INTRODUCTION

TO THE

CAPE CATALOGUE OF 1159 STARS,

FOR THE EPOCH 1860.

The Royal Observatory, Cape of Good Hope, was established by an Order in Council, dated 1820, October 20. The leading idea was to establish a first class Observatory in the Southern Hemisphere, for work of a similar character to that of the Greenwich Observatory in the Northern Hemisphere. The observations were to be made with instruments of the same class, and the results were to be drawn up in the same form, in order that the whole might constitute two corresponding series capable of comparison in all their parts. No opportunity of making observations capable of improving the Theory of Refraction was to be neglected.

The Observatory Buildings were completed; the instruments, similar to those at that time in use at Greenwich, mounted; and observations commenced in 1829. But the hand of death was almost upon the first Director. The Assistant, Capt. Ronald, broke down, and left in 1830; and Fallows, after struggling on, somewhat hopelessly, as best he could with the aid of his wife, died in July, 1831, at the early age of 43, with the expectations which had drawn him to South Africa unfulfilled. Much could not have been done under the circumstances in which Fallows was placed, and not much was done. A Catalogue of approximate places of the principal stars, south of the zenith of the Cape, made with small instruments, in Cape Town, was published in the Philosophical Transactions for 1824, and another Catalogue, formed from observations made at this Observatory 1829-1831, appears in the Memoirs of the Royal Astronomical Society, Vol. XIX, published in 1851. It contains the Right Ascensions of 425 Stars: but of these only 88 have corresponding observations in North Polar Distance; a considerable portion of these places are those of well-known Stars observed for clock error.

Fallows was succeeded by Mr. Thos. Henderson, who remained at the Cape a little more than a year; but that year must ever be a memorable one in the annals of the Cape Observatory. Henderson discovered the sensible parallax of α Centauri, and determined its amount with an accuracy which has left to his successors little more than a

Gift of U.S.N.O.

314001

verification of his result. He reduced and published, in 1835, the declinations of 172 Stars, and in 1844, in the Memoirs of the Royal Astronomical Society, the Right Ascensions of 174 of the principal Stars, the results of the observations made by him and his assistant at the Cape in 1831 and 1832. It is impossible to over-estimate the value of these papers as affording accurate places of a limited number of Stars at the epoch: but the extent of the Catalogue is small. Henderson removed all the records of his observations from the Observatory, with a view to their subsequent reduction. It is desirable that the original records should be returned for preservation at this Observatory. Mr. Henderson was succeeded by Mr. (now Sir Thomas) Maclear, who arrived at the Cape on the 5th of January, 1834. The observations made by Mr. Maclear and his Assistant in the year 1834 were published and distributed for the use of Astronomers, and some advance was made in the printing of the observations made in 1835, 1836, 1837; but the reductions of these years were never completed, and the printing was stopped. It would appear that attention was called off from attempts to form a Star Catalogue to the measurement of an arc of meridian. The field work of this arc was finished in 1847; but it was not until 1866 that the volumes containing the results were completely printed and published, and Sir Thos. Maclear placed in a position to receive the congratulations of his contemporaries on the completion of his work. Of the value of this work there cannot be two opinions: but it was allowed to disorganize the other work of the Observatory to such an extent that, when I assumed the Directorship in 1870, I found myself, with a very limited staff, unexpectedly confronted with the results of 36 years of miscellaneous observing in all stages of reduction, nothing completed, and nothing which could be brought forward for publication and use without a very considerable expenditure of time and skilled labour. I fear the course pursued of continuous miscellaneous observing without reduction, has not tended to the advancement of accurate Astronomy to any extent proportional to the labour expended upon the work, and still required to be expended upon it before the results can be rendered useful. Such observing is rarely conducted in a way to facilitate the subsequent reductions or to economize labour in observing. This will be apparent to any one who will count the number of observations of Stars between 67° and 117° North Polar Distance and consider that a Catalogue formed from the results of other years would contain observations of these Stars to very nearly the same relative extent. Of the large number of observations accumulated here from 1834 to 1855, with the Transit instrument and Mural Circles, the places of the Southern Stars, out of the reach of the Northern Observatories, will when reduced, still be of value for proper motions; but the immense number of observations of well-known Stars made here with

the old instruments can now, I fear, never repay the labour required for their reduction.

The Right Ascensions of those Stars which have been used for clock error can do little more than reproduce the assumed tabular places employed in the reductions, and the Right Ascensions of other Stars not further from the Equator than those of the usual clock-star list can never differ much from the results of the Northern Observatories.

The North Polar Distances of the same well-observed Stars can now be of little value. The results are not likely to be compared with those of the Northern Observatories for a discussion of the errors of the refraction tables when results made with more powerful instruments are available.

I have made these remarks, not only in justice to the present staff, and to explain the work upon which they have been employed, but because it was these considerations which led me to pass over the earlier observations, and to commence the systematic reductions with the year 1856, when the Transit Circle was first brought into regular use. I felt that these reductions could not be any longer delayed without the value of the results being greatly diminished. I had, and still have, hopes, that the data collected in the present Catalogue for corresponding observations at the Northern Observatories would be found sufficient to meet the actual requirements of Astronomers, so far as these requirements can be met by the material collected here, and that I might be relieved from the laborious and somewhat useless task of completing the reductions of the earlier observations of Stars whose positions have been fixed already with an accuracy greater than could be expected to be attained in the observations made with the, comparatively speaking, inferior instruments in use at this Observatory before the introduction of the Transit Circle.

The present Catalogue has been formed from the volumes of results of observations made at this Observatory in the years 1856, 1857, 1858, 1859, and 1860, the reductions for which have been completed and the results published since I took charge of the Observatory work in October, 1870. The observations of Stars near the South Pole observed in 1861 have also been included. The whole of the observations combined for the formation of this Catalogue were made with the Transit Circle, an instrument similar in all respects to the Greenwich instrument which has been in use since 1851. The results of the observations made at Greenwich, 1854 to 1860, have been formed into a Catalogue reduced to the epoch 1860. There exist two other Catalogues, of great value, reduced to the same epoch. January 1, 1860, has therefore been chosen as the epoch of the present Catalogue. This choice of epoch affords great facilities for a comparison between the Greenwich and Cape results, and also for the formation of a more general Catalogue, for the whole heavens, by the combination of the different Catalogues reduced to that epoch.

Comparison of the Mean Right Ascensions of Clock-stars in the Greenwich Catalogue for 1860, with those contained in the Cape Catalogue of 1159 Stars for 1860.

This list contains the Stars whose Right Ascensions have been employed for the determination of clock error in the reduction of the observations included in the present Catalogue. The Mean Right Ascensions adopted for the determination of clock error have been those of the Greenwich Catalogue of 2022 Stars for 1860, and the results have been carried back to the year of observation with the precessions, secular variations, and proper motions given in that Catalogue. No correction for epoch has been applied, and the fundamental epoch of this Catalogue should therefore be that of the Greenwich Catalogue. The differences between the Right Ascensions adopted for clock error and the resulting Right Ascensions are generally small, and the mean difference is only $+0^{s}\cdot002$. But the differences are not quite constant throughout the twenty-four hours.

The following are the Mean Differences for intervals of three hours :

GREENWICH R.A.—CAPE R.A.

h h	h h	h h	h h	h h	h h	h h	h h
0 to 3	3 to 6	6 to 9	9 to 12	12 to 15	15 to 18	18 to 21	21 to 24
−0·007	+0·005	+0·030	+0·003	−0·007	+0·010	−0·006	−0·005

The only one of these differences which is very strongly marked is that from 6^{h} to 9^{h}, but the Greenwich Right Ascensions from 5^{h} to 9^{h}, both inclusive, are systematically greater than the corresponding Cape

Right Ascensions, the mean difference being $+0^{s}\cdot021$. These Stars were generally observed at the Cape during the months of December, January, and February. The changes of temperature in the evening are exceedingly rapid, the average change of temperature in January between 6^{h} and 12^{h} being $5^{\circ}\cdot4$ F. I think it probable that, so far as the above differences indicate errors in the Cape places, they may be attributed to the mean rate not being strictly applicable over a group of Stars extending from soon after sunset to late on in the night. The Transit Clock was not, and is not now, protected from rapid changes of temperature, and the compensation most probably lags behind in its action.

The North Polar Distances have been reduced with the refractions of the Tabulæ Regiomontanæ to 85° Z.D.; but below 85° Z.D., instead of introducing the break in the mean refractions recommended by Bessel, the tables have been extended by using the mean refractions from the Fundamenta multiplied by the constant required to bring up the mean refractions of the Fundamenta to those of the Tabulæ Regiomontanæ.

The latitude of the Observatory assumed in the volumes of results has been that determined by Henderson, 33° 56′ 3″·2 South.

In the formation of this Catalogue I have adopted, from a preliminary investigation, 33° 56′ 3″·56 South latitude.

The following table exhibits the corrections which this adopted quantity would still appear to require with the refraction tables in use. The weights in this table have been calculated from the probable errors at different zenith distances, given in my paper in the monthly notices of the Royal Astronomical Society:

LATITUDE INVESTIGATION.

In these equations it is assumed that the true refraction = Tabular $(1-y)$.

South latitude = $33^\circ\ 56'\ 3''.56 + z$.

From them we find, for the South latitude of the Observatory,—

$33^\circ\ 56'\ 3''.55 + 91''y$.

There are not a sufficient number of Stars, far removed from the pole, observed at their upper and lower culminations in North Polar Distance to allow of any accurate determination of y from the results of this Catalogue.

The latitude of the Cape Observatory must therefore be still considered as uncertain to half a second. If the value of y be determined from these equations, the results are,—

$z = +0''.416$. $y = +0.0047$.

The following method has been employed in the formation of the Catalogue :

In the first place, it must be remarked that the observations contained in the separate volumes of results are not corrected for the proper motion for the fraction of the year of observation except for the Nautical Almanac

Stars, for which Stars it has been included in the Star correction. All the observations of Stars common to this Catalogue and the Greenwich Catalogue for 1860, which are not contained in the Nautical Almanac, and for which proper motions are given in the Greenwich Catalogue, were first corrected for the proper motion for the fraction of a year, and then all the Stars common to the Greenwich Catalogue brought up to the epoch 1860, January 1, from the different years with the precessions, secular variations, and proper motions of the Greenwich Catalogue. The places for the Stars not contained in the Greenwich Catalogue were then brought up to 1860, with the precessions for the year of observation, or mean precessions, or the precessions approximately corrected for secular variations from the British Association Catalogue, and very approximate places for 1860 thus found. With these places the precessions and secular variations, for 1860, were computed. The results for the several years were then brought up to 1860 with greater accuracy, and combined in proportion to the number of observations in each year for places which were so far uncorrected for proper motions, except for the Nautical Almanac Stars to which they were applied.

A comparison was then made between these results and the places of the same Stars given in the following Catalogues:

Brisbane, in N. P. D. only, Fallows, Johnson, Henderson, and an unfinished Cape Catalogue for 1840, formed from the observations made, 1834 to 1840, the reductions for which were examined and completed so far as necessary for this comparison. From these comparisons proper motions were adopted for use in the present Catalogue. These proper motions were then applied, for the Stars not in the Greenwich Catalogue or Nautical Almanac, for the interval between the mean time of observation and the epoch of the Catalogue 1860, January 1. In cases where the adopted proper motions for Nautical Almanac Stars differed from those used in the Nautical Almanac the necessary corrections were applied. The whole of the results are therefore reduced with the proper motions given in the Catalogue, and the corrections for proper motion for the fraction of the year of observation have been applied in all cases when required. The intervals between this Catalogue and those compared with it for proper motions are but small, and no extreme accuracy can therefore be expected in the resulting proper motions; but after the experience of Baily, and some further trials of my own, it has not appeared to me desirable to trust to Lacaille's places for proper motions, and these adopted proper motions are therefore probably the best available. I believe them sufficiently accurate to bring up the places of the present Catalogue for twenty years with at least the accuracy of the earlier Catalogues.

I have not thought it necessary to give the Star constants. Very approximate constants computed for the reductions will be found for the Southern Stars in the volumes of results for the several years, 1856—1860,

and the constants for the Greenwich Stars are given for 1860 in the Greenwich Catalogue. The secular variations have been corrected for the change of m and n, as well as for changes in place. In some cases, where southern stars have been observed in North Polar Distance but no corresponding observations in Right Ascensions have been available during the period 1856 to 1861, I have reduced observations made in other years to fill up the gaps. These cases are clearly marked by the mean year of observation and by a note.

The references to other Catalogues have been much restricted for want of room. The Greenwich Catalogue generally referred to is that for 1860. When the places of a star are not contained in the Greenwich 1860 Catalogue, but are contained in the Greenwich Catalogue for 1864, references are given to the latter Catalogue and distinguished by an *. Henderson's Catalogue is only referred to for stars not contained in the Greenwich Catalogues. The letter H is prefixed to Henderson's numbers. Fallows' and Johnson's Catalogues are distinguished by the letter J. being prefixed to Johnson's Catalogue. In a few cases references have been made to the Radcliffe Catalogue for 1860, under the letter R. During the time this Catalogue has been in preparation the Observatory Staff, which should consist of four assistants, has consisted of but two. The first assistant, Mr. Mann, was absent from serious illness, which led to his resignation, and, very shortly afterwards, death. The third assistantship has been vacant for three years owing to deaths and delays in filling up the appointment. Under such circumstances, a very considerable portion of the mere arithmetical work has fallen directly upon me, and all of the examination. I have, however, when the computations have been made by me, re-computed the work again after an interval, and have taken all the precautions which occurred to me to insure accuracy. I hope that the errors contained in this Catalogue will be found but few, and those not important, and that the Catalogue may be found not unworthy of the Observatory. The reductions of the observations which this Catalogue contains, and the formation of the Catalogue, have occupied my chief thoughts during the three years I have been at the Cape.

It may be mentioned that the present is the first Star Catalogue ever printed at the Cape, and the first of any extent yet published from materials collected at this Observatory since its foundation. The printing has been done by Messrs. Saul Solomon and Co., who, at their own instigation, ordered out a fresh fount of type for the printing of the Cape observations. My thanks are due to them and to their leading printer, Mr. S. Wiid, for the care bestowed in passing through the press a very heavy work, and one of an unusual character in their office.

E. J. STONE.

1873, October 5.

THE
CAPE CATALOGUE OF 1159 STARS

FOR

1860,

DEDUCED FROM

OBSERVATIONS

MADE AT THE

ROYAL OBSERVATORY, CAPE OF GOOD HOPE,

1856—1861.
