The fact that the housewives of the country are boycotting the sugar trust in all the large cities, and turning to other forms of sweet, partic-

ularly to honey, may have a tendency to offset the effect of a big crop. The general advance in all food products will have a decidedly strong tendency to hold honey up to its present level. But the probabilities are that along in September and October, particularly toward November, the prices on *extracted* clover will be somewhat lower than at present. Producers who have honey to sell would do well to get it on the market early; for when the laggards begin to dump their product prices may sag.

The supply of comb honey from last year is still large, and there is no question but that prices on comb honey are going to be easier than last year. A good many misinterpreted our advice to produce extracted instead of comb this season; but if they knew the actual market supply, so far as comb honey is concerned they would not be inclined to question our statements.

Taking it all in all, the reader should understand that it is still early to make any positive statement concerning the probable yield of clover honey thruout the United States. Weather conditions from now on may be unfavorable, with the result that the crop will be only half what indications now promise. At one of our outyards, where there has been a good deal of cutting of alsike, we are noticing a decrease in the flow of nectar, and the bees are getting a little cross, just as they always do when the flow begins to check up. While white clover is abundant, it is apparent it is not yielding as heavily as alsike. However, this applies only to our own locality. See another editorial on this subject.

### A Representative from Great Britain Investigating Bee Paralysis in the United States

THERE have been reports of bee paralysis again this year; but so far nothing serious has developed in the northern states. Mr. C. H. Bocoek, of Newmarket, England, is now in this country under the direction of the Department of Agriculture of Great Britain to study the trembling bee disease or what showed itself in various places. He comes here for the sole purpose of ascertaining whether there is any relationship between the disease of Great Britain and something similar that has been making various outbreaks in this country. He is at present working with Dr. Burton N. Gates at Amherst, Mass. He has found the *Nosema apis*, supposed to be the exciting cause of the Isle of Wight disease in some American bees. While it has been determined that

this parasite is present in healthy bees, it is supposed that, under favorable environment and in some strains, it may develop something serious.

Mr. F. R. Beuhne, of Tooberac, Australia, had a very severe attack of what he believed to be bee paralysis. He finally developed a strain immune to the disease. With this strain he had no further trouble; but when he introduced another strain, bee paralysis broke out in all its fury. He naturally concluded that the exciting cause was present all the time, and that, when favorable subjects were introduced, they fell easy victims.

Mr. Bocoek expects to go to Washington, D. C., and, later, to Medina. In the mean time he is examining specimens of paralytic bees or other bees that seem to die for no apparent reason.

In some cases the Isle of Wight disease shows no outward symptoms, except that bees are dying in great numbers. Usually the affected bees will be found at the entrance, unable to fly, dragging their bodies on the ground as tho they were scarcely able to walk. In some specimens one or more wings will be out of joint. There may or may not be a distension of the abdomen, and there may or may not be any discoloration. Usually there is associated with bee paralysis black and shiny bees with distended abdomens; but even bee paralysis does not, in its early stages, show such bees. About the first symptom is a few trembling bees. They seem to be itching all over, and scratching their bodies as if distressed. Other healthy bees keep pulling at them as if to get them away from the entrance. As the disease develops, some bees will become black and shiny. The symptoms thus given seem to tally very closely with the Isle of Wight disease, except that with this disease the bees will be dying in large numbers, and congregated in bunches at the entrance of the hives, or even in the hive itself.

If we have Isle of Wight disease in America, the sooner we know it the better. We do not expect anything very serious, however, even if we do find it here, as the conditions in most places in this country are unfavorable for its development. It needs cool, moist, chilly rainy weather; and that is the reason why so much bee paralysis (which is like the Isle of Wight disease) showed itself in so many places last season in this country, and particularly around Portland, Oregon, where conditions are much the same as they are in Great Britain. There are so many symptoms in the Isle of Wight disease and bee paralysis that are identical that it is hard to escape

the conclusion that they are one and the same thing, differing only because modified by the season and environment.

### Are Bees a Source of Infection in the Transmission of Blight on Fruit-trees?

IN this issue, on page 605, appears an article by Prof. Gossard, in reply to our editorial on page 384, May 15, wherein we held that the professor had drawn some wrong conclusions, and incriminated the bee in a way that hardly seemed warranted from the facts in hand.

In order that the reader may better understand this discussion, perhaps it would be well to make a statement concerning blight as we find it on pear, quince, and apple-trees, and variously called pear-blight and twig-blight. The latter rarely goes beyond the current year's growth on apple-trees, and disappears the next year because it does not live over as it does on the diseased wood of the pear and quince, or at least that is the generally accepted opinion. Blight, therefore, is not to be feared to any extent on apple-trees, but it may be the ruination of whole pear-orchards. The only remedy is thoro pruning and cutting off the diseased portions. Very little attention need be paid to the twig-blight on apple-trees except to prevent this general source of infection to pear or quince trees.

Referring to the article of Prof. Gossard in this issue, we are very glad to give this space, not only because he stands high among our entomologists, but because we believe him to be perfectly fair. It is evident that we misunderstood his viewpoint, because he says if he had to make a choice between the extermination of the bees and the sacrifice of the two species of fruit (apples and pears) he would render his decision in favor of the bees, and then make shift to other fruit, of which there is plenty in the world. This shows that he is a very warm friend of the bees.

Scientists are not all agreed as to how blight is disseminated. At one time it was thought that bees were the main distributors of it, because if they visit the blossoms of fruit-trees containing the bacteria they could carry it to healthy blossoms. While this is true in part later investigation seems to show that biting and sucking insects piercing the tissue of the twigs that are diseased can and do carry the infection when they bite into healthy trees. It has been determined that in the early spring months blighted limbs which had been allowed to remain over winter exude a watery

substance containing these bacteria. The inference has been that the bees would take up these juices, carry them to the hive, and then again to the field. Any one who knows anything about bees knows that they would have no occasion whatever to visit trees *unless the trees were in bloom*; and the very fact that young pear-tree orchards (which we have seen in California, and *which never bloomed*), were badly blighted, would indicate that bees, at least, were *not* the carriers of the infection. Indeed, the strong probabilities are that the bark biting and sucking insects are the main cause.

Prof. Gossard says in this issue that both fruit-growers and beekeepers alike agree that the blossom-blight does not appear to a great extent until some time after the blooming season has opened. He seems to have the impression that they might carry it, after the trees are out of bloom. Any practical beekeeper could inform him that bees do not visit trees or plants unless when the trees are in bloom, such bloom having either pollen or nectar to offer. Unless the blossoms are badly blighted in the first place, which they will not be in the early spring, as we understand it, they would not be likely to carry any blight-germs; and even if they do carry them to the hive, they could not live long enough to do any harm.

If we understand the theory of blight transmission, where and how it affects the trees, it would seem, in view of the evidence in hand, such evidence as is furnished here by Prof. Gossard and others that our bees rarely carry any blight-germs. It is conceivable, however, that the birds might come in contact with the watery substances containing the bacteria that caused blight and carry it from tree to tree. Ants and other insects that crawl over the tree and over portions that are diseased could very easily carry it to trees that are healthy. Bark biting or sucking insects could likewise do it, and do do a large part of it if the testimony of careful men is correct.

To summarize, bees do not visit trees except when the trees are in bloom. They would have no occasion for crawling over the bark of infected trees, *and never do* like ants and other insects; neither could they nor would they bite into the bark, and never do they have occasion to suck the juices from the bark. The very strong testimony offered by Prof. Gossard in favor of the bees would condone for all the mischief that might be laid to their door.

We are not denying that bees may transmit blight from diseased to healthy blossoms; but as the bloom is rarely infected we may infer that bees seldom carry blight.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

MENTION is made, p. 416, of full combs, made the year before, and the bees put nothing in them that year. Isn't there some mistake about that? Do bees ever build comb in advance of immediate need?

INSTRUCTION is given, p. 490, to *shake* all bees in front of the new hive, and afterward to use the queen-cells on the shaken combs. Beginners should be informed that brushing is meant instead of shaking. Shaking might ruin the cells.

ALLEN LATHAM, p. 480, accounts for the greater immunity of Italians to European foul brood by saying that blacks suck out the juices of the dead larvæ, and Italians don't. That's entirely new to me. I wonder if others have observed the same thing. [This was also new to us. We shall be pleased to get reports.—Ed.]

In the Gravenhorst skep, movable frames can be put, p. 481. The novice may understand that to mean that it is a skep rather than a hive, and that frames are not always used in it, altho they *can* be. Gravenhorst was one of Germany's greatest beekeepers, and his hive, altho having walls of straw, is just as much a hive as the Langstroth, and no more used without frames than the Langstroth. [The Gravenhorst hive is in reality the Long Idea hive, with this difference, that it must be turned upside down to manipulate, and that the outer shell is made of straw in place of wood.—Ed.]

How often it is that a thing that looks all right to us turns out to be all wrong when submitted to the bees! There's that idea of feeding *very slowly* when getting queen-cells built, p. 466. I should have said, "If honey is not yielding, the more you feed the better." Then I'd have lost my cells and wondered why! [There are two reasons why slow feeding is better than rapid. If the food comes too fast, it excites the bees, causing them to rush outdoors, expending energy and wing-gear that is utterly useless. The second reason is, fast feeding very soon results in a stoppage of the *incoming supply*. The bees may have ever so much honey or syrup in the hive; but unless there is something *coming* in all the time, cell-building is quite likely to be stopped and cells destroyed.

Cell-building will go on when the supply comes in rapidly; but in a short time the brood-nest will become congested, and the

queen will have no room for egg-laying. There is every reason for slow feeding rather than rapid, either for queen-rearing or raising bees.—Ed.]

P. C. CHADWICK says, p. 473, "I have learned better than to try to compel bees to put up nice comb honey when the flow is not sufficient." I'm beginning to think that a poor colony is much the same as a poor flow. At any rate, this year I'm picking out the colonies that make poorest work in sections, taking off their sections, and giving them extracting-combs. [You are right; and if so, does this not argue that it is an advantage to produce both comb and extracted honey in the same yard, and very often on the same colony? Besides, there is the factor of the season, the factor of the colony, and the factor of the individual or owner? The latter, if he is a beginner, will succeed better with extracted than with comb honey. We therefore advocate the production of both extracted and comb honey in the same yard. But this year we advise the large producer to run mainly for extracted, as there will be enough comb honey produced to take care of all market demands this year, and then some.—Ed.]

PARDON a mild plea for correct English. If "diarrhea" be the correct word, it ought not to give way to an incorrect word that is smoother, altho to me "diarrhea" sounds much smoother than "dysentery." The claim that the latter has become so engrafted into our literature as to make change seem impossible, p. 469, is only a seeming. I've known those into whose language "hadn't ought" was quite thoroly engrafted, yet in time they learned to say "ought not." ["Hadn't ought," of course, cannot be tolerated in any dignified English. Such a phrase is not engrafted in the pages of our regular magazines and papers, altho it is a part of our every-day spoken language. Dysentery is a part of our bee literature.

We have had some experience in trying to change our nomenclature, and we find it an uphill business. It has taken us years to change "nameless bee disease" to "bee paralysis." We attempted to change "fertile worker" to "laying worker," as the former term was thought to be less accurate, but we never really succeeded. If you were making books and magazines, you would not attempt to make a change from "dysentery" to "diarrhea." Does not the former term indicate the meaning of the word closely enough? Then why attempt what is difficult at best?—Ed.]

J. E. Crane

## SIFTINGS

Middlebury, Vt.

Shall we try to eradicate sacbrood as well as foul brood from our yards of bees by the destruction of combs and brood?

\*\*\*

In Japan they call white clover "Jesus grass" because it was introduced by an American missionary.

\*\*\*

If a wire imbedder is kept hot over an oil-stove it works much better, especially if the foundation is cold.

\*\*\*

Our friend Holtermann reminds us, page 310, April 15, that when looking for queens we should keep our minds right on what we are doing, even if we have to keep saying mentally all the time "queen, queen, queen," as tho we were trying to call her out from her hidingplace.

\*\*\*

G. C. Greiner, page 312, April 15, tells us how to get bait sections that, when filled, will be in no way inferior to sections filled by the most approved method. This is the formula: Let them be drawn and filled, and taken from the hive, extracted, and cleaned up by the bees as soon as possible, and then stored in air and dust proof compartments until wanted. Good!

\*\*\*

I wonder if there is any business other than beekeeping so stimulating to the mind and that leads one to be so interested in everything about us—plants, flowers, other insects, birds, animals, and even soils and climates! No need to go to the movies, nor to read stories to find something interesting. The book of nature is a very interesting book.

\*\*\*

Louis H. Scholl says, page 390, May 15, that this spring has afforded a most convincing experience in favor of a divisible brood-chamber. Here, he says, was the same old condition of nearly twenty years ago, and for which reason he adopted a divisible hive. The question arises in my mind whether it will pay to make changes in our hives to suit conditions that do not come oftener than once in twenty years.

\*\*\*

"Favorable spring for bees," says the editor, page 382, May 15. "While the spring is a little late, and fruit bloom has been delayed, the conditions were never better for bees." Well, I should say so! Our bees are swarming two weeks ahead of any-

thing I have ever before known. Dandelions must get a good deal of credit for it, for they are getting to be a great help during May, stimulating brood-rearing and giving bees a chance to fill unoccupied combs with honey.

\*\*\*

We are under obligation to Arlie Pritchard, page 298, April 15, for his experiments on white rats and toads. We know that it sometimes happens that what will poison one thing will be harmless to another. Sheep will eat with impunity aconite—a deadly poison to man. We may not, however, conclude from these experiments that all creatures that eat live bees are immune to their stings. A lady of my acquaintance was bothered with skunks feasting on her bees. She set a trap, and caught the offender. She said she thought she would give Mr. Skunk all the bees it wanted and left it in the trap in front of the hive. But when the sun was up, and the bees had a fair show, it did not take them long to kill the skunk.

\*\*\*

LET SWEET CLOVER KILL OUT THE WEEDS.

My good friend Byer, page 349, May 1, objects to sweet clover because it sometimes comes up in meadows where it has once been sown. The same objection might be raised against alfalfa, as I see more or less of that growing in meadows where farmers have tried to raise it, and the plants that persist in remaining in the soil appear as hard and worthless as dried-up stalks of sweet clover when left till time timothy is fit to cut. Formerly the sweet-clover seed sown was one-half hard seed that would not germinate the first year. Now it is easy to buy scarified seed that will practically all grow the first season and prevent the later growths. There is yet much to be learned about the cultivation of this plant, and its greatest value may be in pastures where it will not harm the crop of timothy, but will produce two or three times what the pastures are now producing. Mr. Byer speaks on the same page of hundreds of acres of limestone formation about Brockville, used mostly for pasturage, that paintbrush has run over and ruined. Suppose this were sown to sweet clover. It would doubtless kill the paintbrush as that plant has killed other plants, and furnish more feed than they ever produced before, besides enriching the land so it will get better from year to year, rather than poorer as in the past.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The pictures of the bees on the bicycle, page 493, June 1, brought to my mind a story I once heard of a cow-boy who was riding a very wild pony. It chanced that the pony in some of his antics got a rear foot in the stirrup of the saddle, whereupon the boy said, "Say, if you are going to get on I will get off."

\*\*\*

Mr. Scholl says, page 471, June 15, that by his method "it is possible to take off more than a thousand pounds of honey in half an hour." Then he adds, "The writer holds an actual record of 1140 pounds of honey removed in exactly 28 minutes." I figure that to be just a fraction under 41 pounds per minute. No, thanks; I do not care to have any one slamming around among my pets like that.

\*\*\*

Dr. Miller says, page 469, June 1, "My observation has shown that bees decidedly prefer old black combs for either eggs or honey." I am not as ready to proclaim my observation as to honey-storing as I am to egg-laying; but I do know that Dr. Miller is entirely right about the egg-laying. I have seen queens skip a new comb to get to an old black one to deposit her eggs, not merely once but a number of times.

\*\*\*

Dr. Miller says, page 469, June 1, "An easier way is to let the bees clean the cappings." Well, it may not seem good manners for me to be scolding my elders; but, doctor, you should be a bit explanatory when making such assertions. One of the worst things we have to contend with out in this neck of the woods, where one range overlaps the other, is that just such work is practiced, even where disease is plentiful, and the results may be imagined in many instances where the bees from several apiaries may be helping to clean up the caps. The worst feature, however, is the tendency to encourage robbing, so I am wondering whether you set your cappings out in a kind of free-for-all way or have a perfectly safe way.

\*\*\*

In a recent conversation with Chas. W. Mixer, who is interested in bees in the Coachella Valley, I was informed that climatic conditions are a great factor with them, and that this season their crop would be short on that account. Mr. Mixer is in

the upper end of the Salton Basin, and Imperial in the lower end. Here almost the entire hope is in the irrigated alfalfa, and climatic conditions are all that could affect the crop, as the soil is irrigated the same from year to year. Mr. Mixer said, also, he thought much of their trouble this season was due to cold nights and not to very warm days. This seems to be the foundation for most of our climatic troubles—lack of heat at the critical time. It is undoubtedly a fact that we have more large honey yields when the springs are late than we do with extremely early seasons. Even when the weather is so cold and the spring so backward that we become impatient, hot weather usually comes with a good flow of nectar when the rains have been sufficient.

\*\*\*

## CLIMATIC CONDITIONS.

The older beekeepers are often sighting things in relation to honey crops that they believe are factors in the output. One of these situations is "climatic conditions." I have given this question some consideration, and have come to the conclusion that it is not always a mere myth. It is my opinion that we have been affected, to some extent, by such conditions this season. Vegetation on the foot-hills this season, until recently, has shown no ill effects of the lack of late rains, and all thru the blooming period of the sage there was no apparent lack of moisture in plant growth, yet the nectar was not in the plants in quantities heavy enough to cause a heavy honey-gathering. The button sage bloomed profusely, as did the white variety, yet no yield of consequence.

But what are the climatic conditions that so affect the honey yield? That is a hard question to answer. The variation in my scale-beam this season from day to day gave me a little insight to some of the so-called climatic conditions. During the white-sage bloom we had many cool foggy mornings, followed by moderately warm days. From one-half to three-fourths of a pound was all my scale colony could make in 24 hours; yet when we failed to have the fog, and the heat climbed up around 100 degrees for a day or two the scales would show from 1½ to 1¾ lbs. gain in the same time. This condition is typical of the white sage.

In the season of 1905 the white sage did not bloom much until July, by which time the temperature was going up around 110 degrees daily, it being an unusually warm spell, and such a crop of white sage has not been harvested since that time.

# BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas

Until recently I have believed that hives could be made with halved corners, nailed both ways in such a manner that they would stand just as rough handling as dovetailed hives. This is not true, however. Thru the purchase of bees we have quite a number of them in a few of our apiaries, made by skilled workmen, that become loose in the corners and lose their shape. There are several ways of making these corners so that the walls may be nailed from both sides, but none of them equals the dovetailed corner. This is especially important with us, since we handle all our colonies and the honey crop in hive parts, instead of individual frames or combs, and haul them long distances the year round.

\*\*\*

While there are various ways of fastening foundation sheets into shallow frames I like none so well as the melted-wax method used by ourselves, and described in detail some time ago. Our frames have plain, smooth, grooveless top-bars. These are laid successively on to our frame-rack for holding three frames, and the sheets of foundation are simply laid against the spacing-boards, close to the top-bar, and a spoonful of melted beeswax poured along this and the job is finished. There is no time lost in first working the edge of the sheet into a groove, which, by the way, becomes useless after being once filled with wax as well as weakening the top-bar. This plan is also much more rapidly done than by the methods employing the rolling or pressing to the top-bar about  $\frac{3}{8}$  inch of the foundation sheet. The latter method is also a more expensive one on account of the costly foundation that is wasted in fastening the sheet. Then, too, it does not adhere quite so well as the melted-wax fastening; and in this case the same wax, scraped from the top-bar again and again, whenever the comb is removed, is used to fasten other sheets.

\*\*\*

## QUICKLY REMOVING THE SURPLUS HONEY.

An interesting article was that of J. A. Green, p. 351, May 1—freeing supers of bees in out-apiaries by means of carbolized cloths laid over the supers to be freed of bees, in connection with some smoke.

I tried this some years ago, when mention of this method was occasionally made, but gave it up as impracticable, in our method of management at least. It may work better with others. First, it requires more time

in the proper preparation of the cloths themselves, and to remove the supers with them than with our method of hurriedly smoking out the bees, removing the supers, and shaking out the few remaining bees when the supers are carried to the wagon or truck. The second objection was the danger of the odor affecting the honey, which it did in several cases. While this may be overcome to some extent, perhaps by using more care and by the use of highly refined carbolic acid (as suggested by Mr. Green it is rather expensive just now), and with hired help, it is more of a problem to have things attended to with the same carefulness as when one does it himself.

## TWO FORDS BETTER THAN ONE.

Yesterday we returned from a trip to five apiaries where we put on additional supers of full sheets of foundation for bulk comb honey. At the last yard we "picked up" a load of the finished product and brought it back with us to the honey-house. With the supers, frames, and honey there was about 1200 pounds of weight to the little Ford truckload. We left at about 10 A. M., and were back at 6 P. M., covering a distance of over fifty miles, and going into and thru pastures and over rough roads. Today I read the editorial on page 466, June 15, in which the editor gives his experience with one of these small cars. My experience in out-apiary work with the Ford warrants me to add "amen" to what is said there. My dreams have been about one of the somewhat larger trucks for the heavier hauling, in addition to the small runabout, and the delivery and larger bee-moving platform spring wagon and two horses; and until recently I thought that my equipment would not be complete without such a larger truck. After trying it, however, I changed my mind. It was impossible to make the fast time with the large truck that I desired, nor to haul as safely supers filled with foundation or tender comb honey. A load of 84 of our shallow ten-frame supers on the larger truck resulted in a good deal of torn or jolted-down foundation sheets, while there was no such trouble with my loads of 50 such supers on the Ford, and yet we made far faster time. Taking into consideration, therefore, the great difference in expense, first cost, and the cost of upkeep thereafter, I have decided upon another Ford to enable me to take somewhat lighter loads but in considerably quicker time. In fact, most of the running around of the beekeeper can be more economically done in this manner.

E. G. Baldwin

## FLORIDA SUNSHINE

Deland, Fla.

Very timely, and pertinent to the statement on page 525, June 1, comes a letter from Mr. Roy M. Seammel, of Eau Gallie. Mr. Seammel was a very extensive bee-man at one time, having had 500 colonies that he owned and managed. Now he has about 70, but is building up to the former number as rapidly as he can. He says:

"Don't you think that good hives, carefully managed, means half the battle?"

"Good hives" for this climate means water-tight covers, in our opinion. Without that no hive is good nor even passable. So far we have found nothing equal to the metal covers, and are discarding all others for them. The second part of your query, "carefully managed," takes us out into manipulation, and we agree with you that manipulation is not only half but three-fourths of the battle, or even more, granted that one is in a good location for nectar, of course. Without that, no management or manipulation is any worse than another so far as profits are concerned!

"Do you sell your honey in bulk or in small packages?"

A limited amount I sell in one-pound glass jars, and five and ten pound tin pails, locally. Most of the crop is sold to dealers away, whom I know, to whom I ship in 60-lb. tin cans or barrels (seldom orange honey in anything but tin cans), and who take all I can produce of good quality. Poor grades I dispose of to bakers.

"Do you get any honey from the berry of the palmetto?"

In certain years, late in summer, when the berries are ripe, bees will gather the exuding juice from the bursting and over-ripe berries of the palmetto just as they will from the over-ripe and bursting apples, pears, and grapes in the North. This juice, even when stored in the combs, is not honey, nor can be. It will candy quickly, as you say; is black and strong, and fit only for feeding to stimulate breeding in times of dearth. I get none here, however, only on the East Coast, and then only in certain years, as, I understand, is the case with you also.

"Have you bees on the St. Johns River? I used to think that a good location."

None now—formerly a small apiary there. There are some good locations along that river, especially where one can get near enough to large orange-groves, as well as to the palmetto (saw and cabbage) that are

found more or less along the river banks and tributaries to it. It is better still if one can get a place where willow, maple, and elm are among the hard woods of the hammocks on the banks. The three latter furnish spring stimulation, and even surplus, according to some reports, tho I am inclined to believe such places rare. Mr. Clute, now of Sanford, seems to like the St. Johns for outyards—at least as navigation on the water is easier than on land.

"Do you get honey from heartease and Spanish needle?"

Not here; on East Coast, in certain seasons; but not more than is needed to carry bees over to spring, after last extracting in the summer, which, with us there, is after mangrove. I do not know of any heartease even there, but reports have come to me of considerable of it along the rivers inland, south of here.

"Do you know whether the yellow jessamine yields poisonous honey?"

We have "oodles" of the yellow jessamine (*Gelsemium sempervirens*), and bees are humming about it and burying themselves in the yellow blossoms all spring, from February to March, unless orange happens to be yielding well, then they seem to prefer orange-blossoms. We have never noticed any peculiar effects, one way or the other, from the activity of the bees about these blossoms, nor have we ever been able to notice that it had any effect on the honey supply, as it never makes a showing in supers. Nor do the bees seem to suffer from it at all (see A B C and X Y Z, p. 428, 1913).

We believe it is useful among other plants for spring stimulation. By the way, I should like to note here that the spelling in the A B C referred to above is jasmine, and probably an oversight on the part of the contributor. The so-called "yellow jessamine" should be spelled "jessamine," not "jasmine." The latter is quite a different plant—the *jasminum* belonging to the olive family, while the latter, the gelsemium, or false jessamine, is of the *Logania* family. The jasmine (Arabian *jasmine*, for example) has white flowers, and not yellow, like the yellow jessamine referred to above. See Baerecke, Ferns and Flowering Plants, Atlantic section, middle Florida; News Pub. Co., De Land, Fla., p. 111.

"Does the water hyacinth yield honey?"

Never, in all my experience, have I seen a bee on the water hyacinth of the rivers (*Piaropus crassipes*). I don't believe it has a bit of nectar.

To be continued

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York

CHILLED BEES, ETC.

"On page 416, May 15, Henry S. Bohon says he found a colony of bees starved out with a temperature of 10 below freezing, with the bees apparently dead. He brought the colony to the house where the warmth and a sprinkling of warm syrup brought all the bees to life. I never was able to bring a bee back to life after it had been frozen. It seems to me that 10 below freezing should freeze bees."

It will be noted that Mr. B. lives in Virginia, and undoubtedly on a spring morning the temperature could be 10 below freezing, and the bees inside the hive on the bottom-board not be frozen, as the hive and the warmth from the ground below would keep them from the frost of an early morning. Several times in my 40 years' experience I have brought individual bees and whole colonies back to life under similar circumstances. My first experience along this line was about 55 years ago, when as a boy in roaming the woods in the maple-sugar season I heard bees in flight. Looking up I located a colony of bees on their cleansing flight from a tree. The sun was shining bright, but the air was cool, so that some of the bees fell on the snow in the shade and became chilled. That night it rained all night, but kept mild for two or three days more. Father rather doubted my finding a bee-tree, and three days later I passed that place again. Having a little box in my pocket I picked up about a dozen of the "bedraggled dead bees," put them in the box, and the box in my inside vest pocket. Arriving home I took the box out to prove to father that I had found a bee-tree. On pulling out the box a buzzing was heard inside, and on opening it before a window every bee flew to the light.

In later years I tried chilling bees by shaking them on the snow near dark with a temperature of 35 to 40, then, gathering them up, putting them in the cellar where a temperature of 40 degrees was maintained, dreaming that whole colonies might be kept in a "hibernating state" by some such scheme; but from ten days to two weeks was all I could get, even when the bees had been made to fill themselves with honey.

On page 425, June 1, I see that Editor Root thinks that "a sudden chilling kills them." I do not believe that the suddenness has anything to do with the matter. The editor mentions "a zero atmosphere."

One of his slowly chilled bees would succumb in such an atmosphere just as quickly, for on the freezing of the juices of the bee that bee dies just as surely as if "crushed under the foot of man." It is in the freezing that the life goes out.

TIME FOR THE EMERGING OF QUEENS.

"Dr. Miller and H. H. Root, p. 427, June 1, are having a scrap over the time it takes for the emerging of the perfected queen from the time the egg is placed in a queen-cell by the mother queen. Which is right?"

Perhaps Dr. Miller will accuse me also of going by traditions; but it was in the year 1869 that I read from Moses Quinby that the queen is in the egg form 3 days, in the larval form 6 days, and in the pupa form 7 days, or 16 days from the egg to the perfect queen. He said that cool weather, to a certain extent, prolongs the time, and hot weather shortens it a little; but for all practical purposes, 16 days is quite dependable. Now, when the bees are becoming somewhat sluggish thru a desire to settle down for their winter nap I have known queens to take 18 and 19 days in perfecting. Then in the excitement and bustle of the swarming season, with the mercury soaring up in the nineties the most of the time, I have had queens emerge in only 15 days and two or three hours; but I have never known of a single queen emerging in as short a time as 15 days. In most of the short-time queens they have been proven to be such as are held in their cells by the bees after they are mature, when the figuring is done with swarming colonies. Bear in mind that a queen at maturity is as white and weak as any worker when it begins to gnaw the capping of its cell, and a newly matured queen cannot fly any more than can a newly matured worker. Such white weak queens do not push the covers off their cells and fly off while you are cutting the queen-cells off the combs, as we are told hatching queens often do.

HONEY IN CELLS CONTAINING EGGS.

Dr. Miller, on this same page, says that Arthur C. Miller has "a new one" on him in saying that "bees sometimes put honey in a cell that contains an egg." I do not now have A. C. M.'s article where I can turn to it, but I have known bees having laying workers that put both eggs and honey in embryo queen-cells, and to a certain extent in drone-cells, but not in worker-cells.

# GENERAL CORRESPONDENCE

## THE COST OF HONEY PRODUCTION

BY ARTHUR C. MILLER

*Prepared from an address delivered at Syracuse, Dec. 7, 1915, before the New York Association of Beekeepers' Societies.*

Do you remember when the colt shied at the paper and left you sitting in the dust in the middle of the road? Some jolt and some surprise. Well, that is just how I've felt every time I've tried to get any of the "boys" to tell us what it costs to produce a pound of honey. They have shied at the question even worse than the colt did at the paper. I've tried them several times, and now I'll try again; and perhaps this time I can get them to walk right up and investigate. As an aside, let me tell you that some of the "boys" I've tried were frisking around threescore and ten or more—full time they were steady enough not to side step at such an innocent question.

Why do I want to know what it costs, do you ask? What difference will it make? Even if you know you cannot get any more for your crop, can you? Fair question; and the answers are that I want to know if I am doing a profitable or a losing business. If the former, is it a fair profit—worth continuing? and if the latter, can I make it profitable or shall I abandon the business altogether? I also want to know what each step in the business costs me that I may know where I can better matters or stop some leak. That I get money enough out of the business to support me and have a little left over is not to the point at all. The same capital and energy put in some other line might pay far better; or even my time alone, perhaps, could yield me a greater income. Enjoyment and health are not under consideration now—just cold dollars and cents.

How shall we get at the cost? Just as they do in any business—find the basis of it and build on that. The basis is "capital and labor." First, we must determine the amount of capital we have invested; then we must determine the value of the labor used in working that capital. That our figures may be the more readily applicable to apiaries of different sizes, or to a plant embracing many apiaries, it is essential that we establish a unit of value; and that unit is the capital *per colony*, just as the mill men figure at so much *per spindle*. In the figures which follow, the basis used is of one hundred colonies. A larger plant would lower some items but increase others, while in a smaller plant the reverse would be true.

After consideration the hundred-colony basis has been deemed a proper one.

The capital per colony on this basis is approximately \$10, divided as follows:

Hives, supers, honey-boards, escapes, frames, and brood foundation, \$4.32; making up, painting, tools, extractor, tank, etc., 68 cts. Total, \$5.00. Cash for working capital, \$5.00.

The first items may vary a little under different local conditions; but from figures obtained from several sources I believe them to be reasonably accurate. The item of "cash for working capital" should equal the investment in fixtures and appliances. This is something that is all too often overlooked or underestimated, not alone in honey production, but in most lines of business. More failures come from having too little capital for the business than from any other one cause.

This cash capital must supply sections, crates, super foundation, food, cans, bottles, labor, freight, and take care of all the "overhead" charges. All these things must be paid for; and when the crop is sold the money expended for such items must be returned to the business. If you will consider these things a moment, I think you will see the necessity of the classification.

With the capital determined we must next ascertain the cost of using it, the "expenses" of running the business. The following items are to be recognized:

Interest, 6 per cent; depreciation and upkeep, 10 per cent; insurance and taxes, 1½ per cent; labor, 10 per cent.

This makes a total of 27½ per cent which must be earned each year before the business can pay the owner any profit. Let me explain these items.

Interest: It should be charged; because if the same capital were invested in a mortgage, for instance, it would yield the owner interest without labor on his part.

Depreciation and upkeep: The plant must be "kept up," which means both repairs and replacements; obsolete appliances must be superseded by new and better ones, so this item must enter into our determination of costs. Ten per cent is a fair rate at which to figure this. Some lines of business figure much more than this, while few figure much less.

Insurance and taxes: Few beekeepers insure their plant, and in many states they are not taxed; but these items should be estimated, for insurance is good business and taxes may be imposed.

Labor: The determination of this item was not easy. Labor at ten per cent means one dollar per colony per year. I have been told both that it was too much and too little. It does not mean a dollar just to handle a colony of bees for one season; but it does mean the amount you must charge against each colony for all the labor connected with handling it, the crop secured from it, and the labor of preparing that crop for sale. That does not have anything to do with the cost of selling it, which is another part altogether. We are now considering cost of production only; and getting it into condition for sale is part of that cost. This labor item has been figured for a skilled man at \$5.00 per day. The beekeeper should charge for his own labor as much as he could earn in any other line at which he is skilled. If he can earn \$10 or \$20 a day in some other business, then he must charge his time at the same rate if he goes into the honey business. Naturally the man whose time is so valuable is going to conduct the bee business on a scale sufficiently large to yield him such a return for his time. Some critics have questioned whether a beekeeper's time is worth \$5.00 a day. If his time is not worth that of any of the skilled trades he had better quit the honey business and hire out as a day laborer. But other critics agree with me that \$5.00 is a fair value to use in estimating the cost of honey production.

When it comes to an estimate of one dollar to handle a colony of bees, the crop therefrom, and the labor of upkeep, I can only say that the figure is the result of some careful records and figuring. If you differ, just go over your estimates and figures again before you refuse mine. At the worst, I believe you will be likely to place the cost higher rather than lower.

Accepting the percentages given, let us see what it costs to produce a pound of honey; but before I give you figures let me disturb your equilibrium by telling you that counting "sections" as equal to "pounds" of extracted, the cost of producing a crop of comb honey differs very little from producing one of extracted honey. "If this is reason, make the most of it!"

At an operative per-colony cost of 27½ per cent on a capital of \$10 we have an expenditure of \$2.75. The average per-colony yield from statistics in several states and Canada is given as about 50 pounds.

That figures as 5½ cts. per pound. If this estimate is wrong I believe it errs on the side of being too low rather than too high. Some may say they can get along with less capital, but they must have a care that it does not force cost up in some other place. Others may say that an increase in the average per-colony production to, say, 100 pounds would mean a cost of 2¼ cts., but it would not. While it would cost less to produce 100 pounds per colony than 50 pounds, it would not cost half as much. Don't get fooled there. The figures given are based on average production. If your average for good years and bad is above this, *your* per-pound cost will be lower, that is all. First be sure what your average for *a series of years* really is.

It will be noticed that I have not estimated the value of the bees. That was intentional. While the first few colonies are usually purchased, the rest are "grown," the product of "labor." The apiary may be decimated by disease, cold, or starvation, and we restock it by dividing or by swarms—in other words, by "labor." You say an apiary of well-stocked hives is worth more than the same hives without the bees. True, if you are closing out the business; and even so the presence of the bees merely enables you to get more nearly the real value of your hives and fixtures. In most cases the beekeeper raises his own bees, and then surely they cost only labor; and if he is buying an apiary he seldom pays more than the value of the hives and equipment, if as much, and that little more is very properly chargeable to labor. For the purposes of figuring the costs of honey production I have deemed this classification of the bees the proper one.

There is another very necessary explanation in connection with these remarks on cost of production, which is that the labor charge given is only for the time actually used in the work connected with one hundred colonies; but it gives the per-colony cost, which we must know. If a person is making honey production his exclusive business he must charge his whole year's time against the cost unless he is engaged in some other gainful occupation during the "off" season of the year. While the big operator has to charge a year's time to cost of production, it is distributed over so many colonies that the per-colony cost is not materially increased, and he has really less *unproductive* time during the active season to charge to cost.

The foregoing is submitted for your consideration and criticism. I do not ask you to agree with me unless you are satisfied

that I am right. I do believe that the basis of estimate you will find is right, tho you may differ as to the amount of investment

and cost of operation. If it is your pleasure to debate these items, stick to the "percolony" unit in your estimates.

Providence, R. I.

## EASY QUEEN-REARING

BY ALLEN LATHAM

Not a few beekeepers fail to renew the queens in their colonies with sufficient frequency because of the difficulty of getting the queens. They do not feel like buying so many queens, and they do not find it an easy task to rear their own queens.

The various methods in vogue will work in the hands of their originators. When some one else tries a well-advised scheme he runs upon snags. In the end the queens he raises cost as much as or more than queens bought outright. I have probably tried every plan of queen-rearing that has ever come to my notice—some with fair success, others with rank failure. Either I got too small a percentage of queens or else the queens were poor.

After years of trial and effort I stumbled upon a method which is giving me more uniform success than any other. It is so simple that it would seem as if any one could succeed with it, and so economical that even professional queen-rearers will probably find it worthy a trial. The objection to be found with the majority of methods of queen-rearing is that they give too few queens for the bees employed.

It is generally taught that a colony will not rear over a score of good queens at a time. This means the employment of a full colony of bees for some ten days and only a dozen or score of queens to pay for the expense. If that same colony can be made to turn out 50 to 100 good queens in the same time, it is easy to see that the expense is tremendously lessened. Many a year I have neglected to rear as many queens as I desired, simply because it meant the employment of so many colonies to do the work. Now one colony will give me all the queens I want in one batch.

The photograph shows that the cells tho numerous are good ones, and never by any methods that I have employed have more uniformly good queens been obtained.

This method in Connecticut can be used any time from April to September, but it gives the very best success during the swarming season. The steps to be followed are these:

1. Prepare cell cups to the number of queens desired up to 100. Fasten these closely together on slats, crowding them so

that 18 or 20 come within a length of 11 inches. This can be done by zigzagging them on a strip one inch wide. Two or even three such strips can be fastened in one frame. Two or even three frames can be prepared.

Not peanuts but queen-cells—illustrating Allen Latham's easy method of rearing queens.

2. Put small pieces of foundation at the ends of the strips so that the wax bees will have a chance to use up surplus wax, otherwise many cells will be engulfed in comb. Also put in a lower strip of wood with only foundation on it. These strips should be placed about 1¾ inches apart—enough, any way, to allow the cells to clear the strip below them when they are finished.

3. Select some strong colony in the afternoon—a colony which has a host of nurse

bees. Find the queen. Remove her and all the brood. If there are no combs well stocked with pollen and honey, then find such in other colonies. If there are enough bees leave a few on the combs of brood and set those combs with queen and bees in a closed hive near by. Now place one comb of pollen and honey in the selected hive, then place in all the prepared frames of cells, and then the other comb of honey and pollen. If it seems desirable, pour some water into the vacant cells of one comb. Put the cover on the hive and leave it till the next day.

4. The following day pick out the comb from which the larvæ are to be taken. Best results follow if this selection has been forestalled by putting in a sheet of foundation for the breeding queen to lay in, feeding the breeding colony so that there will be a fine lot of larvæ of the right age. Take the ready comb into a warm room which has a moist atmosphere, and where there are no drafts.

5. The royal jelly, which must be ready (and this can be obtained by removing the queen from some colony four days before, if one has no other source of supply), is now diluted with distilled water or else saliva. If saliva is used it is well to rinse the mouth out well so that all foreign substances likely to injure the larvæ will be removed. Dilute to the consistency of heavy cream. By dipping a blunt stick into the jelly, place a small drop into each cell. By this time the distracted colony has worked more or less over every cell cup, and it is ready for a larva.

6. The transferring of larvæ takes time, and there is danger of the royal jelly glazing over and the larvæ being seriously injured. One must work with celerity, and much speed will be gained if the most promising portion of the comb containing the young larvæ is cut out, and shaved down so that the picking up of an individual larva is made very easy. It is well, in case two frames are to be stocked, to do one and place that in the colony before the other is done.

7. Put the stocked cells into the colony. Feed each night for four days from one pint to one quart of much-diluted honey, unless there is a honey-flow. Do not feed after the fourth day, for by that time every cell is about to be capped, and feeding is useless. There is one exception to this. If there is a great dearth of honey on, it is well to feed enough to keep the bees fat and contented.

8. On the tenth or the eleventh day, according to the age of larvæ you select, all

cells must be removed and each given to a nucleus, or cared for; for when those cells are ripe the work may all be lost by the emerging of queens and duelings.

9. Most of the bees of the colony can be used to build nuclei; but if that is not necessary, then replace the frames of brood, young bees, and queen which now occupy the hive which, ten days or so before, was set near by. The colony will go on and show practically no ill effects from its task of rearing 100 queens.

From its lengthy description one might be staggered by this plan of rearing queens; but when once tried he will find that the method involves as little labor as any method in use, measured on the basis of the number of queens obtained. Indeed, it involves far less labor than most of the methods. There is no swarm-box nuisance attached to it; there is no need to shut bees up to get them distressed; there is no set time to be followed in regard to the preparation of the colony and the grafting—anywhere from six to twenty-four hours giving good results.

If one needs from fifty to one hundred queens he will find it very gratifying to get those queens at the expense of but one colony for ten days. And if he has no nuclei to care for the cells and emerging virgins, he can put them immediately into the colonies which are to be requeened. It is only necessary to remove the old queens three days before the cells are to mature. If this is done at a well-selected time, say just after the honey-flow, little if any loss can follow, because the colonies are without laying queens for some ten days or a fortnight. Also, there is but a small percentage of loss in wedding-flights when virgins fly from full colonies.

I have never tried to see how many good queens can be reared by this method. I have said from fifty to one hundred; but I really believe that a powerful colony could easily give two hundred or even more. It would be no task at all for a colony to feed 8000 worker larvæ for four or five days, and it would not be unfair to assume that the feeding of 300 queens would be equally easy. In my opinion the number is limited rather by the beekeeper's ability to get the cells grafted with sufficient rapidity so that they may be all equally cared for.

One statement more is desirable before closing. It will be observed that the arrangement of frames and cell cups is such that they lie bunched within the midst of a great cluster of bees. Much of the secret of success is in concentration.

Norwichtown, Ct.

One of the classes in zoology at the Germantown High School. "An intimate knowledge has been gained of one of the most remarkable phases of insect life."

## BEES FOR HIGH-SCHOOL STUDENTS

BY ADELENE H. JACOBS

That beekeeping can be incorporated in a course in elementary zoology has been demonstrated at the Germantown High School for girls in Philadelphia. It was a notable day in September, 1915, when a colony of Italian bees was housed in a double-walled hive on the lawn outside the zoological laboratory. Remarkably fearless, the students gathered around the hive and received their first instructions in the life-history and activities of the bee.

Instead of reading about *Apis mellifica* and looking at museum specimens of queens, drones, and workers, our pupils in groups of ten, protected by veils of their own making, began their study of insects at the buzzing hive. Here we watched the foragers returning with their balls of golden pollen; learned to distinguish the kinds of bees on a crowded brood-frame; became fa-

miliar with the cells used for storing pollen and honey, or in which were developing the whitish wormlike drones and workers, and observed the attendants cleaning a bee that had been spattered with honey. These and many other things we learned at first hand with keen interest and enthusiasm. In addition we found that biological problems of an abstract nature became more real and significant. Adaptation of structure to function; relationship between environment and individual development; instinct vs. intelligence; division of labor and communal life—all these topics were vitalized, and had practical meaning when interpreted thru our own colony of bees.

The pupils showed a sustained interest in the bees, even during the winter. They reported to us, now and again, that the bees were flying "at recess time" when an occa-

sional mild sunny day came. With the return of spring, our demonstrations at the open hive were resumed. Not only were those who had watched the bees in the fall eager to see the hive opened again, but new classes which had entered the school in February were curious about the big white box. With more confidence the teachers who had been studying bee-literature zealously during the winter months handled the frames before the ever interested audience.

It was one of the students who came into the laboratory on May 25 with the words that sent such a thrill thru us all: "The bees have swarmed! They're up in an apple-tree!" Forty feet up on the branch of an apple-tree was a wonderful compact conical cluster of thousands of bees which we had known heretofore only in books. A real problem confronted us. Never did a teacher have a more delighted and attentive class, remaining long after the dismissal bell to watch the hiving of the swarm. A new hive had been provided weeks before for just such an occurrence. The Germantown school was now the proud possessor of two colonies of bees.

In the fall of 1915, when school was resumed, the students were attracted to one of the hives, at that time increased in height by two supers. To give a practical turn to our study of bees, we sold the sections to the students. And very attractive they looked, too, in printed cartons on which we stamped the school name. Incomplete sections were cut into small cubes placed on crackers. Two students played shopkeeper, and sold these "tastes" for a few cents to the eager purchasers. These funds are to place the colonies on a self-supporting ba-

sis, so that we need not apply to the school board to defray expenses for the equipment of the past season and the coming one. Last autumn we had bought sugar for feeding, so that the bees would surely have sufficient winter stores. We also bought a new queen to replace the one reared in the old colony, and which had mated with a black drone. The offspring, hybrids, were unpleasant to handle in class demonstrations.

In our year and a half acquaintanceship with the bees there came the new experience of moving the hives. The old school was vacated on the first of November, when we moved into a fine new building. One day in December the janitors carried the two hives to their new stand. They constructed a wooden carrier or support on which they bore each hive a distance of two city blocks, being most careful to avoid jolting the hives.

When we tell of incorporating the rudiments of beekeeping with our lessons in zoology we are usually asked, "Do not the students get stung?"

The question is easily and definitely answered. Now and then a girl is stung, but there have not been any serious swellings among the students. They rather glory in their intense but brief suffering, for the spirit of martyrdom assumes strange forms in this age. In view of the fact that in the spring and fall over a hundred girls receive instruction at the open hive, the number stung is a very small percentage.

In any event, the lessons in zoology have been vivified by contact with a living subject, and an intimate knowledge has been gained of one of the most remarkable phases of insect life.

Philadelphia, Pa.

## HOW TO GET ALL THE HONEY FROM CAPPINGS

BY H. H. M'INTYRE

Any contrivance that will get all the honey from cappings, and have it stored and sealed in combs without danger of transmitting possible foul brood to more than one colony in the yard, will save beekeepers much disagreeable work, and thousands of dollars in spoiled and wasted honey. I have invented a plan along this line which I predict will supersede all contrivances for squeezing, melting, and draining cappings.

I use a cleaning-box made like the diagram shown herewith. It is very simple and inexpensive, and a pleasure to operate. I allow the day's cappings to drain over night in the uncapping box or tank, and

the next morning dump them into the cleaning-box. The bees will do the rest. If there is a colony in the yard slightly dis-

eased with American foul brood it is a good plan to use such a colony for cleaning the cappings, for the disease exists in the combs anyway, and it can be treated in the late fall after the work is over. The combs above the excluder may be combs that have been above an excluder over a diseased colony, so nothing is wasted.

The box may be any size to fit requirements, but one should be careful to get it large enough. I used the plan last season with a small box, and it worked so well that I feel safe in recommending beekeepers to use a large one. My new box is 4 feet square and 3 deep.

One would naturally ask what is to prevent honey dripping from the wet cappings above the screen down on to dry cappings below? I have had no such trouble, because I chop up my cappings at the end of the day and allow them to drain all night in the uncapping-tank, so that by morning there is not enough honey left in them to drip.

Furthermore, the bees take all the drip that comes their way before it has a chance to fall down on the dry cappings. I have had colonies that would take 30 pounds of syrup from a feeder in one night, so I feel confident that one colony will take all of the drip from my large box.

The galvanized screen that the cappings rest on should be  $\frac{3}{8}$  or  $\frac{1}{2}$  inch mesh. The bees, being on the under side of the screen, stick their tongues in between the chopped-up pieces of cappings and take out all the honey they can reach. Then I suppose they clear away the dry particles so as to reach the honey further in. At any rate the dry cappings fall to the bottom of the box.

I use a glass tube to connect the hive with the cleaning-box. This causes the bees to enter the box quickly, and also enables them to find their way back into the hive readily, as the tube permits a little light to get into the box.

## LET THE BEES DO THE WORK

### A Plan for Cleaning Honey from Combs after Extracting, or from Partly Filled Sections. A New Way of Finishing them

BY G. A. DEADMAN

Before putting away our extracting-combs in the fall or at the close of the honey harvest we much prefer having them clear of honey, as they are certainly nicer to handle, apart from the possible souring of honey adhering to the cells when put away direct from the extractor.

There are different ways of doing this. The common way, probably, is to place them indiscriminately on the hives. Apart from the possibility of having a cluster of bees in the super next the brood, which have to be gotten rid of when removing, there is more danger of spreading disease that may exist in the apiary. I am inclined to the belief that the little honey in each super is as good as lost when divided up among so many. It does more harm by the excitement caused than good.

The plan we have been using for many years, and described at the Ontario beekeepers' convention in Toronto, is as follows:

A stand or platform is made that will be large enough, not only for the colony of bees that is to do the cleaning up, but for five tiers of supers; viz., one tier on each of the four corners and one directly behind this colony. This stand should be large enough so that, when the supers are in place, there will be sufficient space between

each tier of supers to allow the covers to be placed on each tier. This space between the tier is covered so that no bees can enter from without. It is better to allow a little extra, so if the stand should sag somewhat in the center there will still be room enough for the covers. As will be seen in the illustrations a lath is nailed around the outer part of the bottom of this platform on which to rest the supers. A piece of lath two inches or so long is also nailed in the center corners for this same purpose. Now, when the hive containing the colony of bees is in place there will be a bee-space below, giving access to every super in each tier.

When making this platform, which, of course, varies in size, depending upon the size of the frame you use, a simple plan is to take an empty hive which is to represent the colony that does the cleaning up, and place it on a level place or floor. Next place a super on each side of it, one at each back corner, and one behind. Put covers on each, and allow half an inch or more between them. The space between the hive and supers is the width of the strip you will require to go between, which rests on the lath that provides the bee-space below. Now you can either make the platform a little larger and nail on a strip to keep the supers in place, or can make it the same

G. A. Deadman's stand with 20 supers of wet extracting-combs that have been cleaned up by a colony of bees. The cart is shown ready for the removal of the supers.

size and nail a lath or strip all around the stand. This is not really necessary, but it prevents any possibility of the supers shifting and allowing the bees to gain access from the outside. If they should it might be all up with your colony of bees that are employed in this way. The front entrance can be contracted to possibly two inches, as the bees, having access to so many supers, their forces are divided. Make the bottom of this stand either of matched lumber or well jointed, and that will not shrink. Some 2 x 4 scantling, or better, 3 x 4, make good supports to nail the floor to. If only two of these are used (which makes it easier leveling) then place them 8 inches or so from the end of your boards. This will prevent your platform or stand from sagging in the center, which it might otherwise do.

There is a choice between having enough stands to accommodate all supers that are not required for the fall flow, and leave them in there until ready to pack for winter, or to have only one, and have one colony do all the cleaning, removing the supers and replacing by others as fast as they are dry. The former plan has these advantages: Your supers are not taking up valuable space in the honey-house, and any danger from moth-worms is obviated. When removed late in the season not a bee remains, and the supers are so tightly held together that a tier can be lifted at one time. The

photo shows four supers in each tier: but we sometimes have five, and our frame is two inches deeper than the Langstroth.

For obvious reasons I select the first colony in any row or rows nearest the honey-house for this job. By this plan combs from diseased colonies can be kept by themselves, and then any free from pollen I consider safe to use again. I keep the others frequently for use again in such colonies; but that is another story.

I might say that supers are preferably put on these stands about sunset, or on a rainy day. Just as soon as these begin to accumulate in the honey-house we draw them out, even tho not sufficient to fill a stand, as more can be added any time. If colonies are in pairs one may have to be moved a little to make room for the stand, but the bees soon find their location.

#### FINISHING PARTLY FILLED SECTIONS.

Those who have had any experience in the production of comb honey know too well that it is very difficult to have every section completed, or sufficiently so as to make them all salable. Apart from those that may be sold as second class, there will be others that are not, tho possibly coming very near it, while there are others again that can only be extracted. We used to extract them by inserting half a dozen in frames made for the purpose. Not so now, however. Those that require only a little

If desired, partly filled sections may be placed over the colony, and the honey from the wet combs used to finish them up.

finishing to make them salable are put in a section super and placed over the colony of bees on the stand, while the others are put in section-supers also with no separators, first uncapping any that may be capped. We put the supers on the stand the same as the extracting-supers. The honey in these will be carried by the bees to finish up those on the hive.

It is a good plan to place a wet extracting-super below each tier of comb honey

so as to get the bees started. Of course, one can use wet extracting-combs only to finish unfinished sections. There are many sections that are practically filled, but not capped. These, when finished, may class as extras. Sections that are capped or partly capped, but very thin, should be uncapped. Otherwise the bees may build over the cappings, or back of them, making an irregular surface.

## THE SWARMING PROBLEM ANALYZED

BY J. E. HAND

I am aware that my views upon this subject will not be regarded as orthodox doctrine; but before judgment is rendered it is the part of wisdom to weigh the evidence carefully. For several years I have believed that the law of swarming is not correctly interpreted; and this conviction became a certainty when my mammoth 16-frame colonies built queen-cells and began swarming two weeks before clover harvest, with plenty of room in brood-chambers. This experience led me to look for the real basic cause of swarming, and resulted in the conclusions recorded in this article. While we cannot point with certainty to one independent factor as a sole cause of swarming, it has been ascertained that the queen is the pivotal point of the swarming problem. Give me a queen of undiminished fecundity and I will show you a non-swarming colony, proving the correctness of my thesis.

### THE LAW OF QUEEN-CELL BUILDING.

Queen-cells are inseparably associated with swarming; therefore, before we can fully comprehend the swarming phenomenon we must have a correct interpretation of the law of queen-cell building in its true relation to the law of swarming. While queen-cells are built under two different conditions, the basic cause of all queen-cell building is "supersedure," therefore there is virtually one kind of queen-cells with a manifold mission—1, to supersede a failing queen; 2, to supersede a departed queen; 3, to precipitate swarms. Nature has ordained that preconstructed cells shall be built upon the slightest indication of diminished fecundity of the queen, and at no other time. Queens are subject to the laws of nature and physiology; therefore the heavy strain upon the organs of reproduction required to develop several thousand

eggs per day often results in temporary exhaustion of fertility, causing the immediate construction of supersedure cells. This condition is likely to occur during the height of breeding, known as the swarming period.

#### THE LAW OF SWARMING.

It is well known that a capped queen-cell is an element of antagonism to a vigorous queen, and that, during her period of temporary exhaustion, or broodiness, a queen will tolerate queen-cells and assist in her own supersedure by laying eggs in them—a purely normal impulse analogous to that of a broody hen wherein the mother instinct predominates—and will lay eggs in queen-cells under no other conditions. By the same law of nature and physiology, the queen usually passes the broody stage and regains her wonted power of fecundity in a few days, in which condition the presence of capped queen-cells is an element of discord, and a reaction occurs which culminates in the precipitation of a swarm if other conditions are favorable; otherwise the queen will destroy the cells and resume her duties with rejuvenated energy. An open cell is not an element of antagonism; therefore the reaction occurs, and the swarm usually issues shortly after the first queen-cell is capped. The potency of capped queen-cells to precipitate swarms is abundantly demonstrated by the issuing of after-

swarms, often repeated as long as a quart of bees and a queen-cell remain.

From these observations the following deductions are drawn: 1, swarming is a momentary impulse and not a premeditated act; 2, preconstructed queen-cells are the *cause* of swarming, not the *effect*; 3, every queen born is cradled in a supersedure cell; 4, special swarm-cells, other than post-constructed, are purely nominal; 5, the presence of a queen of undiminished fecundity is proof against queen-cells, therefore immune from swarming. We prevent swarming by requeening before the zenith of fertility merges into broodiness, thereby equalizing the breeding season between two queens without exhausting the fertility of either. This method simplifies manipulation and keeps the brood and bees together without developing the swarming impulse, which is purely a matter of diminished queen fecundity. It would seem that colonies in large hives would be more likely to swarm than in smaller ones; but there is another angle to the situation. Queens cannot control egg production; and if time is wasted in looking for available breeding-cells, eggs are promiscuously scattered over the surface of combs much more rapidly than in normal laying; therefore such hives tax the fertility of queens more severely than larger ones. Under such conditions some queens drop several eggs in a bunch.

Birmingham, Ohio.

Our Ford runabout converted into a light truck, as mentioned editorially June 15.

## TIMELY HINTS ON QUEEN-RAISING

### Using Naturally Built Cells without Transferring

BY JOSEPH GRAY

The underlying principle of all queen-rearing may be condensed into four words—*crowded, clustering, queenless bees*. Some may question the queenless part of this statement; but the *principle* is there, even tho a queen may reign in another part of the hive.

Queens should be produced from healthy stock, and in a perfectly healthy neighborhood, therefore a strict watch should be kept for both types of foul brood, and, I am sorry to add, *Nosema apis*. As regards locality for a heavy or light flow I am somewhat undecided. I do know that my greatest hatch—40 cells on one comb—were raised during a heavy flow. The nuclei do well at such a time; and so, while a light flow may give a little less trouble from the crowding of combs with honey, still I rather favor a heavy flow of nectar.

#### METHOD.

All queen-raising falls under two heads—man-made cell cups and grafting, and bee-made cells and natural selection. I have always pinned my faith to the latter. “Queens raised direct from the egg” has been my slogan.

It is immaterial who first used the flat comb. Suffice it to say that in 1909 at the Lancashire Royal Agricultural Show, England, in a lecture on queen-raising I exhibited a quarter-frame hive and flat comb with 9 fine queen-cells thereon, and brought forth the principle of “crowded, clustering, queenless bees.” Do I still advocate so small a frame as 4 x 7? No. Why? Because the larger and bigger the cluster, the better, both for raising and mating.

At the present time I am using the full-size American standard frame here in the Far West. The more we can cut out the fads and make one article serve two purposes the better. It is next to impossible to store combs except on the colonies. The moths get them every time.

#### SELECTING THE BREEDER.

One season I was going thru 1000 colonies. At yard No. 7 I came across a colony that for two seasons had filled two supers to the others one. I never saw that queen, yet she was my favorite. Somehow I think it is habit; but I cannot help marking a queen a breeder if her colony shows exceptional honey-gathering qualities.

After honey-getting comes temper. At

yard No. 8 didn't we “beat it” double quick? Colony No. 4 was the mischief-maker. That queen did not reign long. She interfered too much with our work. The temper of the bees from my favorite queen was always even.

The drones, being the production of the queen only, are full-blood with the queen; the workers and virgins are half-blood, hence the drones should be the equal of the queen in color. I note the evenness of the worker's markings last. These are the index to the purity of the queen's mating.

#### THE EQUIPMENT.

Take a shallow super; make two saw-cuts at each end, as shown, and chisel out the side wall between the saw-cut, and level with the rabbet for a depth of about 2 inches, leaving 2½ inches below the frame. This allows the top-bar to drop in the slot.

and forms a pivot for opening and closing the frame. Two nails are driven thru the end walls as supports for the bottom-bar end of the frame. This allows the frame to be opened and closed like the leaf of a book, without removal from the super—a great convenience when said frame is covered with a big cluster of bees. It takes very little smoke to uncover the cells sufficient to examine or cut out.

Having previously inserted our combs into the breeding colony, we are ready to prepare for cell building. It is easier to

handle combs than hives, therefore a fresh hive is placed on a new stand, and the combs and queen that we do not want are carried to the fresh hive, leaving, besides the bees, two full combs of honey and pollen, which, along with two empty combs, are arranged as shown in the diagram. For vigorous cell-building use as many field workers as nurses. They bring in pollen, and add to the general air of prosperity. Add more empty combs as needed.

If all the bees are taken it would be best to cage the queen, remove a strong stock from its stand, and place the beeless hive in its place. The flying bees coming home make a colony, and care for the beeless brood. Later in the season the preceding colony of cell-builders can be utilized to care for the brood and queen, so that, while the fresh bees produce each batch of cells, only one colony is actually in use during the whole of the season.

PREPARING THE COMB.

Selecting a comb full of eggs, we use the cap of a fountain pen to break down the walls joining the cells, leaving the cells we desire standing with their eggs intact. A match-stick will remove the broken walls and damaged cells, leaving no opportunity for the bees to build two or three cells together. It is best to prepare the comb first and place it temporarily in a super; or if the colony is ready first, lay a comb of brood in place till the cell comb is ready.

After the cell-building comb is in position a strip of cloth or canvas the size of the frame should be laid on the frame, and over the canvas a sack which is tucked in and reaches down into the lower hive. The sack forms a connecting wall between the flat comb and the upright combs below. The center space gives the big cluster room.

the frame should be laid on the frame, and over the canvas a sack which is tucked in and reaches down into the lower hive. The sack forms a

Finish the work by marking the hive on the back as follows: 16/5 A, cells due. This means that the colony was prepared May 4 from breeder A. This allows the cells 12 days, and allows a margin of time for the apiarist to use the cells.

Mishaps will happen sometimes, and it is well to examine. The cluster may not form, or all the eggs may be missing; also, if not enough cells are started, another colony may be started cell-building.

THE NUCLEUS HIVE.

In this climate one needs no heavy double-walled hives for the nuclei; and as lightness and convenience are important factors I looked around to secure a box needing the least work to convert it to a nucleus hive. Apple-boxes fill the bill, one end making the two nucleus hive-ends 5 inches wide, allowing room for a three-frame nucleus. No dummies are needed when only one or two frames are used.

One of the difficulties of nuclei is robbing. The Dr. Miller wire-cloth tube entrance is excellent, but not convenient in use. Hence we employ the same principle. Our nucleus entrance consists of a 3/4-inch hole bored in the center of one end, then a groove cut half way thru the end. Over the center is two-by-three-inch screen. This makes an entrance away from the ground—a miniature alighting-board at each end, and the passageway protected from robbers. When desired a bit of soft paper or cotton will close the ends, leaving a screened entrance for ventilation.

MAKING NUCLEI.

If the brood has been spread according to the plan I gave on page 1041, Dec. 15, 1915, and repeated every two weeks, the making of nuclei is simple. When bees are flying freely, and most of the field workers are away from home, open a stock with as little disturbance as possible, taking out a comb of brood and all the nurse bees, also a comb of honey and bees. This should be sufficient to form a nucleus. Close up the entrance with soft paper, as previously mentioned, for one or two days. By this method nuclei can be made in the same apiary. The cells, when cut

from the cell-building colony, are inserted into the nuclei by cutting out a piece of comb and pressing the cell into the apex, leaving the space below for the nurses to crowd around. At the same time a cell so placed is neither crushed nor torn by crowding against the next comb.

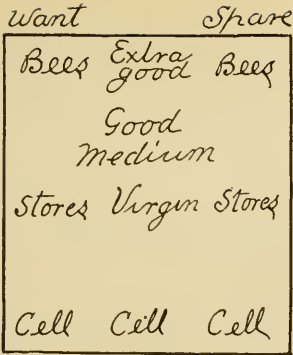

THE RECORD.

The nucleus record, as given in a previous article, I have slightly improved. The want and spare columns are the same; the simple

terms cell, virgin, queen, are the same except that three grades are added for the queen—extra good, good, and medium.

The queen is judged by looks; and experience enables the apiarist to detect the appearance of an extra-good queen. The nuisance of carrying around blocks, and the wind blowing the same way, is done away with by the use of harness rivets, which can be carried in the

pocket, and as many used on each hive as required. Small holes are bored at the points indicated, and the rivets pushed into the holes.

The diagram would read as follows: The two rivets shown in the want column indicate bees and cell wanted; the rivet at medium, queen combined with cell wanted, shows a poor queen; hence cell wanted because the queen is too poor, but she will hold the colony in shape if no cell is available. At the same time it is known there is a queen to look for and kill before inserting the cell. Furthermore, more bees are required, the nucleus having become depleted thru delayed mating.

## SUPERS OF HONEY ON A TOBOGGAN SLIDE

BY G. E. PHILBROOK

During extracting time I run my supers in and out of the honey-house on slides or tracks made of 1 x 4-inch material on edge. These pieces are set in the side of the building about 3 feet from the floor, and they project the width of one super outside and the width of two supers inside. A thin strip is nailed outside the track so that the supers will not run off. I grease the tracks with tallow, so that the supers will slide easily.

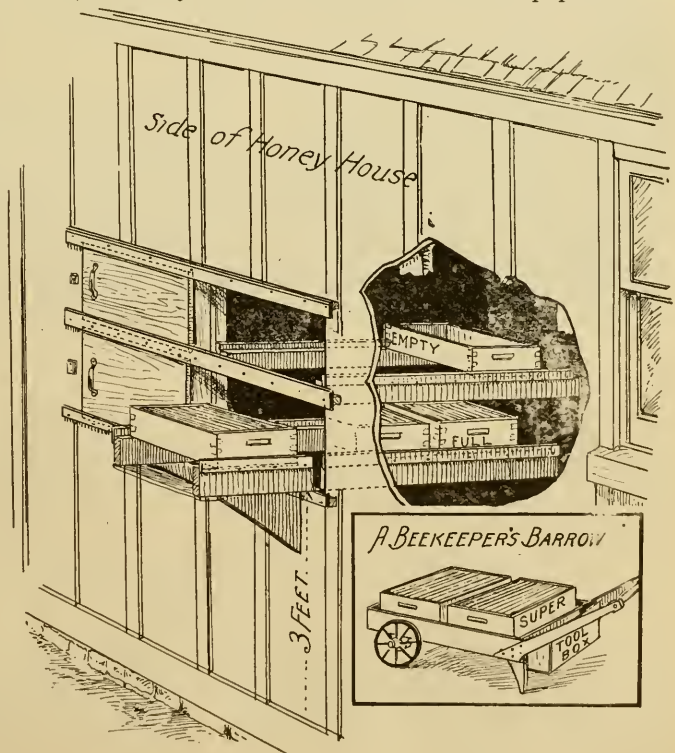

Another set of slides is put in just above the first one—for the empty supers. These do not project outside the building.

Each opening is provided with a sliding door on the outside of the building. When bringing the supers in, it is the work of but a moment to slide in the doors, push in the full supers, and pull out the empty ones.

I use a honey-cart that is very convenient. I make a box the size of two supers set side by side, and per-

haps 9 inches deep. Eight inches from one end I locate the axle on which are wheels 18 inches in diameter. The legs and handle go on the other end of the box.

I line the bottom with tar paper to catch

any dripping of honey and wax. Between the handles there is room for a tool-box.

#### HELPING OUT THE BEE-ESCAPE.

To hasten the work of the escape-boards I put them on about four or five o'clock in the afternoon; and then a little later, just before dark, I remove the covers of the

supers for a few minutes to let the bees out, at the same time blowing a little smoke in the top of the super. When the covers are replaced, so many of the bees have escaped that the few remaining are surely out by the next morning.

Lakeside, Cal.

## "FORDING" COMB HONEY OUTYARDS

BY H. O. CRAMPTON

My honey-house was used by the federal soldiers during the Civil War as a store-room and supply-house, and was the scene of much fighting, so the old citizens here tell me.

year. It is just coming in bloom now, May 22, and the bees will be working on it well in about a week if the rains don't come about that time.

I use a Ford to visit my out-apiaries. I

## BEE-CLUBS FOR SAN FRANCISCO BOYS

BY RALPH R. BENT

For the past few years considerable work has been done by the United States Department of Agriculture and the University of California in organizing agricultural clubs

for boys about the state. Every country boy has the opportunity of growing his acre of corn or raising his litter of pigs. But with the city boy it is different. It is im-

possible for him to get a plot of ground upon which to exercise his latent abilities in this direction. He can, however, keep bees, as they require but little space and may even be kept upon roofs of buildings if necessary.

The first beekeeping club for boys in San Francisco started with but five members. Under the leadership of the writer they secured a room in one of the San Francisco churches. Three of the five boys each purchased a hive of bees, and the other two looked eagerly forward to the time when they too might have some. Thus the first club was organized.

This club has now about forty members. The boys have their own officers, and hold regular business meetings. After the business is over, the leader or some experienced beekeeper, or other person with a practical knowledge of the subject, gives a talk on beekeeping. Some evenings the entertainment consists of a live-bee demonstration. At other times they have the use of a stereopticon and set of slides to illustrate lectures on particular phases of the subject. The motto of the club is, "A Million Things to Learn about the Bee."

After the program of the evening is over, the boys supply themselves with honey to sell. This honey is put up for them by one of the local dealers and bears their own label. This honey they sell at a good profit, the proceeds from which go toward additions to their bee equipment. The meetings close with honey refreshments. Parents,

being always welcome, often come to visit the meetings.

On Washington's birthday, Feb. 22, all the boys, as well as all adults living about San Francisco Bay who were interested in beekeeping, met at the writer's home in Sausalito. This is a little town at the foot of the hills in Marin Co., just across the bay from San Francisco. Here they held a bee-club picnic or field day. Every one brought his lunch and prepared for a thoroly enjoyable time. Live-bee demonstrations, lectures, and practical working explanations of the hive and fixtures constituted the program of the day. Those who were interested started a collection of the honey-producing flora of that part of the state. A large number of people who had never seen the inside of a hive before had the opportunity to work practically with the bees and handle the frames. Efforts were made to organize better the clubs in the various towns, and make it possible to have a boys' union apiary, located in San Francisco.

As time goes on and this work grows, many clubs will be organized about the country. The greatest problem will be to find capable leaders who are willing and anxious to give a part of their time to such work. It is hoped that these clubs will some day extend into the schools and institutions of learning in our country to such an extent that young people may come more and more to learn of the mysteries of nature thru these wonderful insects.

Sausalito, Cal.

## THE ROLE OF INSECTS AS CARRIERS OF FIRE BLIGHT

### A Reply to the Criticism, page 384, May 15

BY PROF. H. A. GOSSARD

In GLEANINGS for May 15 is a review, not of a bulletin published by the Ohio Experiment Station as your wording might lead your readers to suppose, but of a paper read by me before the Ohio State Horticultural Society; therefore whatever of blame may be attached to its publication must rest upon me alone, for no other official of the station is in any way implicated.

Now, a paper that gives rise to so many and such gross misunderstandings as you gather from it would certainly seem to need some additions or explanations to make its purport clear. You have gotten an entirely wrong idea as to my attitude of mind and beliefs regarding the entire question. The usefulness of the honeybee to the orchardist can hardly be called in question, no matter if it does carry blight; and the pre-

mise manner of the disease-transmission is yet less important if the bee is conceded to be a numerous carrier. The real question under investigation is, regardless of whether bees are or are not carriers, can they be so handled that they will prevent or reduce the damage incidentally caused by themselves and by other carriers of the blossom form of blight while performing the indispensable work of pollination? Since the honeybee is the only one among the pollinators that is subject to human manipulation for a definite purpose, it is the only insect in which a possibility inheres of being advantageously used for such an end. The mode or modes by which it transmits the disease may be helpful in determining the practicability of employing it for such use.

If I have any prejudice regarding the

status of the honeybee as a useful insect I must confess that, rooted in my mind only a little less firmly than the law of gravitation or of chemical affinity, is the conviction that the age-long association of the honeybee and of the fruit-grower cannot be dissociated as a permanent or general practice, on any account, without great and useless losses to all who make use of fruits or seeds or the plants grown from such seeds.

If the choice had to be made between the extermination of bees from the earth and the total sacrifice of the two species of fruits—apples and pears—most affected by blight, I confess that, were I consulted, I would at once give the decision to keep the bees and then makeshift with other fruits of which there are plenty in the world. The sacrifice of two or three species of fruits, however important, would seem to me of less consequence than the immeasurable damage that would ensue from the destruction of our most important pollenizer, and

The kind of swarm that always looks good. From Page Bros., Avon, N. Y.

the one subject to human control. I am not conscious of any other belief that might disqualify me for such an inquiry; and I regard this creed as legitimate, for, without being a scientific dogmatist, one must adopt at least a few broad and accepted principles as already proved, against which to measure the facts he accumulates or the theories he forms, to ascertain if they harmonize.

You make an inference that, if the hive should be found a distributing center for germs, the bee must at once be considered the very worst of all carriers, and seem to think the conclusion axiomatic. Now let us shift the viewpoint. I think that both fruit-growers and beekeepers alike agree that blossom-blight does not appear to a great extent until some time after the blooming season has opened, and that in some seasons, like the present one, it arrives very late or not at all. I am quite sure the hive is beyond all reasonable suspicion in the spring, because, so far as we know, the germ does not live in honey for much longer than 70 hours. If, therefore, the orchardist keeps blight centers from his own orchard by trimming them out, and puts a sufficient number of hives in the orchard before the bloom appears, will he not insure the earliest pollination possible, and have a larger number of fruits beyond the danger of blight before it arrives than he could otherwise secure? If the bees themselves carry it later, is it not the more necessary to have them present in abundance, while still clean, to do as much work as possible before the blight-wave appears? If, at the end of the blooming period, they should be carrying it more rapidly than at any other time, whether from flower to flower only, or in accelerated degree by adding distribution from the hive, is it not the more necessary that, as soon as the bloom arrives, there be in the orchard an abundance of clean bees to insure the earliest pollination possible of every available blossom before the blight-wave appears? Whether a removal of the hive at some stage of the work might be advantageous is an additional question. But is there not a possibility here of manipulating bees to the mutual advantage of both the beekeeper and the fruit-grower? Is it much of a paradox that the orchardist who trims blight from his orchard, and keeps many hives of his own instead of depending on his neighbors' bees, almost uniformly has a larger crop and suffers less than his neighbors from the effects of blight? I plainly stated in the paper criticised that I did not think any developments relating to the manner of distribution of blight would

change the status of the bee as a beneficial insect in the orchard, and still maintain that opinion. On the contrary, as suggested above, it seems to me the bees may be so manipulated that they will, to an important extent, reduce blight damage, regardless of any and all modes by which it is transmitted, either by themselves or other insects. Your conclusion does not appear to me to have been axiomatically correct at all. The above questions are frankly speculative and interrogatively stated. The paper you criticize was frankly speculative, and an "interrogation-point followed the heading, 'Is the Hive a Center of Infection?'" Much scientific work is first based on a theory which is later tested exactly as I wished to test this question. We have not yet taken the record on this season's work; but there would seem to be little likelihood of securing data, for there was almost no blossom-blight in our orchard. The question seems to me to be subsidiary—one on the side—and, however answered, not likely to injure either the keeper of bees or the orchardist. It seems to me that every bit of light we can obtain on this question is certain to benefit both classes, for certainly the mutual dependence of our fruit-trees and bees upon each other is too well established to be shaken by such a comparatively trivial question as to their method or methods of transmitting a single disease, affecting only a few species of fruits, and which has been with us for scores of years without exterminating these fruits, and under conditions that strongly suggest that said fruits can be partially freed from blight effects by the intelligent use of bees. If I erred in raising the question so early, as to the hive being concerned in the transmission, it was because I, like you, was relying too much on what seemed to be axiomatic reasoning, but I do not understand how anybody could conclude that I supposed I had answered the question, and I do not see how I could wish to answer it finally one way more than another, since my opinion as to the usefulness of the honeybee would hardly be modified at all by the result. We are doing, and have been doing for three seasons, many of the things you criticize us for not doing, but have not reported them because somebody else reported them first, and the results were, therefore, already in print. The paper in question was not intended for wide circulation, and no attempt was made to give a balanced treatment of the entire subject. The fruit-growers simply wanted to know if we were trying to advance somewhat the knowledge already possessed about the disease, and if we were making any

progress beyond what was already known to them.

In some places in your critique you seem to me to be unfair in the extreme in the impression you give your readers as to the character of the paper read, as in this:

"These facts should satisfy any prejudiced defender of the bee, to whom Professor Gossard jokingly gives the name 'bee monomaniaec.'"

The paragraph in my paper from which you quoted read thus:

"If any quarantine monomaniaec proposes to banish bees to restrict the spread of blight, I favor immediately incarcerating him in a cold-storage plant and lowering the temperature until he can dream of nothing except fragrant flowers, humming bees, and summer weather. The bee monomaniaec who will believe nothing at all adverse to his pets is still nearer sanity, in my opinion, than the extremists who suppose that the Creator and all his creatures and laws can be regulated by legislative enactments."

Two swarms clustered together on a 1/2-inch limb of a peach-tree, Sent by Daniel Whitmer, South Bend, Ind.

The paper was frankly and aboveboard speculative, and I am sure it was not misunderstood by those who listened to it, as the discussion following the reading proved. However, your criticism of some other phrases and expressions in the paper are quite justified, for I perceive, now that my attention has been called to them, that they might be construed to imply a wish to obtain certain results, when I meant we were merely seeking to learn if certain facts would be obtained which would agree with the theory interrogatively propounded. I hope these slips of language, due to rapid writing of a paper, against time, for the Horticultural Society, will be interpreted as they were meant and not as they were written. In your conclusion you express the

hope that I "will not drop the problem until I have found out how much truth there is in the theory." Thank you most heartily for the implied confidence that I will give an honest report. I esteem your belief in my integrity much more than I would your confidence in my scientific activities, tho, of course, I should appreciate both. All the work has been so checked, and will continue so to be, that I could not give a wrong report, even if I were so minded.

May I ask if you will give space in your paper for this somewhat extended reply, in justice to the other officers of the Ohio Station, as well as to myself, and I shall much appreciate the kindness.

Wooster, Ohio.

## COMB-HONEY PRODUCTION IN OUT-APIARIES

BY W. A. LATSHAW

About May 1 we go over all our bees to make sure that none lack for honey, to feed them up, to clip all the queens' wings, and to help out the weak somewhat by giving frames of brood and bees from the stronger colonies. Thus we keep doing until we have them fairly well equalized, and shaped up in good condition for the raspberry-clover honey-flow, which begins here about June 9, and with it swarming starts with a vengeance.

With the swarming season at hand it becomes necessary for us to visit our bees more often, especially when it is at its worst; and this we do, making the rounds once each week to each out-apiary to give more storing room, and to take off the finished comb honey, and case and grade it, and to prevent and control the swarming.

Now, our method of swarm control and prevention is very simple. During the height of the swarming season we go over all the colonies and cut the queen-cell out of all that are preparing to swarm, once each week, or every seventh day. As the swarming season advances, and when the swarming mania begins to wane, it is necessary to go over them for swarm-cells only once every ten days; but during the worst of the swarming we have found it best to cut cells once each week, especially as we have to make the weekly visits anyway, to take care of the finished comb honey, and to give more room; for when swarming is worse, honey is "worse," provided your bees are prevented from swarming, and they will be if you have the queens' wings all clipped, and make a careful job of the cell-

cutting, being very careful not to miss a single one.

Only the hives that are preparing to swarm are opened during our cell-cutting rounds, and this we ascertain by turning the hives one after another off their bottom-boards (which are loose) and smoking the bees back off the lower half of the brood-combs, so as to be able to see the queen-cells, if any, that have been started; and only such as have queen-cells started are opened, it being necessary only to turn the rest back on their bottom-boards, and to proceed to the next. In this manner an out-apiary can soon be looked over for swarming, and the cells cut out, provided you have a big smoker and use plenty of smoke in the smoking-back operation. Another thing, don't be afraid to switch the hives around on their upside-down corner, or turn them upside down, if need be, to get the light so you can see down in.

If you do a good job of looking for cells and cell-cutting, and have your queens' wings all clipped, and do it regularly once every week or ten days you will be absolute master of the swarming problem so far as comb-honey production is concerned.

When we wish increase we make it naturally by living swarms that issue during our visits to the out-apiaries, or else we take two frames of brood and bees with the queen from the old hive, then place them in the center of the new hive on the old stand, and then set the old parent colony off on a new stand and give a ripe cell. This throws the working force mostly with the two frames of brood and bees and queen on the

old stand, and the brood mostly with the old parent hive on the new stand.

All sections are started, supplies worked up, and hives nailed and painted, at the out-apiary honey-houses where they will be needed; and in the same manner the honey is scraped, graded, and cased ready for the market at the outyards. Most of this work is done by our crew of helpers which we take from yard to yard during our weekly visits, some doing the shop work, while the rest are busy with the bees, tho we sometimes find it necessary to make special trips to work up supplies. We use a Ford auto to go from yard to yard and to do our light hauling with, and find it a great convenience.

As soon as the honey crop is over, which is about the middle of August here, the escapes are put on, and the supers stored

away in the honey-houses until next season; and then if any of the hives need repainting, they are repainted at this season of the year. We try to see that all colonies are headed with good queens during July and August.

All colonies are fed for winter between September 15 and Oct. 1, and we make sure that every colony has an abundance of stores to last until fruit-bloom the following spring. In order to make a certainty of this matter we have scales rigged on a wheelbarrow, and go down the rows and weigh every hive, and mark the weight on the back of each. Then each is fed so as to contain 25 lbs. of stores.

Our bees are all wintered in the cellar, and are hauled to and from the out-apiaries on sleds.

Clarion, Mich.

## SHOULD THE POETRY BE SEGREGATED?

BY GRACE ALLEN

[By an oversight the following protest or "retort courtoeous" referred to by Mrs. Allen, p. 428, June 1, was held over, tho written just before the appearance of Mr. Baldwin's reference to Dr. Phillips' views of poetry as given in *The Beekeepers' Review*, page 89, March 1.—ED.]

And now see what has happened! A great scientist—even our very own beekeeping scientist, Dr. Phillips, so universally respected and so earnestly studied—has said that we ought to keep our poetry on a separate shelf from our practical working prose! And then Prof. Baldwin, for all the courtly (and thoroly appreciated) bow with which he ends, says in effect, "Aye, aye, sir!" But now aren't you glad, all of you, that God doesn't run the universe on that separate-shelf system? Had he felt it necessary or wise to divorce beauty and poetry utterly from practical everyday work and necessity he doubtless could have made some satisfyingly prosy fruits without the scarlet of the apple or the gold of the orange or the poetry of green, sunlit trees, or the shower of fairy bloom in April and May. He quite surely could have caused the earth to bring forth some pretty sustaining and nourishing meal and flour for our bread without the poetry of fields of grain swaying and rippling in the wind and shadowed by every passing cloud. He need not have put the scarlet on the tanager's wings nor the song in the throat of the mockingbird, nor let the bees hum so rapturously in June. And he could doubtless have skipped the rainbow altogether. But he did not. He spread beauty all around over our common fields and hillsides, made birds to sing even while we labor, and shot all our days thru and thru with shining light. Merely to make a

practical day and night, need the sun come up and go down again in such a trailing glory? Even the land and the water God has not kept completely apart, in dread of that mud referred to as the result of their mixing; but he makes growth and even life itself quite dependent upon the combination. for the dry prose of the dusty earth needs always the poetry of living water on it and in it and thru it to bring growth and flowering and fruit.

Or to be a bit more scientific, as perhaps the occasion demands, when the ancient nebulous mass cooled and developed and grew into this world as we know it today, not even evolution in the process or the study could ever separate the poetry of living growth from its prose. There are no separate shelves in life nor in human hearts; for over all this fair earth people thrill to sunsets and babies' eyes, and orchards in bloom and stars in the sky at night, while women everywhere sing to their children, and men go even into battle with a song on their lips. Are you not glad it is so, dear people, scientific and unscientific? And you who love bees, will any one of you handle your frames less carefully or introduce your queens less skillfully, or sell your honey less profitably, or go into winter quarters with an ounce less packing around your hives, because you have been a "great lover" of the poetry of swift silken wings shining in the sun? or because you have let

the grinding wheels of the day's prosy routine pause a bit while you catch the rhythm and beat of the great heart of things? or because you let yourself drift out for an instant into the infinite depth of wonder

and dream and poetry and prayer? I find that hard to believe, because of my faith, my many faiths, in beauty and poetry and science and people and God.

Nashville, Tenn.

## A SIMPLE METHOD OF ADVERTISING HONEY

BY MAURICE E. MILLER

I read with interest Walter S. Poulder's article, p. 151, Feb. 15, on using stamps to raise money for the purpose of advertising honey. That idea works very well for the Red Cross Society, because people are willing to support a benevolent institution; but I fear that, if tried in the interest of honey-producers or any other self-supporting business, the results would not pay for the trouble.

I have before me a form of advertising which I believe would work admirably for bringing attention to honey, and attention spells sale. A certain concern manufacturing roofing makes up a double letter-head, the two inside pages of which are filled with catchy advertising regarding their product. These are printed by the thousands, and distributed in lots of a few hundred each among the dealers handling their goods. These dealers have their own regular form of letter-head printed upon the first page, and use them in their daily correspondence.

To me this idea presents unlimited opportunities for advertising if used by honey-producers. In the first place these double letter-heads with the inside pages printed with catchy information, such as the food value of honey, uses of honey in cooking, interesting facts in regard to the cleanliness

of honey, etc., could be produced in large quantities for a nominal sum. Judging by the present price of a good grade of bond paper I believe these could be produced for four or five dollars per thousand, which is little if any in excess of what most beekeepers have to pay for their letter-heads in small lots. This would permit them to be distributed among a vast number of people, but would not be the limit of possibilities of this "double-purpose" letter-head. Beekeepers wishing to advertise still more could furnish these in desirable quantities to dealers handling their goods. Dealers would be glad to use them, as the only cost would be the printing of their own form on the first page, and a sale thru their use would mean a profit to them as well as to the beekeeper.

I believe that this idea, if tried out, would prove to be the most effective method possible of advertising without raising an enormous sum, such as would be necessary to float a campaign of extensive magazine advertising. Each beekeeper who uses these letter-heads and distributes them would be independently assisting in a co-operative plan that would spread thruout the country, and each would receive results in proportion to the effort he extended.

Addison, N. Y.

## MY WAY OF HEADING OFF SWARMING

BY J. P. BLUNK

The easiest, quickest, and surest way to head off swarming is the plan I am now using, which I think has all the earmarks of the Davenport "swarm secret." Prepare a hive with an empty comb to catch the pollen, a comb of suitable brood from which queens can be reared, and fill up the rest of the space with dummies. Put this hive on the stand of any strong colony that is preparing to swarm, with a couple of supers on top. Put on a good wire escape-board, and on top of all set the strong colony without its bottom-board. The flying force will all go downstairs in twenty-four hours, and so few bees will be left in the original hive that they will tear down

all queen-cells which might be on the combs—the queen, of course, being left in the old brood-chamber on top.

The queen will keep right on with her laying. In fourteen days take the old hive off, remove the queen, or leave her, as desired. If one desires to requeen, now is the time. Put one of the queen-cells built in the lower story in the old hive and set it on a new stand. Contract the entrance and remove all cells except one from the new colony. Supply frames of foundation, put on more supers, and the job is done.

If no increase is desired put the combs in the prepared hive below back in the old brood-nest, after removing the queen from

the latter. This will not take long, as the bees are scarce, as above mentioned. It is necessary to remove all queen-cells but one on the frame of brood in question.

If desired, the colony may be made up from two colonies. Set the prepared hive on top of the strong colony; place the escape between the two upside down to run the bees up into the prepared hive. Close the entrance of the lower hive; slip the upper prepared hive far enough ahead on the escape-board to provide an entrance

over the old one below. Put on a good supply of supers, then another escape on top of the super, and finally put on another colony without the bottom-board, as mentioned above. Remove the old hive in forty-eight hours, or leave it longer as desired. The flying force is now in the center hive.

Mr. Davenport was shaking to head off swarming when he discovered his plan. The reason he never had a failure was because bees without a queen will never swarm.

Moorland, Iowa.

## TEN-FRAME HIVE WITH SUPER MAKES IDEAL BROOD-NEST

BY L. K. COLE

J. J. Wilder's plan, page 454, June 1, is so near the plan that I use that I wish to add my experience. I have done a great deal of experimenting in the production of both comb and extracted, using a single ten-frame Langstroth body, a double body (and contracting to one body at the beginning of the white honey-flow), a single body, and one shallow extracting-super. I have also used the Danzenbaker hive and system in the production of comb honey. By repeated experiments year after year during the past twelve years I find that for this location a ten-frame Langstroth hive and a shallow extracting-super, each containing five Hoffman frames, a regular division-board on the east side of the body, preferably, and a  $\frac{7}{8}$ -inch division-board with spacing strips on one side, all held together by two super springs, make an ideal brood-nest for this locality. One has full control of all colonies at all times. The honey can be put just where it is wanted, and the brood-nest is large enough for the most prolific queen. The division-boards on both sides give plenty of ventilation; and by using the  $\frac{7}{8}$  board with the spacer, a little more room is provided for easy removal of the frames.

In the extracting-supers I prefer full-depth frames, spaced wide, by using only eight frames to the ten-frame super.

In producing extracted honey, all hives are looked over in the spring and graded good, fair, and weak. Each colony in grade 1 is given a shallow extracting-super, and in one or two weeks (depending on the weather) the colonies in grade 2 are also ready for the supers. The colonies in grade 3 are worked in different ways to get them built up to full strength.

When nearly full of bees, brood, and honey, the colonies of grades 1 and 2 are given a set of extracting-combs with an ex-

cluder between the brood-nests and super, whether much honey is coming in or not, as the super forestalls any preparation for swarming.

When the first super is perhaps two-thirds full, it is raised up and an empty super placed underneath, next the brood-nest. By tiering up in this way, especially since the queen has an abundance of room for egg-laying, one practically has control of swarming.

The upper portions of the brood-chamber (that is, the shallow super) can be manipulated in any way with any other colonies needing help, with stronger colonies.

In the fall, if the fall honey-flow is not suitable for winter stores, the shallow supers may be left in place until all the honey supers are removed and the honey-flow is over. Then this shallow super, which is the upper part of the brood-nest, may be removed. Under such conditions the deeper part of the brood-nest will not, as a rule, contain enough honey for winter, especially in case of colonies that have good queens. Sugar syrup can then be fed. If stores of honey alone are desired, the shallow super can be placed under the deep one long enough before the fall honey-flow is over so that the deep brood-nest will contain at least 30 pounds of honey (35 or 40 would be better, perhaps). Then when it is time to prepare the colonies for winter the shallow supers can be removed, as they will contain very little honey.

In a good year I have produced as much as 250 pounds of extracted honey from a single colony; or in case of colonies run for comb honey, 202 pounds, with plenty of honey left over in each case for winter. I am sorry to say, however, there are too many seasons when the production of fancy comb honey is out of the question.

Stanton, N. J.

# Heads of Grain From Different Fields

THE BACKLOT BUZZER

BY J. H. DONAHEY

*They say the reason the patient camel has such an ugly disposition is because they have never found the right word to say to him, and about the time you think you have found it for the leas you discover that they've changed the countersign.*

## Contentment.

Sitting in my sunny kitchen  
 With my simple lunch,  
 Sometimes bread and milk and honey,  
 Sometimes fruit to munch,  
 Straight across the light I'm looking  
 Toward a queer old shed,  
 White, except two nut-brown doorways  
 And the roof o'erhead.

There across the ragged roof-line  
 And the doors below,  
 Back and forth the bees go flashing.  
 And I love it so!  
 Then I think of formal luncheons  
 With their chit-chat ways  
 And thank God for bees and kitchen  
 And my home-grown days!

Nashville, Tenn.

Grace Allen

## Black Italian Queens the Mother of Well-marked Italians.

I have an Italian queen that is of good color, and produces uniform three-banded bees of a good yellow color; but every queen reared from her is as black as coal. Can you give a reason for it? Did you ever see such a case? I bought her for a breeder and

have reared several queens from her, and every one is black. Her bees are uniform and gentle, and hustlers. Her sisters give nice yellow queens and bees, her mother was a five-bander and a good breeder. I have not had time to test any of these black queens yet, so I can't tell what they will do. But they are as lively as crickets.

I have also struck something new. I have a colony that will accept artificial cells all right in large numbers, but will not accept the royal jelly and larvæ put into them. Why is that?

Gimlet, Ky.

W. L. Lovejoy.

[There is a great difference in breeding-queens. One queen that will produce uniformly nicely marked Italian bees will also produce queens that are quite dark, some of them black. We have sometimes had to reject an otherwise good breeding-queen because her queens were too dark to suit the trade. One of the blackest queens we ever had produced very nice Italian bees, very gentle, good workers, having three yellow bands, altho the third band showed rather indistinctly.

Sometimes a queen-breeder is a little careless in his treatment of the cells for the queen. If ripe queen-cells are exposed to a chilling atmosphere, the queens, when they hatch out, will be dark, sometimes almost black.

Some years ago we had two different queen-breeders working for us, and both breeding queens from the same queen. The queens that one breeder reared were black, while those of the other were light-colored. When we came to examine into the causes we discovered that the man who was having the black queens was careless in the handling of his queen-cells. He left them exposed until they became partially chilled. After we cautioned him he was able to get as bright-colored queens as the other breeder.

We believe you will find that the black queens will be as good as any that you ever had for actual work; but if you enter into the business of selling queens you will find the trade will not take these dark ones.

In relation to the last question, possibly there was something wrong with the royal jelly. Perhaps it was too dry. You should get it of about the right consistency. We know of no reason why a colony should reject queen-cells containing royal jelly unless the royal jelly itself was not quite right.—Ed.]

## Sealed Brood Only for Cell-building Colonies.

The writer was very much interested in an article which appeared in the May 15th number of *Gleanings* entitled "Queen-rearing for the Beginner," by J. E. Jordan. He brings up one interesting point on which I should like to have some additional informa-

tion. We refer to the idea of taking one or two strong colonies, dequeening them, and using them for starting queen-cells and for drone hives during the whole season. This is a good idea. We have followed the practice described in the A B C and X Y Z of Bee Culture, and have given queen-cells to a colony just made queenless, but there is some difficulty in keeping the queen in some place until it is time to return her to the hive again. We have had queens killed repeatedly when they were put on a frame over some other colony. We used a queen-excluder between the two hives, but it seems the workers killed the queen just the same. We found that it was better to put the queen in a hive by herself with one or two frames of brood. In this warm climate we can do this without any difficulty. We keep raising queens right thru the season, and that means making various hives queenless at different times. We find, however, that taking out queens and returning them again to their hives (they are not kept out long either) impairs their efficiency. We find that they do not live as long as they ought to when they are taken out of their hives repeatedly or even twice.

Therefore Mr. Jordan's idea of using some queenless colony during the entire season makes a strong appeal to us. Before adopting it, however, there are a few points which we don't quite understand. Mr. Jordan says, "These colonies must be kept well supplied with brood in all stages." We cannot see how he can get the bees to start grafted queen-cells in a hive that has any unsealed brood in it. We have found that the bees are much more interested in starting queen-cells on any frame where there is some unsealed brood rather than fill out grafted cells, so we are anxious to know how Mr. Jordan gets his bees to fill out his grafted queen-cells under these conditions.

We should also like to know if he has not been troubled with laying workers in a hive that is kept queenless for any length of time, even tho it is kept well supplied with brood.

San Juan, Porto Rico. A. W. Kuenzli.

Our Mr. Pritchard replies:

over a strong colony with a queen-excluder between would be sure to result in the killing of the queen. But if a piece of wire cloth is used instead of the queen-excluder the queen may be kept several days in good condition. Having brood in all stages is a mistake. Nothing but sealed brood should be given to these colonies.

We do not like the plan of keeping colonies queenless all the season. Fertile workers are very apt to get started. We prefer to make a colony queenless and leave all their brood with them. At the end of six days, destroy all the queen-cells they have started; then graft into them every day until the brood is all hatched. Then we give them a laying queen. These colonies get

back to a normal condition in a few weeks, and go thru the winter in good shape. If grafting colonies are kept queenless all the season they are not worth wintering.

#### A Swarm that would Not Stay Hived.

Here is a swarm that I hived twice last summer, but the bees refused to stay where they belong. The third time I found the queen and caged her, and shook the bees upon the frames, and that time they stayed. St. Paul, Minn. A. W. Aamodt.

A bunch of rebellious bees that did not know when they were well off.

#### A Half-starved Queen Received by Mail Run Directly into a Hive.

The last week in May I took one brood-comb and queen and put it in a new hive, and requeened the old colony having the remaining seven brood-combs. The new queen was accepted, and allowed to stay four or five days, and then, to my surprise, when looking to see if she had any brood started, I found no brood, but two queen-cells, evidently built from young brood of the old queen. I cut out these cells, but failed to find the new queen, which I had seen three or four days before.

A second queen came in by mail late one afternoon. I put her away over night, and when I looked at her the next morning I

found a couple of dead bees stuck in the opening of the food-compartment of the cage. Most of the rest of the bees had starved except the queen and a few bees whose lives I saved by feeding honey at once.

There seemed to be only one thing to do—to introduce the queen at once, even at the risk of having her killed. I put a queen-trap over the entrance, took all the frames out, shook them on the ground so that the bees would have to sift thru the trap in going back into the hive, and, as I expected, found no queen. On one of the combs from which I had shaken the bees I put the half-dead queen. Several times the few remaining bees on that comb made a rush for her; but I blew a little tobacco smoke on them to keep them away and held the comb in my hands about ten minutes, then placed the comb with the queen in the hive and finished shaking the rest of the frames.

Four days later I opened the hive and there found the queen in good condition.

Brooklyn, N. Y. F. Duesterwald.

#### Well-soaked Ground in the Fall Insures Clover Honey Crop.

Following a long wet cold spell, with but now and then a working day for the bees, warmer days have set in; and with oceans of white clover on every hand our honey-makers are reveling in nectar. It was predicted by a writer in Gleanings that the setting-in of winter with well-soaked soil would insure a crop of white clover, and more—that it would yield plenty of honey. The beekeepers of central Wisconsin may well rejoice, for that prophecy is being fulfilled; and, altho the weather is not as yet ideally warm, the bees are gathering honey fast and furiously.

The prospect now is that, with the warmer weather we have reason to expect, and an occasional rain to keep the white clover flourishing, another bumper crop of honey appears very likely.

Manawa, Wis., June 25. E. E. Colien.

#### Held up and Killed.

My apiary contains 120 colonies of bees in two rows six feet apart, and hives 16 inches between, all resting on 2 x 12 planks set edgewise. At one end is my bee-supply and work-house, which I sleep in during the busy season.

I had just put on my first supers, and some were partly filled, when one morning, just before daylight, I was awakened by what I thought was a mouse trying to eat its way into my shop. I got up, but the gnawing still continued. I opened the door, and not over eight feet away I saw a skunk with both front feet on the alighting-board, his head turned to one side, and nose close to the entrance; and as I watched him he would raise his head and one foot, and scratch on the hive a few moments, just as a mouse sounds when gnawing. The skunk then

would stick his nose at the hive entrance, and, I suppose, eat all bees which answered his early call. I drove him away into the sage brush and returned and got my gun and loaded it, as it is an old muzzle-loader. I opened the door, and not over twelve feet away was my morning caller. I set my lamp on the floor so as to get a good clear sight and fired. It took off his head; it was done so quick that he left no apologies. In the morning I found he had visited eight hives. I then set a coyote-trap and in a couple of nights caught another. I then put around my apiary a five-foot chicken-wire, and yet the skunks would get in by digging under, so I had to fasten the wire net down with spikes, since which I have not been bothered.

Hudson, Wyo.

Geo. E. B.

#### “Sweet but Pow’ful Sticky.”

I note the reply of P. C. Chadwick, page 184, to A. F. Bonney, defending the mail clerks in their handling of honey in the mails. Mr. Chadwick is right—emphatically so. All honey, especially comb honey, shipped by parcel post, should be plainly labeled to show contents, and marked “outside mail.” It will then be handled outside of the sacks, and, if properly packed, will arrive at its destination in good order. During the past winter I have handled two packages of comb honey that were in extremely bad order. Not only were the honey-packages in bad order, but everything else in the sacks was covered with honey—a sweet mess, but “pow’ful” sticky. One of the packages was about a dozen sections in a pasteboard box, nothing to show on the wrapper what the contents were, nor even that they were fragile. The other was a few combs in a tin cracker-box along with some dry goods—dry at one time, but not when I saw them—nothing to show on this wrapper either.

Such cases as these are what bring the parcel post into disrepute, and may cause the shipping of honey by parcel post to be forbidden by the Postoffice Department before we have had a fair chance to try it out.

When shipping honey by parcel post, pack it in a container that will be honey-tight under ordinary circumstances. Label it “Honey,” and endorse on the wrapper, “To be handled outside of sack,” or say “Honey, Outside Mail.” The boys will know what to do with it, and 99 times out of 100 it will go thru all right. If in doubt as to whether it is properly packed, ask your postmaster about it.

I have put in ten years “on the rails,” and am still at it on the Lincoln & Billings W. D., but find time to handle about 40 colonies during my lay-off periods.

Huntley, Mont.

Frank E. Clift.

How would it be if we had a label contest? I think it would be interesting to see the ideas of the beekeepers about honey-labels.

Chico, Cal.

R. Deimer.

**Two New Ways of Introducing Queens.**

Last season I used two plans of queen introduction that to me are new. Both plans have proven highly successful and satisfactory.

Of course my queens are clipped. When a swarm issues, the queen is caged; and if she is one that I want to supersede, I simply kill her and put another in the cage, lay it at the hive entrance, and, when the swarm returns, and about one-third of the bees have entered the hive, I liberate the new queen and let her run in with the swarm, and all is well.

When I have a queen in any hive that I wish to supersede I set the hive to one side and put an empty one on the same stand; then I take the combs from the old hive, one at a time, looking them over carefully; and when I find the queen I kill her and throw her away some distance so that the bees will not find her. Then I shake all the bees off the combs in front of the empty hive, which I have previously filled with empty combs. I also jar all of the bees from the old hive and carry it to the other side of the yard, after putting back into it the old combs and brood. Then I liberate my new queen on the combs of hatching brood, close the entrance, and leave the hive thus for one hour. At the end of this time all the bees in the new hive will be aware of the loss of their brood and queen, and will be running over the front and sides of their hive, in their eagerness to find a queen. I then remove this hive from the old stand and set the old hive and brood back again, open the entrance, remove the combs from the empty hive and shake all the bees in front of their old hive, just as they were in the first place. When they go in and find their brood, they seem to think that their queen is the old queen. It is not necessary to open the hive before the next two or three days after. The queen is introduced all right and they should be left alone.

Before liberating the new queen on the combs of brood I destroy all queen-cells, if there are any; and if the weather is cool at the time, I carry the hive in the house to prevent any possibility of chilling brood.

Union Center, Wis. Elias Fox.

**Red-clover Bees.**

I should like three-banded Italians that work on the red-clover bloom as those are the kind raised here. Please let me hear where I can get them.

Mrs. Mary E. Adams.

Ransomville, N. Y., June 12.

[There are some strains of Italian bees that will work on red clover; but as a general thing the conditions have to be somewhat favorable, so far as the season is concerned. When there is a drouth on, or when there has been backward or chilly weather, the corolla tubes of the red clover are enough shorter so that the bees can reach the nectar. When the clover is developed so that

the blossoms are large, the ordinary Italian bees do not get very much of the nectar; still, there are some strains that have a little longer tongue. See our advertising columns.—Ed.]

**The El Paso County Beekeepers Organize.**

The beekeepers of El Paso County, Texas, seeing the need of greater co-operation, met at Ysleta, Texas, on June 10 for the purpose of organizing. A very successful meeting was held, and the El Paso County Beekeepers' Association organized with Mr. W. J. Stahmann acting as temporary chairman, and F. C. Belt as temporary secretary.

Following a discussion of the need of such an organization, the following officers were elected: W. J. Stahmann, President; J. G. Saurenmann, Vice-president; F. C. Belt, Treasurer; Albert S. Blanks, Secretary.

A constitution and by-laws were adopted, and the resolution was passed that F. C. Belt be recommended to the State Entomologist as bee inspector.

Clint, Texas. Albert S. Blanks, Sec.

**Sacramento Valley Beekeepers Organize.**

A few of the beekeepers of this section met on the evening of June 7 and organized an association to be known as The Sacramento Valley Beekeepers' Association, with A. W. Morgue, of Durham, as President; J. A. Williams, Durham, Vice-president; F. M. Washburn, Chico, Secretary.

F. M. Washburn, Sec.

Chico, Cal., June 16.

**Sounds Good for the Breeders.**

I have bought queen-bees from several western breeders, one eastern, and one southern, and in every case have bought the untested queens with entirely satisfactory results. Every queen, I think, was purely mated. One was dead and one was a cripple when received, but these were replaced at once by the breeders.

Edgewood, March 20. W. A. Gridley.

**Barbed Wire for Reinforced Concrete Hive Bottom.**

Referring to the excellent plan of Mr. E. A. Harris on page 629, August 15, 1914, I beg to offer the suggestion that barb wire be used for the reinforcement. The barbs keep the wire from the surface, and the advantage of barb wire over smooth wire as a reinforcing medium is apparent.

San Juan, P. R. F. E. Hartwell.

Can you tell me of a better way than scraping to clean supers and fixtures? I use the Danzenbaker bodies and supers.

Ralph P. Smith.

New Garden, Pa., June 22.

[There is no better way to free supers from bee-glue than to immerse them in boiling water with a little lye so as to cut and remove the glue. You could use gasoline or alcohol, but that would be too expensive.—Ed.]

### Dwarf Worker Bee from Small Cells.

I am mailing you a very small worker-bee. I have only once before in my life seen another like it. I have found that they hatch from a smaller cell than the regular size. The bees in drawing out their comb from a one-inch starter will start at several places in the length of the frame; and when they come together they have room for only a very small worker-cell.

This is my idea of the cause of the small bee I am sending you; but as your experience is much broader you probably might have a different cause for the dwarf bee. For the novelty of the thing I should certainly like to have a colony of these bees; but the only way I think they could be raised would be to make a smaller size of worker foundation. However, you may have a better suggestion to offer.

Lancaster, Pa., June 19. W. D. Sellers.

This was referred to Dr. E. F. Phillips, of the Bureau of Entomology, who replies:

[This bee proves to be a worker honeybee, apparently normal in every respect except size. Under certain abnormal conditions such dwarf bees may be raised in a bee colony. In the article entitled "Honeycomb" in A B C and X Y Z of Bee Culture, it is stated that "By making the cells smaller than ordinary we get small bees with very little trouble."

Several years ago I experimented with the production of drones in worker-cells, and, as is well known, they are greatly reduced in size.]

### A Pollen Ration Necessary.

1. Can bees raise brood that will produce perfect bees without pollen of any kind, providing they have all the sugar syrup and water they need?

2. If bees are fed sugar syrup when raising queens for the market, and they depend entirely upon this source of food supply, would it not be natural for the bees of these queens to depend upon the same source of food supply?

3. What object has a bee in life?

Meadville, Pa. A. B. McGuire.

[1. Bees cannot raise brood without pollen of some sort. Natural pollen from the field is a great deal better than the artificial pollen in the form of meal or flour.

2. No, this would not follow. The feeding of sugar syrup only takes the place of a natural light honey-flow, because the bees cannot prepare the food for the young queens unless they have honey and pollen, or syrup and pollen. Either one of them will answer an equally good purpose, altho the honey would, of course, be a little better.

3. We do not know that we quite understand your question. We may say in a general way that the bee has no thought of its owner. It simply has an instinct that impels it to gather nectar and pollen to take care of its young and to carry its colony

thru a period of the year when there is no supply of food from natural sources.—Ed.]

### Are Bees Taxable Property?

When the assessor was around last fall I gave in my 50 colonies of bees, which was put down as personal assessment, with the understanding that I would not be taxed for them unless it is the custom or law of this state to tax bees; but now they have the bill against me, or it is included in with the other taxes. The commissioners meet on July 6. I want to go before them and try to get the bee part of the tax cut out; for if I start to paying tax on bees I shall have to keep it up as well as other beemen.

Of course, if it is just, and the custom to pay tax on bees or the bee industry, I would not kick on the tax (\$1.49 county and 32 1-3 cts. state). I understand the poultry business is not taxed here, and I believe that is one reason why bees should not be taxed.

H. C. Davis.

Upper Marlboro, Md., June 29.

[Bees are taxable property in most if not in every state in the Union, and we know of no reason why they should not be put on the taxable list like other property. If they are not taxable property they have less standing in law. You had better let the matter stand as it is. We know of no reason why poultry should not be taxed like other property. If chickens are exempt, bees should be also.—Ed.]

### Sweet Clover in Pastures.

Mr. Crane is on the right track, page 836, Oct. 15, when he says sweet clover would be more helpful to beekeepers if grown in pastures than that grown for hay. Every sweet-clover grower I know cuts the crop twice a year just as the blossoms commence to be valuable for bee pasturage.

To get the best results, from the dollar-and-cents standpoint, sow the seed any time, then keep all weeds mowed down for the first six months. The second year as the crop comes up from the previous year's roots it should be let alone until some of the first seed is ripe. At this time half of the field should be cut for hay, and the hay stacked half and half, every other load with alfalfa, or clover, or timothy. This makes the hay better, and leaves the other half of the field for seed and bee pasture; and, besides, the bees will get nearly all the honey from the first half of the field cut, as it will come up again and blossom, and produce honey until freezing weather.

E. W. Benson.

Beatrice, Neb.

### Has No Hands.

I have only a thumb—no hands, and I can manage six or seven swarms very nicely with the aid of my wife.

William Gardner.

Mechanicsville, N. Y., Dec. 11.

## OUR HOMES

Editor

Behold the Lamb of God, which taketh away the sin of the world.—JOHN 1:29.

He is brought as a lamb to the slaughter, and as a sheep before her shearers is dumb, so he openeth not his mouth.—ISAIAH 53:7.

Thinkest thou that I cannot now pray to my Father, and he shall presently give me more than twelve legions of angels!—MATT. 26:53.

The first of our texts has been one of my favorite ones ever since I began reading God's holy word understandingly. Who was it that called Jesus the Lamb of God? It was poor John who, later on, was persecuted and *put to death* "for righteousness' sake." The Lamb of God! what an expression! When God saw fit to send a messenger to this wicked world, what sort of messenger would humanity naturally suppose he would send? John terms him the "Lamb of God." A little lamb is about the meekest and most inoffensive of all God's creation. It has been the emblem of innocence ever since the world began. The lamb does not fight. It does not endanger anybody nor anything. When we speak of a disposition that is lamblike it is paying about as high a compliment as we can pay to a human being. Jesus was ushered into the world with this lamblike disposition—the disposition to be unselfish and to do good, in contrast to average humanity.

Just now it seems that throout the whole wide world there is a division of sentiment. We have had it here on the pages of GLEANINGS. Quite a number of writers all the way from Sheldon (the author of *In His Steps*) down to others not so well known have counseled "non-resistance;" and I grant you there seems to be a tendency to go to extremes either way.

Just as I write, on the third day of July, there is a strong prospect of a war with Mexico; and the question is constantly coming up, "What would Jesus do?" A few weeks ago I copied a tract entitled "War on Christian Principles," and it brought forth much comment. We are just about printing 2000 more for the good lady who sent a sample—see page 460, June 1. Suppose we study the character of Jesus a little in order to decide better what he *would* do. A nephew of mine away out in Arizona takes me to task and quotes scripture to show that I should not be undecided. He says, "Not by might nor by power, but by my Spirit, saith the Lord of hosts." He quotes again, "Seek ye first the kingdom of God, and his righteousness, and all these things shall be added unto you." Just once, if I am correct, Jesus not only reproved

and rebuked *but drove* out wicked men. In this one instance the lamblike demeanor seems to have been changed to one of authority. He overturned the tables of the money changers, and said, "Take these things hence." He then added, "Make not my Father's house a house of merchandise. My house shall be called the house of prayer; but ye have made it a den of thieves." Strangely enough, those wicked men hustled out with their trade and traffic when he showed he could present them something besides a lamblike demeanor. Now, there is one other instance that is not exactly parallel, but I often think of it. It illustrates that, beneath that lamblike exterior, there was a hidden power that not only *defied wicked humanity*, but spoke peace even to the winds and waves. No wonder that his followers were awed and astonished as they said, "What manner of man is this that even the *winds* and the *sea* obey him?"

The question continually comes up, and is sent in to me, "Would Jesus, if he were here, indorse enforcement of law?" I think he would. Did he not say "I came not to bring peace but a sword"? And at another time he said, "I came not to destroy the law, but to fulfill." A. F. Foster said on page 377, May 1, that insane people would have to be taken care of; and I think abundant experience has shown that policemen, magistrates, etc., are needed in every part of the world. In some towns where there are no saloons one policeman might take charge of quite a large number of people; but for all that, it seems that one or more police are still needed. In our lynchings where mob rule takes the place of law, we have not only *one* crazy man, but it seems crowds get together where it would seem that a hundred or even more have gone insane and have to be restrained. What is our nation coming to if a crazy mob, and often a drunken mob, takes law into its own hands? In such cases it seems to me that even the Lamb of God which taketh away the sin of the world would authorize an armed force to insist on strict obedience to the laws of the land and on giving every accused person a chance for a fair trial. I saw a statement recently that quite a number who had lost their lives by lynching were proved afterward to have been *entirely innocent*; and this came about because the poor victim had no chance to explain things and defend himself. May God help us to do away with lynching, not only in the far South, but everywhere else.

The last one of our texts makes reference

to the sin of the world. Well, the most striking illustration of the depravity of the present age I clip from the *Independent*. I have put on a head of my own, as you will notice.

COSTS \$10,500,000; WAS SIX YEARS IN BUILDING; 1000 MEN WERE ABOARD OF HER, AND SUNK IN SIX MINUTES.

Six years ago the British determined to build a battle-cruiser that should be bigger and swifter and stronger than any afloat. Hundreds of skilled workmen labored for years in her construction. Ten and a half million dollars were spent on her. She was protected with armor plate of the hardest steel nine inches thick. She was propelled by the most efficient of steam-engines, the turbine. She was armed with ten 13.5-inch guns, which could discharge a 1400 pound projectile every thirty seconds; also with sixteen 4-inch guns, twelve 6-inch guns, and two torpedo tubes. The British, properly proud of her, named her after their queen. A thousand men were put aboard of her, and she was sent into action on the last day of May.

The German warships opened fire, and within six minutes the "Queen Mary" was torn asunder by a terrific explosion, and sunk.

I suppose this great warship was paid for and built by taxing good honest hard-working people. To say nothing of the waste of life, think of the property and the hard work that were wasted *in just six minutes*. Will the great wide world learn a lesson from the above event? or will the nations keep on building warships on such a scale, or even a larger scale, to meet a like catastrophe and disaster? Who can answer? Will any power on earth put a stop to it unless it is the Lamb of God that taketh away the sin of the world? If he should command the nations to cease such awful and wicked waste, would they obey him as did the money changers in the temple? I read somewhere that somebody suggested that these war times have demonstrated the failure of religion; but a bystander quickly replied, "Not so, my friend, for religion has not *even been tried*."

And now in closing this Home paper I want to give you the contents of a tract just sent me by the good woman who gave us "War on Christian Principles." On the first page of this tract there is an excellent picture of a shoemaker working with his last. By the way, it used to be the fashion some fifty years ago for shoemakers to entertain a lot of loafers, and too often they wasted their time in denouncing Christianity and in holding up to view the faults of Christian people. It seems that a Bible-reader went into the shop, and the skeptical shoemaker commenced on him, with the result as follows:

#### THE SKEPTICAL SHOEMAKER.

"I have read," said the shoemaker, "a good deal about the heathen gods, and I believe the account of Christ is taken from some of the heathen writings or other."

"Will you abide by your own decision on two questions which I will put to you?" said the Bible-reader. "If so, I will freely do the same; I will abide by your own answers. By doing so we shall save much time and arrive more quickly at the truth."

"Well," said he, "out with it, and let us see if I can answer; there are but few things but what I can say something about."

"Well, my friend," replied the reader, "my first question is: Suppose all men were Christians, according to the account given to us in the Gospels concerning Christ; what would be the state of society?"

He remained silent for some time, in deep thought, and then was constrained to say, "Well, if all men were really Christians in practice as well as theory, of course we should be a happy brotherhood indeed."

"I promised you," said the reader, "that I would abide by your answers: will you do the same?"

"Oh, yes!" he readily replied; "no man can deny the goodness of the system in practice. But now for the other question; perhaps I shall get on better with that. You have got a chalk this time against me."

"Well, my next question is this: Suppose all men were infidels; what then would be the state of London and the world?"

He seemed still more perplexed, and remained a long time silent. At length he said, "You certainly have beaten me, for I never before saw the two effects upon society. I now see that where the Christian builds up the infidel pulls down. I thank you. I shall think of what has passed this afternoon."

The sequel was that he was fully persuaded in his own mind to give up his infidel companions and follow the Lord Jesus Christ. But the change did not stop here. When first the reader called he found him sitting on an old dirty chair, with a number of half-starved children in rags on the floor around him, neglected and uncared for; now they have removed to a better home in a cleaner street. Within all is cheerful and happy. The father, no longer faithless, delights in the company of his wife and children, all of whom are neatly dressed; and his chief happiness is to read and speak of the things which belong to their everlasting peace.

AMERICAN TRACT SOCIETY,  
150 Nassau St., New York.

There are several points in the above that come home to me with considerable force. First, the Bible-reader did not propose to argue the matter; and I have often thought that it is a waste of time as well as a waste of breath to undertake to argue with one who opposes Christianity and the Bible. Second, the Bible-reader tells the shoemaker he can be his own judge and jury, and that he, the Bible-reader, will *agree* with his decision. The shoemaker answered with considerable confidence. He had had a lot of practice in defending infidelity. The Bible-reader's reply is the same as every sane man or woman will be obliged to give. He says, "If all men were all *really* Christians." Our friend the shoemaker had received a stunner the first clip; but he recovered a little, and thought he could do better next time. The poor foolish man! what *would* be the condition of London and all the world if we were all infidels?

Now for the winding-up. The effect of those few kind words, inspired by the Holy Spirit, worked a transformation in that dirty, dusty shoeshop; and, what is of far more importance, the transformation was also in the shoemaker's home. You need not say the above is fiction, for there is not a town or neighborhood in the whole United States that will not furnish something parallel. Billy Sunday's faithful and earnest labors are doing just what was done for that poor shoemaker in thousands upon thousands of homes while I write. The work in Kansas in some respects, we are told, outstripped his former record. It is the outcome of a faithful holding-up before a sin-cursed world "the Lamb of God that taketh away the sin of the world."

Somebody, I do not know who, has been kind enough to mail me a postal card with the following matter printed on it. It needs no explanation.

"Es fer war, I call it murder."—*James Russell Lowell.*

"Amidst the thunders of Sinai God declared, 'Thou shalt not kill.'"—*Charles Sumner in "True Grandeur of Notions," Lee and Shepard.*

By all means "raise your boy to be a soldier," but have him enlist for the "higher soldiery." Show him the difference between "carnal warfare" and the "good fight" which some minds fail to distinguish.—*A Wellwisher.*

Ponder well the contrast between the bloody method of almost Indian-extirmination as pursued by

some early colonists, and the holy experiment of brotherly love which that old hero William Penn had the courage to try even with savages.—*A Freelance.*

Wisdom is better than weapons of war.—*ECCL. 9:18.*

THE GREAT-GRANDDAUGHTER, THE LADY EGLINTINE CHICKENS, AND THAT NEW GARDEN CULTIVATOR.

It has been one of the great pleasures of my life to see things grow. I think I might safely say that for 70 years or more I have almost invariably looked over something every morning to see how much growth it has made during the night; and I examine again several times during the day to watch the gradual growth and improvement; and especially do I like to see seeds push thru the soil out into daylight; and it rejoices my heart to see *boys and girls* grow, not only in physical stature, but, more than all, in that rugged pathway from earth and earthly things toward heaven and heavenly things. Some years ago Mrs. Root made the remark, in speaking of Huber, our last-born boy, "We shall probably not live long enough to see him married."

Well, thru the mercies of a kind Providence we have lived not only to see him married, but to see him the father of a bright little girl who visits her grandmother almost every day when we are here in our northern home. And we have lived to see one of the grandchildren married, and who

The great-granddaughter and her mother when the baby was only 18 days old.

FIG. 2.—The whole flock of 9 chicks, 3 of them 10 weeks old and 6 of them about 7 weeks old.

now has a little girl "of his very own." And it affords me wonderful pleasure—in fact, a thrill of joy and thanksgiving, to be able to present to the readers of *GLEANINGS* the happy mother and the bright little baby with that wondrous smile that she gave her friends when just 18 days old. I think some good woman called that first smile that the baby gives her friends a "three-cornered smile." Just notice that sweet little mouth opened enough to indicate that she too is feeling happy and thankful to get just a brief glimpse of this great and wonderful world and all the rest of the attendant vast universe.\* Oh! what is a home without a baby? May I digress just a little right here?

I once knew a beautiful woman. She married a bright and educated man; and as the years passed by he wanted a baby, one or more of them, in his household. Then there was a disagreement in the matter. If I am correct a divorce resulted. She gave her reasons, so far as I can recollect, something like this:

"My good sir, if you thought when you married me that I was going to be mother to a lot of babies, I want to tell you that you are greatly mistaken."

She declined the office of motherhood, probably because of its cares and burdens. I have heard people talk about living for self, without care or regard or feeling of responsibility for anybody else or for coming generations after them.

\*A BRIEF SKETCH OF THE ANCESTRY OF THE BABY IN THE PICTURE.

I was born Dec. 9, 1839. Mrs. Root and I were married Sept. 29, 1861. Our first-born daughter, Mrs. Maud Calvert, was born April 16, 1865, the day after the death of Abraham Lincoln. Mr. and Mrs. Calvert were married Sept. 1, 1885. Their oldest child, Howard R. Calvert, was born Nov. 13, 1891, and was married June 29, 1915. The baby in the picture was born May 21, 1916.

Thru a kind and merciful Providence I am able to say today, June 26, 1916, there has been no death among the children, grandchildren, or great-grandchildren up to date.

Let us now talk about chickens a little.

In our Home paper for May I told you about Lady Eglintine and the nine chicks, and their successful trip to Ohio when part of them were only a week old. I am glad to tell you that not a chick has been lost. In pictures 1, 2, 3, 4, I give you a glimpse of them when the oldest were about ten weeks old. The young rooster in No. 1 has been giving

us a delightful little crow every morning for two or three weeks. Nos. 3 and 4 give you a picture of our poultry-yard; and No. 5 is a picture of myself running that new cultivator. When Huber took the picture No. 4 I supposed I was all out of sight; but he played a trick on me. I did not know I was going to be taken, so I neglected to straighten up, and there you have got me stoop-shouldered. In No. 5 I straightened up a little better. To tell the truth, I never realize that I am getting to be stoop-shouldered (or in danger of becoming so) unless somebody takes a picture of me unawares. Well, now about that poultry-yard.

We have only a limited amount of space around our home in Medina, and I wanted to give the 9 chicks a place for exercise without encroaching on my garden. In order to keep off the west and north winds, years ago I planted a line of evergreens about eight feet apart; and the ground on each side of these evergreens is no good for gardening as a matter of course; so I put

FIG. 1.—Lady Eglintine's chicks when the little rooster was about 10 weeks old.

FIG. 3.—The poultry-yard and the Philo coop under the evergreens.

up some netting and made a yard for them about 20 feet wide and toward 100 feet long.

The poultry-house you will see in Nos. 3 and 4, which is one that Huber bought of Philo. It was made particularly to keep a dozen hens and never let them out at all. It is very ingenious and pretty; but as I want my chickens to get out and in the yard whenever it is daylight, I pulled out

a pane of glass to give them a doorway. But a great lot of sparrows soon found this opening and learned to go in and out. I suppose you know my way of feeding chickens is to leave the feed plainly before them all the time. Well, the sparrows were getting to be too much of an expense, and therefore I put the pane of glass back again and taught the chicks to go out and in thru a tunnel under the sill of the house. It stands on a little bank so that this tunnel will not catch or hold water when it

rains. Well, the thing worked completely so far. If the sparrows should learn to get into the tunnel, when they wanted to get out they would fly up against the poultry-netting, for there is poultry-netting on the roof as well as on the sides; and when it does not rain a part of the roof is raised up.

Now, there is another thing that pleases me very much about my poultry-yard. Mrs.

FIG. 4.—The poultry-yard with a glimpse of Mrs. Root's back-yard lawn.

FIG. 5.—The Barker cultivator in the back-yard garden.

Root suggested having it run up to the pantry window so she could toss out to the chickens anything she did not want in cooking or in preparing our meals. Picture No. 1 shows the whole tribe up near the pantry window. The opening shown in No. 2 goes into the basement where I take my noonday nap; and whenever I open my eyes after a refreshing sleep my beautiful little flock of chicks are sure to be first before the window for me to talk to them when I awake.

By the way, friends, don't you think that that is quite a pretty poultry-yard as shown in Nos. 3 and 4? No. 4 shows something else. In our new home we have a lawn out in front of the house; and Mrs. Root petitioned for a lawn in the back yard also. I told her it was the best ground we had on the premises, and I did not want to spare it, and we had some little disagreement about it. But one day I happened to think something like this: Suppose the dear woman should be taken away, and I should

look back and remember that I objected to giving her just a little bit of green lawn in the back yard, where she spent so much time hanging out her clothes and doing other things to keep our premises neat and tidy. Then I went straightway and got a professional lawn-maker to level off the ground and sow the proper kind of seed; and now we have a lawn as you see it, and a man comes around and mows it once a week. You might think that the white mark in the lower edge of the picture was a cement walk out to the clothes-line reel; but it is really a glimpse of the galvanized pipe that sprinkles the garden and the back-yard lawn. It has not been used this year so far, for nature has done all the sprinkling.

Picture No. 5 gives you a glimpse of this same sprinkler and also a glimpse of our Medina clay soil. When the ground is just right after a rain, this little machine makes about the best dust-mulcher around the plant, and does it at less expense than any other tool I have ever gotten hold of. On top of the cultivator, if you look carefully you will see the three keen steel curved blades I have spoken of. It is a good plan to turn the cultivator over and use these first and then finish with the mulching attachment. As the two oldest pullets I have mentioned are today, June 24, about 12 weeks old, I shall be watching for the first egg, *possibly* in July, but probably not till August or some time later. In picture No. 2 you get a glimpse of the whole flock looking thru the basement window to see if I have woken up yet. In fact, they went down thru the window to make me a visit until I put some poultry-netting across to keep them out.

Oh, yes! here is another picture of the Eglintine chicks, after all. It was taken down in our Florida home just before I sent them north by express. They are just in front of the pineapples that were planted partly in the shade of that rubber-tree I have mentioned. Three of them were four weeks old, and the other six were only one week old. There were two difficulties in regard to the shipment. Day-old chicks, of course, go long distances safely; but with *week-old* chicks it is a little different. They must not only be fed and watered, but they must be kept warm. The number was almost too small to keep up the needed temperature in that thin light market-basket; so I put a wooden division in the middle of the basket, and this inside sleeping-room, as we might call it, was lined with a thin cushion filled with cotton batting. On their long trip there was liable to be considerable change of temperature, and therefore I

The nine chicks and their Rhode Island Red mother just before I put them in the basket for their long trip north.

arranged so the whole nine could crowd into the sleeping-room when they were too cold. But should the weather be warm they could stay outside with nothing but poultry-netting overhead. The feed and water were

in this outside apartment or "dining-room." The fact that they are still all alive, and spry as crickets, seems to indicate that they are at least a hardy strain of White Leg-horns.

---

## HIGH-PRESSURE GARDENING

### SWEET CLOVER DOING MISSIONARY WORK.

I think something has already been made mention of in our columns in regard to transforming the worthless hills of Kentucky into "a land flowing with milk and honey." Here is some further evidence in regard to it which I clip from the *National Stockman and Farmer*:

#### A PLANT IN PLACE.

Those who live on rich land and emit occasional sarcasms about sweet clover should take a little trip to Pendleton County, Kentucky. Twenty years ago that county was in a bad way. The land was badly eroded and gullied. Land was cheap because it produced little. Then somebody started sweet clover, a plant with a mission on barren land if not elsewhere. Today the hills are productive, the gullies are gone or at least are out of sight. Sweet clover and alfalfa, which followed it, are the foundation of a big dairy industry and a considerable business in seeds and honey. Trying to produce the wrong things—grain and tobacco—almost ruined Pendleton County. A plant which is called a weed and may be a weed in some parts of the country has redeemed it. There are communities here and there in this broad land which would profit by sending a delegation to Pendleton to absorb some facts and shuck off some prejudices.

There is just one thing in the above that I am not ready to subscribe to. Altho the

writer does not say so, there is an implication that sweet clover may be a weed in some parts of the country. Somebody has said—I do not know who—that not one of the legumes can ever be called a weed anywhere or under any circumstances. If sweet clover should happen to get in somewhere where it is not wanted, just cut it and feed it to the stock, and the stubble that is left has already done valuable work in improving the soil so you can grow alfalfa or almost anything else. Notice what is said on next page about growing nice potatoes on our sterile clay soil on a railroad embankment after sweet clover had made it possible.

#### SWEET CLOVER AND ALFALFA.

Prof. Bowers, of the Iowa State Experiment Station, compares the two clovers as follows, which we clip from the *Rural New-Yorker*:

#### SWEET CLOVER COMPARED WITH ALFALFA.

Sweet clover and alfalfa are very similar plants when young, and at this time they are difficult to determine from each other unless one is familiar with their distinguishing characteristics. Sweet clover is bitter to the taste, while alfalfa is not; the

leaves of sweet clover are broader than those of alfalfa and are smooth on the under surface, while the leaves of alfalfa are hairy on the under surface. After blooming, sweet clover is readily distinguished from alfalfa by the white or yellow flowers of the former in contrast to the purplish-colored flowers of alfalfa.

Sweet clover usually grows more dense than alfalfa, and is coarser. It will thrive on soils where alfalfa will not, and has a wider range of climatic adaptation. Sweet-clover roots do not as a rule penetrate as deep into the underground as alfalfa roots; but the root development of the former is much greater, and these large succulent roots decay more rapidly and give less trouble in plowing. Sweet clover is more succulent than alfalfa, and is thus more difficult to cure for hay than the latter. Cumarin is found in sweet clover, but does not occur in alfalfa. Alfalfa is a perennial in duration, while sweet clover is only a biennial.

Sweet clover superior to alfalfa—easier to get a stand; fits better into rotations; better for cattle, sheep, and bee pasture; rarely causes bloat; furnishes earlier spring pasture; roots decay more rapidly; will grow on poorer soils; will resist extreme drouth better; will grow on soils too wet for alfalfa; will grow on soils too hard for alfalfa; will grow later in the fall; practically free from insect pests and plant diseases; produces less washing effect on animals, and is a better green-manure crop.

Alfalfa superior—better hay; better pasture for hogs; more palatable at first; does not become so coarse and woody; is a perennial; has less hard seed, and is less difficult to cure for hay.

The protein analysis of the fresh forages shows in favor of sweet clover, but it contains a smaller percentage of all the other nutrients. In case of the hay the analysis shows that sweet clover possesses a higher per cent of protein and fat, while alfalfa contains slightly more ash and carbohydrates. According then to the nutritive coefficients sweet-clover hay surpasses alfalfa hay, and fresh sweet clover excels fresh alfalfa in protein content.

TOWNS Experiment Station. W. E. BOWERS.

I think I have before mentioned that I have for forty years or more championed sweet clover. In view of the above it is a little refreshing to see now every farm paper more or less interested in testing sweet clover. And just notice the concluding sentence in the above extract from one of the foremost experiment stations of our land.

Now just a word in regard to the ability of sweet clover to grow anywhere. In 1890 a railway was cut thru a dry clayey hill close to our factory. The dirt piled up was pure yellow clay, and the clay on top of the pile, that came from perhaps ten feet below the original surface, was spread out over several square rods. For some little time not a weed of any sort made its appearance. The ground was so hard and yellow that it was no good, evidently, for any plant. Finally sweet clover gradually got in, and soon grew with rank luxuriance. One spring, when it was up about two feet high, for experiment I had it plowed under and planted to potatoes. People laughed at me for thinking I could grow potatoes on that yellow clay bank without any manure.

To the surprise of everybody, and somewhat to my surprise, I got a fair yield of smooth potatoes. Without the "green manuring" of sweet clover I should not have had a potato, and perhaps hardly a green leaf.

EARS HIGHER UP THAN A MAN CAN REACH,  
AND THREE OR FOUR EARS ON A STALK.

On page 559, July 1, Mr. C. L. Harrison speaks of some ears of corn higher than he can reach. Well, on June 24, just 22 days later, the man who has charge of my Florida garden writes as follows:

The corn is doing nicely. Each stalk has from three to four ears on it. I think we shall have a fine lot of corn to house. The velvet beans are running up on the corn, but that does not seem to hurt the corn. WESLEY WELCH.

Bradentown, Fla., June 24.

MULCHING YOUR FRUIT-TREES AND OTHER TRUCK.

Our Ohio Experiment Station at Wooster has a block of fruit-trees mulched clear out around as far as the limbs extend, and kept mulched the year round. The mulch is heavy enough to keep down all the weeds or grass. Well, adjoining this block of trees is another one just like it, only the ground is kept under cultivation. In other respects the treatment of the trees is as nearly alike as possible; but the mulched trees are far ahead, and have been ahead for years in every respect. The difference in vigor of the mulched trees is visible as soon as one gets in sight of the orchard. This matter was brought to mind by the following, which I clip from the *National Stockman and Farmer*:

Another word about mulching. It should be more generally practiced. In driving over the country, enormous quantities of mulching material may be seen here and there—old straw stacks, spoiled hay, weeds, and grass growing in nooks and corners. Why not utilize all of these materials for mulching the strawberries, fruit-trees, brambles, currants, gooseberries, asparagus, tomatoes, celery, and many other horticultural crops? Bear in mind that a heavy mulch conserves moisture better than the most perfect tillage, and that the soil is enriched every time you apply a mulch. There is satisfaction, too, when you are busy harvesting the general farm crops in knowing that the mulched plantations are not being neglected. Try mulching.

It seems to be much the fashion, when you commence making a garden, to make a big bonfire of the trash; but it pains me every time I see it. Everything that can be burned up is valuable for mulch. When I protest they often tell me they want to burn the weeds that may contain seed. My friends, you do not need to worry a bit about weeds and their seed, even docks. Pile them up around your trees; and if the

dock seed or any other kind of seed commences to grow, put on more mulch—old dirty newspapers, or paper that has been wrapped about your meat—anything and everything. When this trash gets well rot-

ted it makes a most excellent fertilizer; and if you should happen to get more around a certain tree than it needs, work it into your garden in place of buying manure. Save the fertility.

## TEMPERANCE

### PROHIBITION IN KANSAS AND THE FRA MAGAZINE.

In our June 15th issue I spoke of that article from the *Fra* magazine, and copied a sentence in regard to prohibition in Kansas, in which I suggested that the closing of 220 schools in Kansas in 1914 was because of the plan of consolidating rural schools. In a lengthy article in the *New Republic* of June 23 the Governor of Kansas replies in full, and not only corroborates my suggestion, but replies to all the points made in that article. It would seem this man who wrote the article for the *Fra* was employed by the liquor party to hunt up everything he could in the way of statistics that might be construed so as to cast a slur on Kansas. What little truth there was in the statement was so construed as to make it appear derogatory, when the real facts were wholly otherwise. And with it all is a great lot of whole-cloth falsehood. Any one who cares to go all over it can get it in the *New Republic*, Westerville, Ohio.

### COMING OVER TO OUR SIDE.

It appears that the proprietor of the *Denver Post* was once against prohibition; but he now comes out announcing his change of mind, and, I hope, change of heart, as will be seen by the following, which I clip from the *New Republic*:

#### WAS BUN PROPHET; GLAD OF IT.

The terrible things that I predicted did not come with prohibition. It is doing wonders out here. Colorado is happier, wealthier, healthier, wiser, and more prosperous with prohibition. I am glad that my predictions did not come true.—H. H. TAMMEN, Proprietor of the *Denver Post*.

#### "THE WAY OF THE TRANSGRESSOR IS HARD."

*Dear Friend:*—I send you a clipping for your temperance department. It shows how we deal with the liquor-sellers in this part of the country. This is only one case of the many that have been convicted and fined lately. I clip it from the *Bystander*, Macomb, Ill.

Macomb, Ill., June 24.

GEO. J. STURM.

County Judge C. I. Imes imposed a heavy sentence on Samuel T. Danley this morning in county court. It will be remembered that Danley was convicted by a jury this week on six counts on the charge of selling intoxicating liquor in anti-saloon territory.

Judge Imes imposed a sentence of 60 days on each of the six counts and \$100 on each of the six counts.

Danley, it is believed, cannot pay the fine; and if this be the case then his imprisonment in the county jail will total 893 days, or over two years and a half.

#### THE SENTENCE.

In imposing the sentence Judge Imes said:

"You have been indicted, given a fair and impartial trial, found guilty of six violations of the law, after twice having violated the same law. Under statute it becomes my duty as the judge of this court to pronounce sentence upon you under this charge and verdict, and I desire to temper justice with mercy toward you as an erring brother-man, and also do my duty to the community in which you live, and whose peace you have disturbed by repeated violations of the law of this state.

"The unlawful sale of intoxicating liquor is not only a misdemeanor under the law, and wrong, but public sentiment is growing strongly against any use of intoxicants as a beverage; and those who have acquired a habit which demands a use of such beverage should be discouraged in the pursuit of that which increases their desire for strong drink and eventually brings trouble to themselves, their families, and the community in which they live.

"And you must be induced to stop your illegal pursuit for your own good, the good of your customers, and the good of society at large; and you should realize that society demands this, and that society is stronger than you, and will succeed in crushing you if you persist in opposing their wishes.

"The defendant, Samuel Danley, is sentenced to be confined in the county jail of McDonough County, in the state of Illinois, for a term of sixty days on each of the six counts of the indictment upon which he was convicted, the term of confinement on the second count to commence when the term of confinement on the first count ends, and so on till the six terms are served; and that he pay a fine of one hundred dollars on each of the said six counts, and the costs of this suit.

"In default of payment of said fine and costs, the defendant is required to work out the same on the streets and alleys of Macomb, Ill., at the rate of one dollar and a half per day, such work to begin at the end of the last term of confinement as pronounced by this sentence."

How many wise and good judges like the one in the above have we in this land of ours? Long may they live.

### REDUCTION IN THE NUMBERS OF MURDERS COMMITTED IN ARIZONA UNDER THE DRY REGIME.

We clip the following from the *American Issue*:

During the past 18 months with prohibition in effect in Arizona, there were six murders in the state. The last six months under the saloon regime there were 30 murders. Had this ratio been kept up under prohibition, there would have been 90 murders the past 18 months instead of six.

## DRUNKENNESS BEFORE BIRTH.

In times past much has been said about inheriting an appetite for strong drink; but many physicians, if I am correct, rather doubted it; but it is very probable that the common soothing syrups—Mrs. Winslow's, for instance—all contain both alcohol and morphine. These often have much to do in giving persons a tendency toward the drink habit from what they have received when babies in the way of medicine. In the clipping below is a statement that is really astounding. Just notice the sentence, "The child has been drunk many times before it has been born."

## INDUSTRIAL PUBLICATIONS FIGHT LIQUOR TRADE.

An editorial from "Craneing," published by the Crane and Engineering Company, is typical of the outspoken attitude of industry toward drink. In part the editorial says: "The worst effect of alcohol is the result of its use by women while bearing offspring. The child has been drunk many times before it has been born. Scientific men stated in a very positive manner that children generated and born under the influence of liquor frequently do not have an equal chance with better-born children; they are not brought into the world with normal minds. Often the bodies, too, are puny. Men and women who do not wish to be under the curse, till they die, of having borne undersized, shrunken, mentally stunted children, will study up on the effect of alcohol on the cells of the human body."—*Methodist Board of Temperance.*

## GROCERIES OR BEER—WHICH WILL DO HUMANITY THE MOST REAL GOOD?

We clip the following from the *American Issue*:

The Minneapolis *Journal* is authority for the statement that the Great Northern Railroad during the last wet year in Itasca County, Minnesota, shipped in 79 tons of beer, and in the first dry year shipped no beer at all, but shipped an increase of 79 tons of groceries.

This causes Louis Albert Banks to remark that "since the scientists tell us you have to drink 31½ tons of beer to get one ton of food, that was some change for one station."

## WISE SUGGESTIONS FROM "MRS. HETTIE GREEN."

We are just informed that Mrs. Hettie Green, "the richest woman in the world," as she has been called, is dead. She died at the advanced age of 82. Now, whatever may have been said of her and of her special faculty for "laying up treasures on earth," she has given us some excellent rules for living to a good old age, and preserving the use of her faculties to a remarkable degree thruout a life devoted to making riches multiply. We clip the following from the *Cleveland Plain Dealer*:

## HETTIE GREEN'S LIFE RULES.

Hetty Green once gave an interviewer the following list of rules which she said were those of success:

- Eat only good, wholesome food.
- Don't cheat. You may worry yourself into the grave in remembering your misdeeds.
- Don't envy your neighbors.
- Don't overdress. It makes others jealous.
- Dress warmly. Vanity in cold weather causes many deaths.
- Go to church. The church needs you, and you need the church.
- Don't forget that if your riches have been gained by unfair means the doors of heaven will be bolted against you.
- Be charitable. Don't falsify.
- Take a lot of exercise. Walk whenever you can.
- Obeys all God's laws, including the precept: "Give unto Caesar that which is Caesar's and unto God that which is God's."

## THE CIGARETTE AND THE TOBACCO HABIT.

I hold in my hand a neat little pamphlet of 76 pages entitled, on the front cover, "The Case against the Little White Slaver." Part 4 is just out, and contains much important matter in regard to tobacco and cigars. From the last page I quote one sentence as follows:

The world of today needs men, not those whose minds and will power have been weakened or destroyed by the desire and craving for alcohol and tobacco, but, instead, men with initiative and vigor, whose mentality is untainted by ruinous habits.

The pamphlet in question can be obtained by addressing Henry Ford, Detroit, Mich.

## WORDS ALMOST EXTRAVAGANTLY KIND, AND SOMETHING ELSE.

*Dear Mr. Root:*—I have sent you some copies, a report, and an almanac which I have preserved until now. I would hardly part with them. They seem to spur me on to more earnest efforts to do the will of our God. I think you will rejoice when you look the looks over to learn that there is one more man in the world who is depending entirely on God for all he needs. I like to hunt such people up; and let me say right here I am not trying to flatter, for it is the truth, when I say that many times I have cried when I have read your writings; and when I thank God for blessings received I surely must thank God for A. I. Root. I do not keep bees now. I have taken GLEANINGS from away back in the eighties; and you can guess why—the old story that many before me have said, because of the Home papers.

Chelmsford, Mass.

C. L. AKERSTROM.

The literature referred to in the above is in regard to the "Children's Home" at New Britain, Ct. Years ago we sold and gave away many copies of "Mueller's Life of Trust." The wonderful story of how Geo. Mueller received millions of dollars for his orphanage *solely* in answer to prayer, interested our class in the Medina jail more than any other book. Well, I did not know until just now that a similar work was going on here in America. For further particulars address as above.

# There is Money in Our 3-banded Italian Bees

## 20 Years of Select Breeding Gives Us Queens of Highest Quality

### Queens for Honey Production - - Queens of Unusual Vitality

Our select colonies used for breeding purposes, larvæ and select drones are those of the highest standard, the choice of over 1000 hustling, honey-producing colonies of pure Italian bees. These select colonies are located at such a distance from all other bees as to assure pure mating, and thus very effective use of our select drones. The larva we use in grafting is as small as can be seen and handled, having just come out of the egg. These are placed in cells which in turn are placed and nourished in strong ten-frame colonies, which, when honey is not coming in sufficiently, are heavily stimulated by feeding. Thus we get cells that produce large, long-lived, and hardy queens, which give workers unexcelled as honey-producers. We use no baby nuclei. All our queens are hatched and reared in strong three and five frame full-depth hives. Thus natural conditions are preserved.

All orders will be filled promptly by return mail or soon. We have no disease of any kind. Satisfaction and safe arrival we guarantee.

Select untested . . .65 cts. each or \$60.00 per 100      Tested . . . . . \$1.00 or \$ 90.00 per 100  
 Untested . . . . .50 cts. each or 45.00 per 100      Select tested . . . . . 1.25 or 115.00 per 100

All queens are warranted purely mated. Wings clipped free of charge.  
 Write for descriptive price list.

M. C. Berry & Company . . . . . Hayneville, Alabama

## 50c-- Golden and 3-banded Italian Queens-- 50c

We guarantee them to be as good as money can buy. Our breeders are of the very best, our methods are the best known. If they are not satisfactory you can get your money back for the asking. Where can you get any more for big money? Virgins, 25 cts.; untested, one, 50 cts.; 100, \$45.00. Special offer to members of association thru their secretary. Get your secretary to write us. Queens we are offering you are choice. 1 lb. bees, \$1.25; 2 lbs., \$2.00; 1-fr. nucleus, \$1.25; 2-fr., \$2.25. Full colony 8-fr., \$6.00; 10-fr., \$7.00. No queens at these prices.

We also have breeders direct from Dr. Miller and can furnish queens of his strain, which is the best in the world. Start right, get some of the best in the world for the foundation of your strain.

*To inquirers:—I am rearing no queens for sale, but am keeping The Stover Apiaries supplied with breeders from my best stock; and from thence you can obtain the same queens you could get directly from me.*  
 C. C. Miller, Marcngo, Ill., March 1, 1916.

Prices of Dr. Miller's strain: Virgins, 50 cts. each; 12 for \$5.00; Untested, \$1.00; 12 for \$10.00; Tested, \$2.00; Select Tested, \$3.50; Breeders, \$5.00 to \$10.00.  
 Capacity over 2000 per month. Safe arrival and satisfaction guaranteed.

THE STOVER APIARIES, MAYHEW, MISSISSIPPI

## QUEENS!

In the Beginning is where Quality starts

Our breeding stocks, our methods of breeding cannot be surpassed anywhere

If you want to know who we are, read "How to Produce Extracted Honey," also "Modern Queen-rearing," both of which we wrote for The A. I. Root Co., while we were their head apiarist some 12 years ago. Untested queens, \$1.00; tested, \$2.00. Other prices on request.

Geo. W. Phillips, Lebanon, Ohio

## ITALIAN QUEENS, NORTHERN BRED

are surely most hardy for Canada and northern States. Try one. Untested, 75 cts.; select tested, \$1.50. List free. Plans "How to Introduce Queens, and Increase," 25 cts.

E. E. MOTT, Glenwood, Mich.

BEE SUPPLIES Send your name for new 1916 catalog.

Dept. T, CLEMONS BEE SUPPLY CO.,  
 128 Grand Avenue, Kansas City, Mo.

## Forehand's Italian Queens

Gentle, good honey-gatherers, bred for business. Their mothers were imported — the best to be had. If you buy once you will buy always. Just look at these prices. Where can you find better?

Untested, . . . July to Oct. 1, one, \$0.50 up to 25.  
 Select Untested, " " 1, .75; 6, 4.25; 12, 8.00  
 Tested, " " 1, 1.25; 6, 7.00; 12, 13.00  
 Select tested, " " 1, 2.00; 6, 11.00; 12, 20.00

If queens are wanted in large quantities send for prices.  
 We guarantee that all queens will reach you in good condition, to be purely mated, and to give perfect satisfaction.  
 All orders filled at once.

L. L. Forehand, Fort Deposit, Ala.

## Italian Queens

with a Record of 30 Years

Leininger's strain of Italian bees and queens have been carefully bred for 30 years; for gentleness and honey-gathering qualities are unexcelled; 95 per cent pure mating guaranteed. Queens ready June 1. Untested, each, \$1.00; 6, \$5.00; tested, \$1.50; 6, \$8.00.

Fred S. Leininger & Son, . . . Delphos, Ohio

# QUEENS

## HELP WANTED

WANTED at ONCE.—A man with experience to work with bees. Good wages.

W. A. CHEEK, Merino, Col.

## CONVENTION NOTICES

Owing to the large flow of honey, and not being able to get prominent beekeepers to attend, I will call the field meet off which was to be held July 27 at my house.

Fairfield, Iowa, July 5.

J. I. DANIELSON.

SEVENTH ANNUAL FIELD MEETING OF THE CONNECTICUT BEEKEEPERS' ASSOCIATION AT CONNECTICUT AGRICULTURAL COLLEGE, STORRS, CT., THURSDAY AND FRIDAY, AUGUST 3 AND 4, 1916.

PROGRAM.

THURSDAY, 2 P. M.

"Producing Comb Honey without Separators," Allen Latham.

Mr. C. P. Dadant, of Hamilton, Ill., editor of the *American Bee Journal*, and an authority on beekeeping of international renown is expected to be present and address us upon a topic to be announced later. This is a rare opportunity for the members of our association to meet a distinguished pioneer and expert in our industry.

"Foul Brood and Honey Prospects in Connecticut," August Hillman.

Demonstrations at the college apiary by Inspectors A. W. Yates and H. W. Coley.

8:00 P. M.—Question-box and round-table talk.

FRIDAY, 9 A. M.

"Requirements of Successful Wintering," O. S. Rexford.

"Production and Marketing of Extracted Honey," D. R. Bristol.

"Requeening: How? When? Why?," A. E. Crandall.

Those members who attended our field meeting at Storrs last year will need no urging to attend this one, and those who have never yet attended we refer to those who have, for a complete report of the royal good time we enjoyed and the many interesting things seen. Meals cost at the rate of 50 cts. for single meal or 3 for \$1.00. Rooms and beds furnished without charge to those providing their own sheets, pillow-cases, and blankets; otherwise the charge is 50 cts. per night.

Transportation by auto-bus from Willimantic is 50 cts. each way. By special arrangement with Storrs Garage our members will be carried, upon presentation of their membership cards, for 40 cts. each way. These autos leave Willimantic at 10 A. M. and 6 P. M. Returning leave the college at 8 A. M. and 3 P. M.

Members may accompany their wives or husbands.

L. WAYNE ADAMS, Sec'y.

15 Warner St., Hartford, Ct.

ANNUAL FIELD-DAY MEETING OF MASSACHUSETTS SOCIETY OF BEEKEEPERS.

The annual field-day meeting of the society will be held at the Glenwood Farm (summer home of Frank R. Sweet), West Mansfield, Mass., Saturday, July 29, 1916.

Social hour, 10:30 to 11:30.

Basket lunch, 11:30 to 12:00.

Business session at 12. Meeting called to order by President Frisbee.

Action on new members.

Address by Prof. A. C. Miller, Inspector of Apiaries in Rhode Island.

Prof. Burton N. Gates, Inspector of Apiaries in Massachusetts, and C. P. Dadant, of Hamilton, Ill., editor of *The American Bee Journal*, have been invited to address the meeting.

Addresses by prominent beekeepers.

## PRIZES.

No. 1. For the best twelve sections of honey: A baby hive of bees, donated by Henry W. Britton, Stoughton, Mass.

No. 2. For the next best: A copper smoker, donated by Frank R. Sweet, West Mansfield.

No. 3. For the next best: A queen-bee, donated by E. Clinton Britton, Canton.

No. 4. The person who, up to our November, 1916, meeting, shall have brought the largest number of new members into the society will receive an observatory hive.

No. 5. The person who introduces the second largest number of new members, a baby hive.

Other matter of interest—non-swarming hives,

fancy fowls, turkeys, 1870 hive, queen-mating hives used by the late W. O. Sweet in 1860, and a medal won by him at the Horticultural Hall, Boston; old hive made by Mr. H. N. Nason.

Trains.—West Mansfield trains leave South Station, Boston, at 9:03 and 12:34. Boston trains leave West Mansfield at 2:52 and 5:52 P. M. No electric cars near.

PHILIP S. CRICHTON, Secretary.

75 Westland Avenue, Boston.

Field-day Committee: Frank R. Sweet, West Mansfield; Henry W. Britton, Stoughton; Lyman E. Ware, Boston.

Bring basket lunch. Ice cream and coffee will be furnished by Mr. Sweet. Automobiles at station. Stoughton, Mass. HENRY W. BRITTON.

# BEE-LINE QUEENS

## Golden and Three-banded Italians

From Caraway's prize-winning stock. Every queen purchased of me I will guarantee to give satisfaction. If she does not I will replace her with another queen or refund your money. They are hustlers, long lived, not inclined to build burr-comb, cap their honey white, and are not given to swarming, and are gentle to work with.

My bees and queens are winners of over 100 first premiums in the past eight years. This speaks for itself. If you are going to buy queens you cannot do better than buy the Bee-Line Queens.

Queens are postpaid, and safe arrival is guaranteed to all points in United States and Canada. No diseases of any kind in my apiaries.

State inspector's health certificate with each shipment.

### PRICES FROM MAY 10 TO NOVEMBER 1.

Italian Queens: Untested....one for 75 cts.;...six for \$4.00;...twelve for \$ 7.75  
 Tested .....one for \$1.00;...six for 5.00;...twelve for 10.00  
 Select Tested .....one for \$1.50;...six for 9.00;...twelve for 17.50  
 Untested by the 100, \$60.00; breeding queens, fair, \$5.00; extra select, \$10.00

## B. M. Caraway, Mathis, Texas

### Bee-line Apiaries

Reference: Mathis First State Bank, Mathis, Texas.

## LOCKHART'S SILVER-GRAY CARNIOLANS.

"LINE BRED" for the past 30 years. They are VERY hardy, gentle, prolific, great workers, and builders of VERY WHITE combs, and use mostly wax in place of propolis. Untested queen, \$1.00; six for \$5.00; dozen for \$9.00. Select untested queen, \$1.25; six for \$6.00; dozen for \$11.00. Tested queen, \$2.00; six \$9.00; dozen for \$15.00. Select tested, \$3.00. Best breeder, \$5.00. Extra select, the very best we have, \$10.00. Safe arrival guaranteed in United States and Canada. No foul brood here.

F. A. LOCKHART & CO., Lake George, N. Y.

DEAR SIR:—I want another of your fine select untested Carniolan queens. I am more than satisfied with your strain of bees in the past, for they have rid my yards of all European foul brood.

Sierra Madre, Cal., June 27, 1916.

HAROLD DAVINES.

F. A. LOCKHART & CO., Lake George, New York.

**Queens--Queens--Queens.** We are breeding from the best three-band Italian stock. Untested, 50 cts.; select untested, 60 cts.; tested, \$1.00; select tested, \$1.50 each. We have been breeding queens for more than 25 years. We guarantee safe arrival, no disease, and every one purely mated.

## Be Efficient in BEE CULTURE

Grasp the experience of others in beekeeping by reading the best that has been published. The pamphlets and books listed below compel interest. Place a X in the margin opposite the publication wanted.

- THE DEVELOPMENT OF THE APPLE FROM THE FLOWER. By O. M. Osborne. Here's the latest scientific information about why apple blossoms can not do without bees. Free.
- MY FIRST SEASON'S EXPERIENCE WITH THE HONEYBEE. By "The Spectator," of the *Outlook*. A leaflet humorously detailing the satisfaction of beekeeping. Free.
- CATALOG OF BEEKEEPERS' SUPPLIES. Our new complete catalog, mailed free to any address on request.
- THE BEEKEEPER AND FRUIT-GROWER. Do you know that bees are necessary in modern fruit culture? This 15-page booklet tells how beekeeping is doubly profitable to the fruit-grower. Free.
- SPRING MANAGEMENT OF BEES. The experience of some successful beekeepers on solving this perplexing problem. Price 10 cents.
- THE USE OF HONEY IN COOKING. Just the thing for the up-to-date housewife. Price 10 cents.
- BEES AND POULTRY, how they work together profitably for others—why not for you? Some valuable pointers on hens and honeybees. Free.
- HOW TO KEEP BEES. A book of 228 pages detailing in a most interesting manner the experiences of a beginner in such a way as to help other beginners. Price \$1.00 postpaid.
- THE A B C OF BEE CULTURE. A standard encyclopedia on bees. The largest and most complete published anywhere. 712 pages, fully illustrated. \$2.00 postpaid.
- WINTERING BEES. A digest of all the information on the subject. Thoroughly modern and practical. Price 10 cents.
- THE BUCKEYE HIVE, or the management of bees in double-walled hives. Will interest the amateur especially. Illustrated. Price 10 cents.
- SWEET CLOVER, the all-around forage crop. Just off the press. Investigate this astonishing plant. Free.
- ADVANCED BEE CULTURE. A summary of the best ideas of experts in apiculture. The book is beautifully printed and bound. 205 pages. Cloth. \$1.00 postpaid.

## TRADE NOTES

### MOLDED TOP FRAMES.

We have in stock, packed 100 to the box, about two thousand Hoffman frames with 19-inch top-bar molded on the under side instead of with double groove and wedge. These we offer, to close out, at \$3.00 per 100, and 200 metal-spaced, with the same style of top-bar at \$3.50 per 100.

### SEED.

We have closed out our stock of buckwheat seed, and will have no more to furnish. We can still supply the several kinds of sweet-clover seed; but our supply is limited; and when sold out we will not carry it any more. We have a surplus stock of annual yellow on which we ask for offers; can supply about 2000 lbs. at your price. Make us an offer.

### CHOICE SECOND-HAND CANS.

Why spend money for new cans when you can buy for half price good second-hand ones, free from rust, and satisfactory, for even white honey if carefully cleaned before filling? We do not save the poor ones, but only those which are good enough to use again. We have a supply at Medina, Philadelphia, and New York, at \$4.00 for 10 cases, \$8.50 for 25 cases; \$30 for 100 cases of two 60-lb. cans in good boxes.

### BEESWAX MARKET LOWER.

We have had an unusual number of offerings of beeswax from beekeepers as well as dealers for this season of the year, and have an unusually large stock on hand. For several years before the war there was a shortage of wax at this season of the year, and prices reached their highest level in May and June. Till further notice we quote 27 cts. cash, 29 trade, delivered at Medina for average wax.

THE A. I. ROOT COMPANY, Medina, Ohio.

## "The Management of Out-apiaries"

72-page book by the well-known writer, G. M. Doolittle, New York

Non-swarming, or the control of swarms in the home yard, is a comparatively easy problem; but the securing of perfect control of the swarming impulse in four or five yards located some distance from your dwelling is not so easily accomplished. The author tells how he secured this and an average of 114½ lbs. of comb honey in a poor season. His latest methods are fully described in the fourth edition of the above. Price 50c postpaid. Order now from the publishers.

The A. I. Root Co., Medina, Ohio

# Mental Demons Are They Holding You Back?

Does a host of mental demons bar your path to success? Do you feel yourself incapable to meet important situations? Do you lack the power to make people recognize you—to make others see things *your way*—to compel people to listen to you? Are you weak in a crisis?

Most men have the brains and the ambition to do big things—but a weak personality—a lack of self-confidence—timidness—poor vocabulary—unreliable memory—“stage fright”—hazy, unorganized ideas—*ineffective speech*—are holding them back from the success they deserve.

Send the coupon below at once and let us tell you how you can drive these mental demons away forever—how you can occupy a place among men who do things—how you can learn to express your ideas forcefully and convincingly—how you can acquire a powerful, magnetic personality—how you can develop a strong dominating will—how you can become a powerful, public speaker. Our new scientific Course in

## Effective Public Speaking and Mental Development

will quickly train you to speak forcefully and convincingly in public

- |                                  |                                                     |                                                                   |
|----------------------------------|-----------------------------------------------------|-------------------------------------------------------------------|
| --talk before your club or lodge | --sell more goods                                   | --become a clear, accurate thinker                                |
| --address board meetings         | --train your memory                                 | --develop your power of concentration, diligence and self-control |
| --propose and respond to toasts  | --enlarge your vocabulary                           | --equip you with power to be the master of any situation.         |
| --tell entertaining stories      | --develop self-confidence and a winning personality |                                                                   |
| --make after-dinner speeches     | --strengthen your ambition and will power           |                                                                   |
| --converse effectively           |                                                     |                                                                   |
| --write better letters           |                                                     |                                                                   |

This Course and Service is under the personal supervision and direction of R. E. Pattison Kline, Dean of the Public Speaking Department, Columbia College of Expression, Chicago, one of the foremost authorities in the country on public speaking and mental development. You can now secure the personal instruction of this eminent authority right in your own home, by mail, in spare time. Hundreds have acquired a powerful address and a winning personality through his instruction.

### RESULTS!

“Your Course is a most valuable training to anyone who desires to be able to speak in public without embarrassment.”

—C. C. HOFFPAUIR, Att’y, Texas.  
“Not only has it enabled me to speak in public in a way that is most gratifying to me, but it has helped me in business as well.”

—G. M. COSSITT, Banker, Illinois.  
“It has given me greater confidence in my own ability, a better memory, a more polished vocabulary, and a stronger personality.”

—W. L. WILDER, Mgr., Chicago.  
“Your Course is a splendid training for the salesman or sales manager, and I heartily recommend it.”

—O. P. BOURGEOIS, Pres., Chicago.  
“A fascinating and practical training that overcomes one of the common weaknesses of business men—inability to express themselves.”

—GUY H. SHEARER, Banker, Idaho.  
We have hundreds of similar testimonials in our files from men in every walk of life. Send the Coupon today. You owe it to yourself to find out what this Course will do for you.

# Southern Headquarters for 3-band Italian Queens

Photo of part of Achord's queen-yard, taken April 15, 1916, showing where neither labor nor money is spared to produce the very best queens that can be had. We pay special attention to honey-gathering qualities, but do not forget gentleness, beauty, etc. Having several hundred colonies in outyards to select our breeders from, we are sure we offer you something good, as hundreds of our old customers testify to same

| June and July                                                                                   |                               | August and later              |  |
|-------------------------------------------------------------------------------------------------|-------------------------------|-------------------------------|--|
| Untested Queens . . . . .                                                                       | 1 for 60 cts.; 12 for \$ 7.00 | 1 for 55 cts.; 12 for \$ 6.00 |  |
| Tested Queens . . . . .                                                                         | 1 for \$1.05; 12 for \$12.00  | 1 for \$1.00; 12 for \$10.75  |  |
| Select Tested Queens . . . . .                                                                  | 1 for \$1.75; 12 for \$19.25  | 1 for \$1.65; 12 for \$18.00  |  |
| Very best queens for breeding, \$3.00. 1 lb bees in package, \$1.25; 2 lbs. in package, \$2.00. |                               |                               |  |

Add price of queen. If any of our untested queens should prove to be mismatched we are willing to replace them free of charge. No foul brood has ever been in our vicinity. I guarantee safe arrival on all I send out.

**W. D. ACHORD, FITZPATRICK, ALABAMA**

## EUROPEAN FOUL BROOD

is spreading in various parts of the country. The first step in its cure is a vigorous strain of ITALIANS.

## The Root Strain of Bees have shown Themselves to be Highly Resistant

While we do not claim their introduction will alone cure European Foul Brood, or that it will not make a start in their colonies, we have reports of where they have, with a little help, fought themselves nearly clean of European Foul Brood which was all around them in black and hybrid colonies.

These queens will be ready for delivery about June 1. Orders will be filled in rotation. Later in the season we will make delivery promptly.

PRICES.—Our regular price is \$1.50 in June and \$1.00 after July 1 for untested queens; but we will club them with Gleanings in Bee Culture for one year and a queen for \$1.50, provided we can fill orders for queens when we have a surplus of them. This will probably be July and August.

# SPECIAL BARGAINS IN SHIPPING CASES

With the bountiful crop of honey being gathered there will be need for shipping-cases in which to place the comb honey for market. During the past few years we have made several changes in the style of our cases, and have some stock of styles formerly made, but not now listed in our catalog. There are some people who prefer the older styles to the later ones, and there may be others who would use the older styles if bought at a low price, and prompt delivery were made. We have on hand the following stock which we offer, to close out and subject to previous sale, at the special prices here named:

- 8 crates of 50 each, 9 1/2-inch, 2-row, at \$4.00 per crate.
- 20 crates of 50 each, 10-inch, 2-row, at \$4.00 per crate.
- 15 crates of 50 each, 6 1/4-in. 3-row, at \$4.00 per crate.
- 56 crates of 50 each, 12-lb. cases, at \$4.00 per crate.
- All of the above have either 2 or 3 inch glass, and take 12 sections 4 1/4 x 4 1/4 x 1 1/2 plain.
- There are also for the same size section: packed 10 in a crate:
- 12 crates of 10 each, 9 1/2-in. 2-row at 85 cts. per crate.
- 4 crates of 10 each, 6 1/4-inch, 3-row at 85 cts. per crate.
- 4 crates of 10 each, 10-inch, 2-row, at 85 cts. per crate.
- For the 4 1/4 x 1 1/2 beeway section we have:
- 15 crates of 50 each, 15 1/4-inch 2-row, for 15 sections, at \$4.50 per crate.
- 9 crates of 10 each, 15 1/4-inch, 2-row, for 15 sections, at 95 cts. per crate.
- 15 crates of 50 each, 11 3/8-inch, 2-row, for 12 sections, at \$4.00 per crate.

- 8 crates of 10 each, 12-lb. safety cases with carton, at \$1.20 per crate.
- 5 crates of 10 each, 8-inch, 3-row, for 12 sections, at 85 cts. per crate.
- 2 crates of 50 each, 11 3/8-inch, 4-row, for 24 sections, at \$8.00 per crate.
- 2 crates of 10 each, 12-inch, 4-row, for 24 sections, at \$1.80 per crate.
- For 24 sections, 4 1/4 x 1 1/2 plain:
- 5 crates of 25 each, 9 1/2-inch, 4-row, at \$4.00 per crate.
- 2 crates of 10 each, 9 1/2-inch, 4-row, at \$1.75 per crate.
- 3 crates of 10 each, 10-inch, 4-row, at \$1.75 per crate.
- For 12 sections 4 x 5 x 1 3/8 :
- 37 crates of 50 each, 3-row cases, at \$4.00 per crate.
- 3 crates of 50 each, 8-row for 15 sections, at \$4.00 per crate.
- For 12 sections, 3 3/8 x 5 x 1 3/8 :
- 6 crates of 10 each, 3-row cases at 85 cts. per crate.

THE A. I. ROOT COMPANY, MEDINA, OHIO

# WARDELL STRAIN OF ITALIANS

Descendents from the Famous Root \$200 Queen

I was head queen-breeder for The A. I. Root Co. for a number of years, and during that time I originated the famous \$200 ROOT BREEDER whose stock has gone the world around. These bees for GENTLENESS, GENERAL VIGOR, and HONEY-GATHERING qualities have ESTABLISHED A REPUTATION. I have been for years developing and perfecting this same strain. While my prices may be higher than some others, my queens are cheap in comparison with their value.

You Can Open and Close the Doors on Your Barns, Sheds, Garage and Similar Buildings, the Year Through, without a Single "Cuss Word" if They Are Hung with

## EASY TO PUSH MYERS EASY TO PULL

### TUBULAR OR STAYON DOOR HANGERS

They roll away the old-time door troubles by preventing and overcoming the bulky, off-the-track or frozen-up door. The Adjustable Construction permits a door to be raised or lowered, or moved in or out, as conditions require—A monkey wrench does the trick. Roller Bearings and Large Trolleys insure light operation. Stayon Device prevents door being thrown off the track. Flexible Hinged Joint produces tight fitting doors. You get all these features on MYERS DOOR HANGERS. You also get High Carbon Flat Stayon Track or Reinforced Girder Tubular Track.

Myers Giant and New-way Hangers for Tubular Steel Trac.—The All Weather Hangers—are our latest productions—They add the finishing touch in door service on any building.

You want MYERS—Year Through—"Easy Door Ways", and our Catalog tells how to get them. Write us or ask your dealer.

351 ORANGE ST.  
**F.E. MYERS & BRO. ASHLAND, OHIO.**

## EMBARGO ON BEE SUPPLIES

Pennsylvania, New Jersey, New York, and New England states beekeepers should not delay putting in their stock of supplies as early as possible. The eastern railroads are so heavily laden with freight it is indefinite as to just how long it will take to receive goods after they leave the factory or dealer. Ordering your requirements a month earlier than usual will cost no more, and will assure you of having supplies on hand when the time comes to use them. This will allow for any delay which might occur in transit.

As never before we are especially prepared to take care of the beekeepers' orders and give prompt service. Above all, we assure the purchaser of satisfaction, and we never consider a deal closed until we feel sure our customer has received the guarantee of satisfaction which goes with every package, crate, or box leaving our factory.

Those beekeepers who have not received a copy of our new RED CATALOG should not hesitate to send for a copy. It gives descriptions and prices of all the beekeepers' supplies, from the requirement of the smallest to that of the largest beekeeper. A postcard will bring it to your address free.

Red Catalog, postpaid.

## HONEY GRADING RULES

### GRADING RULES OF THE A. I. ROOT COMPANY, MEDINA, OHIO.

In harmony with the Federal net-weight regulations and the statutes of many states, all comb honey we handle is figured with the weight of the section box as well as the case excluded. To get the net weight, deduct the weight of the empty case and 1 lb. 8 oz. for the weight of 24 sections (1 oz. each).

#### COMB HONEY.

Extra Fancy.—Sections to be evenly filled, combs firmly attached to the four sides, the sections to be free from propolis or other pronounced stain, combs and cappings white, and not more than six unsealed cells on either side. No section in this grade to weigh less than 14 oz. net. Cases must average not less than 22 lbs. net.

Fancy.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white, and not more than six unsealed cells on either side exclusive of the outside row. No section in this grade to weigh less than 13 oz. net. Cases must average not less than 21 lbs. net.

No. 1.—Sections to be evenly filled, comb firmly attached to the four sides, the sections free from propolis or other pronounced stain; comb and cappings white to slightly off color, and not more than 40 unsealed cells, exclusive of the outside row. No section in this grade to weigh less than 11 oz.

No. 2.—Combs not projecting beyond the box, attached to the sides not less than two-thirds of the way around, and not more than

60 unsealed cells exclusive of the row adjacent to the box. No section in this grade to weigh less than 10 oz. net. Cases must average not less than 18 lbs. net.

#### CULL COMB HONEY.

Cull honey shall consist of the following: Honey packed in soiled second-hand cases or that in badly stained or propolized sections; sections containing pollen, honey-dew honey, honey showing signs of granulation, poorly ripened, sour or "weeping" honey; sections with combs projecting beyond the box or well attached to the box less than two-thirds the distance around its inner surface; sections with more than 60 unsealed cells, exclusive of the row adjacent to the box; leaking, injured, or patched-up sections; sections weighing less than 10 oz. net.

#### EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 lbs. per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained clean light honey may be used for extracted honey.

#### EXTRACTED HONEY NOT PERMITTED IN SHIPPING GRADES.

Extracted honey packed in second-hand cans, except as permitted above.

Unripe or fermenting honey, or weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

GRADING RULES OF THE COLORADO HONEY-PRODUCERS' ASSOCIATION, DENVER, COL.,

FEBRUARY 6, 1915.

COMB HONEY.

**FANCY.**—Sections to be well filled, combs firmly attached on all sides and evenly capped except the outside row next to the wood. Honey, comb, and cappings white, or slightly off color; combs not projecting beyond the wood; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 13½ gross. The top of each section in this grade must be stamped, "Net weight not less than 12½ oz."

The front sections in each case must be of uniform color and finish, and shall be a true representative of the contents of the case.

**NUMBER ONE.**—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped except the outside row next to the wood. Honey, comb, and cappings from white to light amber in color; sections to be well cleaned. No section in this grade to weigh less than 11 oz. net or 12 oz. gross. The top of each section in this grade must be stamped, "Net weight not less than 11 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

**NUMBER TWO.**—This grade is composed of sections that are entirely capped except row next to the wood, weighing not less than 10 oz. net or 11 oz. gross; also of such sections as weigh 11 oz. net or 12 oz. gross, or more, and have not more than 50 uncapped cells all together, which must be filled with honey; honey, comb, and cappings from white to amber in color; sections to be well cleaned. The top of each section in this grade must be stamped, "Net weight not less than 10 oz." The front sections in each case must be of uniform color and finish, and shall be a true representation of the contents of the case.

*Comb honey that is not permitted in shipping grades*

Honey packed in second-hand cases.

Honey in badly stained or mildewed sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honey-dew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the minimum weight.

All such honey should be disposed of in the home market.

EXTRACTED HONEY

This must be thoroly ripened, weighing not less than 12 pounds per gallon. It must be well strained, and packed in new cans; sixty pounds shall be packed in each five-gallon can, and the top of each five-gallon can shall be stamped or labeled, "Net weight not less than 60 lbs."

Extracted honey is classed as white, light amber, and amber. The letters "W," "L A," "A" should be used in designating color; and these letters should be stamped on top of each can. Extracted honey for shipping must be packed in new substantial cases of proper size.

EXTRACTED HONEY.

This must be well ripened, weighing not less than 12 pounds per gallon. It must be well strained; and, if packed in five-gallon cans, each can shall contain sixty pounds. The top of each five-gallon can shall be stamped and labeled, "Net weight not less than 60 lbs." Bright clean cans that previously contained honey may be used for strained honey.

*Honey not permitted in shipping grades.*

Extracted honey packed in second-hand cans.

Unripe or fermenting honey weighing less than 12 lbs. per gallon.

Honey contaminated by excessive use of smoke.

Honey contaminated by honey-dew.

Honey not properly strained.

**HONEY MARKETS**

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchants. When sales are made by commission merchants the usual commission (from five to ten per cent), cartage, and freight will be deducted; and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage and other charges are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

CHICAGO.—For the past month there has been little doing in honey, so that a market price is really a difficult thing to quote, as parties who have carried over their honey are accepting what they are offered. We look for new comb honey to sell at about 13 cts. per lb. for the best grades of white, and for the time being the ambers may bring nearly as much, as there does not seem to be much of that in the market. Extracted ranges from 7 to 8 for the white and 6 to 7 for the amber. Very little of the harvest of 1916 is on this market, and what there is has not been sold. The weather now being warm, the retail trade are not endeavoring to sell. Beeswax is bringing 28 to 30, according to color and cleanliness. Chicago, July 18. R. A. BURNETT & Co.

ALBANY AND SCHENECTADY.—There is no new comb honey in our market yet, and stock of last season closed out. Some producers have offered us light extracted in 60-lb. cans, but there is no demand as yet. The present outlook for white honey is reported good. We could sell some No. 1 comb in a small way, but there is no established price yet. We think, however, it would bring 15.

CHAS. MACCULLOCH.

Albany and Schenectady, July 21.

KANSAS CITY.—There is a lot of native honey coming into the market now. Most of it is white clover, the best fancy white selling for \$3.50 a case, or \$3.25; No. 2, \$3.00. Last year's extracted honey, amber, sells at 6½ cts., and white clover at 8 cts. There is a fairly good demand.

C. C. CLEMONS PRODUCE CO.

Kansas City, July 20.

ST. LOUIS.—Comb honey out of season, dead dull, and none selling. Some little inquiry and movement in extracted honey with market for this grade improving. Extracted honey ranges in price from 6 cts. per lb. for dark amber to 7 cts. per lb. for light amber, according to color, quality, and quantity. Comb honey nominal, and ranging in price from \$2.50 to \$3.25 per case. Beeswax brings 29 cts. for prime; inferior and impure, less.

R. HARTMANN PRODUCE CO.

St. Louis, July 20.

DENVER.—New crop comb honey is selling in the local market at the following jobbing prices: Fancy, per case of 24 sections, \$3.38; No. 1, \$3.15; No. 2, \$2.93. White extracted, 8½ to 8¾ cts. per lb.; light amber, 8 to 8¾ cts. per lb., and amber, 7 to 8 cts. per lb. We pay 26 cts. per lb. in cash and 23 cts. per lb. in trade for clean, average yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION, Denver, July 22. Frank Rauchfuss, Mgr.

**For Sale** Bee supply and honey business. Established more than a quarter of a century. Splendid location. Rare opportunity for the right man. Big money-maker. For information, address J. W. HARRINGTON, 1506 Mechanics Bank Bldg., Indianapolis, Ind.

**BANKING BY MAIL

# Preparedness!

Your success this season, Mr. Beekeeper, depends on being ready. You need to buy your supplies now.

**Root's Goods mean Real Preparedness.**

We sell them in Michigan. Send for catalog. Beeswax wanted---

---

**M. H. Hunt & Son, 510 Cedar St. N., Lansing, Mich.**

## "If Goods are Wanted Quick Send to Indianapolis"

Indications just now are very favorable for a good season; but we are, of course, at the mercy of the weather conditions. A good season means an excessive demand for the line which we handle, and we mention this, urging our friends to place their orders before the goods are really needed, that none may be disappointed.

We carry Root's goods and sell at their prices; and considering this as a shipping-point, we can save you time and freight by having your orders come to this house.

If you are new to the business we should like to explain that Root's goods are the very best that can be produced. If you have been using THE ROOT LINE you will recognize the truthfulness of the above and will want more of the same goods.

Promptness in filling orders is the motto here. We also give small orders the same careful attention that are given to large orders.

Let us have the pleasure of mailing you our free catalog.

# Bingham Honey Uncapping Knives. . .

with the New Improved Cold Handle

**A. G. WOODMAN COMPANY**  
Grand Rapids, Michigan

Standard length, 8½ in.; 75 cts.; ship. wt., 15 oz.  
Extra long, 10-inch; each, 85 cts.; ship. wt., 16 oz.  
Steam-heated with 3 ft. tubing, \$2.50; ship. wt. 24 oz.

Our knives are made of the best razor steel, and we could produce them at least 10 cts. per knife cheaper by using inferior material. Mr. W. W. Culver, of Calexico, Cal., writes, "We have had difficulty in getting Bingham knives, such as we are accustomed to—that is, a light flexible knife that will give somewhat in moving the comb. If you can furnish such a knife, send two standard and one steam knife. If the steam knife suits me I shall want about three." This is just the kind of knife we furnish, the kind Mr. Bingham furnished years ago, before others crowded him out with their inferior substitutes. We know, because we have kept bees nearly 40 years. Old timers will again find what they want in our Bingham knife.

## Tin Honey-cans---Low Prices

Five-pound Friction-top pails, lots of 50, \$3.25; 100, \$5.35; 203, \$10.35; 1015, \$50.00.

Ten-pound Friction-top pails, lots of 50, \$4.30; 100, \$7.60; 113, \$8.35; 565, \$40.00.

Sixty-pound cans, two in a case, 70 cts. per case; over 10 cases, 69 cts; 25 cases, 68 cts.; 50 cases, 67 cts.; 100 cases, 65 cts. per case.

All F. O. B. Chicago, Ill.

We are making prompt shipments.

## For New England

Beekeepers, we have everything you need in the way of supplies. Remember we are in the shipping center of New England. Let me send you a new catalog.

H. H. Jepson, 182 Friend St., Boston, Mass.

# Wanted---Honey

## Both Comb and Extracted

If comb honey, state grade and how it is put up, and your lowest price delivered Cincinnati.

Extracted honey, mail a fair-sized sample, state how it is put up, and your lowest price delivered Cincinnati.

If prices are right we can use unlimited quantities.

---

C. H. W. Weber & Company, Cincinnati, O.

2146 Central Avenue

# What do you know about that

We are getting an almost innumerable number of orders to go by parcel post --- a great thing for beekeepers on rural delivery. **BUT REMEMBER** to always include enough in the amount sent to cover the postage required. . . .

For instance, if you are within 150 miles of Syracuse, and need 500 sections, we can mail them for 41c; 250 sections for 21c, and 100 sections for 11c. Foundation in 5-lb. lots, can be mailed for 11c; 2 lbs. for 7c; 1 lb. for 6c. Always figure postage more than foundation weighs. Rates inside of 150 miles once the total weight plus 4.

---

F. A. SALISBURY, Syracuse, New York  
1631 West Genesee St.

# Nominated by Acclamation Lewis Sections

The kind that does not break in folding

Beekeepers everywhere, no matter what their preference may be for hives or special apparatus, agree that when it comes to sections that

There are no sections like Lewis Sections!

**WHY IS THIS TRUE?** BECAUSE LEWIS SECTIONS are made of Wisconsin basswood—the best material for sections—out of carefully selected white stock. The V groove which allows the sections to fold is scientifically made. LEWIS SECTIONS are polished on both sides and are neatly and accurately packed in a tight wooden box, insuring delivery in good order.

At the same price you pay for other standard makes of sections you get all of the above. The making of Lewis Sections has been under the supervision of a Lewis section expert who has "been at it" for over thirty years. No wonder Lewis Sections are perfect. One of our customers tells us that he has put up (folded) thirty thousand Lewis sections in a season, and has not found one section in the whole lot that was not perfect. Can we mention any more convincing evidence of quality? Can you say the same of even five hundred of any other make?

**INSIST ON LEWIS SECTIONS. LOOK FOR THE BEEWARE BRAND.**

**G. B. Lewis Company, Watertown, Wisconsin**

Catalog on request giving nearest distributor.

# DO YOU WANT Your Bee Supplies Shipped Promptly?

We carry from four to six carloads of the finest BEEWARE on hand at all times, and can fill your orders without delay. . . . BEE-HIVES, SECTIONS, Shipping-cases, Tin Cans, and all other Bee Supplies; also

## Dadant's Foundation

by return freight, mail, or express

DADANT & SONS, Hamilton, Ill. Dear Sirs:—The box of foundation arrived a few days ago in fine condition. I have kept bees for over thirty years, and have purchased foundation from many firms, and must say that your foundation is the nicest that I have ever used, and I wish to thank you for the prompt shipment and large amount of wax you secured for me.  
A. W. DARBY, Alburg, Vt., May 3, 1916.

We have forty years' experience and thousands of satisfied customers. Are you one of them?

## EDITORIAL

IN our issue for July 1 we should have made special mention of the article by H. H. McIntyre on how to get all the honey from the cappings. There is another article that deserves special mention—the one by G. A. Deadman on a plan for cleaning honey-combs after extracting. If the reader has not already read these two articles he should do it yet.

### Idiosyncrasies of the Clover Flow

IN our locality, which is dryer than most places in the United States, the clover yield has been somewhat fitful. Bees would be idle until about noon, and then they would get busy again as the day wore on. Our extracting had to be postponed in some cases on this account. There would be nothing doing in the morning; but in the afternoon the combs began to show raw nectar.

In some localities the bees will be busy all day. In one place in particular they will bring in more honey in the morning than in the afternoon; and the suggestion has been made that perhaps the bees stay out all night because they are too far away to get home; and when the sun is up they hike for home with a big load of nectar.

### The Net-weight Law, Again

QUESTIONS continue to come in about this law, and we are obliged to repeat that it is not necessary to mark the net-weight on honey sold around home and within the state, provided, of course, there is no state law requiring the marking of net weights. But we advise every one to mark the minimum net weight on their sections and to see that all labels on glass or tin packages show the net weight in pounds and ounces. Do not make the mistake, for example, of saying "17 ounces." but say, instead, "1 lb. and 1 oz."

It is not necessary, as we understand the

ruling, to mark the net weight on a whole shipping-case of honey; but as a matter of expediency we advise it. This net weight must be exclusive of the weight of one ounce for each section in the case and the case itself. Better not mark at all than to mark it wrong.

### Preparedness against Bee Disease

THE other day as we were going over a set of combs to give to a swarm we found one in which brood had died the previous season. The yard from which it came indicated that it was only a case of chilled brood; but it had somewhat the appearance of a comb that formerly contained American foul brood; and had we not known the prior conditions we might have been in doubt. Even as it was, we instructed the boys to burn all such combs, in view of the danger that was possible tho remote.

Foul brood of either kind in a beeyard is an expensive proposition at best. Moreover, a comb that is smeared up, and has the carcasses of dead brood in it, will be an ideal place for the propagation of bee disease provided that the germs were already in the apiary, or, we will say, in the hives. In this day and age one cannot afford to use anything but good clean combs, and that means that all combs when put away in the fall should be carefully inspected and put into bee-tight compartments, hive-bodies provided with cover and bottom.

### Importance of Advertising and Introducing Honey into the Family

THE reader's attention is called to the wealth of reading-matter on the subject of marketing honey, in this issue. We have tried to cover every phase of it. This year of all years it is important to know how and when to sell honey, because it will prob-

ably go down in history as one of the greatest if not the very greatest clover year ever known. It will, therefore, be necessary for all of us to get busy in getting honey introduced, especially at this time, when complaint is made that sugar is abnormally and perhaps unnecessarily high. The producer who will not take advantage of the situation of the high price of sugar is losing the opportunity of his life to introduce his product to his neighbors. If it can once be introduced into a family, its use will continue year after year. Don't miss the opportunity that may not come back again in a decade.

### "Safe Arrival Guaranteed"

THIS is a phrase that is used in advertising that too often does not mean what it says. Worse yet, there are other times when no guarantee of any sort is stated, and the prices are made very low.

A customer recently complained that an advertiser sent him a nucleus containing wormy combs, old-style and rotten frames, and on top of it all the shipment arrived in bad order. The customer complained, but the shipper came back with the statement that his prices were very low, and therefore he could not afford to guarantee safe arrival nor replace the wormy combs.

It is the usual custom, in the delivery of bees and queens, to guarantee satisfaction and safe arrival. This puts up to the shipper the responsibility of making a package of bees that is up to a standard. If the carrier is responsible for delay or breakage, it should be up to the shipper to seek damages from the carrier. If the shipper does not guarantee safe arrival it will make no difference to him what kind of package he uses; and, no matter in what condition the bees arrive, he will come back with the statement that "it was not my fault." This is precisely what some are saying.

Another year, if we know ourselves, advertisers for bees and queens, in order to get in our columns, must put up a guarantee to meet certain specifications. Among them shall be safe arrival, good stock, good frames, good combs, from a yard free from disease or hybrid stock, and everything as represented. To ship hybrid bees for Italians or to send bees out of a yard that has foul brood, or to send bees two or three weeks after the time promised, to send poor or wormy combs—any and all of these things are a vexation, and lead to no end of controversy in which the publisher is involved sooner or later.

Those who are seeking to buy bees, if lured by low prices, should first ascertain whether those prices cover a suitable guarantee of quality and delivery. To receive a shipment of bees in combless packages, a third or a half of them dead, is making a very poor delivery. Our experience shows that when a third of them are dead a large number more will die soon after putting them in the hive. The prospective buyer should find out exactly what the shipper will do in the case just cited. He will do a whole lot more when he is seeking business, and wants the cash, than after he has got the cash in his pockets. Don't forget that.

### Honey-crop Conditions and Prices

REPORTS from the clover districts of the United States continue to be favorable. Clover honey at this writing, July 24, is still coming in, in most places, and it appears as if the flow might hang on for some days yet. While early in June we were getting too much rain, and were hoping we might have some dry weather, we are now getting to the point where there is too much of drouth, and we are now wishing for rain. A survey of the government weather maps shows there have been thunderstorms in many localities that will give a new lease of life to clover; but in most places a little more rain would be very helpful.

The reports show one, two, three, and even four supers of clover honey already on the hives, and more coming in. Out of all the letters received there is only one report of failure.

Clover seems to be yielding well, from Maine to the Dakotas, and from the northern states clear down to Tennessee. It began yielding in June, and in many localities it will be furnishing some honey even up to the first of August. This probably means an enormous crop of clover honey.

Late reports indicate that alfalfa areas may not come up to their usual average; but these reports are so meager that no definite statement can as yet be made.

The high price of sugar and the slight shortage in the alfalfa regions may have a tendency to hold up the prices on honey; but the probabilities are they will be easier than last year at this time.

To help stem the tide of a possible and probable drop in prices the A. I. Root Company has entered on a vigorous campaign of honey advertising. This will begin at an early date and primarily is intended to stimulate a demand for honey and to educate people to eat more honey. Now

that the price of sugar is soaring, we think it will set the good housewife to thinking. See later editorials for further particulars in regard to this campaign.

In the mean time, clover-honey producers should advertise honey in all their local papers. Get your customers to thinking about honey for general use, for canning fruit, as a table delicacy, and as an important food.

### Railroads Discriminate against Comb Honey in Western Territory

IN the new issue of the Western Classification, becoming effective September 1, and applying to territory west of Chicago and the Mississippi River, we discover that the rate on comb honey has been raised to double first-class, which means that all local shipments of comb honey, in the territory affected, of 100 pounds or more, and less than a carload, for longer or shorter distances, will have to pay double the freight after Sept. 1.

Without question the careless packers and shippers of comb honey are responsible for this advance in rate, and it seems decidedly unfair to those who put their honey in cartons or partitioned cases and then pack the cases in carriers, that they should have to suffer the penalty of paying such excessive freight charges, because of the large claims on comb honey improperly packed and shipped.

This question was up before the Western Classification Committee two years ago. At that time they proposed making the rate three times first-class. We learned of the proposed change before the meeting of the Committee, and arranged for a hearing. As a result of this hearing the rate was left unchanged; but we were given to understand that unless there was a decided reform in the method of packing and shipping comb honey, so as to reduce the number and amount of claims entered against the railway companies for breakage, they would be compelled later to make a change in the classification.

We have since then uttered repeated warnings, and have endeavored to institute a reform in the method of packing comb honey; but there have been too many penny-wise-and-pound-foolish producers who were not willing to pay the price of adequate protection to their very fragile product, and as a result all producers of comb honey must suffer by paying a double freight charge on all local shipments.

But we need not accept without protest the ruling of the Western Classification

Committee. In the Official Classification governing the territory east of Chicago and the Mississippi and north of the Ohio, comb honey protected by carriers is carried at second-class rate. If the producers and associations of beekeepers interested will take prompt and united action, and will write to R. C. Fyfe, Chairman of the Western Classification Committee, Transportation Building, Chicago, Ill., protesting against the discrimination, and asking for provision for a lower rate on comb honey properly packed and protected for shipment, we may still hope to obtain some redress.

### Hand Extracting vs. Power Extracting; a Small Extracting-outfit at Every Outyard, vs. One Large One at the Home Yard

THESE two questions will invariably come up in the mind of every producer of extracted honey with outyards. There are some who believe it is more economical and more satisfactory to have a hand-power extracting-outfit at each yard. But there is another class, and it is growing larger, who believe it is more economical to have one large power outfit at home, and haul the combs from the outyard to the home yard, extract and return. One strong argument in favor of the latter is that the large outfit will do a more thorough and much cleaner job. We have definitely proven that a hand-driven machine cannot extract as clean as a power outfit.

Again, the conditions at the outyard are not usually favorable so far as a building is concerned for extracting. Practically all the work will have to be done in a small outbuilding or under a tent. If the extracting is near the close of the season, robbers will be ever present and annoying. Besides, they will be the cause of a general uproar in the yard. On the other hand, if the combs are taken from the hives and freed from bees they can be put into extracting-supers hauled home, and brought back again in very short order. Two men going with an automobile truck will clear the combs of bees while an extracting force at home can have a set of empties to send back; but suppose there are only two men to do the work. The combs can be shaken at an outyard, taken away late in the day, extracted, and brought back some time the next day.

The objection has been made that the central extracting-outfit at the home yard will cause more or less of a mix-up of

combs from the different yards, involving a risk of bee disease if one yard has foul brood. This does not necessarily follow. The combs of an individual yard can be kept separate with a central outfit for extracting, but it will be necessary to wash out and clean thoroly the extractor and the tools for doing the work for each individual yard. They ought to be cleaned anyway, and hence the risk of bee disease will be no greater in the one case than in the other.

We have been in quite a number of extracting-yards where a little outfit was used in each yard. Some of the worst robbing fracasces we have ever seen was where extracting was carried on in an outyard building or under a tent, and where it was practically impossible to screen out robbers. When we consider the further fact that a central outfit will extract ten per cent more honey, the outyard operator can hardly afford to consider the individual outfit.

Of course, where one has only one apiary, and does not expect to make a very large increase, a small hand-power outfit is the only thing that can be or should be considered.

### Is it Possible to Secure Samples of Honey Each from One Individual Source, without Admixture from Some Other Source?

A CORRESPONDENT has written, saying he would like to secure several samples of clover, basswood, alfalfa, mountain sage, orange, buckwheat, each without the mixture of any other honey, for exhibition purposes at this county fair. He wishes to know how many of these he could secure, and how he could vouch for each being free from any other honey. For his benefit and that of others, it may be well to make a general statement.

Most years, and especially this year, it would be possible to secure a pure clover honey. Indeed, where there is no alsike grown one may be able to get a pure white clover; but as a general thing clover would include alsike and white, with a little of red, perhaps. Some years it is possible to secure a pure basswood; but usually it will have a little admixture of clover, because in most localities basswood begins before clover is over. But the aromatic flavor of basswood is so pronounced that if it is two-thirds basswood and one-third clover it would naturally be classed as a basswood honey. Generally speaking, we would say it would be difficult to get a pure basswood without clover; but for educational purposes a sample of honey that is largely basswood

would answer quite as well as one that is basswood only. The same statement might be made concerning buckwheat. The flavor is very pronounced; and even if there is an admixture of aster, goldenrod, or clover, if it is two-thirds buckwheat it will be classed as a buckwheat; but we doubt very much if there is any such thing as pure buckwheat honey, as there will probably be something else in bloom either at the beginning or at the close of the buckwheat flow.

A pure alfalfa honey can be secured in many localities; for when alfalfa is the only source of nectar it can be had in all its purity. The same may be said of mountain sage up in the mountains, because nothing else may be in bloom at the time, altho there may be alfalfa in the valleys, and orange in the groves. Mountain sage, while largely such, may contain some orange and perhaps a little alfalfa.

There are some seasons and some localities where pure orange honey can be produced. Last year Prof. Baldwin, at De Land, Fla., produced an orange honey that was as nearly pure as it is possible to secure, and it was indeed a beautiful honey. But usually orange will have a little of palmetto, and perhaps a little gallberry. Orange in California will have both alfalfa and perhaps a little mountain sage, altho there are seasons and localities in California when the pure article can be produced.

When it comes to the fall honeys, they are generally mixtures of everything. In our locality the asters and goldenrods will have a little buckwheat, and perhaps a little second crop of red clover. There are some localities in the western states where pure heartsease may be secured; but heartsease will generally have a little aster and goldenrod mixed with it.

For general trade purposes we would say that a honey that is two-thirds basswood, two-thirds sage, two-thirds orange, two-thirds alfalfa, could be sold under the name of the two-thirds source. For example, a basswood that was made up of one-third of other honey could be sold as basswood, because it is very difficult to get basswood that does not have at least some other source. Whether it would be safe to bottle honey and label it as a basswood under the federal law we do not know. Generally it is wiser to err on the safe side, and call the honey somebody's brand of pure extracted, not naming the exact source. As a rule it is not possible to secure, year in and year out, any one flavor; and large bottlers are in the habit of making up a blend of several pure honeys and keeping that blend entirely uniform from year to year.

Dr. C. C. Miller

## STRAY STRAWS

Marengo, Ill.

MRS. ALLEN wonders, page 522, whether bees would suffer drones in a super till the general drone-slaughter. In cases I have known, whether it was the indoor confinement, or whether they were starved by the bees, it was not long before they were all gone, and nothing left of them except their polished thoraxes lying on the excluder.

"AN ORDINARY frame of sealed brood" is pictured on p. 488. Is that a fair sample taken from a good colony in the height of the breeding season? So many unsealed cells among the sealed do not seem entirely satisfactory, altho it may be all right if the picture be taken rather late in the season, when laying has become more scattered. At any rate, such a frame is hardly the ordinary thing in my hives in June. [The comb was not shown because it was perfect or normal for the time of year, but because it showed all kinds of brood, worker and drone, sealed and unsealed. Perhaps we ought to have had another frame showing all the cells sealed. But our main purpose was to illustrate to the novice the difference between the different kinds of brood. Perhaps the word "ordinary" is not quite the correct qualifying adjective. We will change it when it comes out in book form.—Ed.]

THE last paragraph, p. 549, intimates that when a queen becomes a drone-layer she lays two and three eggs in a cell. I wonder. I'll tell you what I think, subject to correction. When a queen becomes a drone-layer she has the same instincts as before, will lay in the same kind of cells, and the same number of eggs, only they'll all produce drones. A laying worker seems to consult her own comfort, and prefers the larger cells because more comfortable. (I saw one once laying an egg in a worker-cell, and her wings were crowded up about her head so uncomfortably that I don't wonder she should want a larger cell.) So when each drone-cell has an egg she prefers to duplicate them rather than to use a worker-cell. A queen-cell is still more comfortable, and three times as many eggs may be found in a queen-cell as in a drone-cell. But when scarcity of larger cells obliges laying workers to use worker-cells, there's one egg in a cell; and until the cells are sealed you can't tell the work from that of the best queen. At least that's the way "in this locality." [When we read over your first sentence, referring to page 549, we felt

sure you must be referring to some correspondent, because we certainly believed just what you say; but when examination showed that you were referring to our own statement, we have to confess we did not say what we meant, because we had in mind laying workers. It is true, just as you say, that a laying queen that turns drone-layer does not lay eggs like a laying worker; but a queen that never met a drone, and never laid worker eggs, will behave very much like a laying worker. Thanks for your correction.—Ed.]

"RELIABLE estimates show that the total amount of honey produced is not far from 200 million pounds," page 547. That sounds like such an enormous quantity it seems there must be some mistake about it. But when we remember that that's to feed a hundred million people, what a stingy morsel it is! Less than a tenth of an ounce a day for each individual! My daily ration is 15 to 30 times that much, and I'm a very small eater. The average beekeeper does a lot of grumbling because he isn't better paid, and I don't know that I blame him. But let him take comfort in the thought that he's engaged in a work of true philanthropy with every pound of honey he produces, in helping to bring up the annual average from 2 pounds to 50 or more. I'm not getting rich producing honey, but I'm taking pride in knowing that I'm doing my little share toward making the people of this country just a little healthier and happier because of the honey they eat. [The government census shows 100,000,000 lbs.; but from reliable data it is very evident that it would be safe to double these figures and make it 200,000,000. The census took no account of beemen in cities and towns, and many of the large producers live in town but operate their outyards at points remote from town. Furthermore, the canvass at conventions and elsewhere shows that some of the large producers furnished no figures nor estimates to the census enumerators. This year we shall not be surprised if the actual gain in honey would be nearer 400,000,000 lbs.]

Yes, it is a comforting thought to feel that, while we are not only getting a living out of our bees, we are helping other people to live longer. When the world wakes up to the fact that the carbohydrates are energy-producers, and that honey stands at the top of the list, and that it is partially digested, the demand will be a great deal larger than it is now.—Ed.]

Grace Allen

## THE DIXIE BEE

Nashville, Tenn.

Well, Dr. Miller, I surely thought it was the little bee's antennae that held that tiny egg that blew away so quickly. The mistake, as you suggest, must have been due to inaccurate observation, for it was not mere careless reporting. Thanks for the correction, tho it docs force me to un-see what I seem to see very clearly in my mind's eye.

One thing that I *have* seen accurately, tho, and as you see it, is the beauty of the daudction. I am glad you love it too. A field of them is so beautiful that history's famous Field of the Cloth of Gold on which the two great kings met seems a dead unthrilling thing by contrast.

\* \* \*

As to the queen's preference for new comb, we have often remarked it, having frequently found the queen laying in comb only partly drawn, even when not forced to it by lack of room.

\* \* \*

Mr. Scholl says, page 471, "It is possible to take off more than a thousand pounds of honey in half an hour." My marginal comment, in the light of our own recent experiences, reads merely "Whew!" May I repeat it here? *Whe—ew!*

\* \* \*

There are certainly plenty of fine suggestions in that special advertising number—national honey week, honey stamps, and all the splendid schemes for co-operative advertising action. The next thing is the co-operation and the action.

\* \* \*

May with her lavish clover bloom raised high hopes in the hearts of Tennessee beekeepers; but June with her uncompromising rains laid them low. The crop seems to be merely an average one, probably slightly under a hundred pounds per colony, judging from reports received. Considerable of the new crop is already on the market, and the quality is unusually fine. The constant rains have interrupted many attempts at extracting, causing many beekeepers merely to mark time. The worst of this rain, tho, is the really serious damage being done further south.

\* \* \*

While Mr. Allen was carrying those heavy supers from the wheelbarrow up the steps into the house (for of course we do our extracting in the kitchen) I could do

nothing but stand by and give moral support and open the screen door; but whenever he got hold of one of the new supers, purchased this season, I could and did join him in a strenuous objection to the lack of hand-hole cleats. It seems to me that, even if I were strong enough to lift seventy or eighty pounds, I'd rather not have to do it with just the tips of my fingers.

\* \* \*

We were puzzled at finding a laying queen in one extracting-super, with brood in all stages from eggs to sealed worker brood. It is true we had raised considerable brood one time and another, but were always very particular not to put up the queen. This one we found wasn't clipped, anyway, so she almost certainly wasn't put up from below. As we sometimes failed to look later for queen-cells above, the bees might easily have reared a queen; but being over the excluder, she could not have been fertilized. Yet there were the eggs, and we are still puzzled.

Then we did a silly thing. Not knowing from which colony this particular super had come, and being rushed and busy as perhaps only backlotterers are apt to be about their extracting, we just set it out in the yard on a new stand, with its honey, brood, queen, the bees that had stayed on the combs, an entrance-contractor, and our best wishes. What the robbers did! We didn't mind their doing what robbers are supposed to do, for we had given them the chance; but they tore those combs almost completely to pieces, and we never saw the little queen again.

\* \* \*

We have good-looking covers in your sense too, Prof. Baldwin, when they are well-painted and don't look sort of speckly. They do take a deal of painting, tho, don't they? Painting every five to ten years won't do for metal covers, as Mr. Miles, page 475, says it will for hives—not, that is, to keep them looking well. The only other thing about these covers that distresses me, for I am very partial to them, is their well-developed talent for getting insufferably hot. I realize there is an air-space below; but even at that, it seems as tho when they are so hot that I can scarcely bear my hand on them, as they are in a hot sun, when unshaded, it must be decidedly and uncomfortably warm inside. We have resorted to shade-boards a few extra-warm days this season—when it didn't happen to be raining.

# NOTES FROM CANADA

J. L. Byer, Markham, Ont.

Mention was made in my last batch of notes of the fact that the acreage of buckwheat was likely to be high. With the sudden change from very wet to very dry weather, the land lying idle has baked so hard that comparatively little has been worked hard; and, as a result, the acreage of buckwheat, instead of being heavy in our locality, will actually be smaller than usual. But with the present program of 16 hours or more a day looking after the bees during clover flow, we are not doing much thinking of a possible dark-honey flow later on.

\* \* \*

The Weather Bureau at Toronto officially reports that we had 24 days in June in which rain fell at that station. As we are but 25 miles from that city, it is needless to say we have had all the precipitation that was needed. But we have had a change just as decided, as the most anxious dry-weather wisher could have hoped for; and at this date, July 12, many are thinking that a nice shower would be acceptable again. What changeable mortals we are! and how hard to satisfy!

After all the heavy downpours of June, on June 26 here in York Co. old Sol decided to show his face, and we have now had 18 days of warm bright weather. Clover started to yield the day the weather cleared, and we have had a steady flow ever since, and a fair crop seems to be assured. No honey has come in during the forenoons, and even in afternoons the flow has never seemed to be heavy, as, for instance, in 1913. Yet the *supers seem to fill up*, and that, after all, is the most important test of a honey-flow.

\* \* \*

## WHAT WILL THE HARVEST BE?

Before these notes appear in print, no doubt the Honey-crop Committee will have met and considered the question of prices for the current year, and will have advised beekeepers as to their opinion in the matter. In the meantime the question of prices to ask seems to be a rather hazy proposition in the minds of many. Nearly if not all food products have gone up in price. In some cases—sugar and meats for instance—the rise is about 100 per cent over two years ago. Will honey sell at a much higher figure than it did last year—that is the question many are debating.

Present indications are that the crop will

be fair over Ontario, as the abundant rains of May and June were general, and present fine weather is also general. If people believe or can be taught that honey is a food as *cheap* as or cheaper than many other articles of diet, then honey should sell at quite an advanced figure over last year. If, on the other hand, the consumers decide that honey is a luxury rather than a food necessity, then higher prices would curtail consumption. Much will depend upon size of crop, and also on the apple crop—the latter at present looking none too good in spite of rosy prospects earlier in the season.

\* \* \*

## ENCROACHMENT ON BEE TERRITORY.

Page 386, May 15, Dr. Miller refers to the matter of a law in force in Australia that defines the limit for a beekeeper to place an apiary, and forbids others encroaching on such premises. Some time ago Dr. M. and yours truly had a rather verbose argument on this same question, and I suppose both chaps were of the same mind as before the discussion started. I have no desire to debate the question further at present, but simply wish to remind the good doctor that conditions are very different in Australia from those in the more closely settled parts of Canada and the United States, where so many beekeepers reside. In Australia it is a common thing in the sparsely settled districts for neighbors to be miles apart, the country being given over to ranching almost exclusively. It is easy to see how such a law as we have under discussion might be workable under such conditions, and just the opposite in a thickly settled country.

No, Dr. Miller, much as I might desire, from a selfish viewpoint, to prohibit others from keeping bees in my neighborhood, I do not for a moment see how, for any reason whatever, I could object to a man, owning property near me, keeping bees. But there are cases where *beekeepers* (by this I mean those who follow the business as a specialty) have actually started large apiaries within two miles, or even closer to apiaries of long standing. That is a different matter altogether, and often, I am compelled to admit, it would make almost any one engaged in the business wish that such a law as that mentioned might be incorporated in our statutes. But I haven't the slightest hope that such a law will ever be enacted, so I do no worrying about these things, for, after all, the *thing generally adjusts itself satisfactorily in time*.

# BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado

The Boulder County Fair will be held September 5 to 8 inclusive, at Longmont, Colorado. The premiums for the Apiary Department amount to \$75.00, which is an increase of \$50.00. The amount is sufficient compared with premiums offered in other departments. The Boulder County Fair is equipped with the best buildings and grounds of any county fair in Colorado, and the attendance will undoubtedly be very large.

\*\*\*

Grasshoppers are reported very bad in places, and the farmers are beginning a fight on them. Alfalfa was not injured by late freezes, except in a very few localities. Horsemint was injured by freezing, however, and also suffered by the drouth in June.

\*\*\*

The bees were checked in their swarming preparations according to rule this year. Just as swarming was about to get under way the alfalfa was cut, and sweet clover was not yielding sufficient to keep up swarming preparations. We shall doubtless get swarms in August this year, if the flow is good, but we look for the swarming proposition to be easily controlled this season.

\*\*\*

The weather has been very unfavorable in Idaho, but there will doubtless be some honey produced this year for shipment. Colorado, as a whole, has had a flow from the first alfalfa, and the bees are well started in supers; if sweet clover and alfalfa will keep them going, things may come out well. A bumper crop will not be harvested unless there is a quick change in the matter of moisture.

\*\*\*

## SWEETEN BERRIES WITH HONEY.

The Colorado Honey-producers' Association is distributing among the fruit-grower beekeepers near Denver thousands of little slips printed with these words: "Have you ever sweetened berries with honey? If not, try it! It is delicious!" These slips are put in the bottoms of the berry-boxes; and when the berries are emptied out, there is the slip for the lady to read. It will have a wonderfully good and stimulating effect, now that the price of sugar is so high. There is no patent on the idea, and beekeepers are urged everywhere to copy it. These uses of honey, where honey is so manifestly superior to sugar, should now be pushed. Honey for sweetening coffee is fine where

the quality of honey is the best. For sweetening lemonade, honey is not as desirable as sugar, in the writer's estimation.

\*\*\*

## DROUTH HURTING SWEET-CLOVER FLOW.

The first crop of alfalfa is now (July 6) all put up, and sweet clover is in full bloom. The flow from the first crop was better than it has been for several years. It is exceedingly dry, and a few good rains would mean much to the beekeepers of Colorado. If we do not get rain, the yield from the second crop of alfalfa will be light and the flow from sweet clover will be very small indeed. The precipitation is about four inches below normal, and all we can depend on now is snow, which is melting very rapidly these hot days.

\*\*\*

## SUPERING.

It is well to remember that all comb-honey supers should go on top until the second crop of alfalfa proves what it will do in the way of nectar secretion. Lifting supers and putting empty ones beneath, during the first alfalfa flow, is poor practice with most colonies. If we had all colonies like the best, it would be different, but we never do unless we have but a few colonies. When the second alfalfa blooms, then we can judge pretty well whether supering may be liberally done. It is always safe to keep an empty super on top as a safety-valve.

\*\*\*

## HONEY PUBLICITY.

A few years ago the raisin-growers of California were up against a glutted market, and they began a publicity campaign, carrying it forward with such efficiency that there was no railroad running out of California but that served raisin bread, and *raisin bread only*, on their dining-cars. I have been in dining-cars when I could get no plain bread. I have never liked the raisin-growers for this, for I do not like raisins in my bread. Let them push raisin pie all they wish to, but stop putting raisins in bread for me. And I hope that honey publicity will keep fairly within the realm of common sense. I boost honey all I can; but I don't like honey in my tea, coffee, or postum, and maple syrup tastes just a little better on hot cakes than does honey—probably because we have honey on the table every meal, and maple syrup is a scarce article. There is a limit to honey publicity, and we must use it or we shall do no permanent good.

# BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Weather conditions have been most peculiar since early in June. It rarely happens that so much fog is present during that month; but what is still more peculiar is that it has continued down into July.

Today, July 13, the fog was exceptionally heavy in the early morning, with a sultry heat during midday that was torture, and this is only one day of most of them so far this month.

\*\*\*

A joke is going the rounds which involves one of our honey-buyers in a not altogether favorable light. Honey samples sent this particular buyer were believed to be graded far from the lines that their similarity in color would justify, and so to test the matter four samples were taken from the same 60-pound can and mailed to the buyer by four different beekeepers, and, strange to say, each was given a different grade, and a different price quoted.

\*\*\*

G. W. Bereaw, page 489, June 1, after reciting approved plans for handling bees, says, "When putting the excluders between the supers it is a very good plan to examine each comb below and cut out all drone comb that may show up." Well, Bro. Bereaw, in this day of foundation and wired frames the beekeeper is not supposed to be parading around his apiary with a big knife and basket to round up drone comb. Besides, if he is the right kind of beekeeper he would know long before spring time that there was drone comb in his frames and where to find it.

\*\*\*

Mr. Editor, you say, page 523, July 1, in your footnote to my paragraph on powder-paint, that "Cold-water paint is certainly better than no paint at all;" then, further, "the hot sun checks the wood because the dark color of the weather-stained wood draws the heat." If color is all that is desired, why not use whitewash as a still cheaper article? I have a friend who uses whitewash on all his metal covers to reflect the heat, and claims it to be better than paint. Of course, that is on galvanized metal that needs little or no protection from the weather; but if it will reflect heat from metal it will also from wood—but paint for mine. I have hives in my apiary that have been in constant use for 28 years that are in perfect condition, and I will not trade even, with a gentleman whom I know

who has some hives 18 months old that have not been painted.

\*\*\*

## A CASE OF UNEVEN EXCHANGE.

A short time ago I found a colony headed by a laying worker; and as it was an unusually strong colony I decided to give it a queen at once. I removed two combs from the center of the brood-chamber and filled the vacancy with two combs of brood with adhering bees and queen from another colony. The two fertile worker combs with the adhering bees were placed in the colony where the queen had been removed. I was gratified to find the queen I had transferred to the laying-worker colony busily laying the following day. As I was engaged in raising some virgins I decided to give the queenless colony a stick of cells to care for and finish. In a few days I examined to see what progress they were making with my cells, when, to my astonishment, I found no cells at all. I made a thoro search to find the trouble, and, to my surprise and disgust, discovered that I had transferred the laying worker to the other colony, and the bees seemed to think I had done them a great favor in the transaction. Well, the joke is on me.

\*\*\*

## THE LIFE OF A BREEDER.

The purchasing of high-priced breeding queens to be transported a long distance thru the mails is very discouraging, to say the least, when mailed in the ordinary breeding queen-cages. It is my opinion that all breeding queens that are very valuable should be shipped only in nucleus hives accompanied by sufficient young bees to keep up their normal condition while in transit, old bees being eliminated as much as possible. This season I ordered queens for trial purposes, both the Golden and ordinary Italians. For these I paid anywhere from \$3.50 for extra select tested to \$10 for guaranteed breeding queens, to say nothing of those that were sent me free of charge to enter the tryout. One of these queens was sent in a three-frame nucleus, and is in the best condition of any. One, after twelve days, had laid no eggs, and was returned to the sender. One disappeared after some two hundred queens had been raised from her. One, after ten days of open-hive life, has laid but a few eggs. One shows ordinary laying qualities, while the tendency of all much traveled queens seems to be to retire in favor of younger ones, shortly following their introduction.

# CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

## IMPROVING THE BEES.

"What is being done along the line of improving bees by selection in breeding? There is a whole lot of talk about it; but who is doing anything? All know that there is a great difference in colonies as regards results in honey storing; but what are we doing about it? Those who keep bees, with possibly a few exceptions, keep them for the profit they may yield; and it is quite safe to say that, when they cease to yield a profit for several years in succession, they would cease to have owners; and if they existed at all it would be in the wild."

I will give a bit of my history, and advance a few ideas which may be worth thinking about. I commenced beekeeping with black bees, and possibly might have given up the pursuit in disgust had not new hope dawned by the introduction of the Italian bee. When the seasons were propitious results were satisfactory. Two or three years of unfavorable conditions showed that these bees could not "stand grief." The wax-moth was very troublesome, and weak colonies would be greatly injured or put out of existence, the combs either being entirely consumed, or so much spoiled that when the bees came to fix them up they built drone comb. Thousands of drones resulted, which consumed much of the honey.

The black bees were much disposed to rob. Like some people they must do a big business or nothing. Then in a poor spring they were prone to desert their hive and swarm out, leaving brood, honey, and all the conditions one would think favorable to contentment, such as clean comb and clean hive. After flying like a natural swarm they would either alight or try to force an entrance into some other hive already occupied, and if they succeeded in gaining an entrance they were sure to be killed.

In 1873 I procured my first Italian queen, raised queens from her, and gave these young queens to about half of my colonies. The next spring I kept a careful watch of proceedings, and find this jotted down in an old diary of a year later: "I find the Italians proof against the wax-moth. They do not desert their hives in early spring; and whenever a small amount of honey is obtainable they will secure that and gain in stores, while the black bees require feeding." This settled the superiority of the Italian bees, and I soon had only Italians.

But when the black blood was all eliminated I found that the Italian bees were

not all alike profitable. Previously my thought had been that the queen that would lay the most eggs must certainly be the best. That idea proved to be a mistake. Some queens producing not nearly the number of eggs that others did would give much better results in surplus honey. A few years of experience will convince any that it is not the most prolific queens that will have the strongest colonies at the beginning of the clover flow, or give the most substantial results for the season. These facts being known, it remains for the beekeeper to state the reason why. If we cannot account for the fact of one colony collecting one-half more to twice as much as another in the same apiary, we can take the short cut and supersede the queens of the less productive ones with stock that gave twice as much. I have practiced this plan to quite a large extent during the past 35 years, and results show that it has not been in vain.

We have been told by the successful honey-producers that the introduction of new blood helps much by way of avoiding the evil effect of inbreeding. This can be brought about by bringing home colonies or queens from out-apiaries, by exchanging queens with other successful apiarists, or by an occasional purchase of a good queen.

But some one may ask, "How do you account for the difference in productiveness?" This is not always easy to tell. I incline toward the longevity and vitality of the workers of certain queens as being very desirable. When workers hatching from August 30 to September 10 were found doing a "land-office" business at gathering nectar from the clover bloom on June 25 to July 4 of the next year, I lost no time in rearing young queens from their mother, so that these young queens could replace all inferior stock in the apiary; and as the mother of this longevity stock showed a disposition to place the maximum number of bees on the stage of action at the blooming of clover, and when they entered the sections with their first nectar without a desire to swarm, I considered said queen of still more value. Such queens should be kept till they are two or more years old, rather than to have their lives "snuffed out" annually, as so strenuously advocated by many, that all colonies may be headed each spring with queens less than a year old. In this pruning-out of inferior stock, it is well to keep an eye out for vicious colonies. A vicious colony should not be tolerated any more than a vicious horse.

# CO-OPERATION IN SELLING HONEY

## THE UPS AND DOWNS OF THE CALIFORNIA ASSOCIATION

BY J. EDGAR ROSS

[There are a number of local co-operative honey associations in this country—The Colorado, The Imperial Valley (California), The Western New York, etc. We regret that we cannot give the full outline of the plan of the Colorado Honey-producers' Association, as this, we believe, is the oldest and most successful organization of the kind in the country. However, several illustrations of their store and warehouse were given in connection with Wesley Foster's article, Feb. 15th issue for last year, page 153. The histories of three of the other associations in this country are given herewith, together with the very interesting plan of our friends across the sea in New Zealand. Think of government inspection of honey!—ED.]

It was about nine years ago that a few of Imperial Valley's pioneer beekeepers got together and formed an organization that finally led to the incorporation, on June 9, 1908, of The Imperial Valley Beekeepers' Association.

The organization was born of necessity, as most co-operative organizations are; but in this case the necessity was unusually acute. Beekeeping in the mountain districts of California is a precarious occupation, and there are very few of the mountain beekeepers who ever attain affluence. About once in five years they harvest a bumper crop of very fine honey. But in most cases it requires all the proceeds, even when the price is a good one, to square up the old scores resulting from poor seasons. The beekeeper who can fight foul brood thru about four seasons, two of which may yield a moderate surplus, and feed thru two seasons of total failure, may bring thru a fair percentage of his colonies to gather the next bumper crop.

Imperial Valley recruited her pioneer beekeepers from the mountain sections of the state. Some drove in with a team of burros; others came in immigrant cars paid for with borrowed money. But not one drove in an automobile, nor even a Ford. The climatic conditions and honey-flow were so different in the low hot valley that different methods of management were necessary. That alone was sufficient to bring the beekeepers together for the purpose of comparing notes. But still more imperative was the necessity of finding a market for the crops of honey that came as regularly as the seasons, and getting cases in which to ship it.

There were no local honey-buyers, and no one who sold cases. Local freight rates to Los Angeles are prohibitive, so everything had to be handled in carload lots. This was too heavy a burden for any one of the early pioneers, so they were really forced to pool their interests.

The "gentlemen's agreement" plan under which they at first worked had some disad-

vantages. These they thought to eliminate by organizing a corporation and issuing capital stock at ten dollars a share. At first one of the members attended to the business of the corporation, which was of a very simple nature. When a carload of cases arrived each stockholder was notified to come and take from the car the number he had ordered. When a carload of honey was sold, each producer was notified to bring in his *pro rata* for shipment. But this plan also had its disadvantages; and as the beekeepers became more prosperous they felt able to afford better service.

The next step was to build a warehouse and employ a manager at a regular salary. To raise the additional capital needed, each stockholder bought enough additional shares of stock to represent an investment of twenty-five cents per colony for all of the bees he owned. A suitable building-site was leased from the railroad company, and a warehouse of ample capacity was erected where the freight cars could be shunted to one door and wagons driven up to the other.

To this warehouse the beekeepers could bring their honey at any time, set their price upon it, and, if they saw fit, take away a load of cases or other supplies which were charged to their account. When a carload was sold the proceeds were prorated among those who had offered their honey at the price secured; and after deducting twenty cents a case for handling the honey, and any charge that might be standing against each shipper, the checks were mailed to the individual stockholders. This plan relieved the producers of all the work and worry incident to the finding of a market, making up a carload, and shipping. There was no warehouse charge, no matter how long the honey was held. The charge of twenty cents a case on the honey sold, and a small profit made on cases and other supplies was ample to keep up the expense of the association and accumulate a small surplus. The arrangement was ideal, and the corporation was ready for the next step in its co-operative evolution.

Those who have studied American co-operation will know, without being told, the details—that the step following success is disformation among the members and the formation of factions within the organization to strive for control of its affairs. The association had contributed very largely to the success of its members thru its credit, which was equal to the combined credit of all. But when some of its supporters got to the point where they were able to ship out their own honey in carload lots, and even ship in cases in the same manner, their co-operative ardor grew cold.

There arose a disagreement between the president and manager over a private business transaction in which the corporation had no part. The details are of no consequence. As a result of the trouble the president and his supporters withdrew their support from the association. The stockholders elected another president, and continued to prosper. Then came disquieting rumors that the ex-president was buying the stock of the disaffected ones for the purpose of securing control of the company. It was an ordinary stock company in which each share had a vote; and to guard against the danger of its passing into the control of one man hostile to co-operation, the stockholders met and voted to dissolve the corporation.

The stock had cost the shareholders ten dollars a share. The dissolution showed them to be worth sixteen dollars a share, and that was the sum returned to shareholders. Even the disaffected ex-president was satisfied with the settlement.

Steps were immediately taken to reorganize. In the new association no member was permitted to own more than one share of stock. To make up the necessary working capital each was required to loan the association, for five years without interest, a sum equal to twenty-five cents for every colony of bees in his possession at the time of organization. The association bought a lot where shipping facilities were nearly equal to the old location, and promptly erected a larger and better warehouse than the first one had been.

The affairs of the new association were conducted along almost the same lines as those of the old one had been, and it enjoyed one season of prosperity. Then came the old trouble, with new actors; new details cropped up, and the business of the association began to dwindle. It has been dwindling ever since. It has now almost reached the vanishing-point.

During its palmy days the association shipped 17 carloads of honey in a season,

when the entire output of the valley was about 25 carloads. Last year the output of the valley was 39 carloads, of which only three were handled by the association. It has neither working capital nor credit in the business world. The five-year notes to its stockholders are past due, and there is little prospect of their ever being paid. The association is virtually dead, and sooner or later the courts will preach its funeral sermon. When that time comes, the one thing that will save it from complete wreck is the fact that its real estate has trebled in value.

A few old wheel-horses of the organization are clinging to the wreck with more fidelity than business judgment. One of these not only gives his time without compensation to attend to the company business, but meets the overhead expenses from his private funds in the hope of a regeneration that will never come. There has been only one quorum of stockholders for more than a year, and that was secured by personally soliciting proxies.

The passing of the association should be regarded as a calamity to all the beekeepers of the valley, for its benefits have redounded to the non-member as well as the member. The first year I came to the valley I sold my honey at 6½ cents thru the association, while very little was sold outside of the association at more than 5½, and much of it brought only 5. During succeeding years there was less disparity in the price because that season taught the outsiders a lesson. The determination of its competitors to undersell it has made the price of bee supplies cheaper in Imperial Valley than anywhere else in the state. These are facts that even those opposed to the association are compelled to admit. Yet the organization has been permitted to die from lack of support.

Human nature is the same the world over, and every man wants to have his own way. Only the press of stern necessity will make him willing to yield it to another. Co-operation requires a yielding of the individual co-operators, and without the press of necessity it can never be a success. Beekeeping in Imperial Valley has been too profitable to make co-operation necessary. Individual prosperity was the rock upon which our co-operative ship stranded.

There are plenty of dealers in cases and other apiary supplies in Imperial Valley now. The producer is no longer forced to look for a carload buyer, tho many of them are able to sell in carload lots. Some of the Los Angeles distributors have a resident agent in the valley who will buy for cash any quantity of honey offered. Others send

a representative to the producer's door three or four times during the season. It costs us something to get along without the associa-

tion, but we can afford the cost in order to enjoy the luxury of having our own way. Brawley, Cal.

## THE WESTERN NEW YORK HONEY-PRODUCERS' ASSOCIATION

BY WM. F. VOLLMER

This association was formed because of conditions that were, we might say, detrimental to beekeepers. It was a case of every one paddling his own canoe. This is a condition under which beekeeping does not exactly prosper. The honey was sold at any fair price, as every one was ignorant of what his fellow-beekeepers were doing. Now, we have not gotten together and advised any price; but the idea in general is to get together and learn what the other fellow is getting and doing, and so some improvement on methods will always be found. In unison of ideas, facts will always spring forth.

It has been found that something can be saved by buying supplies in a co-operative way. In regard to marketing honey, every member sells all he can locally, as the slogan of this association has always been, "Supply your local home trade first." Those that have more honey than their local trade requires are usually taken care of by some of the other members who may be able to sell more than they produce. So in this way we also co-operate in marketing.

Proper grading is always required. Aside from this there are many other ways that we can help each other. We have two meetings a year where all general subjects are discussed, such as standardization, breeding, new ideas in labor-saving devices, etc. I have never failed to see some good accomplished.

### CO-OPERATION.

Taking the word "co-operate," which is, to work or act together or in unison, we are naturally confronted by many ideas; and to work together many conditional requirements are necessary. The more closely the efforts are placed together the more nearly perfect will be the achievement. Take, for example, the California Citrus Association (Sunkist); The Florida Citrus Exchange (Sealdsweet); The Alaska Pack-

ers' Association; The Chautauqua and Lake Erie Grape-growers, and many others, including also the Colorado Honey-producers' Association. In each of the industries we are forced to take notice of one thing in advance of all others: Each is located or built up in a locality as close as possible to the producers, which usually makes earload loading facilities more convenient to arrange than if the producers were scattered all over the country.

We will now look at some other lines in which co-operation is carried on, such as horticultural societies and co-operative creameries. These associations do not as a rule market in earload lots, as their markets are usually nearer and do not ordinarily absorb that amount—especially butter. Thus we will look to fruits and butter and see whether we cannot solve the honey question. Each grower or producer places his product in a package of uniform standard, on which is stamped the grade and variety of the product, and he is at liberty to sell where he pleases; or in case he cannot find a suitable market, some associations handle these products for their members, and usually have such warehouse facilities as are necessary to take care of the products in question properly. The essential thing in nearly all cases is to have a uniform grade as nearly as possible, and thus the selling proposition will be simplified considerably. Honey is, therefore, the hardest product to market because of its variety of flavors in different sections, and because the beekeepers have adopted so many different-sized packages.

Thus the different steps are, first, harmonization; second, organization; third, concentration, not only of the products but also of the minds of the persons involved and of their efforts. If these steps are all in harmony the inevitable result is action or co-operation.

Akron, N. Y.

## CO-OPERATION IN NEW ZEALAND

BY E. G. WARD

The question of a steady market for honey at a remunerative price has occupied the attention of the leading beekeepers of

the Dominion for a number of years. Till very recently it was much "go as you please," and, as a consequence, the honey-

producer was at the tender mercy of the buyer, who often played one man against another to keep prices down.

Seven or eight years ago the idea of a co-operative association to handle the output was mooted in Canterbury, but fell thru. Taranaki and Waikato beekeepers had also been trying to establish a co-operative association. The idea took shape in Taranaki about three years ago, and the New Zealand Honey-producers' Association, Limited, was established. Correspondence had passed between leading men in New Zealand; and after a conference held in Wellington two years ago the remaining districts agreed to fall in line with Taranaki, and include the whole Dominion instead of following the idea on Provincial lines.

The aim of the company is to include all honey-producers in New Zealand; and the articles of association have been framed with this object in view.

One of the chief attractions to the honey-producer is the fact that, instead of having to pay for shares in cash, payment is made by deduction of  $\frac{1}{8}$  of a penny per pound from the value of the honey sent in. It is compulsory for all suppliers to take one share for each four hundredweight of honey supplied, and power is given to the directors to allot shares on this basis, with or without the consent of the shareholder.

It is also provided that no shareholder shall compete with the company by supplying to the trade. If this is done, the directors have power to forfeit the shares held by the offender.

Shares may be taken up on a cash basis also, but this has not been done to any great extent so far.

A contract is in existence for the supply of a minimum of 100 tons and maximum of 500 tons per annum for a term of three years to a British firm. One year has expired. Provision is made to continue indefinitely if mutually agreeable. All honey exported is graded by a government expert, and paid for according to grade; but by

the selection of a suitable market and judicious blending the lower grades can be handled to the producer's advantage.

Honey for the local market is standardized, and, when necessary, blending is resorted to bring the honey up or down to the standard.

As beekeepers in all parts of the Dominion are becoming shareholders, provision has been made to insure adequate and just representation on the directorate. The Dominion has been divided into seven honey districts, and the shareholders in each district have power to elect a director to represent them.

Up till now the distribution has been effected thru the ordinary channels—the merchant purchasing from the company, the retailer from the merchant. The most popular package is the two-pound tin, which is packed four dozen in a case.

The honey is received at the depots in 60-pound tins, chiefly in liquid form. Payment is made on the 20th of the month following delivery.

Unfortunately for the company the past three seasons have been very poor, so that the support given has not quite come up to expectations. However, one encouraging feature is that, wherever the company's honey has been introduced, a market is secured. The standard of excellence is high, and merchants prefer to deal with the company rather than individuals, on account of being assured of a continuity of supplies. The honey is sold under a registered brand—H P A.

Recent reports from the English distributing agent are decidedly encouraging. The company's honey may be obtained from about 3000 shops in the United Kingdom, including all the large stores in London, under the registered brand—N Z H P A. Window displays have been made, and a vigorous advertising campaign started, and, as a consequence, it is certain that all it is possible to export will find a ready sale.

Christ Church, N. Z.

## A NATIONAL CO-OPERATIVE SOCIETY URGED

BY J. F. ARCHDEKIN

There is very evidently in progress the beginning of a great movement among the beekeepers of America. This movement is in the direction of better markets and better marketing facilities for honey. Every one is thinking about this subject, which is of vital interest. The exact form which this movement will assume is indeed problematical; but the goal to be attained is plain to

all. It is not my purpose to suggest any definite plan in this discussion, but merely to outline a few ideas presented by my correspondents, together with some of my own. Below is a letter that is typical of a number I have received.

Dear Sir:—I am a commercial traveler, and have kept bees as a hobby all my life, and enjoy a few hours among them each

week. The problem of marketing any product is a large one, and especially in marketing honey. In one community we find large supplies practically unsalable, and a few hundred miles away we find a keen demand. Could not the beekeepers put on an advertising campaign and sell their own honey? It could be carried into buying supplies, and every beekeeper would gain. Personally I should be glad to spend a great deal of my spare time in preaching the cause, and would not accept a cent. If each member paid \$10 a year a great deal of advertising could be done. I always feel that we are all one family, and all are working for the good of all. It is with just that feeling that I am writing you. C. D. McLean.

Windsor, Ont., Feb. 14.

I heartily agree with our brother. Co-operation has always been a distinguishing feature of the human race. It is true in every department of life. Look at the giant trusts and monopolies that have sprung up in recent years. They are composed of many single units. Why not let the beekeepers organize? If they do organize, will they stick?

If there is a set of rules to be followed by the members, how are they to be kept in line with the rules? How is the new organ-

ization to avoid the fate of the National in regard to the selling of honey? These and many other questions are going to be burning ones when the new organization appears. It will be national in its scope, and it is going to be a difficult matter to harmonize all the different sections of the country so as to benefit all.

Mr. O. S. Mullin, President of the Kansas State Beekeepers' Association, writes me, urging an organization of the beekeepers. I agree with him that the National Beekeepers' Association had a great opportunity before it at one time, but failed to grasp it.

The *Booster* is trying to accomplish the desired object, and I sincerely hope it will; but, like all other projects, it has weak points that will have to be overcome. I do not wish to be understood as criticising; but how many state vice-presidents do you suppose would attend a meeting at Chicago, or anywhere else for that matter? There is work ahead for the *Booster*, and trials and troubles; but I am for it all the time.

Bordlonville, Ia.

[See the following article by Wesley Foster.—Ed.]

## THE NEW NATIONAL HONEY-PRODUCERS' ASSOCIATION

BY WESLEY FOSTER

The successful marketing of the honey crop of the United States is not dependent upon co-operative marketing associations, except in a few districts. Co-operative marketing, however, has been an important influence in the moving of the honey crop, and is bound to become more so. The honey-producer who has a near-by market and few honey-producing competitors needs little help from co-operative associations.

We have too few honey-distributing agencies that know the honey proposition. Individual beekeepers do not have the means, time, nor ability to build a honey-distributing business such as will aid the honey-producers in a substantial way.

The honey-producers of the West do not require a high-priced market, but they want, and should have, a stable market at a fair price. They want a marketing agency that will take their honey and advance to them a part of the value of the crop and get the remainder to them in a few weeks, or at most a few months.

The National Honey-producers' Association is an organization capitalized at \$50,000, and closely follows the organization features of The Colorado Honey-producers' Association and the Idaho Honey-producers'

Association. It is made up of specialist beekeepers who, however, do not depend upon the Association to market all their honey. It is so far something in the form of a safety valve to help out in marketing when marketing is difficult. So far, the honey of non-members has been more largely handled than that of members for the reason that the members, doubtless, have better means of disposing of honey than many non-members.

The National Honey-producers' Association has its headquarters in Kansas City, Missouri, where a honey-store is maintained with a manager in charge. A salesman has been kept on the road as is found profitable. Sales direct to the retailers have been featured, while the jobbing of large lots is done when stocks are heavy and an opportunity offers. Honey has been handled in carlots from California, Arizona, Nevada, Idaho, and Colorado. It is not desired that the membership be large, for there is danger of having more honey produced by our membership than can be successfully handled.

The main features where we claim success has attended our efforts are that we are building substantially a honey trade among the thousands of retail grocers in the Kan-

sas City territory. Our trademark brands of honey are handled by over eight hundred grocers in Kansas City alone.

We are blending the white, mild-flavored honey with the darker, stronger-flavored grades from the territory we serve, and have learned to put out a product that surpasses in color (a beautiful golden light amber) the water-white, and in flavor gives more general satisfaction than the mild flavors or the pronounced grades. We put out a grade that can be put out in quantities the year round, and we have it always on hand.

Concerning the handling of comb honey, our members vary somewhat in grading methods; and while standardization is advocated, our market is so wide that various kinds of honey can be placed fairly well. If a member's grading is faulty, he hears from the manager and also suffers in the price secured, just as he should expect to. We do not expect to have to curry favor with the beekeepers, neither will they have to scrape to the association. If they are honorable and fair in their dealings, the business will be satisfactory all around. Beekeepers who can do business on business principles are welcome, and the other kind are not wanted. In fact, the best way for prospective members to do is to deal with the association some and find out whether they want to come in.

The prices secured for members have not been much higher than the market, but it has helped numerous beemen to dispose of crops that could find no market. It is simply a commission business owned by the beekeepers. Whether it succeeds greatly is not important; it has succeeded nominally. The beekeepers are learning to trust each other, work together, and put out a product more suited to the market. No single member of the association can put up a product so uniform thruout the year.

Our finances are still low, and we will have to wait and build slowly. This is as much an advantage as a disadvantage. Some funds have been advanced by the directors to pay part on members' honey. The beekeepers have been very patient in waiting for their money, and this helps in starting any co-operative enterprise.

Concerning the future of co-operation, the writer believes that it will not be many years until there will be a federation of co-operative honey-marketing associations for securing various desired objects, the development of more markets, the better distribution of the honey crop preventing a glut in any one place. This federation will doubtless be rather loose in form at first:

that is, it will not affect the local association's management to any extent. In time, the federation may be so centralized that it will dictate that all of a member's product shall be marketed thru his association, and thus thru the federation. This may never come, for the reason that beekeepers will not find it expedient or feasible to curtail the individual work of beekeepers developing their local markets. No association should hamper the beekeeper's activities along this line.

The various local associations organized into a federation would doubtless put out four or perhaps six brands of extracted honey to cater to the tastes of the various sections of the country, and use up the total surplus extracted-honey crop. There should be trademarked "baking honey," a trademarked "fruit-canning honey," and several brands of table honey.

The comb honey could be cartoned and trademarked to suit the market and the product. This trademarking is now done by our association and several others. If they all got together in a federation, it can be easily seen that something of the same, along advanced lines, would be taken up.

A conference of the various honey-marketing associations would be conducive of good results, and there will doubtless be such a conference before many years pass. Our association will gladly co-operate with others in the work.

#### THE NATIONAL HONEY-PRODUCERS' ASSOCIATION.

The president of the National Honey-producers' Association is Mr. D. C. Polhemus, of Lamar, Colorado. Mr. Polhemus owned and operated the honey business in Kansas City taken over by the association. He is a man of large experience in producing and marketing honey. His apiaries comprise more than two thousand colonies, and his honey sales are much greater than his own production. He is a man of standing in his community and enjoys the confidence of all who have done business with him.

Mr. G. P. Stark is the manager in charge of the Kansas City store. He has had large experience in the honey business in Kansas City, and is thoro, business-like, and straightforward in all his work, and is enthusiastic, and is building the business very substantially. Mr. Stark is one of the members of the association, and will be glad to have beekeepers visiting Kansas City call at the store, 928 Garfield Avenue, Kansas City, Missouri.

Boulder, Col.

## HOW TO MEET COMPETITION

BY JAMES A. BROWN

Consternation reigned in Beedom. The aerial scouts had brought in startling reports of strange and mysterious operations among men. They had sat beside office windows and heard high officials talk of a new and marvelous product which should take the place of honey. They had heard the whirl of a thousand wheels where this new product was being manufactured. Finally, they had seen it advertised in great flaring letters, this mysterious substitute for honey.

All this could mean nothing but ruin to the business of the bees, they reported. The report spread until it had become a fact. "Our business is ruined—ruined!" they wailed.

Work ceased. Everywhere there was frenzied discussion. The workers proposed to organize a labor union and defend their rights to the bitter end. The queens became so perplexed that they forgot to lay any eggs. The drones moved a little more rapidly than usual, gorged themselves a little more than usual, and sagely offered a little more advice than usual.

The militarists, who were first to be heard, because loudest in their cries, were for immediate declaration of war, and for continuous bombardment of their competitors until they surrendered.

The ultra-pacifists, on the other hand (having fought for an opportunity to speak), proposed the appointment of a committee which should visit the manufacturers and solemnly protest, in the name of justice and on the ground of long precedence in the business, and further kindly suggest and earnestly solicit the immediate abandonment of the offending project.

At this point, fearing dire consequences should the advocates of these widely diver-

gent views continue their discussion longer, the laziest and "wisest" old drone arose to propose a solution out of the fund of his "wide observation and experience."

The crisis was not really serious in his estimation. Undue alarm was being manifested. All that was necessary to save their business without sacrificing either peace or honor was to stop making honey and make this new product themselves. This was perfectly self-evident and logical. Nothing could be more simple or more sensible—to a drone, who had never done a day's work nor made a drop of honey in his life.

At this moment, however, two more scouts returned, weary to the point of exhaustion, but evidently bearing most important tidings. Not satisfied with what the others had seen, they had carried their investigations to the stores and finally to the consumers. In the store windows they saw large displays of the goods. Some went inside to buy, and the scouts followed these to their homes. Singularly enough, in every home they heard what might almost have been a stereotyped conversation:

"Pretty good, isn't it?"

"Yes, but it doesn't taste like honey."

"That's right; it doesn't. When I want honey I want the best the bees can make."

The bees' convention waited to hear no more. It rose *en masse* and rushed forth with a mighty roar of satisfaction. Very soon, wigwagging signals of joy to one another, each was in its accustomed place, working harder than ever. The life of Beedom was once more tranquil, and filled with deep contentment.

The bees had learned that the best way to meet competition is to do the thing you can do best, the best you can do it.

Warren, Ohio.

---

## JUST HOW ASSOCIATIONS CAN HELP

BY R. DIEMER

With much interest I have read the articles in GLEANINGS and other bee-papers about marketing honey. Most beekeepers cry for higher prices, but do very little on their part to get them by advertising and developing their home market. Everybody seems to think the other fellow will do it also. The market for honey will not become better before every honey-producer, small or big, does his share in advertising and enlightening the public as to the value of honey. The first thing every beekeeper

should do is to give the public information about the value of honey as a food compared with other products; he must strive to keep his customer supplied the year round, not only just about six or eight weeks after the harvest.

Our main competitor is the cheap syrup, and we can combat that competitor only by showing the superior food value of honey, and bringing on the market a really superior product, all the year round, and at as low a price as the best grades of syrup.

We beekeepers must, therefore, try to produce as cheaply as possible. This is a point very much overlooked, and most beekeepers don't like to hear it. Everybody is crying for a living price, and thinks the other fellow should pay him an easy living, but he will do nothing himself. Work hard and try to produce cheaper, so you can sell cheaper and still make a good profit. What did you do last winter to be better posted on your business this season? Do you know all the tricks of the trade? If you catch only one new idea in a bee-book, is it paid for ten times over?

Having produced cheaply we must try to bring our product cheaply on the market. I think it is wrong to put up our honey in the finest flint-glass jars so that the container costs just as much as the contents. Very few housewives care for more jars when they don't need them. The canning time is gone when the honey comes on the market. It would be better if the container were so cheap that little would have to be added to the selling price of the honey. We must avoid as much as possible the small packages—the smaller the package the greater the comparative cost.

The attractiveness of honey in flint-glass jars is lost in cheap tin cans; but we must make this up by very nice labels. In none of the catalogs could I find a label that I wanted. I looked for an attractive label which at the same time would advertise and show the superiority of honey over artificial products.

The label printers should bring out new ideas, and not use the same cuts indefinitely. If a new label costs a little more, I am willing to pay it, and I think most beekeepers would do the same if they could get what they want.

In supplying our customer the year round with honey he will not think of buying syrup if he is once accustomed to honey. If the honey supply is cut off we force him to do this very thing. After

using syrups regularly ten months in the year, very few are willing to buy honey the other two months. They regard honey as an extra luxury to give to the children in teaspoon doses as a cough remedy rather than as a food. The market problem for honey is for the most part a distributing problem which could be better solved if we would try to distribute our product over the whole year. The trouble is that nearly every beekeeper is eager to dump his honey on the market as soon as harvested, to get rid of any further trouble.

#### WHERE AN ASSOCIATION CAN HELP.

Most of the smaller beekeepers, and many of the bigger ones too, will wonder how they can keep some of the honey over to the next season in order to sell it the year round. The honey will candy, and they have neither time nor proper equipment to liquefy it. All this trouble would disappear if there were a well-founded and well-managed association which could take over every pound of honey and grade and blend it so that there will be a uniform article the whole year round, so that every buyer knows exactly what he gets when he asks for California first-class light-amber honey or Michigan first-class water-white white-clover honey, etc. Hitherto there has not been the right spirit in an association. Every beekeeper should be a member, even if he has only two colonies of bees. Now, the big fellows overlook the small ones, and the small ones spoil the market in selling off grades of honey (sometimes big fellows do the same). We must try to get those little fellows, and teach them. The wise guy who knows everything you can't teach.

Local associations must federate into state associations, and they in turn must be federated into the national association. The national association can't manage local affairs, and the local association can't do national work.

Chico, Cal.

## DROPPING FRUIT AND POULTRY TO TAKE CARE OF HONEY TRADE

BY INEZ A. BEALS

A hustler in the honey business, and a man whom some beemen and honey-dealers know, and others should know, is Mr. Herbert B. Phillips, of Auburn, Me. Mr. Phillips keeps but a few colonies now, altho he is increasing his number. He devotes his time almost wholly to the bottling of honey for his trade at home as well as elsewhere. His business is mostly with extracted honey, altho he handles a good deal of comb honey

and some beeswax. There is nearly always a call for good comb honey.

Mr. Phillips' home is situated about two miles from the business section of the city, and it is there that he keeps his bees and his storehouses.

His liquefying is done by steam. At the time we visited him he had about seven tons of honey on hand, and four or five more *en route*. His packages are very attractive,

the honey being put up in 15, 8, and 5½ oz. bottles. He also carries three and six pound cans which all bear his brand, "Hillcrest."

The individual-size bottle is used extensively in hotels near by, and the demand is increasing more and more, so dainty are they. Many summer visitors coming into Maine every year become acquainted with this brand of goods, and send to Mr. Phillips from their homes for the honey. Thus by parcel post his trade reaches to New York, New Jersey, Boston, and vicinity.

Mrs. Phillips is her husband's partner in the business. She thoroly understands it, and often demonstrates their goods in stores at home and in other cities, where their honey has become known. Their daughter is also a helper in vacation seasons.

An auto truck was added to the business last summer, which enables them to do more business in a much shorter time than before, and also to make trips to surrounding towns and fairs, advertising and selling their honey. This proves the value of the auto to the business man.

Poor grading in comb honey has been very bothersome to him at times. He once received a shipment from a producer where the sections in a case varied five to seven ounces. To one who deals honestly with all, such instances are discouraging and annoying. Care should be taken in grading all honey.

At the Phillips home (Hillcrest Farm) delicious small fruits are to be found—enough to make that a business alone, and

Herbert B. Phillips is an up-to-date beekeeper and honey salesman who was forced to drop his fruit and poultry side lines to care for his honey business.

I think such was the case at one time as well as the poultry business; but the growth of the honey trade, and the scarcity of dependable help, make it impossible for Mr. Phillips to continue this part of his business.

Lewiston, Me.

Mr. Phillips reaches his customers in a truly up-to-date way.

## BEEES HELP SALESMEN

BY J. FRANK FOOSHE,  
*Market Agent, Roanoke Chamber of Commerce.*

[Mr. Fooshe is a son of the well-known queen-breeder, J. D. Fooshe. Because of his former experience with bees he is eminently well prepared to use bees in his demonstration work.—Ed.]

In my work here as market agent of the Roanoke Chamber of Commerce I am using bees for a practical demonstration of the principles of marketing. For this purpose I have screened in a large transfer wagon so that no bees can get out. In this wagon I have a hive of typical three-banded Italian bees. When I get in the wagon on the crowded market square the people swarm around. I handle the bees without gloves, veil, or hat. I make it a point to explain to the on-lookers that there is no magic in my being able to handle the bees in this way, as I go in to do nothing that will disturb them, and to let nothing they do to me rattle me.

I have a twofold object in giving this demonstration in the handling of bees. First, I want to impress upon the large number of fruit-growers and truckers who come to this market each week the importance of handling their fruits and vegetables with the same care that is necessary in the handling of bees. Second, I try to emphasize the great possibilities of this mountain section for producing honey of the very best grade.

The slogan in my work is, "Reducing waste thru better grading, packing, and handling, the only way to bridge the chasm between *more* to the producer at *less* to the consumer." I am using every effort to impress this one truth of cutting out waste, however it may occur. I go right to the farmer's wagon and help him grade, pack, and sell the load he has brought in today, in the hope that he will bring his load tomorrow in better shape. As to whether he will or not, the large number of growers who were using the standard packages for tomatoes and peaches at the close of a month's work here last summer as compared with at the beginning is the best evidence. The principles of farm demonstration are just as applicable to selling as to producing. If the farm is a good place to help the farmer with his growing problems, certainly the market square offers a fine opportunity for helping him with his selling.

As to why I should select a colony of bees for trying to impress better grading and handling, it is easy to answer. The bee and its products represent the highest degree of perfection in marketing anything from the farm that I know of. If bees and queens

are to be put in the cage, each one must be handled with care. If honey is to be carried to the local market, or shipped to some distant point, a very high degree of care is necessary. The perfection with which bees do their part calls for the best methods in handling them at every move.

It is a matter of peculiar gratification to me to be able to use these bees for this marketing demonstration for the purpose of causing the people to think of and to put into practice better methods in the handling of their produce. It is to the bee that I owe my college education, for the bee money at our home in South Carolina was the educational fund, set aside for this specific purpose. While I had not been in a hive of bees for several years till last week, I was delighted to have this experience again. It added greatly to my pleasure to have Mr. C. E. Layman, of Troutville, who furnished me with the bees and all supplies for this demonstration, tell me that several years ago he had secured from my father the foundation of his present breeding stock. I have never taken much stock in bees having knowledge of people; but if there is such a thing, these bees seem to have met an old friend of their parents, for I never worked with any more kindly disposed bees at any time.

Another most gratifying matter to me is the number of people who are wanting information about bees. Some want to transfer from the old-fashioned box hives to those with movable frames; others want to Italianize their bees, and still many others want to get started in keeping bees. The number of business inquiries from the first day's demonstration is a striking instance of the principle for which I stand in my marketing demonstrations. Instead of government experts and college professors running all over the country to speak to a handful of men here today and several hundred miles away tomorrow, some advantage should be taken of the large number of farmers gathered about the market square to preach the gospel of better farming, including both producing and selling. I am an ardent believer in the church as the staying factor in our social and business life; but I am just as enthusiastic over the work of the Salvation Army as a powerful agency in the advancement of his kingdom.

Salvation Army methods are needed for reaching farmers who have not been reached in any other way.

As a further illustration of how the men on the market square may be used for helping to carry forward the gospel of improved methods in the handling of produce, I am sending out this week five thousand government bulletins on the care of butter and eggs. These are being sent thru the large number of country peddlers who come to

this market each week from the far-back mountain country, most of them coming 30 to 75 miles. Two bulletins are being put in each package to be delivered at the homes from which these peddlers buy their produce. They have entered enthusiastically into the plans of this organization for securing better marketing conditions. They are our missionaries for helping to build up the surrounding country.

Roanoke, Va.

## ARE YOU A SALESMAN?

### Some Conditions of Honey-selling and Some Suggestions

BY ARTHUR C. MILLER

So you have a fine crop of honey to sell. Well, what is it and what are you asking for it? You say it is a bright light amber, of good flavor, and should be worth 9 cents; that Jones & Company offered 7½ cts., but you are going to hold for more.

In that paragraph is summed up about all that the majority of producers know about the selling of their crop. Some of the things which they don't know are just where their crop really does grade as to color, flavor, and body; the amount of similar honey within, say, five hundred miles; the general crop of honey the country over; the amount of honey the local market will consume; the amount likely to be offered in that market; the best distant market to ship to, and the level of prices as compared with previous years. Every one of those items is complex, and the knowledge necessary to form an intelligent answer to any one is not to be acquired off hand. Relatively few producers know where to look for the desired information, or, after securing it, know how to use it to advantage.

But even if accurate knowledge is possessed of size of crop and of level of price, the quality of one's own crop may not be known. And on that quality will depend its ready or slow sale, as the case may be. I may think my honey is "fine," but if it possesses some peculiar flavor, is a little light in body, a trifle "off" in color, quick to crystallize, or, for want of thoro curing, lacks good body, it will not bring the price I expect. Under such circumstances I shall probably find fault with the buyer, over-production, etc. If, on the other hand, I have educated myself as to honey flavors, colors, and bodies from many places, and have learned what types the different markets demand, then I can intelligently judge of my own crop, and of its quality and value. If you have not that knowledge,

just send samples of your crop to half a dozen of the handlers who are well posted, and ask them to give you its "grade." The "grade" you must know before you seek a market.
