PICTS, the ancient inhabitants of the north-eastern provinces of Scotland. Everything connected with the history of the Picts has been made matter of controversy, and it is not easy to ascertain the truth, where the information given by early writers is so scanty, and where most modern authors seem only to have looked for materials to support a favorite theory.

It will be unnecessary to enter on an examination of the name itself. The "Picts" of the Romans probably represented a word by which the nation was known in its own language, as well as the barbaric custom to which the well-known expression of Claudian, "nec falso nomine Pictos," bears reference. Of much more importance is the inquiry regarding the origin and language of the Picts. This is what, among Scottish antiquaries, has been emphatically called "the Pictish question;" respecting which the best-known and most amusing, and certainly not the least useful discussion, is that between Jonathan Oldbuck and sir Arthur Wardour, in the sixth chapter of *The Antiquary*. The disputants can hardly even now be said to be agreed; but the prevailing opinion is, what sound criticism always pointed to, that the Picts were a Celtic race—perhaps the first known inhabitants of northern Britain, and (as some hold) to be identified with the Caledonians of the Roman writers. At the time when they became generally spoken of under the name of Picts, they occupied the whole territory n. of the firth of Forth, except the western portion, which had been colonized or subdued by the Scots, another Celtic nation, whose chief seat was in Ireland—the proper and ancient Scotland. The southern boundary of the Picts was the Roman province of Valentia, embracing the territory between the two Roman walls. At a later period, when Britain was abandoned by its imperial rulers, the boundaries of the various nations occupying the northern part of the island may be traced with considerable distinctness. Making allowance for partial changes at various times, these boundaries may be held to be the following: The Pictish territory extended along the whole sea-coast from the firth of Forth to the Pentland firth. It was bounded on the w. by the country of the Scots, which extended along the western coast from the firth of Clyde to the modern Ross-shire; but the precise line between the two nations cannot be ascertained. The country of the Picts was bounded on the s. by the firth of Forth and the province of Lothian, then possessed by the English; while the country of the Scots had for its southern boundaries the firth of Clyde and the kingdom of Cumbria, held by the independent Britons.

The Pictish nation consisted of two great divisions, called the northern and the southern Picts, the boundary between them being the mountain range known afterwards as the Grampians. These divisions seem at some times to have been ruled by different princes, at other times to have been under one sovereign. The Picts were converted to Christianity at different periods. The southern Picts received the faith from St. Ninian, bishop of Candida Casa, early in the 5th century. This is mentioned by Bede, and the fact itself has never been doubted; but controversy, as usual, has been busy with the details. The point in dispute is the situation of the Picts who owed their conversion to Ninian (q.v.). A careful examination of the statements of venerable Bede, and the fuller but less trustworthy narrative of Ailred of Rievaulx, will show that the southern Picts, converted by Ninian, had their seat north of the Forth; that they were, in fact, the great division of the Pictish nation occupying the country between the firth and the Grampians. The labors of Ninian were carried on and completed by teachers whose names are well known to the readers of ecclesiastical history—Palladius, Serf, Ternan, and others. The northern Picts owed their conversion to a teacher of higher renown—St. Columba (q.v.). The life of that abbot, from his leaving Ireland in 563, to his death in 597, was chiefly spent in converting the northern Picts. Their ruler at this time was Brude, son of Mailcon, whom Bede styles a very powerful king. His chief residence was on the banks of the Ness, and there Columba baffled and confuted the heathen Magi in the manner recorded by his biographer Adamnan. It is impossible to ascertain the precise character of the superstitions held by the Picts before their conversion. Those whom Adamnan calls Magi, are by some modern writers styled Druids, and their religion is said to have been a species of Druidism—whatever that may be held to mean.

Brude, the first Christian king of the Picts, died in 586. Catalogues are preserved, of more or less authority, of the sovereigns who succeeded him. It is impossible to reconcile the discrepancies of these lists, which probably contain the names of princes who reigned at the same time in the northern and southern divisions of the kingdom. The limits of the Pictish territories continued much the same till the middle of the 7th c., when a portion of the southern province was subdued by Oswy, king of Northumbria. In the beginning of the reign of Oswy's son and successor, Egfrid, the Picts made an attempt to recover the territory which had been wrested from them. It was unsuccessful; and the power of the English was so firmly established, that the conquered province was erected into a diocese separate from Lindisfarne, the seat of the bishop being fixed at Abercorn. Encouraged by the success which had attended his enterprises, Egfrid seems to have contemplated the subjugation of the whole Pictish kingdom. He advanced northwards with his army; Brude, son of Bili, king of the Picts, retreating before him. The English sovereign passed the Tay, and the Picts made a stand at Nechtansmere, supposed to be Dunnichen, in Angus. A conflict ensued; the English were utterly defeated, and their king was slain. The consequences of this battle, which was fought on the 20th of May, 685, were very important. The Picts recovered the whole territory which they had lost, and even subdued for a time a portion of the proper Northumbrian kingdom.

The next Pictish prince whose name calls for special notice is Nectan, son of Dereli, who succeeded about the year 710. He cultivated learning to some extent, and aspired

to the position of an ecclesiastical reformer. The Pictish church held precisely the same doctrines as the English; but it differed in various points of ritual, the most important of which related to the proper time of keeping easter. The king applied for advice to Ceolfrid, abbot of Jarrow, and the answer, which is addressed "To the most excellent lord, and most glorious king, Nectan," is preserved among the works of venerable Bede. Encouraged by this epistle, he summoned a counsel of his clergy and nobles, and enjoined them to observe the English usages. The royal command met with a ready obedience. He had also applied to the abbot of Jarrow for architects to build a church of stone in the Roman fashion, which he proposed to dedicate to St. Peter. We are told by Bede that the architects were sent, but have no further information on this interesting subject. The plans of the king were probably interrupted by dissensions among his people; and the entire assimilation of the ecclesiastical institutions of northern Britain to those of England was postponed for four centuries.

The most active of all the Pictish sovereigns was Hungus, son of Urgust, who succeeded in 730, and reigned for 30 years. He was engaged in constant wars with the Scots, the Britons, and the English, in which he was generally victorious. After his death, the kingdom began to decline. The history of its latest period is involved in impenetrable obscurity; all that we know for certain is the final result. Various princes claimed the crown, and held possession of portions of the kingdom. But the most powerful competitor was Kenneth, son of Alpin, king of the Scots, who was descended, in the female line, from the ancient sovereigns of the Picts, and was probably the true inheritor, according to the peculiar law of succession which is said to have existed among that nation. Kenneth was acknowledged as king in 843, and fixed his residence at Fort-eviot, in Stratherne, the capital of the Pictish kingdom.

A famous passage from Henry of Huntingdon has often been quoted, in illustration of the supposed utter destruction of the Picts, of their princes, their race, and their language. It is referred to in that sense at the close of the following sentences of a work written some time before, but only published in the year 1864: "The Pictish vessel is seen in the distant horizon; she approaches rapidly, till you clearly distinguish the crew upon the deck; but before you are near enough to hear their voices, she sinks, the waters close over her, and the wreck never can be raised. The total extinction of the Pictish language renders any further inquiry impossible. The acumen and criticism of the 19th c. cannot advance beyond the homely wisdom of the 12th century."—Sir Francis Palgrave's *History of Normandy and England*, vol. iv. p. 294.

The impression conveyed by such words is an erroneous one. The Pictish princes still continued to reign in the persons of Kenneth and his descendants. They were kings of the Picts in reality and by race, as much as James I. and his successors were kings of England. The princes did not cease in the one case more than in the other to be sovereigns of the larger kingdom, because they had previously ruled in the lesser one. Neither did the nation of the Picts cease to exist. They dwelt as before in their own land; their old capital was the capital of the new kingdom; and Pictavia is spoken of by the chronicles long after the accession of Kenneth, and long before Scotia became identified with northern Britain, or ceased to be the ordinary name for Ireland. Undoubtedly, through the influence of the kings, and perhaps of the clergy, whom the later Pictish princes had held under an oppressive bondage, the Scots became the predominant race, and finally gave their name to the united kingdom and nation. Neither did the language of the Picts cease to be spoken. It continued, as before, to be the dialect of the north-eastern provinces, till, first in the extreme n., it yielded to the Scandinavian invader, and afterward—more than two centuries subsequently to the accession of Kenneth—it began to recede slowly before the Teutonic tongue of English and Flemish colonists. The same process which destroyed the Celtic language of the Pictish people, destroyed also the Celtic language of the British kingdom of Cumbria. The subject of the Pictish language has been of late thoroughly discussed by Mr. Skene in his *Four Ancient Books of Wales*. In addition to *Peanfahel*, the sole Pictish word formerly known, Mr. Skene has discovered four other distinct words, besides a number of syllables entering into proper names; and from all these he deduces the opinion that Pictish "is not Welsh, neither is it Gaelic; but it is a Gaelic dialect partaking largely of Welsh forms." More specifically, he holds that Pictish, as compared with Gaelic, was a *low* dialect—that is, different from Gaelic in much the same way that low German differs from high.

The chief ancient authorities for the history of the Picts are Adamnan's *Life of St. Columba*, edited by Dr. Reeves; the *Ecclesiastical History* of venerable Bede; the *Life of St. Ninian*, by Ailred of Rievaulx, in Pinkerton's *Ancient Lives of Scottish Saints*; the Pictish chronicle, in the appendix to Innes's *Critical Essay on the Ancient Inhabitants of Scotland*, and in the appendix to Pinkerton's *Inquiry into the History of Scotland*; and the *Irish Annals*, edited by O'Connor. The best modern works on the subject are Innes's *Critical Essay*, and his *Civil and Ecclesiastical History of Scotland*; Pinkerton's *Inquiry*; Chalmer's *Caledonia*, vol. i.; Ritson's *Annals of the Caledonians, Picts, and Scots*; Mr. Grub's *Ecclesiastical History of Scotland*, vol. i.; a dissertation in Garnett's *Philological Essays*; and Mr. W. F. Skene in his *Four Ancient Books of Wales*; and in *Celtic Scotland* (2 vols. 1875-77).

PICTS' HOUSES, a name popularly given in many parts of Scotland to the rude underground buildings, more commonly and accurately called **EARTH-HOUSES** (q.v.). The name is often given also to a more advanced class of buildings of the same kind, found

Pict's House at Kettleburn, ground-plan.

walls were built without mortar. The objects found within them were remains of animals and shell-fish, fragments of pottery, and implements of stone, bone, horn, bronze, and iron. The name of Picts' houses is also occasionally given in the n. of Scotland to rude stone structures above ground.

***PICTURES** are now protected by the law in a manner similar to books, the copyright of which belongs to some individual. By the act of 25 and 26 Vict. c. 68, if the author of any painting, drawing, or photograph, in which there shall be subsisting copyright, after selling the same, or if any one, without the consent of the proprietor for the time being, repeat, copy, colorably imitate, or otherwise multiply for sale, hire, exhibition, or distribution, or cause this to be done, or knowingly import into the United Kingdom, or sell, etc., such copies, he shall forfeit to the proprietor of the copyright a sum not exceeding £10, and the copies and materials shall belong to such proprietor. Moreover, if any person affix a mark, monogram, or initials of a person who did not execute or make such work, to paintings, drawings, or photographs, or fraudulently sell, exhibit, or offer such for sale, such person shall forfeit £10, or double the price of the thing sold, etc., and all spurious copies and imitations become forfeited to the real owner. This statutory protection to artists and owners of pictures, engravings, and photographs, extends to the United Kingdom. See Supp., page 894.

PICTURES, RESTORATION OF. Some important observations on the action of light on oil-paintings have led to a series of experiments by Dr. David Price of the crystal palace, and he has succeeded in demonstrating that the discoloration of pictures in galleries and dwelling-houses arise in a great measure from the presence of sulphide of hydrogen gas, which reduces the metal in the white lead, and thereby gives the dark dingy appearance which so frequently defaces even modern pictures in some places where the pictures are hung on walls not exposed to the direct light of the sun. Dr. Price shows that pictures which have been thus injured can be completely restored by being fully exposed to light in a pure atmosphere, the light exerting a rapid and powerful influence over the lead compounds, even though well protected with varnish. The same holds good even in a stronger degree in water-color paintings in which lead-whites have been used.

PI'CUS AND PI'CIDÆ. See **WOODPECKER**.

PIDGIN, or PIGEON, ENGLISH. A "lingo" used in California and in the Pacific ports of Asia, between the Asiatics and mercantile foreigners. "Pidgin" is the word for "business," as it issues from the guttural organs of a Chinaman, as "cumshaw" is that for "commission" or gift. The Chinaman accustomed mainly to monosyllabic speech finds it easy to speak the English words of one syllable, or dissyllables whose ultimates are vowels, or, he will vowelize words ending in hard consonants. For this grotesque form of speech the foreigners rather than natives are responsible, since the former, shrinking from the difficulties of oriental speech, first encouraged the Asiatics to use simple foreign words. Pidgin English, though defying all known grammar, is yet available for every-day use, and is duly taught in classes by Chinese "professors," and

in the more northern counties of Scotland. The ground-plan of one of these at Kettleburn, in Caithness, explored and described by the late Mr. A. H. Rhind, of Sibster, is figured in the accompanying wood-cut. The outmost circle represents the extreme limits of the mound which covered the structure; *a*, a bounding wall, 3 ft. thick, and 3 ft. high, rudely built of large unshaped stones; *b*, an inner wall, 4 or 5 ft. high; *c* and *d*, fragments of walls faced outward; *e* and *f*, passages leading to the inner chambers; *g*, *h*, and *i*, passages leading to smaller side chambers, *k*, a wall within the wall of the chamber *s*; *n*, a chamber, so ruined that its walls could not be traced all round; *n*, a large boulder, which, being difficult to remove, had been built over; *o*, a chamber containing a regularly built well (between *p* and *p*), 9 ft. deep, and roofed over. The whole

is the daily and only means of communication between tens of thousands of people in China, Japan, and California. This mongrel dialect, as different from Chinese as Chinese is from English, contains Portuguese, Malay, French, and Hindustan elements, besides English; but in many cases one word is used in a great variety of meanings. Prominent in the vocabulary are *sabé* (French, *savoir*, to know), *pecee* (piece), *peggy*, (Malay, go away, take off, etc.) *top-side* (up), etc. Its syntax is usually formed by arranging the words according to the Chinese order. A Japanese lad, in answer to the writer's question, Doko (where?), answered, "Me Yokohama go" (I am going to Yokohama), according to the native idiom, which requires the object first and verb last. Foreigners, in using their own words, transformed into Pidgin English, think them to be native, while the native imagines they are foreign. Though most persons regard this "lingo" as an absurdly silly kind of baby talk, unworthy of adults, and though the tribunals forbid it for testimony, and most printed specimens of it have a comic flavor, yet earnest students recognize in it a new language in embryo, and predict its ultimate status as an accepted tongue, believing that it will be a powerful aid in "westernizing" China, Japan, and India.

PIE, a well-known culinary preparation, consisting of a crust of dough or pastry, inclosing either meat or fruit, and baked in the oven. The origin of the word is very obscure. There are two kinds of pies, one in which a dish is used, as in cases where much juice or gravy has to be retained; the other, without the dish. The latter are called raised pies, and a particular kind of paste is required; which is made with hot lard and water, and must have sufficient consistency to stand up. When molded into the form or case of the pie it is filled with meat, usually game, and baked. This kind of crust is not usually eaten with its contents, as it is considered unwholesome, it therefore merely serves as a case for the inclosed viands.

PIEDIMONTE D'ALIFÉ, a t. of south Italy, in the province of Caserta, and 20 m. n. by e. from Caserta, at the base of the Apennines, on a branch of the Volturno. It is about 3 m. n.e. from Alifé, the ancient *Alifæ*, a city of the Samnites, now a small town of only 2,689 inhabitants. In a grand and gloomy ravine, called the Val d'Inferno, near Piedimonte d'Alifé, a torrent issues from a cavern, which is supposed to derive its waters through subterranean channels from a lake, about 5 m. distant, amongst the mountains. This and other mountain torrents afford water-power for a number of cottor, paper, flour, fulling, and copper mills in and around the town. Piedimonte d'Alifé is one of the most active manufacturing towns in Italy. The extensive cotton-mills established by Mr. Egg give employment to about 1500 hands. There are copper-mines in the vicinity. Pop. about 6,000. Piedimonte is the name of several smaller towns and villages in Italy and Sicily.

PIEDMONT, or **PIEMONT** (Fr. *piéd*, foot, *mont*, mountain), an Italian principality, which now forms the n.w. part of the kingdom of Italy, is inclosed mostly by natural boundaries, having on the n. the Pennine Alps, on the w. the Graian and Cottian Alps, on the s. the Maritime Alps and Genoa, and on the e. the Ticino and the duchy of Parma. It includes the former duchy of Montferrat, which lies in its south-eastern corner, what was the Sardinian portion of the old duchy of Milan, and contains 11,777 English sq.m., with a population (1881) of 3,070,379. The mountain ranges which form its boundary on the n., w., and s. attain, in various places, a great elevation above the sea; the Col de Tende, Monte Viso, Mont Cenis, Mont Iseran, Mont Blanc, Mont St. Bernard, Mont Cervin, Monte Rosa, and the Simplon being all on the boundary line. As to its general character, the country is partly mountainous, partly hilly, and much diversified with hill and dale; the ranges which traverse the country being spurs from the alpine boundary, and converging towards the central tract, through which flow the Po and its chief tributary, the Tanaro. The valleys which separate these ranges are all watered by rivers which take their rise in the Alps, and pour their supplies into either the Po or the Tanaro, according as they come from the n. and w., or from the s. The amount of the water supply in the country may be imagined when it is considered that in Piedmont the Po receives no fewer than 10 tributaries on the left, and 6 on the right, all of them of considerable size, and some of them, as the Tanaro and Dora Baltea, worthy of being classed as rivers. The valleys of the Po and Tanaro are exceedingly rich and fertile, producing abundant crops of grain, pulse, hemp, chestnuts, olives, and many kinds of fruit. Maize and barley are the chief cereals, the former being the ordinary article of food to the inhabitants, while abundant herds of swine are fed upon the latter. The climate is mild in winter; but in summer, especially on the level country e. of the Dora Baltea and the Tanaro, the heat is scorching, and this portion would be rendered a perfect sandy desert were it not for the complete system of irrigation, which supplies moisture to more than half a million of acres, and renders the eastern districts the granary of the country. So valuable is the privilege of using the water of rivers as a means of irrigation, that a considerable tax is levied upon it. The other products of Piedmont are wine and silk, which are produced in great abundance, especially silk, which is the best in Italy, and is generally exported raw. The chief manufactures are silk, linen, woolen, and cotton goods, hosiery, paper, leather, cutlery, various fermented liquors, glass, and iron. The inhabitants are active and industrious, and mostly belong to the Roman Catholic religion, but are more tolerant than in other parts of

Italy. The Vaudois or Waldenses (q. v.), have from time immemorial inhabited the wild vales at the foot of the Cottian Alps, in the western corner of the principality. Many of the Piedmontese, like the Swiss and Tyrolese, spend their youth and early manhood in traveling through other countries as dealers in engravings, jewelry, and other articles of merchandise, and returning with a small hoard spent the rest of their days in comfort in their native land.

Piedmont, in the 10th c., was possessed by the marquises of Susa, Ivrea, Montferrat, and Saluzzo; and it was not till when, a century afterwards, the marquisate of Susa passed into the house of Savoy, that the latter, then counts of the Maurienne (the s. portion of Savoy), gained a footing in the country. At the commencement of the 12th c. the possessions of the house of Savoy were divided, and the lines of Savoy and Piedmont formed; but they were again united, in 1416, by Amadeus VIII. (afterwards pope Felix V.), who, in the following year obtained from the emperor Sigismund the title of duke of Savoy, which they exchanged for that of king in 1684. During the Spanish war of succession, Piedmont was increased by the addition of the provinces of Alessandria, Valence, Lomellino, and the Val di Sesia (1703), by Tortona and Novara in 1735-36, and by Vigevanese and Bobbio in 1743. In 1796 it was seized by the French and parceled out into six departments, five being incorporated with France, and one with the kingdom of Italy; but after the fall of Napoleon the house of Savoy recovered possession of it. See ITALY, SARDINIA, SAVOY. Since 1860 the name Piedmont, as a provincial designation, has been disused; and Piedmont proper is now divided into the provinces of Alessandria, Coni or Cuneo, Novara, and Turin.

PIE'DRA BLANCA, a t. of the Argentine Republic, South America, in the province of Catamarca, and 20 m. s.w. from Catamarca. Pop. 10,000.

PIEGANS, an Indian tribe in Montana. They belong to the Blackfeet, from whom they separated under the leadership of a chief named Piegan, whence their name. In return for the cession of some of their territory, by treaty, in 1868, the U. S. government agreed to pay them \$1,000,000. In 1870 lieut.-col. Baker led a force against them, and attacked Red Horn's camp on the Marios, killing 173 men, women, and children. The act of congress, April 15, 1874, deprived them of their best hunting grounds. They have suffered greatly from small-pox, but still number over 2,000.

PIE'POWDER COURT, in England, an ancient court held in fairs and markets to administer justice in a rough and ready way to all comers, called also the court of dusty foot (Fr. *pie'd poudreux*). Its jurisdiction seems to have been confined mostly to petty vagabonds, peddlers, and other wanderers. The court has long been obsolete, the only jurisdiction of that kind being now merged in the court of petty sessions (q. v.).

PIER, the block of solid wall between doors, windows, etc.; also a solid mass of masonry built to receive the arch of a bridge. The term is also used synonymously for the pillars (q. v.) of a church; thus, we speak of nave-piers, etc.

PIERCE, a co. in s.e. Georgia; drained by the Satilla and Little Satilla rivers, and Hurricane creek; and traversed by the Atlantic and Gulf, and the Brunswick and Albany railroads; 640 sq. m.; pop. '80, 4,538—4,522 of American birth; 1,473 colored. The surface is level, sandy, and mostly covered by pine forests. Corn, cattle, lumber, and pork, are the products. Co. seat, Blackshear.

PIERCE, a co. in n.e. Nebraska, drained by the n. branch of the Elkhorn river; 540 sq. m.; pop. '80, 1203—780 of American birth. The surface is level and the soil very rich; corn, oats, wheat, and hay are the chief products. Co. seat, Pierce.

PIERCE, a co. in the w. center of Washington territory, bounded on the e. by Cascade mountains, and on the w. by Puget sound and Nesqually river; crossed by the Northern Pacific railroad, and drained by the Green and White rivers; 2,000 sq. m.; pop. '80, 3,319. The surface is varied by mountains, prairies, and dense forests of fir, cedar, and other trees; the soil is fertile in the valleys; the principal products are grain, wool, hay, and lumber. Mount Rainier, 14,444 ft. high, is in the s. part, and is the highest point of the Cascade range. Co. seat, Steilacoom City.

PIERCE, a co. in w. Wisconsin, bounded w. and s.w. by the St. Croix and Mississippi rivers; drained also by several smaller streams; 560 sq. m.; pop. '80, 17,744—12,596 of American birth. Lake Pepin is a small but beautiful sheet of water on the Minnesota border. The surface is partly prairie and partly hilly. The soil is fertile, and produces wheat, hay, and oats in large quantities. Lumber is the chief export. Limestone is found. Co. seat, Ellsworth.

PIERCE, BENJAMIN, 1757—1839, b. Mass.; entered the revolutionary army soon after the battle of Lexington, took part in the battle of Bunker's hill, and was made ensign after the battle of Bemis heights. He obtained the rank of lieut.; remained in the service till the close of the war, and was afterwards appointed brig. gen. of militia. He was in the New Hampshire legislature 1789—1802, was councilor 1803—9, and 1814—18; many years high sheriff, and governor, 1827—29.

PIERCE, FRANKLIN, the fourteenth president of the United States of America, was b. in Hillsborough, N. H., Nov. 23, 1804. His father, gen. Benjamin Pierce, was a soldier of the war of independence, and governor of New Hampshire. Franklin Pierce was edu

cated at Bowdoin college, Maine, and was an officer in a college military company, in which his biographer, Nathaniel Hawthorne, was a private. He spent his first vacation in teaching a country school, studied law with Levi Woodbury, governor and senator, was admitted to the bar in 1827, became speaker of the state house of representatives in 1829, and was elected to the 33d congress, a democrat of the school of Jackson. In 1837 he was elected to the U. S. senate, of which he was the youngest member. He declined the office of attorney-general, offered him by president Polk, and refused the nomination for governor of New Hampshire; and at the commencement of the Mexican war volunteered as a private, but was appointed brig.gen., and led his brigade in the battles of Contreras and Churubusco. In 1852, in consequence of the conflicting claims of the leaders of the democratic party at the Baltimore convention, he was nominated as a compromise candidate for the presidency, against gen. Scott, the whig nominee, and received the votes of all but four states. He appointed an able cabinet, including Jefferson Davis as secretary of war. During his administration, the Missouri compromise was repealed; the treaty for reciprocity of trade with the British American colonies was made, and a treaty with Japan; and the Kansas difficulties which then arose, with the growing animosity between the north and south, led to secession, and the war of 1861. At the close of his term of office in 1857 he traveled in Europe, and, having no sympathy with the party which subsequently came into power, he took no part in politics. He d. 1869.

PIERCE, GEORGE FOSTER, D.D.; b. Ga. 1811; graduated at Franklin college in 1829; studied law, but left it for the ministry; joined the Georgia conference of the Methodist Episcopal church in 1830; was pastor of several churches in Georgia until 1837, when he became president of the Georgia college for women, Macon. In 1848 he was chosen president of Emory college, Georgia, and in 1854 was elected bishop. He was a prominent member of the general conference of 1844 in New York, when measures were adopted for the division of the church. He is an eloquent preacher and an able executive officer. He has published *Incidents of Western Travel*, also several sermons and addresses.

PIERCE, HENRY LILLIE. See page 894.

PIERCE, HENRY NILES, D.D., LL.D. See page 894.

PIERCED, in heraldry, a term used to indicate that a charge is perforated so as to show the field beneath it. The aperture is presumed to be circular, unless some other form, as square-pierced or lozenge-pierced, be specified in the blazon.

PIERCE, LOVICK. See page 894.

PIÉROLA, NICOLÁS DE. See page 894.

PIERPOINT, FRANCIS HARRISON, b. W. Va., 1814; worked in his father's tan-yard until the age of 21; graduated at Alleghany college 1841; studied law three years, supporting himself by teaching; commenced practice 1844. He was a thorough abolitionist, vigorously opposed the dogma of state supremacy and secession, and at a convention of the loyal people of the state held June, 1861, was unanimously elected provisional governor of the "restored government of Virginia." The president, informed of the rebellion in the state, recognized him as governor, and requested him to raise and commission troops. At the end of 6 months he was elected by the people for two years, and then re-elected for four years. He removed the seat of government to Alexandria, and after the surrender of Lee, transferred it to Richmond in the spring of 1865. In a few months he had completely restored the state government. At the expiration of his term he returned to Fairmont, where he still resides. He has been since the war engaged in the coal-trade, and in other ways interested in developing the resources of West Virginia. He has served one term in the state legislature. In 1871 he was president of the Meth. Prot. general conference, the first layman who ever held that position.

PIERPONT, JOHN, 1785-1866, b. Conn.; graduated at Yale, studied law at the Litchfield law school and removed to Newburyport, Mass. After unsuccessful business ventures in Boston and Baltimore, he studied theology at the Harvard divinity school, and in 1819 was ordained over the Hollis street Congregational (Unitarian) church in Boston. His advocacy of anti-slavery, temperance, and other reforms, caused his withdrawal from that pastorate in 1845, after which he was pastor of the Unitarian church, Troy, N. Y., and of the first church (Unitarian), Medford, Mass. In the war of the rebellion he was for a time chaplain of a Massachusetts regiment, but resigned to accept an appointment in the U. S. treasury, where he remained till his death. In 1816, he published a poem called *Airs of Palestine*; in 1840 *Airs of Palestine, and Other Poems*; and in 1851 he read a poem at the Litchfield centennial. He also published a number of sermons and addresses, and a series of school readers.

PIERRE, JACQUES HENRI, BERNARDIN DE ST., a celebrated French writer, was b. at Havre, Jan. 19, 1737. He received his education at Caen and Rouen, and afterward entered the government department of civil engineers. On his dismissal from their service in 1761, he wandered about the continent for several years, endeavoring to realize his dream of a republican colony. He returned to France in 1766, and soon after obtained a commission as engineer for the Mauritius; but after a residence of three years in the island, he returned to Paris. At this time he wrote the story of *Paul et Virginie*. The little book, with its passion, its simplicity, its tenderness, achieved an immense success, and has been translated into almost every language. St. Pierre passed through the storms of the revolution in safety, and was lucky enough to secure the patronage of

Napoleon. He died Jan. 21, 1814. Besides *Paul et Virginie*, he wrote other tales, essays, and several plays

PIERREPONT, EDWARDS, LL.D., b. Conn., 1817; graduated at Yale in 1837; was admitted to the bar 1840; and practiced law in Ohio till 1846, when he returned to New York. He was elected judge of the superior court, New York, 1857, resigned in 1860, and resumed his practice. In 1862 he was chosen by president Lincoln and gen. Dix, to take charge of the proceedings against prisoners of state, then confined in the forts, on charges relative to the rebellion, and in 1867 conducted the case for the government against John H. Surratt, indicted as an accomplice in the murder of president Lincoln. He was appointed district attorney by president Grant in 1869, and resigned a year later. He received the honorary degree of LL.D. from Columbia college in 1871, and from Yale in 1873. He was appointed attorney-general of the United States in 1875, and envoy extraordinary, and minister plenipotentiary, to the court of St. James, which position he resigned in 1877. He is, 1885, consul-general for England at New York.

PIERSON, ABRAHAM, 1641-1708; b. Lynn, Mass.; graduated 1668 from Harvard college. His father was the first minister of Newark, and of Southampton, L. I. The son was his colleague at Newark, was afterward pastor of a Congregational church at Killingworth, Conn., 1694-1707; and for the last six years of his life was the first president or rector of Yale college, which then had its seat at Saybrook, though the classes were taught by Mr. Pierson at that part of Killingworth now known as Clinton. A statue of him, rather ideal than a portrait, was executed by Launt Thompson, and now stands on the college green.

PIERSON, WILLIAM, M.D. See page 894.

PIERS PLOWMAN, or rather *The Vision of William concerning Piers the Plowman*, is a remarkable poem by William Langland or Langley, who was born, apparently in Shropshire, about 1332, was educated for the church, and died in London near the end of the century. The *Vision*, a powerful poem in vigorous alliterative verse, describes a series of nine dreams, in certain of which a person called Piers the plowman appears. Under allegorical covering, the *Vision* exposes the manifold corruptions of the state, of the church, and of existing social arrangements. From the forty-three MSS. which remain, it is evident that the poem, originally written about 1362, was repeatedly revised, altered, and extended, and that it continued to occupy the author all his lifetime.

PIERS PLOWMAN (*ante*). *The Vision of William concerning Piers the Plowman*, is attributed to Robert Langland, Longland, or Langelande, b. Cleobury-Mortimer, Shropshire, England, about the middle of the 14th century. He is supposed to have studied at Oxford, and to have been a monk at Malvern. The scene of his poem is laid in the "Malverne hilles" on the Welsh border, and the frequent allusions to the Bible and the fathers, show that its author was an ecclesiastic. The poem which is written in alliterative verse, recounts, the vision of Piers Plowman, who falls asleep beside a stream among the Malvern hills. It contains much vigorous satire of the abuses of society in church and state. It attained a great popularity, and was often imitated by subsequent political and religious reformers. The most notable of these imitations is *Piers Plowman's Creede*, composed about 1390 in the Wycliffite interest. The best edition is that edited by W. W. Skeat for the early English text society, 1867-77.

PIETÀ' (an Italian word signifying *piety*, in the sense in which that term indicates or includes affection for relatives), the name given in the language of art to representations of the Virgin Mary embracing the dead body of her son. It is a counterpart to the *madonna* with the infant Jesus in her arms. The one affords an opportunity for the representation of the purest joy and highest motherly love; the other, of the utmost pain and grief. The *pietà* has long been a favorite subject, not only with painters, but with sculptors. A famous one by Michael Angelo is in the church of St. Peter at Rome.

PI'ETISTS, a designation given since the end of the 17th c. to a religious party in Germany, which, without forming a separate sect, is distinguished not only by certain peculiarities of religious opinion, but also by the manner in which these are manifested. The peculiar character of their religion is very generally denoted by the term *pietism*, which is frequently employed with reference to the same tendencies of opinion, feeling and conduct, wheresoever and whensoever exhibited. Pietism may be regarded as consisting in an exaltation of the importance of religious feeling, and of the practical part of religion, with a corresponding depreciation of doctrinal differences, and a contempt for outward ecclesiastical arrangements; and has been more or less strongly developed from time to time in all sections of the church, a tendency towards it always existing in a large class of earnestly religious minds. In the church of the middle ages, this tendency was displayed in an endeavor to attain to a superior spirituality and purity by means of religious contemplation and asceticism, and many, consequently, embraced a monastic life. The reformers, adopting the Augustinian doctrines, rejected this mode of seeking deliverance from indwelling sin, and proclaimed the efficacy of faith in the sacrifice of Christ. But the controversies which arose among them, and increased among their successors, gradually gave a too exclusively doctrinal and polemical character to the sermons and writings both of the Lutheran and Calvinistic divines, particularly in Germany, and a reac-

tion ensued, not in favor of the church of Rome, but in favor of a religion of feeling and good works, or of the heart and life. Disgust at the sectarian bitterness and exclusiveness which prevailed led even to an undervaluing of disputed points; and thus the *Pietism* of Germany was generated and developed. The origin of it is referred to a work entitled *Vom wahren Christenthume*, by John Arnd, published in 1605; to the *Invitatio Fraternalitatis Christi* of John Val. Andreae, published in 1617, both of them Lutherans; and to the writings of Cocceius, a Calvinist. But its fuller development is unquestionably to be ascribed to Spener (q.v.), in the latter part of the 17th c., and to his friends and disciples. The name *Pietists* was first given in contempt to certain young *docents* in Leipsic, who began in 1689 to give prelections on the New Testament both to students and citizens, and to addict themselves much to a meditative mode of life. Spener had held meetings of a somewhat similar kind in his own house when preacher at Frankfort-on-the-Main, and in his writings had urged the necessity of a reform in the Protestant church and theology. He and his followers dwelt much upon the importance of studying the Scriptures rather than the symbolical books, upon the unfitness of any unconverted or unregenerate person for the office of the ministry, upon the right and duty of the laity to take part in the exercises of Christian assemblies, and upon the necessity of a practical rather than a systematic religion. But many of the more extreme Pietists carried their antipathy to the doctrinalism and the established services of the church to a degree that alarmed the theologians of the old school, the high and dry Lutherans, or German "moderates," who accused Spener and his disciples, not without reason, of a tendency to make all goodness and virtue consist in mere religious feeling, or pious sentimentalism; to represent the divine grace as operating in too sudden and abrupt a manner; to exaggerate the value of good works; to depreciate the value of learning and of clear intellectual perception in the study of Scripture; and to indulge in a strictness of judgment upon the religious character of the ordained clergy, tending to sectarianism, and indeed incompatible with ecclesiastical unity. The weapons of argument, however, were not the only weapons employed against them. The docents were compelled to give up their prelections, and finally to leave Leipsic; the meetings for mutual edification were suppressed by the government as disorderly conventicles; and Francke (q.v.), the most distinguished of the Leipsic docents, having gone to Erfurt, was prevented from lecturing, and quickly compelled to retire. Spener's influence, however, procured a refuge for his friends in the newly founded university of Halle, and Francke obtained a professorship there. Halle became thenceforth the source of new religious influences, and, indeed, of a new religious life to Germany. The Pietists, although spiritually exclusive—disposed to regard themselves as the "chosen of God," and to look down on all others as "children of the world," or even of the devil—did not attempt to form a separate sect. To do them justice, they were as far as possible from being ecclesiastically ambitious; all their desire was to excel in "labors of love," and to cultivate feelings of intensest piety. The rise of the Wolfian or Rationalistic theology, the spread of that sort of skeptical anti-clerical philosophy which flourished for a while under the name of *aufklärung* (enlightenment), exercised an injurious and depressing influence on Pietism; yet through all the long, obstinate warfare maintained against the doctrines of the church by the rationalists during the last half of the 18th, and the most part of the 19th c., Pietism continued to number some adherents; and it can hardly be doubted that it is to the Pietists, and not to the Lutheran dogmatists, that Germany is in a great measure indebted for that revival of religious faith and feeling which, begun with the great Schleiermacher—himself trained up under pietistic influences—has since widely diffused itself through her biblical scholars and theologians. The patriotic enthusiasm called forth by the insolent conquests of the French naturally allied itself to pietistic tendencies, for, in Germany, the triumphs of Napoleon even as *emperor* were looked upon as the triumphs of revolutionary, republican, and infidel principles; and after the general restoration of peace, the statesmen and upper classes, especially in Prussia, believing that political security could only be obtained by a return of the populace to the simple, obedient, and unquestioning piety of earlier times, countenanced this party in the church; and amiable tea-drinking societies of devout men and women were formed to distribute tracts, and to inoculate the radical and heathen masses with pietistic sentiments. But this attempt to use "piety" for reactionary political purposes sullied its purity, and alienated from it the very parties whom it wished to influence. Still, however, Pietism exists as a distinct element in the religious life of Germany, and now, as ever, its strongholds are Prussia (Berlin, Silesia, Wupperthal), Hesse, and Würtemberg.

PIE'TRA-DU'RA, a name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as jasper, carnelian, amethyst, agate, etc. The real *pietra-dura* work dates as far back as the 16th c., about 1570; and from that time to the present has been almost confined to Florence, where a government *atelier* has existed ever since the beginning of the 17th c., which was originated in order to supply decorations for the Capella Medicea. It is sometimes called *Pietre Commesse*, and *Lavoro di Commesso*. In the inferior kinds, which are sold in Italy, and are manufactured now pretty extensively in Derbyshire and other parts of Britain, pieces of colored sea-shells are used instead of the harder and more valuable colored stones.

PIETRAPER'ZIA, a t. of Sicily, in the province of Caltanissetta, and six m. s.e. from Caltanissetta, on a lofty height rising from the left bank of the Salso. There are sulphur-mines in the vicinity. Pop. 9,909.

PIETRASAN'TA, a t. in the province of Lucca, Italy; 17 m. n.w. of Pisa, 2 m. from the Mediterranean; pop, '74, 13,227. It is on a hill, on the top of which is a large fortress; it is surrounded by a high wall and entered by three gates, one of them opening near the principal square, on which stands an ancient palace, now used for public offices, and the Pretorio. The streets are wide, well paved and straight, and most of the buildings are in the style of the 14th and 15th centuries. The surrounding country, partly level and partly mountainous, is extremely fertile, and the vine and olive are produced in great abundance. The Serranezza marble is quarried here.

PIEZOM'ETER (Gr. *piezo*, I press; *metron*, a measure), an instrument for measuring the compressibility of fluids. Oersted's (q.v.) instrument, the first by which the compressibility of water was satisfactorily determined, consisted of a cylindrical glass jar, into the neck of which a narrower cylindrical tube of glass, open at both ends, was firmly fixed. In this tube worked an air-tight piston by means of a screw. In the interior of the jar was placed a bottle, whose neck was drawn out into a long capillary graduated tube, and along side this bottle was suspended a cylindrical tube, closed at the top, but open at the bottom. When the compressibility of any liquid was to be determined, the instrument was adjusted in the following manner: the bottle inside was filled almost to the top of the capillary tube with the fluid, and being replaced inside the jar, the latter was completely filled with water up to the piston in the neck. The liquid in the submerged bottle, then under pressure of the water above it, fell slightly in the capillary tube, being kept from contact with the water by an air-bubble, the motion of which up or down, according as the pressure was less or greater, served as an index for reading off the graduation. The suspended tube alongside being at first only filled with air, the water rose in it to some extent, and by graduations on the tube it was made to indicate the pressure in atmospheres or parts of atmospheres. Pressure was now applied to the water in the jar by screwing down the piston; the compressed water communicated the pressure to the liquid in the bottle and to the air in the suspended tube; the descent of the air-bubble in the former indicating the amount of diminution in bulk the liquid had undergone (the capillary tube being graduated in inches and parts of inches, and each inch of tube being known to contain a certain fraction of the contents of the bottle), while the ascent of the water in the suspended tube showed the amount of pressure which had been applied.

FIG. See Hog.

PIGEON (Ital. *pigione*, *piccione*, or *pipione*, from *pipiare*, Lat. *pipire*, to peep or cheep). a name sometimes applied, like dove (q.v.), to all the species of *columbidæ* (q.v.), and sometimes almost restricted to those still included by ornithologists in the genus *columba*; having a bill of moderate length, hard, and a little arched at the point, the base of the upper mandible covered with a soft thick skin, in which the nostrils are pierced; the feet with toes divided to the base, and formed both for walking and perching; the wings rather large and pointed; the tail of moderate length, and generally square at the end. The species of this group are numerous, and occur in almost all parts of the world. Some of them build their nests in trees, and some in holes of rocks; they lay only 2 eggs at a time, but breed twice or oftener in a year, and both the male and the female take part in incubation. The original of all the varieties of the DOMESTIC PIGEON is now almost universally believed to be the ROCK PIGEON or ROCK DOVE (*C. livia*), the *biset* of the French, a bird of extensive geographical range, being found as far n. as the Faröe islands, and on many parts of the coasts of Europe, Asia as far as Japan, and the n. of Africa, breeding in crevices of rocks, and often within caverns which open on the sea. It swarms in prodigious numbers in some of the rocky islands of the Mediterranean; and even on the British coasts great numbers are found in some localities, particularly in the Orkneys and Hebrides. Its food consists partly of mollusks and other small animals, partly of grain and seeds; and it often makes unwelcome visits to the corn fields of its vicinity. In a wild state this bird exhibits great uniformity both of size and plumage; being not quite 12 in. in length from the tip of the bill to the end of the tail; the prevailing color bluish-gray, in some parts with green and purple reflections, two broad and distinct bars of black across the closed wings; the lower part of the back white; the tail deep gray, with a broad black bar at the end; the bill blackish-brown; the legs and toes reddish-orange.—Until recently naturalists very generally confounded this species with the STOCK DOVE or SMALLER WOOD PIGEON (*C. ænas*), a species which inhabits woods, and generally builds in trees, preferring the hollows of old decaying trees, or the tops of such as have been pollarded and have become bushy—whence the name *stock* dove. In some of the open parts of England, however, it makes its nest in rabbits' burrows or other holes in the ground. It is rather larger than the rock pigeon; its prevailing color is bluish gray, in some parts passing into pale gray, but nowhere into white; the wings destitute of bands; the sides of the neck with green reflections; the breast purplish red. It congregates in large flocks in autumn and winter. It is partially migratory in some parts of Europe; a summer visitant of the northern regions. In Britain it is found only in the southern parts of the island. Its geographical range includes great parts of

Europe and Asia, and the n. of Africa. It feeds on beech-mast, acorns, grain, pulse, etc., and sometimes resorts to turnip-fields to eat the tender tops. Its voice is very different both from that of the rock dove and that of the ring dove. Its flesh is of very fine flavor.—The RING DOVE, WOOD PIGEON, or CUSHAT (*C. palumbus*), is the most common British species, and is diffused over great part of Europe, either as a permanent resident or a summer bird of passage, although it is not found at all in some of the most northern regions; and occurs also in the temperate parts of Asia, and the n. of Africa. Its soft loud *coo* is one of the pleasant intimations of approaching spring. It inhabits woods, and builds its nest among the branches of trees. It is the largest of the British species, being about 17 in. in entire length. It feeds on green corn, young clover, turnip-tops, grain, pulse, acorns, etc. Where it abounds, its voracity is often very injurious to the farmer. It is gregarious in winter. It is in considerable estimation as an article of food; but it is very shy and wary, not easily approached by an inexperienced sportsman.—These are all the British species of pigeon. Our limits quite preclude us from noticing almost any other. The RING-TAIL PIGEON (*C. Caribbea*) may be mentioned as a West Indian species, much valued for the richness and delicacy of its flesh, which is reckoned one of the greatest luxuries of that part of the world. The BALD-PATE or WHITE-HEADED PIGEON (*C. leucocephala*) is another large and fine species, plentiful in the West Indies. It migrates to the *Keys* of Florida in summer.—The DOUBLE-CRESTED PIGEON (*C. dilopha*) is a large species, inhabiting the n. of Australia and warmer regions to the northward, remarkable for its crest, which consists of two parts, one on the back of the head, and another of lax recurved feathers springing from the forehead, and even from the base of the bill.

Only one species of pigeon has been truly domesticated, and having long been so, it has undergone many remarkable changes, and there are numerous varieties or breeds; some of them, exhibiting very strange peculiarities, and known as *fancy pigeons*, being carefully preserved and tended by pigeon-fanciers. Pigeon-fancying is nowhere carried further than in London, where there are many persons who give great part of their time to it, and whose pigeons are their chief delight. The prices of such fancy pigeons as are deemed most perfect of their kind are very high. The ordinary domestic pigeons, kept for profit as a kind of poultry, differ from the wild rock dove chiefly in color in which they are often very unlike it, although a tendency always manifests itself to return to the original colors, and the bars on the wings are apt to reappear in the progeny even of what may be called the most artificial varieties. Of these may be mentioned, as among the most interesting, the rough-footed pigeon, having the feet feathered; the Jacobin, which has a range of feathers inverted over the head, and extending down each side of the neck, as a hood; the fan-tail, or fan-tailed shaker, in which the number of the tail-feathers is greatly increased, and the bird has the power of erecting its tail like that of a turkey-cock, whilst it has also a peculiar vibratory motion; the tumbler, so called from tumbling in the air in its flight, and further characterized by a very short bill; and the pouter or cropper, which has the power of blowing up its crop to an extraordinary degree, so that the head seems fastened on the top of an inflated bladder. The carrier pigeon (q. v.) is regarded as a variety of the common pigeon.

The law regarding pigeons is stated in the article DOVECOT. For the profitable keeping of pigeons, it is necessary to have a properly-constructed dovecot, divided into cells, a cell for each pair, each cell 16 in. broad, by 12 from front to back, and the door toward one side, so that the nest may not be seen from without; a slip of wood in front of each cell for the birds to sit and coo on. The dovecot must be placed at such a height as to be out of the way of rats and other depredators; and must be frequently cleaned, otherwise it may probably be deserted by its occupants. It ought to be painted white, that color being very attractive to pigeons, and contributing to retain them when a new dovecot is established, in which there is often found to be not a little difficulty. Pigeons begin to breed at the age of 9 months, and breed every month except in very cold weather. The male and female continue faithful to each other from year to year, a circumstance noted by Pliny and others of the ancients, and evidently, as well as their somewhat demonstratively manifested affection, a reason of the poetic references often made to the dove.

PIEGON BERRY. See POKE, *ante*.

PIGEON COVE, a village in Rockport, Essex co., Mass., Cape Ann coast, about 30 m. from Boston. It is a summer resort, and has several hotels. Pop. about 500.

PIGEON ENGLISH. See PIDGIN ENGLISH.

PIGEON HAWK, *Falco columbarius* of Linnæus, a bird of prey of the falcon family inhabiting the warm and temperate parts of America. It is from 12 to 14 in. in length, with a spread of wing, in the female, of from two feet to 26 inches. The male, as is usual with falcons, is smaller. In the adult the back is of a bluish slate color, every feather having a longitudinal black line. The throat, breast, and belly are of a pale pinkish, yellowish white, each feather with a longitudinal line of very dark brown. The quills are black, with ashy white tips; bill blue, legs reddish yellow, with dark lines. It is the most fierce of all hawks in proportion to its size, and lives upon woodpeckers, thrushes, wild pigeons, snipe, and smaller ducks.

PIGEON PEA, *Cajanus*, a genus of plants of the natural order *leguminosæ*, suborder *papilionaceæ*, of which according to some botanists there is only one species (*C. flavus*), a native of the East Indies, but much cultivated also in the West Indies and in Africa; according to others there are two species, *C. flavus*, with flowers entirely yellow, the pod marbled with dark streaks, and two or three seeds in each pod; and *C. bicolor*, called CONGO PEA in the West Indies, the pulse of which is much coarser, and is used chiefly by negroes. The finer kind is nearly equal to the common pea. This kind of pulse is very much used in tropical countries. The plant is a shrub (*Cytisus cajan* of Linnæus) about 18 in. high. It is half-hardy in the s. of England. In tropical countries the plants stand and are productive for several years. They throw off their leaves annually, and reproduce them along with their flowers. The pigeon pea is one of the most valuable of the tropical kinds of pulse. It grows either on rich or poor soils. It is called *doll* and *urhur* in the East Indies. The name pigeon pea is West Indian.

PIGG RIVER: a magisterial dist., Pittsylvania co., Va. Pop. '80, 4,134.

PIGMENTS. See PAINTS.

PIGNEROL. See PINEROLO, *ante*.

PIG-NUT. See HICKORY, *ante*.

PIGWEEED, a name given to some species of *chenopodium*, particularly *C. albrem*, belonging to the goosefoot family (*chenopopiaceæ*), and going by the common name of goosefoot in England. The principal characteristics of the genus are: flowers perfect, all bractless; calyx 5-cleft, with lobes somewhat keeled, more or less enveloping the depressed fruit, stamens generally 5; styles 2, seldom 3. Flowers sessile in small clusters in spiked panicles. The species in this country are all annuals except two. They are quite common, growing in cultivated ground (gardens, plowed orchards, farmyards). The best-known species is *C. album*, sometimes called lamb's quarters, but more often pigweed. It grows from 1 to 3 and 4 ft. high; leaves varying from rhombic-ovate to lanceolate; the lower ones, sometimes all, are angulate toothed, mealy beneath, pale green above. There are several varieties.

PIKA. See LAGOMYS, *ante*.

PIKE—PIKEMAN. Previously to the use of the bayonet, infantry of the line of battle—that is, the heavy-armed troops—were from the earliest times armed with pikes or spears. The Macedonians carried pikes 24 ft. long; those of modern warfare averaged 12 or 14 feet. They were of stout wood, and tipped with a flat iron spearhead, which sometimes had cutting edges. As a defense against cavalry, the pike, from its length and rigidity, was of great value; but though it long survived the introduction of gunpowder, that event was really fatal to it. For success with the pike, especially in offensive war, a depth of several men was essential, and this depth rendered the fire of artillery peculiarly fatal. The pike is now superseded by the bayonet on the end of the musket.

PIKE, *Esox*, a genus of malacopterous fishes, including all the species of the family *esocidæ*, as restricted by Müller, and characterized by an elongated body, covered with scales, a depressed head, and broad blunt muzzle, with very large mouth, abundantly furnished with teeth of various sizes on the jaws, palatine bones, and vomer; no adipose fin; and the dorsal fin placed very far back over the anal fin. The species are not numerous; they are all inhabitants of fresh waters in the northern hemisphere. Only one is found in Europe, the COMMON PIKE (*E. lucius*), a native also of Asia and North America. It is very generally diffused over Europe, and is abundant even in its most northern regions; and is now abundant in lakes, ponds, and slow rivers in all parts of the British islands, although it is supposed not to be truly indigenous to them, but introduced. The statement, which has been often made, however, that it was introduced in the reign of Henry VIII., is certainly erroneous, as there is evidence of its existence in England at a much earlier date. Edward I., graciously regulating the price of commodities for his subjects, fixed the price of the pike higher than that of the salmon, and ten times higher than that of the turbot and the cod, from which we may perhaps infer its comparative rarity at that period. Some of the waters in the fenny districts of England are peculiarly adapted to pike, which are there found in very great quantity, and of superior quality.

The pike is of a dusky olive-brown color on the upper parts, becoming lighter and mottled with green and yellow on the sides, and passing into silvery white on the belly; the fins brown; the larger fins mottled with white, yellow, and dark green. The tail-fin is forked. The pike grows to a large size, occasionally attaining a weight of 60 or 70 pounds, although the stories of pikes much larger than this are liable to suspicion. The excessive voracity of the pike has long been proverbial. No animal substance which it can swallow, and which is capable of being digested, seems to be unpalatable to it; and no animal large enough to attract its attention, and which it can master, escapes being devoured. Mr. Jesse mentions an instance of eight pike, of about five pounds' weight each, consuming nearly 800 gudgeons in three weeks; and one of them devoured four roach, each about four in. in length, in rapid succession, and seized the fifth, but kept it in his mouth for about a quarter of an hour before swallowing it. The pike readily attacks a fish of own its size, and preys freely on the smaller of its own species. Frogs are frequent prey; water-rats and ducklings are sometimes devoured. A large pike often takes possession of a particular hole in the bank of a river, from which it issues to seize

any creature that may pass.—The pike spawns in the beginning of spring, for that purpose ascending narrow creeks and ditches, in which it is very easily caught by nets. Large quantities are caught at the spawning season in Lapland, and dried for future use. The pike grows very rapidly when the supply of food is abundant, reaching a length of 8 to 10 inches in its first year, 12 to 14 in the second, 18 to 20 in the third, and afterwards increasing for a number of years at the rate of about four pounds every year. A young pike is sometimes called a *jack* or *pickerel*. The name *luce* (Lat. *lucius*) is still known as an English name of the pike. The Scotch name is *gedd*, a name similar to those in the Scandinavian languages.

The flesh of the pike is much esteemed, but that of pikes of moderate size is reckoned superior to that of small, or of very large ones.

The pike is not only caught by means of nets, but by the rod, by set lines, and by *trimmers* or *liggers*, which may be briefly described as floats with lines attached to them, the line being so fastened that the bait swims at a proper depth, and that some yards of line run out when the bait is taken. The floats are sometimes made of wood or cork, sometimes of bundles of rushes, sometimes of bottles. In angling for pike various baits are used, such as a minnow, par, or other small fish, a portion of a fish, etc., and sometimes an artificial fly is employed with great success, made of two large hooks tied together, and adorned with two *moons* from a peacock's tail. The angler unaccustomed to the pike must be cautioned as to the manner of the taking the hook from its mouth, as any rashness may lead to severe laceration of his hand by its teeth. Pike may be fished any time from May to February inclusive, except when it is actually freezing. The best month is considered to be November; the pike are then in the best condition. One of the most approved tackles for angling for the pike is the *spinner*, baited with a small dace, bleak, gudgeon, or par of about two ounces. The mode of using it is thus described in Bailey's *Angler's Instructor* (Longman & Co., 1857): "Having cast your bait as far as possible, allow it, if you are fishing in a pond, or lake, or deep water, to sink a little, say 2 ft., then wind away at a brisk rate, holding your rod on one side rather low; if no run, wind out and throw again, but this time wind brisk four or five yards, then all of a sudden stop a moment, then off again, doing so three or four times in one cast. I have often found this a good plan. If you still have no run try another throw and wind brisk as before, but occasionally giving your rod a sharp but short twitch." See also Stonehenge's *British Rural Sports* (London, 1875).

Other species of pike are found in the lakes and rivers of North America, as *esox estor*, which is sprinkled with round blackish spots, and *E. reticularis*, which is marked with a network of brownish lines.

The gar-fish (q.v.) is sometimes called the sea pike. The same name is also given to certain large voracious fishes of warm seas, belonging to the perch family.

The Saury pike is noticed in a separate article.

PIKE, a co. in s.e. Alabama, drained by the head-waters of the Conecuh river and by the Pea river and Patsaliga; 850 sq.m.; pop. '80, 20,640—20,601 of American birth, 6,274 colored. Its surface is undulating and largely covered with thick pine forests. Its soil, fertile along the water courses, is sterile in most sections. On the river banks a sandy loam produces sweet potatoes, wheat, cotton, and is adapted to stock-raising and the products of the dairy. A branch of the Mobile and Girard railroad terminates at its co. seat, Troy.

PIKE, a co. in s.w. Arkansas, drained by the Little Missouri river forming its s.e. boundary, and Antoine creek its e. border; 600 sq.m.; pop. '80, 6,345—6,328 of American birth, 394 colored. Its surface is hilly and well supplied with building timber. Among its mineral products are limestone much used for building purposes, gypsum, marl, etc. Its rivers furnish convenient water-power, which is utilized in cotton factories, saw and grist mills. Co. seat, Murfreesborough.

PIKE, a co. in w. Georgia, having Flint river for its w. boundary; 300 sq.m.; pop. '80, 15,849—15,824 of American birth, 8,071 colored. It is drained by the Potato river, the Elkins, and other small streams. Its surface is hilly, and largely covered with forests. It is intersected by the Macon and Western railroad. Iron ore abounds, and the soil is moderately fertile, suitable for stock raising, dairy products, corn, cotton, and sweet potatoes. Co. seat, Zebulon.

PIKE, a co. in w. Illinois, having the Mississippi river for its w. border, separating it from Missouri, and the Illinois river on the e. border; 770 sq.m.; pop. '80, 33,761—32,138 of American birth, 301 colored. Its surface is nearly level, containing extensive beds of coal, and well-timbered portions diversified by broad, fertile prairie land. Its soil is remarkably fertile, drained centrally by the Salt river. Large crops of grain are produced; also vegetables, honey, and sorghum. Niagara limestone is quarried. It is intersected by the Wabash, and the Quincy, Alton and St. Louis railroads. Its industries are important and varied, embracing the manufacture of carriages and wagons, cooperage, flour, woolen goods, and iron. Co. seat, Pittsfield.

PIKE, a co. in s.w. Indiana, bounded on the n. by White river and its e. fork; drained also by Patoka creek; about 360 sq.m.; pop. '80, 16,384—16,016 of American birth. The surface is level and heavily wooded. The soil is fertile. The principal

productions are corn, tobacco, and wheat. Bituminous coal is mined. Co. seat, Petersburg.

PIKE, a co. in e. Kentucky, adjoining Virginia; drained by the Louisa, Elkhorn, and Russell's forks of the Big Sandy river; about 600 sq.m.; pop. '80, 13,003—175 colored. The surface is hilly, and heavily wooded. The Cumberland mountains are on the s.c. border. It contains deposits of bituminous coal. The soil is fairly fertile, and the principal productions are corn, pork, and live stock. Co. seat, Piketon.

PIKE, a co. in s. Mississippi, having the state line of Louisiana for its s. boundary, drained by the Bogue Chitto and the Tangipahoa rivers; 700 sq.m.; pop. '80, 16,688—16,191 of American birth, 8,115 colored. Its surface is mostly level, partly covered with hard wood forests, and diversified by groves of cypress and magnolia. Its soil is a sandy loam adapted to the production of cotton, corn, and live stock. It is intersected by the New Orleans, St. Louis and Chicago railroad. Co. seat, Magnolia.

PIKE, a co. in e. Missouri adjoining Illinois; bounded on the n.e. by the Mississippi river, drained also by Copper and Salt rivers, and Spencer's creek; traversed by the Chicago and Alton railroad; about 625 sq.m.; pop. '80, 26,716—5,376 colored. The surface is rolling or hilly, and heavily wooded. The soil is fertile, and the principal productions are corn, wheat, oats, tobacco, hay, and live stock. Co. seat, Bowling Green.

PIKE, a co. in s. Ohio, drained by Scioto river, and Beaver and Sunfish creeks, intersected by the Scioto Valley railroad, and the Ohio canal; about 450 sq.m.; pop. '80, 17,927—1227 colored. The surface is hilly and heavily timbered. The soil is fertile. The principal productions are corn, wheat, oats, and live stock. Co. seat, Waverly.

PIKE, a co. in n.e. Pennsylvania, adjoining New Jersey and New York, bounded on n.e. and s. e., by the Delaware river; drained also by Shohola and Lackawaxen creeks, and traversed by the Erie railroad; about 650 sq.m.; pop. '80, 9,661—8,334 of American birth. The surface is uneven, and the soil mostly poor. The principal productions are corn, hay, and potatoes. Co. seat, Milford.

PIKE, ALBERT, b. Boston, 1809; entered Harvard college, but was obliged to leave for want of funds. In 1831 he set out on a western tour and went with an expedition to Santa Fe. In 1832 he explored the head waters of the Brazos and Red rivers, and with four companions went 500 miles on foot, to fort Smith, in Arkansas. After editing the *Arkansas Advocate*, he was admitted to the bar and in 1836 edited the *Arkansas revised statutes*. He served in the Mexican war, and in the rebellion raised a force of Cherokees, and fought on the confederate side. Besides reporting for five years the decisions of the Arkansas supreme court, and publishing *The Arkansas Form-Books*, he has written *Hymns to the Gods*, 1831; *Prose Sketches and Poems*, 1834; and *Nugæ*, 1854.

PIKE, AUSTIN F. See page 894.

PIKE, MARY H. (GREENE), b. Maine, 1827; has published *Ida May*, 1854; *Bond and Free*, 1858; *The Cypressess*, 1865; and other stories.

PIKE, ZEBULON MONTGOMERY, 1779—1813, b. N. J.; entered the army in 1799, and was made capt. in 1806. After the cession of Louisiana to this country, he was sent on an exploring expedition to the source of the Mississippi. Leaving St. Louis in 1805, with 20 men and provisions for 4 months, he returned at the end of 9 months, after great sufferings from hunger and cold. In 1806—7 he was sent on a geographical expedition to Louisiana. After a march of 3 months, his party came, as they supposed, to the Red river; but it proved to be the Rio Grande, and they were arrested by a detachment of Spanish cavalry for trespassing on Spanish territory, and carried to Santa Fe. His papers were seized, and he was subjected to a long examination by the commandant gen. of the province of Biscay, who finally sent him home with an escort. He arrived at Natchitoches in 1807, and was thanked by the government. He rose by rapid promotions to the rank of brig.gen. in 1813, when he was also appointed adjt. and inspector gen., and put in command of the land portion of the expedition against York, upper Canada. He arrived at York, April 27, with 1700 men, landed under a heavy fire, and in storming a battery was killed by the explosion of a magazine.

PIKE'S PEAK, a peak of the Rocky Mountains, in El Paso county, Colorado, lat. 39° n., long. 105° w., discovered by gen. Pike, U. S. army, in 1806. It is made by different measurements 12,000 and 14,500 ft. high, and commands a view of 100 miles' radius of a rugged, mountainous country, containing many lakes, and the sources of four great rivers—the Platte, Arkansas, Rio Grande, and Colorado of California. In 1858 large deposits of gold were discovered here; and during the first four years after the discovery, there were shipped more than £6,000,000 in gold. It abounds in rich gold-bearing quartz. The mining country is 5,000 feet above the sea, with a dry climate, having a rainy season of only seven weeks. See *Tourist's Guide to the Rocky Mountains*, by Frank Fossett.

PIKE-PERCH, *Lucioperca*, a genus of fishes of the perch family, having two dorsal fins, of which the first has strong spiny rays, but resembling the pike in its elongated form, large mouth, and formidable teeth. The muzzle is not, however, broad and depressed, as in the pike. Several species are known, of which one (*L. sandra*) is common in the Danube, and in most of the rivers and lakes of the n.e. of Europe,

extending westward to the Oder and the Elbe, although not found in Italy, France, or Britain. It is highly esteemed for the table, and its introduction into British rivers seems particularly desirable. Salted and smoked, it is a considerable article of trade in some parts of Europe. It is a fish of rapid growth, and attains a weight of 25 or 30 pounds. This fish readily takes the minnow and the artificial fly. It is called *sander*, *sandel*, or *sandat*, in some parts of Germany; *nagmaul* in Bavaria; and *schill* at Vienna. Another species (*L. Americana*), much resembling it, of a greenish-yellow color, is found in the lakes and rivers of North America.

PILAS'TER, in classical architecture, a square pillar, sometimes standing free, but usually attached to a wall from which it projects $\frac{1}{5}$, $\frac{1}{4}$, or other definite proportion of its breadth. Greek pilasters, or antæ, were of the same breadth from top to bottom, and had different capitals and bases from those of the orders with which they were associated. The Romans gave them a taper like the columns, and the same capitals and bases.

PILATE, **PONTIUS**, sixth Roman procurator of Judea. His family name *Pontius* was conspicuous among the Romans at a very early period of their history; and his cognomen *Pilatus*, "armed with a javelin," may refer to military employment and success. He is known in history chiefly as connected officially with the crucifixion. Josephus agrees with the gospels in fixing the date of his administration; and Tacitus unites with the Scriptures, creeds, and all Christian history in affirming that Christ, the founder of the sect of Christians was put to death by Pontius Pilate in the reign of Tiberius. Of his early history nothing is known. On being appointed to the government of Judea he removed the headquarters of the army from Cæsarea to Jerusalem. He greatly enraged the people by introducing the standards bearing the image of the emperor secretly into the city, and to prevent an insurrection was obliged quickly to withdraw them. On two other occasions he almost drove them to rebellion by similar disregard of their religious convictions. His unwillingness to condemn Jesus, his repeated efforts to release him, and ultimate submission to the clamors of the priests and populace agree well with the representations of secular history concerning the unmanliness of his character, and the fears which he habitually cherished of popular accusation preferred against him to the emperor. The accuracy of the gospel narrative concerning his proceedings at the trial is illustrated by several well-known facts of Roman history. As he was only a procurator he had no quæstor to conduct the trial, and was therefore brought directly into communication with Jesus. At an earlier period Roman governors had not been allowed to have their wives with them in the provinces; but in his time the prohibition had fallen into neglect, and the senate refused to enforce it. The judgment seat spoken of in the gospels was a well-known part of a governor's official equipage; and the "tesselated pavement" was so necessary to the administration of justice that Julius Cæsar carried one with him during his expeditions. The power of putting to death had been taken from the Jews on their subjection to Roman rule. And it is well known that the Romans often scourged prisoners before putting them to death. The New Testament says nothing concerning Pilate after the resurrection of Jesus. But Josephus relates that the Samaritans having accused him of undue severity towards them, Vitellius, then president of Syria, sent him to Rome to answer before the emperor. On his arrival there he found Caligula on the throne. Eusebius says that Pilate, wearied with misfortunes, at length committed suicide. The time and place of his death are not known. One tradition points to a pyramid 50 ft. high, at Vienna on the Rhone, which is called Pontius Pilate's tomb; and another asserts that, having sought in vain to hide his sorrows by the lake of Lucerne, on the mountain now called mount Pilatus, he at last plunged into its dismal flood. Concerning his official report of the death of Jesus, see ACTS OF PILATE.

PILATE, ACTS OF. See ACTS, SPURIOUS OR APOCRYPHAL.

PI'LAU, or **PILAW**, a dish common in India, Turkey, Egypt, and Syria, consists generally of rice, but occasionally some animal food is added. It is sometimes seen at tables in this country, prepared for those who have been accustomed to it abroad. The correct method of preparing it is to boil the rice twenty minutes, with sufficient water to soak it thoroughly, and swell the grains to their utmost, taking care not to break them by making them too soft; it is then drained and gently stirred with butter, pepper, and finely-chopped onions, and served up. This is the way in which the pilaus of the poorer classes are prepared; but for the tables of the more wealthy, fowls, lamb, mutton, shreds of ham or bacon, variously cooked, but always much boiled or roasted, are placed on the top of the rice and served up with it. In India very numerous and elaborate recipes are in use.

PIL'CHARD, *Clupea pilchardus*, or *Alausa pilchardus*, an important fish of the family *clupeidæ* (q. v.), referred by some naturalists to the same genus with the herring (*clupea*), and by others to the same genus with the shad (*alausa*). The pilchard is nearly equal in size to the herring, but rather thicker, and the lines of the back and belly are straighter; the scales are also larger and fewer; and the dorsal fin is rather further forward. The mouth is small, and in the adult fish destitute of teeth; the under jaw longer than the upper. The upper part of the body is bluish-green; the sides and belly silvery-white;

the cheeks and gill-covers tinged with golden yellow, and marked with radiating striæ; the dorsal fin and tail dusky. The pilchard is an inhabitant of more southern seas than the herring, being nowhere plentiful on the British coasts, except in the extreme south, and chiefly on the coasts of Devonshire and Cornwall; whilst it occurs on many parts of the Atlantic coasts of France and Spain, and on the coasts of Portugal, and is found in the Mediterranean sea. Like the herring, it was formerly supposed to be a migratory fish, annually visiting the coasts of England and other countries; but, as in the case of the herring, this opinion has now been relinquished; and the shoals of pilchards which are seen on the coasts are believed merely to issue from deeper waters near at hand, for the purpose of spawning. The spawning season of the pilchard begins early in summer; but on the coasts of Devonshire and Cornwall, the principal fishery is in August and September. Pilchards are caught either with drift-nets or seine-nets, but principally with seine-nets. By means of one or more seine, each 360 ft. long and 36 ft. deep, a shoal is inclosed; the bottom of the net is then drawn together by a peculiar contrivance, and the pilchards are taken out at low water by small bag-nets. Prodigious numbers are sometimes inclosed in a single seine. Twenty-four millions and a half are said to have been taken at once from a single shoal, which, however, may have been spread over several sq. miles. The approach of a shoal of pilchards is known by the rippling of the water, and the sea-birds hovering above, and is often watched for and marked from the shore. In some years the quantity taken in the pilchard fishery on the English coast is enormous, and the capital invested in it in Devonshire and Cornwall is probably not much under £1,000,000. The English pilchard fishery is regulated by several acts of parliament, the first of which are of the days of Elizabeth. Great quantities of pilchards are annually exported to the West Indies and elsewhere. Those intended for exportation are pickled, and packed in barrels by means of great pressure, by which oil is expressed to the amount of three or four gallons from a hogshead of fish. The oil, with the blood and pickle with which it is mingled, is generally used for manure. A favorite Devonshire dish is a pie made of pilchards, with their heads protruding from the crust. It is now generally admitted that the pilchard and the sardine are identical, and a Cornish sardine company has been started for preparing pilchards, like sardines, in oil. It is said, that the Cornish sardines cannot be distinguished from those imported from France.—A great number of boats are employed in the pilchard fishery in and near the estuary of the Tagus.—The pilchard is known in Scotland as the *gypsy herring*.

PILCOMAYO, a river of South America, whose course has not as yet been thoroughly explored, draws its waters from the Bolivian Andes, and is formed by the confluence of two rivers, the Suipacha and the Pilaya. Of these head-waters, the south one, the Suipacha, rises in the mountains immediately s. of Potosi; while the northern branch, the Pilaya, drains the valleys around Chuquisaca. These streams unite in lat. about 21° 35' s., to form the Pilcomayo, which flows in a general direction s.e., crosses the Bolivian frontier, waters the n.e. region of the Argentine Confederation, and falls into the Paraguay a few miles below Asuncion. It is at least 1200 m. in length; but its waters are much spent in lagunes on its course, so that it adds no great volume to the waters of the Paraguay. It is navigable for about 500 m.; but numerous hordes of hostile Indians render navigation perilous. Before entering the Paraguay, it divides into two arms, of which the northern is called Araguay-Guaso; and the southern, which is again divided into two branches, the Araguay-Mino. The mouths of the Pilcomayo are narrow, deep and much obstructed by water-plants.

PILE, in heraldry (from Lat. *pilum*, a javelin; or from the *pile* or stake used in the construction of a bridge), an ordinary, or, according to some heralds, a subordinate, in the form of a wedge, issuing generally from the middle chief, and extending towards the middle base of the shield. It is said that a pile should occupy one-third of the breadth of the chief, or, if charged, double that breadth. When a pile is borne issuing, not from the middle chief, but from some other part of the bounding-line of the shield, this must be specified in the blazon. Three piles are sometimes borne conjoined in point. A pile *transposed* is one whose point is upward.

PILE-BRIDGE, a bridge of which the piers are built with piles. These may be either temporary wooden structures, in which wooden piles, driven into the ground, serve also as piers, or they may be permanent bridges, with iron cylinders forming the piles below the surface, and piers above. See **PILES**.

PILES are usually squared logs of wood used in engineering operations, such as dams, bridges, roads, etc. They are sharpened at the point, and, if necessary, protected with iron points, to enable them to cut through the strata they encounter as they are driven into the ground. When used for coffer-dams, or such temporary purposes, they are placed close together, and driven firmly into the earth; the water is then pumped out, and the piles form a dam, to enable workmen to lay foundations of piers, etc. When the force of the water round the dam is great, two rows of piles are driven in all round, and the space between the rows filled with clay, and puddled. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings, roads, etc., may be placed.

Cast-iron is frequently used for piles, which are cast hollow. Wharf-walls are some-

times built of piles; they are then cast with grooves on the sides, into which cast-iron plates (forming the walls) are fitted.

A kind of pile has been invented by Mr. Mitchell, which is of great use in very loose and shifting substances. It is called the screw-pile, and consists of a long shaft (of wrought iron), with a broad cast-iron disk, of a screw form at the lower end. These piles are especially useful for light-houses, beacons, etc., which have to be placed on sands. They are fixed by means of capstans, which give them a rotatory motion. Common piles are driven in by machines called *pile-drivers*. In these a heavy weight (or monkey) is raised to a considerable height between two guides, and then let fall on the head of the pile. The application of steam to these drivers has made them very powerful engines—Nasmyth's steam-hammer being a well-known instance.

In 1843 Dr. L. H. Potts obtained a patent for a new kind of pile, which consists of hollow tubes of iron, from which the sand, etc., within them is removed by means of an air-pump, and the pipes are then sunk.

In recent railway bridges, cylinders have been much used to form both piles and piers. They are of cast-iron, and made in pieces (of about 6 ft. in height), which are applied one on the top of another. The sand or gravel is removed from the inside of the first laid, which thus sinks down; another cylinder is placed above it, and the same process continued till it also has sunk sufficiently; and so on, cylinder over cylinder, till a solid foundation is reached. The requisite number of cylinders is then piled up to form the pier above ground.

PILES, or **HEMORRHOIDS** are small tumors situated either within or on the verge of the anus. They consist of folds of mucous and sub-mucous membrane in an inflamed, infiltrated, or permanently thickened condition, and usually contain enlarged veins. There are several varieties of these tumors. Sometimes the pile is mainly composed of a little knot of varicose veins in the sub-mucous tissue; in this case it is readily emptied, by pressure, of the fluid blood contained in it, which, however, returns when the pressure is removed. Sometimes the blood in a dilated vein coagulates, forming a solid tumor surrounded by tissues, thickened in consequence of inflammation; or the tumor may consist of a kind of erectile tissue formed by an abnormal condition of the vessels of the mucous membrane; this variety is especially liable to bleed. These tumors are divided into *bleeding* and *blind* piles, according as they are or are not accompanied with hemorrhage; and into *internal* and *external* piles, according as they are within or without the sphincter muscle of the anus.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a feeling of heat, fullness, and dull pain about the lower part of the bowel, becomes conscious of a sensation as if there were a foreign body in the anus; and, on examination after an evacuation, discovers a small tumor, usually about the size of a grape, which either remains outside, or is retracted, according as it originated without or within the sphincter. This tumor gradually increases, and others form around it, until a mass at length results as large as a pigeon's egg, or larger. In its ordinary *indolent* state the tumor has little sensibility, and occasions comparatively little annoyance; but when it is *inflamed* (from strangulation of the sphincter muscle, or from any other cause), it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes of the bladder also) difficult and painful. In women an inflamed pile may cause pain in the back, irritation of the womb, with mucous discharge, and many other anomalous symptoms. In severe cases the patient can neither stand nor sit with comfort, and only finds relief in the horizontal position.

Piles may be caused by any circumstances which cause congestion in the lower bowel, such as luxurious and sedentary habits of life, pregnancy, and such diseases of the liver as tend to check the return of blood from the veins of the rectum. Moreover, anything that causes irritation of the rectum, such as acrid purgatives and especially aloes, dysentery, inflammation of the prostate gland, etc., may cause piles. But of all causes, constipation is probably the most frequent; it operates in producing them partly by the pressure of the accumulated and hardened fæces upon the veins carrying the blood away from the rectum, and partly by the straining and irritation such fæces occasion during their evacuation.

In the treatment of piles, it is expedient to relieve the congested state of the lower bowel by one or two doses of sulphate of magnesia, and a cooling vegetable diet, after which the continued use of mild laxatives should be resorted to. A teaspoonful of an electuary, consisting of an ounce of confection of senna, half an ounce of cream of tartar, and half an ounce of sulphur, if taken in the middle of the day, usually acts gently about bedtime, which is far the best time for the bowels of patients of this kind to act, as the parts irritated by the passage of the evacuation become quieted during the night. In long-standing cases, in which there is general relaxation of the mucous membrane, the confection of pepper in doses of a dram may be given thrice daily with advantage, or a scruple of common pitch may be taken at bedtime in the form of pills or in capsules. Amongst the milder forms of local treatment must be mentioned (1) the injection of the rectum with cold water both before and after the motion; (2) washing the anus with yellow soap and water after each evacuation; (3) the application of gall

ointment or of other astringents; and (4) the injection of astringent lotions, as, for instance, of sulphate of iron, in the proportion of a grain to an ounce of water. If these fail, recourse may be had to pressure by means of instruments specially devised for the purpose; to the application of strong nitric acid, which, in the case of internal piles, affords the most speedy and effective means of relief (the operation must, of course, be performed by a surgeon, and if the parts cannot be protruded, the acid must be applied through the speculum); to ligature; or, in the case of external piles, to excision. When the piles are inflamed, leeches to the anus (but not applied directly to the tumors) are sometimes required; but the inflammation generally subsides under the influence of rest in the horizontal position, fomentations, poultices, and low diet.

The treatment of the hemorrhage that frequently accompanies piles requires a few words. If the bleeding is moderate in quantity, and has continued for some time without inducing weakness or any other bad symptom, it is not expedient to interfere with it. When, however, it obviously requires checking, the effect of cold water injected into the rectum, as already recommended, should be tried, and, in case of its failing, astringent injections should be had recourse to. At the same time, the patient should remain in the horizontal position, and take the medicines usually prescribed for internal hemorrhage, amongst which may be especially mentioned oil of turpentine, in doses of 20 drops three or four times a day, or ergot of rye in divided doses to the extent of a dram daily. In rare cases it is necessary to tie a vessel, or to touch it with a red-hot wire (through the speculum), or to plug the anus.

P'ILEUS. See FUNGI.

PILEWORT. See RANUNCULUS.

PIL'GRIM (Ital. *pellegrino*, Lat. *peregrinus*, "a visitor of foreign lands"). A pilgrim is one who visits, with religious intent, some place reputed to possess especial holiness. The early Christians, like the Jews and the pagan Gentiles, regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the passion of our Lord at Jerusalem. St. Jerome (Ep. xlv.) refers the practice of visiting Jerusalem to the discovery of the holy cross by St. Helena. He himself was a zealous pilgrim; and throughout the 4th, 5th, and 6th c., pilgrims habitually undertook the long and perilous journey to the Holy Land from almost every part of the west. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by St. Jerome (*Commentar. in Ezekiel*). St. Basil speaks in the same terms of the tomb of the forty martyrs; and the historian Theodoret tells of not only visiting such sanctuaries, but of hanging up therein, as offerings, gold and silver ornaments, and even models of hands, feet, eyes, etc., in commemoration of the cures of diseases supernaturally obtained as the fruit of these pious visits. The PILGRIMAGE, however, pre-eminently so called, was that of the Holy Land; and even after Jerusalem had been occupied by the Saracens, the liberty of pilgrimage, on payment of a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage that the well-known military orders (q.v.) had their origin. The crusades (q.v.) may be regarded as a pilgrimage on a great scale; the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the west were: in Italy—Rome, Loretto (q.v.), Genetsano, Assisi; in Spain—Compostella, Guadalupe, Montserrat; in France—Fourvieres, Puy, St. Denis; in Germany—Oetting, Zell, Cologne, Trier, Einsiedeln; in England—Walsingham, Canterbury, and many others of minor note. The pilgrim commonly bound himself only by a temporary vow (differing in this from the palmer, q.v.) terminating with the actual visit to the place of pilgrimage, or at least with the return home, and by which he was bound for the time to chastity and to certain other ascetic observances. The costume consisted of a black or gray gabardine girt with a cincture, from which a shell and scrip were suspended, a broad hat, ornamented with scallop-shells, and a long staff. Many abuses arose out of these pilgrimages, the popular notions regarding which may be gathered—although, probably, with a dash of caricature—from Chaucer's *Canterbury Tales*. Pilgrimages, which have always subsisted in Italy, Spain, southern Germany, and Switzerland, had gone much into disuse in France during and since the revolution. In late years, however, pilgrims have resorted in large numbers, not only to the ancient sanctuaries of Notre Dame de la Garde, de Fourvieres, de Puy, etc., but also to La Salette, Lourdes, Paray-le-Monial, and Pontigny. In 1873 and 1874 organized parties of pilgrims on a very large scale from France, Belgium, England, the United States, etc., visited the sanctuary of Paray-le-Monial, the place at which the vision of Marie Alacoque, which gave rise to the devotion to the sacred heart of Jesus (q.v.) is recorded to have taken place. In 1874, 500 English pilgrims visited Pontigny. Numerous pilgrimages have also been held in Belgium.

PILLAR, a detached support like a column; but its section may be of any shape, whereas the column is always round. Pillars have been used in all styles of architecture, and their forms and ornaments are usually amongst the most characteristic features of the style. The Greek and Roman pillars (or columns) are the distinguishing elements

in the various orders. In Gothic architecture; also, the pillars are of different forms at the various epochs of that style. First, in the Norman period, we have plain massive pillars, square, circular, and octagonal, frequently ornamented with zigzag ornaments, spiral bands, etc., on the surface. As vaulting progressed, the system of breaking the plain surface, and giving to each portion of the vaulting a separate little column or shaft to support it was introduced. This was done either by attaching shafts to the circular pillars, or by cutting nooks in the pillar and setting little shafts in them.

In the early pointed style a plain circular or octagonal pillar, with a number of small shafts attached around it, is a favorite arrangement.

In this style, the attached shafts are very frequently banded to the main pillar at different heights, and they are sometimes made of a finer material, such as Purbec marble. In the decorated style the pillar is of a lozenge form, and not so much ornamented with detached shafts as with moldings; plain, circular, or octagonal pillars, however, are used in this, as in all the styles. The moldings and shafts are usually filleted; and some of the moldings run up into the arch without any cap. In perpendicular the same idea is further carried out; the moldings become thinner, and are more frequently run up into the arch without caps. See FLAMBOYANT.

PILLAR SAINTS—called also “STYLITES” (Gr. from *stylos*, a column), “pillarists,” “holy birds,” “air martyrs,” and several similar names—a very remarkable class of anchoretical ascetics (see ASCETICISM), chiefly of Syria, who, with a view to separating themselves more completely from earth and fellow-men, took up their abode on the tops of pillars, on which they remained without ever descending to earth, and exposed to all the variations of a Syrian climate. The earliest of them, and the most celebrated, Simeon (called also Simon) the Stylite, had been a monk, and had lived, in the beginning of the 5th c., in extreme seclusion in his monastery for nine years, without ever moving from his narrow cell. Increasing in enthusiasm, he withdrew to a place about 40 m. from Antioch, where he built a pillar, on the top of which, only a yard in diameter, he took up his position. From this pillar he removed to several others in succession, each higher than its predecessor, till at last he attained to 40 cubits, or about 60 ft. in height. In this mode of life he spent 37 years, his neck loaded with an iron chain, and his lips engaged in constant prayers, during the recitation of which he bent his body so that his forehead touched his feet. His powers of fasting were no less marvelous; he is said to have frequently limited himself to a single meal in the week, and during the 40 days of Lent abstained entirely from food. The fame of his sanctity brought crowds of pilgrims from the most distant countries, even Britain itself, to see him; and the admiration of his austerities is said to have converted many pagans and Saracens to the church. In trial of his virtue, through the test of humility, some neighboring monks reproaching him with vanity and the love of novelty in this extraordinary mode of life, ordered him to come down from his pillar. Simeon prepared without hesitation to comply, and the compliance was accepted as an evidence of his perfect humility and holiness of purpose. It is said that in consequence of an ulcer which was formed on one of his legs, he was obliged for the last year of his life to remain on his pillar upon one foot. In this position he died in 460, aged 72 years. A disciple of Simeon, named Daniel, succeeded to his reputation for sanctity, and to his mode of life, which he maintained for 33 years, in the still more trying climate of the shores of the Bosphorus, about 4 m. from Constantinople. The marvels of Daniel's career are still more startling. He was sometimes almost blown by the storms of Thrace from the top of his pillar. At times for days together he was covered with snow and ice. How he sustained life, what nourishment he took, was a mystery even to his disciples. The emperor at length insisted on a covering being placed over the top of the pillar, and Daniel survived till the year 494. In Syria there were many pillar saints as far down as the 12th c.; but in the west, Daniel is all but a solitary example. A monk named Wulfailich, near Trier, attempted the pillar life in the 6th c., but the neighboring bishops compelled him to desist, and destroyed his pillar.

PILLARS OF HERCULES. See HERCULES, PILLARS OF, *ante*.

PILLAU, a sea-port t. of Prussia, at the entrance of Frische Haff, on the Baltic, 26 m. w. of Königsberg; pop. '71, 2,909. It is also the port for Ebling and Braunsberg, and is beautifully situated on a strip of land called Paradise. It has a fortress and a school of navigation, and is a leading watering-place. It was founded in 1722.

PILLIBHIT', or PHILLIBIT, a t. of India, in the British district of Bareilly, n.w. provinces, 28 m. n.e. by e. from Bareilly, on the left bank of the Gurrāh, and on the road from Bareilly to Petagorah. Pillibhit is a place of considerable trade. The Pillibhit rice, celebrated throughout India for its excellence, is the produce of the south of Kumaon, brought to Pillibhit to market. Pop. 30,000.

PILLNITZ, a palace and ordinary summer residence of the royal family of Saxony, in a beautiful situation 7 m. s. e. of Dresden. The grounds are finely diversified, and the walks ascend to the summits of hills, of which one is nearly 1000 ft. high. Pillnitz acquires a historic interest from the meeting of princes held in the castle in Aug., 1791, when the declaration of Pillnitz was framed, according to which Austria and Prussia agreed to declare the circumstances of the king of France (then a prisoner in the Tui-

eries, after his ineffective flight to Varennes) to be a matter of common interest to the sovereigns of Europe, and to express the hope that common cause would be made for his restoration. The emperor and the king of Prussia were resolved to use force in order to effect this result; but any immediate interference on their part was rendered unnecessary by Louis's acceptance of the constitution as modified by the national assembly, after which he was again placed on the throne.

PILLORY, an engine for the public punishment of criminals, disused in Britain since 1837; but previous to that time commonly employed, as it also was in France and Germany. It consisted of a stout plank fixed like a sign-board on the top of a pole, the pole being supported on a wooden platform elevated above the ground. Above, and parallel to this plank another of similar dimensions was placed in a similar position with respect to the pole, and fixed to the former by a hinge, being thus capable of being moved upwards from it, or closed upon it, when necessary. A large circular hole is cut, with its center in the line of junction of the two planks, and two corresponding holes of smaller size are formed, one on each side of it; the large hole is for receiving the neck, and the two smaller the wrists. When a criminal is to be placed in the pillory, he is made to mount and stand upon the platform; the upper of the two hinged planks is raised to allow the culprit's neck and wrists to be inserted in their proper grooves, and then brought down into its place, and fastened by a padlock, or in some other way. The pillory seems to have existed in England before the Conquest, in the form of the stretch-neck (an instrument by which the neck only was confined), and was originally intended, according to the "statute of the pillory" (51 Hen. III. c. 6), for "forestallers, users of deceitful weights, perjury, forgery, etc.," and all such dishonorable offenses. Its use was exclusively confined to this class of offenders till 1637, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favorite mode of punishing libelers (or those who were considered to be such by the government), authors and publishers of seditious pamphlets, or of strictures on the government; and many eminent men were accordingly from this time put "in and on the pillory," among whom may be mentioned Leighton, Lilburn and Warton the printers, Prynne, Dr. Bastwick, Daniel Defoe, etc. The insufficiency of the pillory as a means of inflicting a definite amount of punishment was now apparent, for to those who were popular favorites it was no punishment at all, while those who were objects of popular dislike were ill-used to such an extent as occasionally to cause death. The sufferers above mentioned being popular favorites, or having at least a numerous class of supporters, were shaded from the sun, fed, and otherwise carefully attended to; while the encouragement, applause, and sympathy of the crowd around converted the intended punishment into a triumph; but such men as Titus Oates, and the class of offenders including perjurers, swindlers, polygamists, etc., who were objects of popular hatred and disgust, were pelted with rotten eggs (the favorite missile), garbage, mud, sometimes even with more dangerous missiles. In 1814 the celebrated naval hero lord Cochrane (see DUNDONALD, EARL OF) was sentenced to the pillory, but the government of the day was not prepared to brave the consequences of such an act, and the sentence was not carried into effect. In France the pillory was anciently called *pilori*, and in recent times *carcan*, from the iron collar by which the criminal's neck was attached to the post; but punishment by this mode was abolished in that country in 1832.

PILLOW, GIDEON JOHNSON, 1806-78; b. Tenn.; son of Gideon, and grandson of John, a revolutionary soldier; graduated at the university of Nashville, 1827; commenced the practice of law in Columbia, Tenn., 1830; soon ranking among the eminent lawyers of his state. President Polk, in acknowledgment of certain services rendered in his nomination and election, commissioned him brig.gen., 1846. He went to the Mexican war in command of a brigade of Tennessee volunteers, and was with Scott at Vera Cruz. He was conspicuous in the operations which caused the capitulation of that city, and was one of the commissioners to negotiate terms. He was wounded at Cerro Gordo while leading an assault; promoted to maj.gen., 1847. He was in the battles of Contreras and Churubusco, and was wounded at Chapultepec. After the war he returned to private life, settling on a large estate. In 1850 he was a member of the Nashville southern convention where he opposed the ultra views of some delegates. He was active in raising men for the confederate army, and was a maj.gen. on that side during the war of the rebellion.

PILLS are the most generally convenient and popular of all forms of medicine. They are formed from masses of a consistence sufficient to preserve the globular shape, and yet not so hard as to be of too difficult solution in the stomach and intestines. This form is especially suitable for (1) all remedies which operate in small doses, as metallic salts; (2) those which are designed to act slowly and gradually, as certain alteratives; (3) those which are too readily soluble when exhibited in other forms; (4) substances whose operation it is desirable to retard until they have reached the lower intestines, as in certain pills for habitual costiveness; (5) bodies whose specific gravities are too inconsiderable to allow their suspension in aqueous vehicles; and (6) fetid substances: while it is unsuitable for (1) medicines which require to be given in large doses; (2) deliquescent salts; (3) fluid or semi-fluid substances, such as oils, balsams, etc., which require a very

large proportion of some dry powder to render them sufficiently tenacious to form into a mass; (4) substances so insoluble, that when exhibited in solid form they pass through the intestinal canal unaltered, as extract of logwood (Paris's *Pharmacologia*, 9th ed. p. 550). Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most substances require the addition of a material termed an excipient, for converting it into a pill-mass. The excipients in most common use are bread-crumbs, hard soap, extract of liquorice, mucilage, syrup, treacle, honey, castor oil, and conserve of roses. From the property of preserving pills for a long time in a properly soft state, the most valuable excipient is the conserve of red roses; and, perhaps, next to it treacle is the most valuable excipient, as it does not undergo any change by time, but maintains a proper consistence, and preserves the properties of vegetable powders unimpaired for years. It is common to place pills in some fine powder, to prevent them from adhering to each other, and to conceal their taste. For this purpose, liquorice powder, wheat flour, starch, and magnesia are generally used in this country, and lycopodium on the continent. Pills retain their moisture and activity far longer in small bottles than in the ordinary pasteboard boxes. The ordinary weight of a pill is 5 grains; if it much exceeds that weight, it is too bulky to swallow conveniently if it consist of vegetable matter. It is very common to meet with patients who express their inability to take this form of medicine. If, however, they practice with a small globular mass, toward which they feel no repugnance, as a pellet of bread or a currant; placing it on the back of the tongue, and gulping it down with water, they will soon get over the difficulty.

PILLSBURY, JOHN S. See page 894.

PILOT is a person specially deputed to take charge of a ship while passing through a particular sea, reach, or dangerous channel. The intricacy of almost all coast navigation renders it impossible that any navigator, however skillful, can be master of all the waters to which he may have to sail his ship; and the risk of failure, through ignorance of local dangers, is therefore avoided by transferring the direction of her course to some one perfectly acquainted with the spot. The man to whom so much is intrusted must be a responsible person, and therefore in all countries qualified sailors are officially licensed to act as pilots in their districts, and they are granted the monopoly. The origin of the word pilot is uncertain; but it is probably taken from or nearly identical with the Dutch *pijlloot*, which is compounded of *peilen*, to sound the depth, and the root which appears in *D. lootsman*, *O. E. lodesman*, and signifies to lead, direct. Pilot thus means one who conducts a vessel by sounding. The laws of Wisby, promulgated at least as early as the 14th c., and subsequently incorporated in nearly every maritime code, render it compulsory on the master of a ship to employ a pilot when sailing near a coast.

The British laws relating to pilots were revised and consolidated by the act 16 and 17 Viet. c. 129. Certain fees are established in proportion to the distance and responsibility; and the master of every vessel, above 50 tons, passing up the channel or the Thames, or *vice versa*, is required to accept the services of the first pilot tendering, provided he shows his license as a proof of qualification. Except in matters of discipline, the command of the vessel is then vested entirely in the pilot, who can have the sails, steering, etc., of the ship carried on entirely at his discretion until the limit of the pilot's district is passed, except that the captain resumes his powers when the question of taking up ground in a harbor is concerned. The fees vary with the draught of the ship and the distance; as specimens, may be cited the highest and lowest in the London district: a ship drawing 22 ft. of water is piloted from Orfordness to Blackwall for £27 12s; a ship drawing not more than 7 ft. is guided from Gravesend Reach to Long Reach for 9s. 3d

Pilots are associated in guilds called brotherhoods, of which the principal are the brotherhood of the Trinity house of Deptford-Stroud, situated on Tower Hill, which has jurisdiction over the Thames, Medway, and the coast from Harwich to the Isle of Wight; and the Trinity houses of Kingston-upon-Hull and Newcastle-on-Tyne. There are also societies of pilots at the larger ports out of these districts, the government in such case being vested in certain officials lawfully appointed as "pilotage authorities." Their powers over the members, etc., are defined in the act above quoted, and in the merchant shipping act of 1854, 17 and 18 Viet. c. 104, sections 330-388.

Pilots board vessels entering their districts in boats conspicuously painted, on the bows and sails of which must be the man's distinguishing number as shown by his license. The boat also bears a flag of comparatively large size, of red and white divided horizontally. A ship requiring a pilot hoists a square blue flag. In passing up or down the Thames, every ship above 50 tons or 6 ft. draught must bear a pilot; but her master or first-mate may act by license in that capacity, if he have passed the necessary examination. A master is subject to a penalty for sailing without a pilot; and, on the other hand, so also is any person, without a license, or whose license has been forfeited, presuming to act or offering to act as a pilot.

In the navies of some countries the pilot is a permanent officer of the ship, and has charge of her course; but his functions in that case approach nearer to those of the British navigating officer. Large French vessels have often several sailing pilots called *pilotes hauturiers*, and a *pilote côtier* or *lamaneur*. The ancient laws of France contained provisions for the education and regulation of both these classes.

The general rule as to the responsibility of the owners of the ship is, that no owner or master of a ship is answerable to any person whatever for any loss or damage, occasioned by the fault or incapacity of any qualified pilot, acting in charge of such ship within any district where the employment of the pilot is compulsory.

PILOT (*ante*). In this country pilots are controlled as to their examinations, qualifications, and conduct, by the laws of the states within whose waters they are licensed to ply their trade. Under the provision of the constitution giving congress power to "regulate commerce with foreign nations and between the several states," the national legislature in 1789, 1837, and 1866, passed acts granting to the states power to enact each its own regulations regarding pilotage. In all they are licensed to offer themselves, and while the ship's master is usually obliged to accept the first pilot boarding him, the pilot on his part is generally compelled to obey the call of the ship-master. The pilot's fee is called pilotage, and for it there is a lien on the ship which may be enforced in an admiralty court. The master need not give up control of the ship when first boarded unless he choose; at New York the pilots often find a vessel two or three hundred miles at sea, but the practice is for the pilot to take control 15 or 20 m. off Sandy Hook. The duty of the pilot does not extend beyond the proper guidance of the ship. The captain is responsible for the proper execution of the necessary orders. It has been held by the U. S. supreme court that the mere fact that a licensed pilot is on board a vessel will not relieve the owners from liability in case of collision. If a ship refuse to take a license, a good defense exists in an action against insurers of goods or vessel. In New York about 180 pilots are licensed by the board of commissioners. The license is revocable for misconduct or inefficiency; and, in case of loss through the pilot's fault, the pilotage is forfeited, and perhaps a suit for damages would lie. The pilotage for taking a ship into N. Y. harbor varies from \$2.70 to \$6.50 per foot of the vessel's draft, with \$4 added in winter, and one-quarter added to the rate if the ship be boarded outside Sandy Hook. Outward pilotage is somewhat less. Vessels going in and out of the Sound through Hell Gate are obliged to take a pilot or pay a fixed sum in commutation. This is generally regarded as a hardship, most coast sailors being fully competent to make the passage safely.

PILOT-FISH, *Naucrates ductors*, a fish of the family *scomberidæ*, and belonging to a section of that family in which the first dorsal fin is represented by mere spines, and there are no finlets behind the second dorsal and the anal fins as in the mackerel, etc. The shape of the pilot-fish is very similar to that of the mackerel. It is usually about a foot long; the general color silvery grayish-blue, five dark-blue transverse bands passing round the whole body. Its flesh is very delicate, and resembles mackerel in flavor. It is common in the Mediterranean, and appears to be widely diffused through the warmer parts of the ocean, often following ships for a long time and very far, in which way it has been known to come from Alexandria to Plymouth. It is, however, of rare occurrence, even on the southern coasts of Britain. It is supposed to be the *pompilius* of the ancients, which was believed to point out their desired course to sailors. It is often seen in the company of a shark, and is therefore very commonly supposed to direct the shark to its prey. Concerning this many wonderful stories are to be found in the writings both of voyagers and of naturalists. It has been contended, on the other hand, that the pilot-fish merely follows the ship along with the shark for the same object that gulls follow the steamboats on our coasts, to feed on anything eatable that may fall or be thrown overboard; or that it attends the shark in order to seize small morsels of its large prey. The following statements of Dr. Bennett may be received with confidence: "I have observed that if several sharks swim together, the pilot-fishes are generally absent; whereas, on a solitary shark being seen, it is equally rare to find it unaccompanied by one or more of these reputed guides. . . . The only method by which I could procure this fish was, that when capturing a shark I was aware these faithful little fishes would not forsake him until he was taken on board; therefore by keeping the shark, when hooked, in the water until he was exhausted, or, as the sailors term it, 'drowned,' the pilot-fish kept close to the surface of the water over the shark, and by the aid of a dipping-net fixed to the end of a long stick, I was enabled to secure it with great facility" (*Gatherings of a Naturalist*).—A much larger species of *naucrates* is found on the coasts of South America.

PILOT KNOB, in Iron co., Missouri, 6 m. s. of Iron mountain, is a conical, circular hill, about a mile in diameter at its base, and 600 ft. high. It consists of beds of iron ore, porphyry, and porphyry conglomerates. The bed of iron ore lies under a conglomerate 140 ft. thick, in which layers of ore are frequent. The extent of the ore bed is about 200,000 square yards. The ore is hard specular, steel-gray in color, extremely brittle, and has little luster.

PILOT MOUNTAIN. See **ARARAT**, *ante*.

PILOTY, KARL THEODOR VON, b. Munich, Bavaria, 1826. He studied art there and at other great art centers of Europe, and devoted himself to historical painting. His first work, 1853, was the "Establishment of the Catholic League." He has since produced many pictures of great merit, among which are "Wallenstein's Assassination" (1858): "Nero Among the Ruins of Rome" (1861), and "The Death of Cæsar." In 1874 he was

elected president of the Munich academy of fine arts, of which he had for many years been a professor.

PILPAI. See BIDPAI.

PILSBURY, AMOS. See page 894.

PILSEN, a t. of Bohemia, in a fertile and beautiful valley at the confluence of the Mies and the Beraun, 52 m. w.s.w. of Prague. The church of St. Bartholomew (built in 1292), the town-hall, and the house of the Teutonic Knights are interesting Gothic edifices. The town also contains a gymnasium and other educational institutions, an arsenal, theater, and a number of churches and convents. Pilsen has leather and cloth-factories, a great alum-work, iron and coal mines, and an important brewery. Pop. '80, 38,883.

PIM, BEDFORD CAPPERTON TREVYLIAN, b. England, 1826; educated for the royal navy. He took part in the search for sir John Franklin, and was the first to pass from the e. to the w. side of the n.w. passage. He was in the Russian war, was dangerously wounded in China, and was made a commander in 1858. He was retired from the service in 1870 with the rank of capt., called to the English bar in 1873, and returned to parliament in 1874. Among his writings are *The Gate of the Pacific*, 1863; *The War Chronicle*, 1873; and *An Essay on Feudal Tenures*. He publishes *The Navy*.

PIMA, a co. in s. Arizona, adjoining Mexico, bounded on the n. by the Rio Gila, drained by the Rio Santa Cruz and Rio San Pedro; about 20,000 sq. m.; pop. '80, 17,007—8,298 of American birth. The surface consists of table-lands intersected by mountain-chains. The soil is fertile in parts. The principal productions are wheat, barley, corn, and grass. Gold, silver, copper, and lead are found. Co. seat, Tucson.

PIMAS, or **NÉVOMES**, an Indian tribe in Arizona, Sonora, and Sinaloa; embracing the Pimas, Eredeves, Joves, and Opatas. The Pimas proper live in earth-roofed huts, in villages. They cultivate cotton, and make baskets and rough pottery. The Pimas in Arizona live on a reservation of 64,000 acres granted them in 1859. They number about 4,000, and support themselves by agriculture. Jesuit missions were established among the Pimas in the 17th c., and there is now a mission of the Reformed church among them. The Opatas live in Sonora, and are the most civilized of the Pima tribes.

PIMEN'TO, **PIMENTA**, **ALLSPICE**, or **JAMAICA PEPPER**, a well-known spice, is the dried fruit of *eugenia pimento* (see **EUGENIA**), a small West Indian tree, which grows to the height of 20 or 30 ft., and has oblong or oval leaves about 4 in. long, of a deep shining green, and numerous axillary and terminal trichotomous panicles of white flowers, followed by small dark-purple berries. The pimento tree is much cultivated in some of the West Indian islands. It is a very beautiful tree, with straight trunk and much branching head, and about the month of July is covered with an exuberance of flowers, which diffuse a rich aromatic odor. The leaves and bark partake of the aromatic property for which the fruit is valued. The fruit, when ripe, is filled with a sweet pulp, and the aromatic property, which so strongly characterizes it in an unripe state, has in a great measure disappeared. The gathering of the berries, therefore, takes place as soon as they have reached their full size, which is about that of pepper-corns. They are gathered by the hand, and dried in the sun on raised wooden floors, during which process great care is taken, by turning and winnowing, to prevent them from being injured by moisture. Their color changes in drying from green to reddish-brown. When dry they are packed in bags for the market. Some planters kiln-dry them.—The name *allspice* was given to pimento from a supposed resemblance in flavor to a mixture of cinnamon, nutmeg, and cloves. Pimento is much employed in cookery, and is also used in medicine as a carminative and stimulant to prevent the griping of purgatives and to disguise the taste of nauseous drugs. It depends for its properties chiefly on a volatile oil, *oil of pimento*, which is obtained from it by distillation with water, and is sometimes used to relieve toothache, and for making the *spirit of pimento* (or of *allspice*) and *pimento* (or *allspice*) *water* of the shops.

PIMPERNEL, *Anagallis*, a genus of plants of the natural order *primulaceæ*, having a wheel-shaped corolla, and the capsule opening by division round the middle. The species are elegant little annual and perennial plants, natives chiefly of temperate climates. The flowers are not large, but very beautiful.—The **SCARLET PIMPERNEL** (*A. arvensis*) is a common plant in Britain, occurring as a weed in fields and gardens; it is common also in most parts of Europe and in many parts of Asia. The flowers are of a fine scarlet color, with a purple circle at the eye. There is a common belief in England, mentioned by lord Bacon, that when this plant opens its flowers in the morning a fine day may be expected; and they certainly close very readily on the approach of rain. They usually open about eight in the morning and close about noon.—The **BLUE PIMPERNEL** (*A. cærulea*) is far less common in Britain but very abundant in some parts of Europe.—The **BOG PIMPERNEL** (*A. tenella*), frequent in bogs in England, but rare in Scotland, is an exquisitely beautiful plant.—Several species are cultivated in our flower-gardens.—Acrid properties prevail in this genus, and *A. arvensis* has been used medicinally in epilepsy, dropsy, and mania.—The name **WATER PIMPERNEL** is given to *sambolus valerandi*, also called *brookweed*, another British plant of the same order, with racemes of small white flowers, growing in watery gravelly places. It is supposed to be the *sambolus* which Pliny says the Druids gathered fasting, with the left hand, and without looking

at it, ascribing to it magical virtues in the cure and prevention of diseases in cattle. Its geographic distribution extends over almost all the world.

PIN. As a requisite of the toilet, etc., pins were first used in Britain in the latter part of the 15th c.; they were at first made of iron wire, but in 1540 brass ones were imported from France by Catharine Howard, queen of Henry VIII. Several inventions, however, were previously in use for holding together parts of the dress, such as buckles, brooches, laces, clasps, hooks, etc. At first pins were made by filing a point to a proper length of wire, and then twisting a piece of fine wire around the other extremity, or fixing it after twisting, in order to form a knob or head; and ultimately these operations were so skillfully conducted that a completely round head was made of very small size, and scarcely showing the nature of its construction. Some pins are still made in this way. It is surprising how many operations are needed to complete so small an article. They are as follows: 1. *Straightening and Cutting the Wire.*—The straightening is necessary, because the wire-drawers coil the wire as they make it upon a cylinder, and when it is unrolled the coils remain. It is therefore drawn through an arrangement of upright iron rods which completely straighten it, after which it is cut into lengths of 30 ft., and these are again reduced to lengths of four pins. 2. *Pointing.*—This is done by two operations and different workmen, each standing at a separate grindstone; the first is the rough grinder, and the second the finisher. Each holds with the thumb on the palm of the hand a number of the wires amounting to 30 or 40, and by a movement of his thumb he manages to make the wires turn round so as to make a point to each as he holds them to the grindstones, the second of which, being of a fine material, gives them a smooth finish; they are then reversed and the other end pointed. 3. *Cutting.*—The length of a single pin is cut off of each end of these pieces; the intermediate portions are then handed back to the pointers, and each end receives a point, after which they are divided into two, and thus the four pin piece is reduced into single pin lengths, each having a point. 4. *Twisting the Heads.*—These are made of very thin wire, which is coiled twice by means of a lathe around the end of another piece of wire the same thickness as the pins. 5. *Cutting the Heads.*—The head being formed on the thin wire it is handed to another workman who cuts it off; these two operations are performed with great rapidity, so great, indeed, that as many as 12,000 have been made in an hour. 6. *Annealing the Heads.*—This is softening them by putting some thousands into an iron ladle, and after making them red hot, plunging them into cold water. 7. *Stamping or Shaping the Heads.*—This is pressing the heads into a better shape by means of a small lever press, and at the same time fixing them on the pins; a good worker will do as many as 12,000 to 15,000 per day. 8. *Yellowing or Cleaning the Pins.*—This is done by a process which is often called *souring*; it consists in boiling them for about half an hour in the dregs of sour beer or a solution of argol or cream of tartar, and then washing them in clean water. 9. *Whitening or Tinning.*—In this process a large copper pan is used, and in it is first placed a layer of about six pounds of the cleaned or yellowed pins, and over these a layer of grain-tin to the amount of about eight pounds. Several alternate layers of pins and tin are put in one vessel, and then by a pipe arranged inside the copper pan water is gently poured in, and goes through the pipe to the bottom, first rising up through the different layers so gently as not to disturb them. Fire is now applied to the bottom of the pan, and when it is nearly boiling its surface is sprinkled with a quarter of a pound of cream of tartar, and the whole is slowly boiled for half an hour, then poured into a strainer and shaken to separate the pins from the grain-tin and liquid; by this process a thin deposit of tin has been thrown on the pins which are now white instead of yellow; without the souring this would not take place, it being essential that they should be quite free from any oxidation or soil. 10. *Washing.*—The pins are now thoroughly washed in pure water. 11. *Drying and Polishing.*—They are now put into a large leathern bag with a quantity of bran and violently shaken backward and forward by two men. 12. *Winnowing.*—The bran is next separated by fanning. 13. *Pricking the Papers to receive the Pins.*—This is now done by an ingenious machine, through which the papers are passed, and which, at regular intervals, arranged according to the size of the pins, pinches up a fold of the paper, and at the same time pricks the holes to receive the pins, and then places the pins in their places. Formerly this required a separate operation. Thus 14 persons were required to make and put up for sale a pin, and in some manufactories this is still the case; but in all the large establishments machines are now employed, and an immense reduction of hand labor is effected by them.

The first machine was invented by Lemuel Wellman Wright, of the United States, in 1824. This did very little more than make solid heads to the pins, by a process in principle like that used for nail-making—viz., by driving a portion of the pin itself into a counter-sunk hole. The action, however, was automatic, and consisted in an arrangement by which the wire was seized in two small grooved cheeks. When both cheeks are placed face to face, and the wire is held tightly in the groove with a small portion projecting, a small ram or hammer connected with the machine strikes on the projecting portion described, and compresses it into a small cup-shaped depression, and thus the head is formed. The pointing and dressing of the pins was afterwards carried on as described in the processes for hand-made pins. Since Wright's invention many remarkable improvements have been effected in these machines, which have consequently

become very complicated in their details, although the principles upon which they act are very simple. No description would convey a satisfactory idea of these wonderful pieces of mechanism, which now, without the aid of hands, complete the pin in all respects except the coloring and polishing; but a slight account of the leading features will enable the reader to understand their mode of working. First, then, a reel of wire as it comes from the wire-drawer is placed in the rear of the machine, and the end of the wire is taken hold of by a pair of nippers, which pull it over a fixed *straightening-board*, and pass it on completely straightened, until it is seized by two cheeks, when a cutter descends and cuts it off, leaving the projecting part for the head; on the withdrawal of the cutter, the hammer flies forward, and makes the head as before described; the cheeks open, and the pins drop on to a sloping metal plate finely grooved, down which they slip with the heads upwards, until the end which is to be pointed comes in contact with a cylindrical roller with a grinding surface, which soon grinds points upon them, owing to two or three ingenious arrangements: the first is, that the grooved surface of the plate by which the pins descend terminates a little above the grinding roller, then a slight depression is given to the sloping plate and also to the roller, so that one end is an inch or two lower than the other; therefore, as the pin descends the groove, and is thus brought down the inclined plate, until it lies on the smooth part, where it is highest, and with its end in contact with the grinding roller which is revolving, the pin itself is compelled by the friction of the roller to turn round, and gradually descends from the upper to the lower part of the inclined plate, and then falls off into a box placed to receive it. These operations are performed so rapidly that they can scarcely be followed by the eye, and the pins fall into the box beautifully pointed in a complete stream. They are then *yellowed, tinned*, and prepared for papering, which is a remarkable process. The machine by which it is done is worked by two children; one feeds the machine with pins, the other with papers. The first part of the machine is a box, about 12 in. long by 6 in. broad, and 4 in. deep; the bottom is made of small square steel bars, sufficiently wide apart to let the shank of the pin fall through but not the head, and they are just as thick as the space between papered pins. The lower part of the bottom of the box is made to detach itself as soon as the row of pins is complete, and row after row at regular intervals is received and passed down a corresponding set of grooves, until they reach the paper, which, as before described, is pinched into regular folds and pierced to receive the pins, which, by the nicest imaginable adjustments, come exactly to their places, and are pressed into them. In this way many thousands of those neat-looking paper packages of pins, with which all are familiar, are put up in one day, by two little girls, aided by these wonderful machines.

PINA CLOTH, a very beautiful fabric made of the fibers of the leaves of the pineapple plant (*Ananassa sativa*), and other allied species. This cloth is only made in Manila, and in its manufacture resembles horse-hair cloth, because the threads both of warp and weft are each single unspun fibers, consequently only small pieces can be made; the workers have, however, a plan of joining the fibers of the coarser kinds end to end, so as to make warp threads of considerable length. Pina cloth is very strong, and the better sorts far excel the finest lawns in texture. It is chiefly employed in the manufacture of ladies' pocket-handkerchiefs, which often have their costliness much increased by beautiful embroidery.

PINACOTHEK, a picture-gallery in Munich, completed in 1836, after designs by Klenze, the architect of the Glyptothek. It comprises also the new Pinacothek, completed in 1853, and in which are placed the works of contemporary artists. The main gallery is one of the most important in its contents in Europe. One compartment contains only the works of Raphael; while the largest hall in the building is devoted to 95 works by Rubens. There are, altogether, about 1300 paintings, including specimens of Cimabue, Giotto, Leonardo da Vinci, Correggio, Titian, Michael Angelo, Albert Dürer, Rembrandt, and Vandyke. It comprises the best works of the royal collections, these being arranged with regard to their various schools, in 9 halls and 23 compartments. The building is itself a monument of art, one of its corridors being divided into 25 *loggie* frescoed by Cornelius, with works illustrative of the history of the fine arts in the middle ages. The lower story of the building contains 9,000 drawings by the old masters; the original drawings for Cornelius's *loggie*; and a cabinet of more than 300,000 engravings. There is also an important collection of Etruscan and other vases. The new Pinacothek contains Kaulbach's "Destruction of Jerusalem," and Wilkie's celebrated "Reading of the Will."

PINAL, a co. in s. Arizona, drained by the Gila river, pop. '80, 3,044—1701 of American birth. The surface is mountainous and contains gold and silver. Co. seat, Florence.

PINAS'TER. See **PINE**, *ante*.

PINCH'BECK is an alloy of zinc and copper, in which the proportions slightly differ from those which constitute brass; 3 parts zinc to 16 of copper constitute this material, instead of 1 part of the former to 2 of the latter as in common brass. Pinchbeck, when new, has a color resembling red gold, and it was at the beginning of the present century much employed in making watch-cases and other small articles in imitation of gold.

PINCKNEY, CHARLES, b. Charleston, S. C.; the second son of Thomas Pinckney, founder of the family. He was educated in England, returned to South Carolina, and there practiced law for many years. In 1752 he was made king's councilor and chief justice of the province. In 1753 chief-justice Pinckney again visited England, where he spent 5 years, returning shortly before his death in 1759.

PINCKNEY, CHARLES, LL.D., 1758-1824; b. Charleston, S. C.; admitted to the bar, and elected to the provincial assembly in 1779. He was captured at the surrender of Charleston, and remained a prisoner till the peace. He was elected to congress from South Carolina in 1785; was a member of the convention which drew up the U. S. constitution in 1787; of the South Carolina convention which ratified it in 1788, and president of the convention which framed the South Carolina constitution in 1790. He was elected governor of the state in 1789, 1791, and 1796; and in 1798 became U. S. senator. He was a leader of the republican party, a warm supporter of Jefferson for the presidency in 1800, and was appointed by him minister to Spain in 1802. While there, he secured from the Spanish government a release of its interest in the territory sold by France to the United States. He was again elected governor in 1806. His last appearance in public life was as a determined opponent of the Missouri compromise.

PINCKNEY, CHARLES COTESWORTH, LL.D., 1746-1825; b. Charleston; son of chief justice Charles. He was educated in England, graduated at Oxford, and studied law. After a short residence at the royal military academy, in Caen, France, he began the practice of his profession at Charleston, in 1769, and soon became prominent in politics. He served in the first provincial congress of South Carolina, was elected col. of a provincial regiment in 1775: was at the capture of fort Johnson, and the repulse of the British squadron off fort Moultrie. He was afterward one of Washington's aids-de-camp, was at Brandywine and Germantown; and returning to the south in 1778, joined the expedition to Florida. Soon after his election in 1779 to the presidency of the South Carolina senate, he joined Moultrie in the defense of Charleston against the British under Prevost. He showed great gallantry in the attack upon Savannah in October of the same year; commanded fort Moultrie during the siege of Charleston, upon whose surrender, which he had vigorously resisted, he was taken prisoner, and he was not exchanged till February, 1782. After the evacuation of the city the following December, he resumed practice. He was a prominent member of the U. S. constitutional convention in 1787; of the South Carolina convention which ratified the new U. S. constitution, and of the convention which in 1790 framed a state constitution for South Carolina. Sent to France in 1796 as U. S. minister, he was received with studied discourtesy by the directory, which finally made him leave the country; nor on his return to France, as a joint commissioner with Elbridge Gerry and John Marshall, was his reception more favorable. Talleyrand assured the commissioners that a gift of money to the French government was a necessary preliminary to the negotiations, and that a refusal would bring on war. Pinckney is said to have answered: "War be it, then; millions for defense, sir, but not one cent for tribute!" On his return to this country a war with France seemed imminent; and he was appointed a maj.gen. His last appearance in public life was as a federalist candidate with John Adams, in the presidential election of 1800.

PINCKNEY, THOMAS, 1750-1828, b. Charleston; brother of Charles Cotesworth, educated at Westminster and Oxford, and called to the English bar. He returned to Charleston in 1770; became a lieut. in a provincial regiment in 1775, and was soon promoted maj. He was appointed aid-de-camp to gen. Lincoln; distinguished himself at the battle of Stono, and commanded a column of the American army in the attack upon Savannah in 1779. After the surrender of Charleston, he joined the army under Gates, and was dangerously wounded and taken prisoner at Camden; remaining in confinement at Philadelphia till the close of the war. In 1789 he was elected governor of South Carolina; in 1792 appointed minister to England, and in 1794 minister to Spain. After negotiating the treaty of Ildefonso, which guaranteed to the United States the free navigation of the Mississippi, he returned, and was a federalist congressman for the Charleston district, 1797-1801. As maj.gen. of the southern military division, in 1812, he fought the Seminoles and Creeks, giving a crushing defeat to the latter, at the battle of Horse-Shoe Bend.

PINCKNEYA, or Georgia bark, a shrub growing in low or swampy land in Florida, Georgia, and South Carolina, rarely found elsewhere. It belongs to the botanical family of *rubiaceæ*, has large oval leaves, and beautiful clusters of purple-spotted flowers at the ends of the branches. It has medical qualities akin to Peruvian bark and is used by the country people as a substitute for quinine.

PIN'DAR (Gr. *Pindaros*), the great lyric poet of Greece, was born about 522 B.C. of a noble family of Thebes, at Cynoscephalæ, a village in that territory. His genius for music was hereditary, and at an early age he was sent by his father, himself a flute-player, to receive instruction in the same art from Scopelinus. At this time his genius for poetry too—foreshadowed, according to later writers, by a swarm of bees miraculously resting on his lips when asleep—began to develop itself, and so he went to Athens to be placed under the tuition of Lasus of Hermione, the founder of the Athenian school

of dithyrambic poetry. Before completing his 20th year he returned to Thebes, where he continued to pursue his studies under Myrtis and Corinna, of Tanagra, two poetesses then famous in Bœotia. With both of his instructresses he contested the prize for music at Thebes, but was five times defeated by Corinna. He was still a young man when he entered on his professional career as a poet, and his services soon came to be in great request on festive occasions throughout all the Hellenic states. He composed choral songs for Hiero, tyrant of Syracuse; Alexander, son of Amyntas, king of Macedonia; Theron, tyrant of Agrigentum; Arcesilaus, king of Cyrene; and also for many free states and private individuals. He won not only the admiration of his employers for his lyrical genius, but also their respect for his independent character, which, amid all the presents and rewards conferred upon him, never degenerated into that of the poet who merely performed for hire. He was especially the favorite of Alexander, king of Macedonia, and of Hiero, tyrant of Syracuse; and it is said that to the praises he lavished on the former of these monarchs his house owed its preservation at the hands of Alexander the great, when he reduced the rest of Thebes to ruins. His life was for the most part spent abroad at the courts of kings, and at the scenes of the great public games; and at one period, 473 B.C., he resided at Syracuse at the court of Hiero for the space of four years. He died most probably in 442 B.C., in his 80th year. Of the immense number of his poems, consisting of hymns to the gods, pæans, dithyrambs, odes for processions (*prosodia*), maidens' songs (*partheneia*), mimic dancing songs (*hyporchemata*), convivial songs (*scolia*), dirges (*threnoi*), and encomia on princes, we only possess fragments. His *epinikia*, or triumphal odes, however, have come down to us entire; and it is from these—divided into four books, and celebrating the victories won in the Olympian, Pythian, Nemean, and Isthmian games respectively—that we must form an opinion of Pindar as a poet. A victory at these games conferred honor not upon the winner and his family only, but also on the city to which he belonged; and for its celebration—which began with a procession to the temple, where sacrifice was offered, and ended with a convivial banquet—a poem was specially composed, and was sung by a chorus either during the procession, or, more frequently, at the banquet (*comus*). Pindar's poetical style is peculiar. Full of bold conceptions and striking metaphors, his manner is so rapid and so subject to abrupt transitions, as to render him not only a difficult but an obscure composer. Typical examples of his strength, as well as of his weakness, will be found in the second Olympian and first Pythian odes, where the description of the islands of the blest in the former, and of an eruption of mount Ætna in the latter, are brilliant offsets to the shadowy mythological allusion and the undeveloped metaphor which also characterize them. His meters, in spite of the able efforts of Böckh, still remain to be satisfactorily elucidated; and all that we can here say of them is, that he makes chief use of the Dorian rhythm, and not unfrequently of the Æolian and Lydian. He has been fortunate neither in his numerous imitators nor translators—Gray being, perhaps, the most successful among the former, and Carey, Abraham Moore, Morice, and Baring among the latter. He has been elaborately explained and criticised in Schmidt's *Pindar's Leben und Dichtung* (1852); while his relation to lyric poetry in general forms the subject of Villemain's brilliant *Essais sur le Génie de Pindare et sur la Poesie Lyrique* (1859). The best editions are those of Böckh; of Dissen, re-edited by Schneidewin; and of Hartung.

PINDAR, PETER. See WOLCOT.

PIND DADUN' KHAN, a t. in the Punjab, stands on a narrow verdant plain on the right bank of the Jhelum, and at the southern base of the Salt range or Kalabagh mountains, 110 m. n.w. of Lahore. The town consists of three groups of houses, four m. from the Jhelum. The houses are built of mud, but the framework is of cedar-wood. In the vicinity, salt is extensively raised in the Salt Range. See PUNJAB. Entire pop. 72, 13,340.

PINDUS, anciently the name of a chain of mountains in Greece (q.v.).

PINDEMONTI, IPPOLITO, 1753–1828; b. Italy; educated at Modena and Este; made a European tour, lived for some time in Malta, and finally took up his residence near Verona. Among his works are *Prose e Poesie Campestri* (1795); *Arminio* a tragedy, (1804); *Sermoni* (1805); *Epistole in Versi* (1819); and *Elogi di Letterati* (1825–26). His brother, GIOVANNI, 1751–1812, published a number of dramas, and a translation of Ovid's *Remedia Amoris*.

PINE, *Pinus*, a genus of trees of the natural order *coniferae*. The Linnæan genus includes all kinds of fir, larch, and cedar; but as now limited, the genus *pinus* is distinguished by monœcious flowers, and woody cones with numerous two-seeded scales, the scales having an angular truncated apex. The leaves are linear and very narrow, of a very dark-green color, growing in clusters or in pairs, and surrounded by scarios scales at the base. To this genus belong many noble and useful trees. They mostly grow in mountainous or other exposed situations, and their narrow leaves are admirably adapted to evade the force of winds, which produce in the tops of pines a peculiar sound, much noticed by the ancient poets, more soft and continuous than in trees of richer foliage. Most of the pines are more or less social, one kind often covering a considerable tract; some of them clothing the sides and even the summits of mountains with mag-

nificent but somber forests; some growing in lower situations, on otherwise unproductive sandy grounds, as the *pine barrens* of North America. The pines growing in the most barren soils, or in the coldest climates and most exposed situations, are often very small; and although very unlike any other shrubs or bushes, are scarcely to be called trees. Pines are widely diffused over the northern hemisphere, being found on mountains within and near the tropics, and in the colder temperate and the arctic regions descending to the level of the sea.

The SCOTCH PINE or SCOTCH FIR (*P. sylvestris*) is the only species indigenous to Britain. It has leaves in pairs, about an inch and a half long; the cones about the same length, obtuse, and with unarmed scales. On very poor soils and at great elevations it is reduced to a kind of shrub, but in favorable situations it becomes a lofty tree. A plank five feet and a half in diameter has been obtained from a Scottish forest. The Scotch pine is of quick growth, but has been known to attain the age of 400 years. Its head is somewhat conical or rounded, and the lower branches die off as the tree grows, leaving the older trees bare of branches for the greater part of their height; but it is more apt to send off large branches than most of the coniferæ. There are still native forests of Scotch pine at Braemar and elsewhere in the highlands of Scotland; and even in the south of Scotland noble trees are to be seen which, probably, were not planted by man. The Scotch pine is not indigenous to the south of England; but, having been introduced, is spreading rapidly and spontaneously, along with the pinaster, in some of the heaths and other unfertile tracts. Immense forests of it exist in some countries of Europe, in some of which it is mingled with the spruce fir. In the middle and north of Europe and of Asia it is found even in plains near the level of the sea, especially where the soil is somewhat sandy; in the south of Europe it grows only on mountains. Its timber is highly valuable, being very resinous and durable, and is the *red deal* or *red pine* used in house and ship-carpentry. There is very great difference, however, in the timber of Scotch pine growing in different soils and situations, rich soils and sheltered situations being unfavorable to the quality of the timber, which becomes white, soft, and comparatively worthless; and there exist several varieties of Scotch pine, some of which yield timber very superior to others. Many plantations in Britain have, unfortunately, been made of inferior kinds. One of the best varieties is that which forms the northern Scottish forests, often designated *Braemar pine* by nurserymen. It is remarkable for its very horizontal branches, and is therefore sometimes called *P. horizontalis*.—The Scotch pine is not only valuable for its timber, which is available for some purpose at every stage of its growth, but on account of other products. Common turpentine is in great part obtained from it, and much tar, pitch, resin, and lamp-black. See these heads. Oil of turpentine is sometimes distilled from the cones, and even from the leaves; the leaves have also been used in Germany for the manufacture of a substance resembling tow, and called *waldwolle* (forest wool), suitable for stuffing cushions, etc. The resinous roots are dug out of the ground in many parts of the highlands of Scotland, and being divided into small splinters, are used to give light in cottages instead of candles. Fishermen, in some places, make ropes of the inner bark, which is applied to a very different use, when most soft and succulent in spring, by the Kamtchatdales and Laplanders, being dried, ground, steeped in water to remove the resinous taste, and used for making a coarse kind of bread.—The DWARF PINE (*P. pumilio* or *P. Mughus*) is found on the Alps and Pyrenees, its trunk often lying on the ground, although sometimes it appears as a bush or low tree. The recumbent trunks are called *krummholz* (crooked-wood) and *kniehholz* (knee-wood) by the Germans.—The leaves are in pairs, very like those of the Scotch pine, but a little longer; the cones are also similar. From the young shoots an oil resembling oil of turpentine is obtained by distillation, which is a kind of universal medicine among the peasantry of Hungary, as is also the resin spontaneously exuding from the tree, which is known as *Hungarian balsam*.—The BLACK PINE, or BLACK FIR (*P. nigricans*, or *P. Austriaca*), is another species closely allied to the Scotch pine, but remarkable for its very long leaves. It is a native of Austria. It abounds in resin more than any other European tree.—To the same group of pines belongs the SEASIDE or TAURIAN PINE (*P. Pullasiana*, *maritima*, or *Taurica*), which also affords resin in great quantity, and of a very pleasant odor. It is found in many parts of the south of Europe. Its timber is of little value; but great part of the turpentine of the *Landes* and other maritime districts of France is obtained from it. It yields also part of the *Burgundy pitch* of the apothecaries' shops.—The ALEPPO PINE (*P. Halepensis*), a native of the south of Europe, Syria, etc., is a very graceful tree of moderate size, with leaves in pairs and slender. It yields a liquid resin or turpentine, which is extracted from it in Provence and elsewhere, and sold as *Venice turpentine*. The wood is extensively used in the Levant for ship-building.—The LARICIO (*P. laricio*) has leaves in pairs, lax, and 4 to 8 in. long, cones 2 to 4 in. long, with the scales slightly pointed. It is often called the CORSICAN PINE. It grows on the shores of the Mediterranean sea, and is valuable both for its timber and for its resinous products. In the island of Corsica, it frequently attains the height of 140 feet. It grows well in sandy soils, and has been made particularly useful for preventing the drifting of the sand, and turning to account the otherwise useless tracts between the mouths of the Garonne and the Adour in France, thus also preserving valuable lands which the sand threatened to overwhelm. The PINASTER or CLUSTER PINE (*P. pinaster*) is another of the most important European species. It has

cones in whorls of 3, 4, or even 8 together, 4 to 6 in. long, leaves in pairs, and very long. It is found on the shores of the Mediterranean, and also in the Himalaya and in China. It has been used in France to a great extent, in the same way as the Laricio, for covering waste sandy tracts. The timber is of inferior quality, but great quantities of resin are procured from it. It yields *Bordeaux turpentine*.—The PYRENEAN PINE (*P. Pyrenaica*) is a majestic tree, a native of the Pyrenees, and producing very fine timber.—The CALABRIAN PINE (*P. Bruttia*) somewhat resembles the pinaster.—The STONE PINE (*P. pinea*) a tree with a broad umbrella-shaped head, a form often seen also in the Scotch fir, forms a characteristic feature of the scenery of the Mediterranean, and is very often introduced in paintings. It is the *pinie* of the Germans, the *pignon* of the French. The leaves are in pairs, 4 to 5 in. long; the cones very large, ovate, and obtuse. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and when fresh have a sweet taste resembling that of almonds. They are used in Italy and other countries in the same way as almonds and pistachio nuts for the dessert, in various dishes, also in emulsions, etc., under the names of *pinies*, *pinioles*, and *pignons*. The use of them, however, is almost entirely confined to the countries in which they are produced, as they very soon become rancid. They are sometimes imported into London in the cone, in which way they can be kept longer, but the cost of importation is much increased. The wood of this tree is very useful and beautiful. It yields resinous products only in small quantity.—The CEMBRA PINE, or SWISS STONE PINE, which grows in the central parts of Europe and the south of Siberia—a stately tree, with the lower branches more persistent than they are in most pines, and rigid leaves in groups of three to five—also produces eatable seeds (*Cembra nuts*), which, although they are extracted with difficulty, are much used. The cuticle contains a resinous juice; but in Siberia this fruit is so much prized, that noble trees are often cut down to obtain it. The Cembra pine yields a pellucid, whitish oil, resembling oil of turpentine, and known as *Carpathian balsam*.

North America produces many species of pine, some of them very beautiful and very valuable. Besides those long known, and which are found in the states and colonies near the Atlantic, a number of the noblest species of this genus have, since the commencement of the present century, been discovered in California and the n.w. parts of America.—The RED CANADIAN PINE (*P. resinosa*) is found from Canada to the Pacific, but does not reach far south in the United States. It is the YELLOW PINE of Canada and Nova Scotia. It delights in dry and sandy soils, and attains a height of 70 to 80 ft., with a diameter of 2 ft. at the base, the trunk continuing of uniform diameter for two-thirds of its length. The leaves are in pairs, and are congregated towards the extremities of the branches. The timber is highly esteemed for strength and durability, and furnishes excellent planks for ship-building. It is also used for masts.—Somewhat resembling this in botanical characters is the SCRUB PINE, or GRAY PINE (*P. Banksiana*), generally only 3 to 10 ft. high, which begins to appear in the northern parts of the United States upon high mountains, and is interesting as an arctic species, extending further north than any other.—The YELLOW PINE (*P. variabilis*, or *P. mitis*) abounds in the Atlantic states from New Jersey to Virginia. It is a tree of 50 to 60 ft. high, 15 to 18 in. in diameter at the base, with leaves 4 to 5 in. long, usually in pairs, but sometimes in threes upon the younger shoots. The timber is very extensively used for ship-building, and is largely exported to Great Britain. At Liverpool it is known as NEW YORK PINE.—The JERSEY PINE, or SCRUB PINE (*P. niops*), abounds in the lower parts of New Jersey, and thence to the s.w. The leaves are in pairs, 1 to 2 in. long, the cones armed with strong spines. The tree is rarely 30 or 40 ft. high. Great quantities of tar are made from it in Kentucky.—The PITCH PINE (*P. rigida*) is a native of the northern and middle parts of the United States, often growing in great miry swamps, and attaining a height of 70 to 80 ft., and a diameter of 2 ft. at the base. The leaves are in threes, varying much in length, as the cones do in size. Immense quantities of it are used for fuel. Tar and lamp-black are sometimes made from it.—The LOBLOLLY or OLD FIELD PINE (*P. Taeda*) grows in dry and sandy soils in the lower parts of the Southern states, often occupying lands exhausted by cultivation. Vast tracts never cultivated, in the Southern states, are *pine barrens*, in great part covered with this species of pine. It attains a height of 80 ft. and upwards, and has a wide-spreading crown. The leaves are 6 in. long, in threes, sometimes in fours on young branches; the cones 4 in. high, with strong spines. The timber is not of much value.—The LONG-LEAVED PINE, or SOUTHERN PINE (*P. palustris*, or *P. Australis*), is perhaps the most important of North American forest trees. It furnishes the greater part of the tar, resin, pitch, and turpentine used in the United States. The timber is also very valuable, and is much used for ship-building. In England and the West Indies it is known as GEORGIA PITCH PINE. The tree attains a height of 60 to 70 ft., and a diameter of about 16 to 18 in.; the leaves are in threes, and about a foot long; the cones 7 to 8 in. long, and 4 in. in diameter, with small spines. The seeds are sometimes eaten.—The WEYMOUTH PINE, or WHITE PINE (*P. Strobus*), attains a height of 150 ft., and a diameter of 5 ft. and upwards. It has lax sub-triangular leaves in groups of five; and pendulous cones 4 to 5 in. long, with thin smooth scales. It is frequently planted in Britain and on the continent of Europe for its beauty. In its native country it abounds chiefly from lat. 47° to lat. 43°, and southward on the Alleghanies. The timber is not strong, but easily wrought and durable.—Of the species

belonging to the n.w. parts of America, one of the most magnificent is *P. Lambertiana*, which is found on the Rocky mountains, between lat. 40° and lat. 43°, chiefly in sandy soils. It attains a height of 150 to 200 ft., and a diameter of 7 ft. and upwards, almost to 20 feet. The trunk is remarkably straight, and destitute of branches for two-thirds of its height; the leaves in fives, the cones upwards of a foot long. The timber is white, soft, and light; and the tree produces great quantities of a pure amber-colored resin, which, when the wood is partly burned, is changed into a somewhat saccharine substance, used by the natives as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes.—*P. flexilis* is found on the Rocky mountains, near the head-waters of the Arkansas, and occurs almost to the limit of perpetual snow. It has a dense crown, formed of numerous and remarkably flexile branches. The leaves are in fives. The seeds are used as food by hunters and Indians.—*P. ponderosa*, another native of the Rocky mountains, is a magnificent tree, remarkable for the heaviness of its timber, which almost sinks in water. The leaves are in threes, and 9 to 14 in. long.—*P. Sabiniana*, *P. Coulteri*, and *P. insignis* are also noble species from the w. of North America. The Himalaya mountains abound in pines, some of which rival in magnificence those of n.w. America. The BHOTAN PINE (*P. excelsa*), much resembling the Weymouth pine in its botanical characters, and attaining a height of 90 to 120 ft., abounds in Bhotan, although it is not found in the neighboring countries of Sikkim and Nepaul. The wood is highly valuable, being durable, close-grained, and so resinous as to be used for flambeaux and candles.—The CHEER PINE (*P. longifolia*) of India is a tree of remarkable and most graceful appearance; with leaves in threes, very long, very slender, and generally pendulous. It is abundant on the crests of hills in the lower Himalaya, growing at a lower elevation than the other pines. It is cultivated in some parts of India as an ornamental tree. It is much valued for its resin. The wood is used in India as a substitute for European deal.—The KHASIA PINE (*P. Khasiana*) is peculiar to the Khasia mountains, and has very much the general appearance of the Scotch pine.—*P. Gerardiana*, a species with leaves in threes, is a large tree, a native of Nepaul. The seeds are eatable.—The mountains of India and the n.w. parts of America produce numerous other species; Mexico has a number of very fine ones peculiar to itself; the mountains of St. Domingo have one; the Canary islands have one; China and Japan also have some. Most of those which have been named, and a number of others, are now readily to be procured in nurseries in Britain, although some of them only at prices which prevent any attempt at extensive plantation. Some wealthy noblemen and gentlemen devote a portion of their grounds to a collection of different kinds of pine, called a *Pinetum*. A few foreign species have become pretty common in plantations. Most of the pines are quite hardy in Britain, but this is not the case with the cheer pine and some of the Mexican species. The name pine is often popularly extended, and even in scientific works, to other *coniferæ*.

PINE-TIMBER.—This term is in general use for the timber of the pine-tribe (see CONFERÆ), and is not confined to that of the genus *pinus*, but embraces the wood of species of *abies*, *larix*, *Araucaria*, *dammara*, etc. From the Baltic ports we receive red and white pine, or deal-timber. The former is yielded by the Scotch fir (*pinus sylvestris*), and the latter by the spruce fir (*abies excelsa*). These two, with the larch (*larix Europæa*), yield the greatest part of the pine-timber of Europe. Next in importance to these is the pine-timber of the British North American colonies, which is chiefly yielded by the Weymouth or white pine (*pinus strobus*), although, doubtless, the wood of other coniferous trees is often substituted for it. It makes excellent masts; but is not so serviceable for large timbers, as it is subject to dry-rot. Of white pine, the dominion of Canada exported in 1876, 289,441 tons, valued at £613,179; and 37,040 tons red pine, worth £62,532, besides large quantities of pine in the form of battens or staves and deal. The wood has a peculiar odor. The celebrated pitch-pine of Savannah, in the southern states is the produce of *pinus rigida*. It is much used for ships' masts and yards, and for all purposes requiring great strength and durability, in both of which qualities it excels most others of its kind. The kinds above mentioned are those which constitute the greater part of the pine-timber used in ship and house building, carpentry, etc., in Great Britain. In France the timber of the Corsican pine (*pinus Laricio*) and the seaside pine (*pinus pinaster*) are greatly used. In Italy the pine-timber is chiefly yielded by the stone pine (*P. pinea*) and the Calabrian pine (*P. Bruttia*); that of Spain is from the Pyrenean pine (*P. Pyrenaica*). In Germany, and especially in Austria, the black pine (*P. Austriaca*) furnishes the greater portion; but the fine-grained, soft white pine, or deal, so much used for sounding-boards of musical instruments, is the wood of the silver fir. See FIR. The trade in this timber is very great, for not only do the Germans use it almost exclusively in their vast toy-manufactories and for lucifer-matches, but considerable quantities are exported. The finest is cut in the forests of Bohemia, where large establishments are formed for dressing and preparing the wood for various purposes.

The timber of the Norfolk island pine (*Araucaria excelsa*) is sometimes imported for making ships' masts, as several other kinds of pine-timber are imported from time to time, but those mentioned form the great staples of the timber-trade. The chief value of this class of timber-woods is in the combination of lightness and strength, with softness of texture and ease in working with ordinary tools; they constitute, in fact, the

principal materials of our builders, and are more used than all other kinds of wood together. Much confusion prevails as to their common designations, for in this country alone *fir*, *pine*, and *deal* are terms applied to all and each of them, according to the caprice of the individual. The two first names are used because the material is derived from one or other of those genera; but the last is a misnomer altogether, as the term *deal* belongs only to pieces of fir or pine timber cut to particular sizes: they are 3 in. in thickness, 9 in. broad, and of variable length; if of less width they are called *battens*.

PINE, a co. in e. Minnesota; divided from Wisconsin on the s.e. by St. Croix river; traversed by the Lake Superior and Mississippi railroads; drained by the Kettle and Snake rivers, and smaller streams; 1450 sq.m.; pop. '80, 1365. The surface is undulating, and extensively covered with pine trees of large size, and other evergreen trees. The soil is heavy, and but little cultivated. Lumber is the chief product. Co. seat, Pine City.

PINEAL BODY, is a small, reddish-gray body, of a conical form, and deriving its name from its resemblance to the fruit of the pine. It rests upon the corpora quadrigemina of the brain, in front of the cerebellum. It is about four lines in length, and from two to three in width at its base. It is larger in the child than in the adult, and in the female than in the male. It consists chiefly of gray matter, and in its base is a small cavity, which contains a transparent viscid fluid, in which are granules composed chiefly of phosphate and carbonate of lime, and termed *acervulus cerebri*. This organ was regarded by the ancients as the seat of the soul.

PINE-APPLE, or **ANANAS**, *Ananassa sativa*, a plant of the natural order *bromeliaceæ*, highly esteemed, and much cultivated for its fruit. The fruit is a *sorosis*, formed by the calyces and bracts of a close spike of flowers, becoming succulent and combined. This is the distinctive character of the genus *Ananassa*. The pine-apple has a number of long, serrated, sharp-pointed, rigid leaves, springing from the root, in the midst of which a short flower-stem is thrown up, bearing a single spike of flowers, and, therefore, a single fruit. From the summit of the fruit springs a crown or tuft of small leaves, capable of becoming a new plant, and very generally used by gardeners for planting; the pine-apple, in cultivation, being propagated entirely by crowns and suckers, as, in a state of high cultivation, perfect seed is almost never produced. The pine-apple is a native of tropical America; it is found wild in sandy maritime districts in the n.e. of South America, but it has been very much changed by cultivation. It has also been gradually diffused over tropical and subtropical countries, and not only as a cultivated plant, for it is fully naturalized in many parts both of Asia and Africa. It delights in a moist climate, and consequently does not succeed well in the dry climate of the s. of Italy, although the warmth is sufficient. The first particular account of the pine-apple was given by Oviedo in 1535. It was in Holland that it first began to be cultivated in hot-houses; but it was introduced into England in the end of the 17th c., and its cultivation rapidly became general in the gardens of the wealthy. It is only since the peace of 1815 that it has received similar attention in continental Europe. Great care is requisite in the cultivation of the pine-apple, which, without it, is generally fibrous and coarse, with little sweetness or flavor; and with it, one of the most delicate and richly flavored of fruits. Its size also very much depends on cultivation. The size varies from 2½ lbs. to 12 lbs. in weight. The pine-apples grown in British hot-houses are generally much superior to those of the West Indies, because the latter grow almost or altogether without cultivation; but the importation of pine-apples from the West Indies having now been carried on to a considerable extent, and promising to add to the sources of wealth for these colonies, has led to greater care in cultivation there, and consequent improvement of quality.

In the cultivation of the pine-apple in Britain, a tropical heat must always be maintained. It is generally cultivated in hot-houses specially appropriated to it, called *pineries* or *pine-stoves*; sometimes also in flued pits; and sometimes even without fire-heat, in frames continually supplied with fresh tanners' bark and dung. The universal practice, till of late, was to grow the plants in pots, plunged to the requisite depth in tanners' bark or other fermenting matter, and these were transferred from one house or one compartment to another, according to their-stage of advancement; three years' culture being deemed requisite from the planting of a crown or sucker to the production of the ripe fruit; but the pine-apple is now often planted in beds, and fruit of the best quality is sometimes obtained in 15 months. The best soil is a rich and rather sandy loam. It is often formed from the turf of old pastures, with dung, peat, sand, etc., thoroughly mixed. Ventilation must be freely allowed from time to time, but care must be taken to keep the atmosphere moist. A pine-apple which has borne fruit is thrown away as useless.

There are many varieties of the pine-apple in cultivation. Of these, some are referred by some botanists to distinct species. But the greater number of varieties are universally referred to *A. sativa*, and differ in the more or less spiny serratures of the leaves, the globular, cylindrical, or pyramidal fruit, its size, etc.

A spirituous liquor (*pine-apple rum*) is made from the pine-apple in some warm countries.

The use of the fiber of the pine-apple is noticed in the article **BROMELIACEÆ**,

PINE-CHAFER, or PINE-BEETLE, *Hylurgus piniperda*, a small coleopterous insect of the family *xylophagi*. See BARK-BEETLE. It is often very destructive to Scotch firs in rich soils and low situations, attacking the young terminal shoot in summer, and soon eating its way into the heart, which it proceeds to excavate so as to convert the shoot into a tube. Pines growing in open situations are little liable to the attacks of this insect; and trees of 30 ft. in height, or upwards, are very rarely attacked. The insect is about the size of a seed of the Scotch fir, and of a black or dark-brown color.

PINE-FINCH, or PINE GROSBEAK, *Corythus*, a genus of birds of the family *fringillidæ*, nearly allied to bullfinches and crossbills, the bill nearly resembling that of the former, but the tongue very similar to the tongue of the crossbills, with the same peculiar bone articulated to the hyoid bone. See CROSSBILL. One species, the COMMON PINE-FINCH, (*C. enucleator*), is a very rare visitant of Britain, but is abundant in many of the northern parts of Europe, Asia, and America. It is larger than a bullfinch, but much resembles the bullfinch in form, wings, tail, etc. The general color of the male is red. This bird frequents pine-forests, and associates in flocks in winter. It is easily tamed. Its song is rich and full.—There are other species in the northern parts of the world.—The name pine-finch is given in North America to a very different and much smaller bird (*carduelis pinus*.)

PINEL, PHILIPPE, a celebrated French physician, was b. April 20, 1745, at Saint-André, in the department of Tarn, France; and after receiving a good classical education at the college of Lavour, removed to Toulouse, where he studied medicine, and took his degree in 1773. He continued his medical studies at Montpellier, maintaining himself meantime by teaching mathematics; and in 1778 removed to Paris, where he acquired some reputation by a translation into French of Cullen's *Nosology* (1785), and the works of Baglivi (1788), and also by some memoirs on subjects connected with zoology and comparative anatomy. Having applied himself with success to the study of mental alienation, he was charged, in 1791, to make a report on the insane inmates of the Bicêtre, became chief physician of this institution in 1793, and in 1795 was chosen to the same office at the Salpêtrière (a similar asylum, but for females). In the latter institution Pinel commenced a class of clinical medicine, which he continued after his appointment to the chair of medical physics and hygiene, and subsequently that of pathology, at the school of medicine in Paris. He was admitted as a member of the institute in 1803, and died at Paris, Oct. 26, 1826. His most valuable works were his *Traité Medico-philosophique de l'Aliénation Mentale* (1791), and *La Nosographie Philosophique* (1798), with its commentary, *La Médecine Clinique* (1802). Pinel gained for himself undying fame by his reformation of the old barbarous methods of treating the insane. The physicians brought up under the old system were not ashamed to offer a vigorous opposition to Pinel's philanthropic opinions; but he fortunately succeeded in thoroughly establishing their correctness, and his system in a few years prevailed over the whole of Europe.

PINERO'LO, or PIGNEROL, a t. in the n. of Italy, on the Clusone, at the entrance of the valley of Perosa, in the province of Turin, and 23 m. by railway s.w. of the city of that name. It was formerly strongly fortified, and was the residence of the rulers of Piedmont. It contains a new cathedral, a bishop's palace, seminaries, barracks, etc. The ruins of the *citadel*, for some time the prison of the *Man with the Iron Mask* (q.v.), are still to be seen on the hill of St. Brigide. Broadcloth, paper, leather, iron, and silk are manufactured. Pop. '72, 11,832.

PINES, ISLE OF, in the s. Pacific ocean, a dependency of New Caledonia, and belonging to France; 12 m. in circumference, situated in lat. 22° 38' s., long. 167° 25' e; pop. 800, exclusive of convicts. The original inhabitants were cannibals, and of the same race as those of New Caledonia. The surface is mostly barren, excepting a wide strip surrounding the shore, which is fertile, and on which a few Europeans have settled. The island was discovered by capt. Cook, in 1774, and is surrounded by smaller islands heavily timbered with valuable wood which is exported. In 1872 it was chosen as a penal station by France for convicts, and many connected with the communal insurrection of 1871 have been placed there. The mountain of N'gu, 872 ft. high, is in the s.e. portion, and is a prominent landmark.

PINE SNAKE, *Pituophis melanoleucus*, a large serpent, found in the s.e. United States, 6 ft. long, 2 in. thick, of a glistening creamy-white color, blotched with dark brown. It is a beautiful variety of snake, and harmless to man. It derives its name from the pine lands in which it is found, emits a strong disagreeable odor, and feeds on eggs, birds, and small mammals. It makes a loud bellowing noise which has given it the name of bull-snake.

PINE-WOOL. Several attempts have been made of late years to utilize the leaves of pine and fir-trees, which are cut down in vast numbers for their timber only. The leaves contain a considerable quantity of fine vegetable fiber, which, when separated, has much the appearance of cotton. In Germany, several works have been established for preparing this fiber, and fitting it for various applications; and, under the name of pine-wool, it is now sold for stuffing cushions, making wadding, etc. The principal

manufacture is near Breslau in Silesia, where it is carried on by the inventor, Heir Pannewitz.

PINEY TREE. See CALOPHYLLUM.

PINEY-VARNISH. See DAMMAR.

PINGRÉ ALEXANDRE GUI, 1711-96; b. Paris; educated at a convent in Senlis. He at first taught theology of the Roman church; but becoming a believer in the Jansenist doctrines, turned his attention to astronomy. Between 1760 and 1776 he went on a number of scientific expeditions for the observation of stellar transits. He calculated the orbits of 24 comets, published *Cometography, or a Historical Treatise on Comets* (1783); a series of nautical calendars, and a translation of the *Astronomica* of Manilius (1786). He also computed the eclipses for the thousand years before the Christian era.

PINGUICULA. See BUTTERWORT.

PING YANG, or **PIENG-AN**, the n. w. province of Corea, bordering on Mantchuria, having its capital city of the same name. The province is bounded on the w. by the Yalu river and the Yellow sea. The only legal place of ingress and egress from China or elsewhere, or out of Corea, is at the t. of Ei-chiu on the Yalu river. Pop. of the province about 1,500,000.

The city of Ping Yang lies on the n. bank of the Ta-tong river, 50 m. from its mouth. It is a place of great commercial and historical importance, and was the capital and royal residence until 1392. Besides suffering many sieges, it was the scene of a great battle between the invading Japanese and the army of succor sent by the Ming emperor from China to the Koreans, in 1593. On Aug. 6, 1866, the heavily-armed (private) American schooner *Gen. Sherman* entered the Ta-tong river on a semi-piratical trading expedition—the venture of an Englishman at Tien-tsin, who also held the post of U. S. vice-consul. The exact truth of the details is unknown; but the entire crew, consisting of three Americans and two British citizens, with nineteen Malay and Chinese sailors, were killed, and the vessel was burned. By orders from Washington, commander R. W. Shufeldt in the U. S. steamship *Wachusett* went over to the coast of Corea, arriving January 23, and waited in the approach to the Ta-tong river for nearly a week, communicating with the authorities. His demand that “the murderers of the crew of the *Gen. Sherman* be produced upon the deck of the *Wachusett*” was answered by the repeated invitation, “Please go away as soon as possible.” After a survey of the inlet, the *Wachusett* returned to Chifu. In May, 1868, the U. S. steamship *Shenandoah* also visited the Ping Yang inlet, and commander J. C. Febiger learned from the natives the circumstances attending the slaughter of the foreigners, by which it appeared that the latter were mistaken for “Frenchmen” (see **KANG-HOA**), and put to death after insults offered to the officials. Finding it impossible to obtain satisfaction, the United States government, not believing the Korean version of the affair, dispatched in 1871 the naval expedition which destroyed the forts along the Han river leading to Seoul the capital. See **KANG HOA**.

PINHOEN, OIL OF. See **PHYSIC NUT**.

PINK, *Dianthus*, a genus of plants of the natural order *caryophyllaceæ*, of which there are many species, annuals and perennials, with beautiful and often fragrant flowers, chiefly natives of Europe and the temperate parts of Asia. The calyx is tubular, 5-toothed, with two or four scales at the base; there are 5 petals suddenly contracted at the throat of the corolla into a linear claw. There are 10 stamens, and one germen with two styles. The capsule is cylindrical, and one-celled. The exquisite beauty of the flowers has attracted admiration in all ages; and some of the species have long been much cultivated in gardens, particularly the **GARDEN PINK** and **CARNATION** (q. v.), which are often referred to one original, the **CLOVE PINK** (*D. caryophyllus*), a native of the s. of Europe, growing wild on rocks and old walls, and naturalized in some places in the s. of England; while some botanists refer the garden pinks in part to the **MAIDEN PINK** (*D. deltoides*), a pretty common British species, and those called pheasant-eye pinks to the **FEATHER PINK** (*D. plumarius*), a native of some parts of continental Europe, differing from the clove pink chiefly in having the leaves rough on the margin, and the petals bearded and much cut. Nearly allied to them is *D. superbus*, found in moist places in some parts of Europe, and not unfrequently to be seen in flower-borders. It has very fragrant flowers. All the varieties of garden pinks, whatever their origin, have been much changed by cultivation, and careful cultivation is requisite to preserve them in perfection. Both single and double pinks are generally propagated by *pipings*, which are short cuttings of the younger shoots. They are also sometimes propagated by layers. A rich loamy soil is the best for pinks. The clove pink, in a wild state, has flesh-colored flowers. The leaves are linear-awl-shaped, grooved, and glaucous. The maiden pink is a small much-branched plant, growing in grassy places, on gravelly and sandy soils; it has rose-colored flowers spotted with white, and a white eye encircled by a deep-purple ring.—The Deptford pink (*D. armeria*) and the **CLUSTERED PINK**, or **CHILDING PINK**, (*D. prolifer*), also natives of England, differ from these in being annuals, and in having clustered flowers.—The **BEARDED PINK**, or **SWEET WILLIAM** (*D. barbatus*), a native of the middle of Europe and the s. of France, with lanceolate leaves, flowers crowded in dense clusters at the top of the stem, acuminate bracts, and bearded petals, has long been a

favorite garden flower, still retaining its place alike in palace and cottage gardens. Although perennial, it is sown annually by florists, to secure fine flowers, and there are many varieties, single and double, exhibiting much diversity of color.—The INDIAN PINK or CHINA PINK (*D. chinensis*) is now also common in flower-gardens.

The clove pink was formerly regarded as possessing medicinal properties, and was used in nervous maladies.—*Sea-pink* is a common name of thrift (q.v.).

PINK COLORS, very light shades of rose-red color: they are usually produced by extreme dilution of cochineal or carmine, Brazil and Braziletto wood colors, with whitening. Some mineral pinks for oil colors are obtained from preparations of manganese, etc. See RED COLORS. The term pink is also applied to several yellow colors (q.v.).

PINKERTON, JOHN, an industrious and learned *littérateur*, was born at Edinburgh, Feb. 17, 1758, and educated at the grammar-school of Lanark, where he was noted for the unusual excellence of his classical attainments, and for his hypochondriacal tendency. He was afterward apprenticed to a writer to the signet, his father refusing to let him proceed to the university; and while engaged in the irksome and distasteful practice of law, he published an *Ode to Craigmillar Castle*, in 1776, which he dedicated to Dr. Beattie. In 1780 he went to London, where he settled as a man of letters. Next year he gave to the public a volume of *Rimes* (as he called his pieces), and a collection of *Scottish Tragic Ballads*, followed in 1783 by a second collection of *Ballads of the Comic Kind*—both of which subsequently appeared under the title of *Select Scottish Ballads*. They professed to be ancient, but many of them were really compositions—*forgeries*, some might say, of Pinkerton's own, and would hardly deceive a critical archæologist. In 1784 he published an *Essay on Medals*, which went through several editions, and long held a high place among books on numismatics; and in 1785 *Letters on Literature*, marked chiefly by a novel system of orthography (e.g., the use of *a* instead of *s* in forming plurals), intended to soften the harshness of the English language, and which was abused as heartily as it deserved. These *Letters* were, however, the means of introducing him to Walpole, through whom he became acquainted with Gibbon and other literary celebrities. Pinkerton's next publication was a most valuable one, *Ancient Scottish Poems never before in Print, from the MS. Collections of Sir Richard Maitland of Lethington, Knight* (2 vols. Lond. 1786). It was followed in 1787 by his once notable *Dissertation on the Origin and Progress of the Scythians or Goths*, in which, for the first time, appears that grotesquely virulent hatred of the Britanno-Celtic race—Scotch Highlanders, Welsh, and Irish—that reaches its climax in his *Inquiry into the History of Scotland preceding the Reign of Malcolm III.* (2 vols. Lond. 1790), where he affirms again and again, obviously with the extremest gusto, that the Highlanders are “mere savages, but one degree above brutes;” that they are just as they were “in the days of Julius Cæsar;” that “like Indians and negroes,” they “will ever continue absolute savages,” and that “all we can do is to plant colonies among them, and by this, and encouraging their emigration, try to get rid of them.” But in spite of this extravagant truculence of speech, the *Inquiry* contains a great deal of important matter—rare and curious historical documents, some of which are to be found nowhere else in print. Pinkerton left England in 1802, and fixed his residence at Paris, where he died Mar. 10, 1826, after a life of hard literary work. His principal publications, besides those already mentioned, are *The Medallie History of England to the Revolution* (1790); *Scottish Poems* (3 vols. 1792), reprinted from scarce editions; *Inconographia Scotica, or Portraits of Illustrious Persons of Scotland, with Biographical Notes* (2 vols. 1795–97); *The History of Scotland from the Accession of the House of Stuart to that of Mary* (2 vols. 1797), valuable for its laborious investigation of original materials, but disfigured, in a literary point of view, by an imitation of the grandiose style of Gibbon; *Walpoliana*, a collection of his notes of his friend Horace Walpole's conversation, in 2 vols.; *The Scottish Gallery, or Portraits of Eminent Persons of Scotland, with their Characters* (1799); *Modern Geography* (3 vols. 1802–7); *General Collection of Voyages and Travels* (16 vols. 1808–13); *New Modern Atlas* (1809–15); and *Petralogy, or a Treatise on Rocks* (2 vols. 1811).

PINKERTON, ALLAN G. See page 894.

PINK EYE. See page 894.

PINKNEY, EDWARD COATE, 1802–28; b. London; son of William; educated at St. Mary's college, Baltimore; joined the navy 1816, serving 8 years. He undertook to practice law, but had no success; tried without result to get a commission in the Mexican navy, and in 1827 began the publication of a political journal called *The Marylander*. He published in 1825 *Rodolph and other Poems*, a later edition appearing in the Mirror Library in 1844 entitled *Rococo*, with an introduction by N. P. Willis.

PINKNEY, WILLIAM, LL.D., 1764–1822; b. Md.; admitted to the bar in 1786, and soon obtained a large practice. He was a member of the Maryland convention called in 1788 to ratify the U. S. constitution; served in the state council, house of delegates, and senate, and in 1796 went to England as commissioner under the Jay treaty. He returned in 1804, and the next year was made attorney-general of Maryland. In 1806 he was again sent to England as minister extraordinary, and he remained as minister resident 1807–11. He was attorney-general of the United States 1811–18, and served in the war of 1812 as commander of a volunteer corps, receiving a dangerous wound at Bladensburg. He was elected to congress in 1815, and appointed minister to Russia the next year. He entered the U. S. senate in 1819.

PINK ROOT. See SPIGELIA.

PIN-MONEY, in law, a sum of money paid annually by the husband to his wife to spend for her personal expenses. On the death of the wife her representatives cannot claim unpaid arrears. The husband is not at any time bound to pay the arrears for more than a single year. Pin-money given to the wife but not spent by her, upon the death of the husband, goes to his representatives. Pin-money, now practically obsolete in England, was never established as a custom in this country. The name is said to have been derived from an old English tax assessed to supply the queen with pins.

PINNA, a genus of lamellibranchiate mollusks of the same family with the *pearl mussel* (*aviculidæ*), and having a shell of two equal wedge-shaped valves, closely united by a ligament along one of their sides. The mantle is closed on the side of the ligament; the foot is small and conical. The byssus is remarkably long and silky; and by it the species affix themselves to submarine rocks and other bodies, sometimes even to sandy or muddy bodies. The best-known species is *P. nobilis*, a native of the Mediterranean, the byssus of which was used by the ancients for fabrics, but chiefly as an article of curiosity, to which a great value was attached. It is still so used in Sicily and elsewhere. It is very strong and lustrous. The only reason against its more general use is the difficulty of procuring it in sufficient quantity. The byssus of this species is sometimes two feet long, the shell is about the same length. Pinnæ are often found in large beds, with only the edges of their shells appearing above the mud or sand. The animal is eaten.

PINNACE (from the Ital. *pinaccia*, a diminutive of *pino*, a ship), was originally a small vessel, usually schooner-rigged, employed as tender to a large ship, for the purpose of communicating with the shore, etc. At present, however, the signification is limited to a large boat carried by great ships. It is smaller than the launch, but larger than the cutters; and is generally rowed "double-banked," by from ten to sixteen oars.

PINNACLE, an ornamental termination much used in Gothic architecture. It is of simple form in the earlier periods of the style, having a plain square or octagonal shaft and sloping roof or top, terminating with a finial; but in later examples the pinnacle is greatly developed, and becomes one of the most varied and beautiful features of the style. It is ornamented with shafts bearing canopies, and niches filled with statues. Pinnacles are most frequently used on buttresses and parapets, and when placed over the former, serve as a dead-weight to increase their power of resisting a thrust.

PINNIGRADES, or **PINNIPEDES**, a section of carnivora, comprising seals and walruses, in which the fore and hind limbs are short and expanded into broad, webbed swimming paddles. The hind feet are placed very far back, nearly in a line with the axis of the body, and somewhat incorporated with the tail by the integuments. The body is elongated and somewhat fish-like, covered with short fur or hairs, and terminated by a short conical tail. The five toes of each foot are united by the skin and form powerful swimming paddles. The tips of the toes are armed with claws, but they have little power for land locomotion, the typical seals being able only to drag themselves along when out of the water. The ears are small, often only indicated by apertures, which the animal can close under water. The dentition varies, but teeth of three kinds are always present. The canines are always long and pointed, and the molars have sharp cutting edges. Sometimes there are only four or two lower incisors, and sometimes they are wanting altogether, as in the walrus, and the upper incisors may also be less than six. The dental formula of the common seal is

$$i \frac{3-3}{2-2}; c \frac{1-1}{1-1}; pm \frac{4-4}{4-4}; m \frac{1-1}{1-1} = 34.$$

The pinnigrades include three families, the earless seals (*phocidæ*), the eared seals (*otaridæ*), and the walruses (*trichecidæ*). The *phocidæ* differ from the walruses by having incisor teeth in both jaws, and moderate-sized canines, and from the *otaridæ* by the absence of ears and inability to use the hind limbs on land. They are very numerous, being found in most seas of temperate and frigid zones, but are most numerous in the latter. Their principal food is fish, for holding and masticating which their teeth are adapted. They are much hunted for their blubber and skins. The eared seals, or *sea-lions*, differ from the typical seals by having small, conical ears, and in the greater use of the limbs, especially the hind limbs, so that they are enabled to execute a sort of walk. The sea-lions are chiefly found in the Pacific and southern Atlantic, s. of La Plata river. The third family of pinnigrades, or *trichecidæ* comprises only the walrus or morse, and is distinguished from the true seals by the dentition. According to Owen there are six incisors in the upper jaw, and four in the lower, but these are only present in the young animal, soon disappearing, with the exception of the outer pair of upper incisors. The upper canines are enormously developed into long tusks, often over 15 inches. The upper jaw has on each side three premolars and two molars, with flattened crowns, and the lower jaw has the same number of premolars and one molar on each side; but the true molars are deciduous, so that the dental formula in the adult is

$$i \frac{1-1}{0-0}; c \frac{1-1}{1-1}; pm \frac{3-3}{3-3}; m \frac{0-0}{0-0} = 18.$$

In all other respects the walruses are very similar to the seals. See MORSE, OTARY and SEAL, *ante*.

PINNULE, in botany, a leaflet of a pinnate leaf, or of one which is bipinnate, tripinnate, etc. See LEAVES. The term is more frequently used, however, to designate the ultimate divisions of the fronds of ferns, when divided in the same manner.

PINSK, a t. of w. Russia, in the government of Minsk, surrounded by vast marshes called the Pinsk marshes, stands on the banks of the Pina, a branch of the Pripet, 752 m. s.s.w. of St. Petersburg, lat. 52° 7' n., long. 26° 6' east. It was founded in the 12th c., was conquered by the prince of Lithuania in 1320, was annexed, together with Lithuania, to Poland in 1569, and came at last into the possession of Russia in 1795. The trade of Pinsk, chiefly transit, has increased, especially since the opening of the Oghin-sky canal, which connects the Dnieper and the Black sea with the Niemen and the Baltic sea. A very considerable number of ships and barges enter and clear the port. They are laden principally with salt, corn, hemp-seed, iron, glass, tar, tallow, wool, tobacco, and timber. The manufacturing activity of the town is not great. The project for a branch line of railway (55 m.) connecting Pinsk with the main line to Minsk, has already been sanctioned. Of the pop. '80, 17,718, three-fourths are Jews, and have the trade almost entirely in their own hands.

PINT, a measure of capacity used both for liquids and dry goods, and equivalent to the eighth part of a gallon (q.v.), or 34.65925 cubic inches. The Scotch pint, still in use, though superseded as a legal measure by the imperial pint, is equivalent to 3.00651 imperial pints.

PINTA'DO. See GUINEA FOWL.

PINTAIL, or **PINTAIL DUCK**, *Dafila*, a genus of ducks, of the section with the hind toe destitute of membrane. The bill is without tubercle at the base, narrow, with laminæ not projecting beyond the margin. The tail of the male is long, and tapers to a point.—The COMMON PINTAIL (*D. acuta*) is a handsome bird, rather longer in shape than most of the ducks; the neck also longer and more slender. It is about equal in size to the mallard. The head is brown, with a white longitudinal line on each side extending down the neck; the back and sides marked with waving lines of black and grayish-white; the lower parts white; the elongated central tail-feathers black. It is a native of all the northern parts of the world, migrating southward in winter, and a regular visitant of many parts of the British coasts. It also frequents fresh-water lakes and ponds, and is common in winter in the valley of the Mississippi. Its winter range extends southward to the Mediterranean and the gulf of Mexico, and even to Africa and the West Indian islands. Its flight is very rapid and noiseless. It is very much esteemed for the table. It has been tamed, and has bred in confinement.

PINTARD, JOHN, LL.D., 1759–1844; b. N. Y.; graduated at the college of New Jersey in 1776; studied but did not practice law; was a volunteer in the revolutionary war, and for three years a clerk to his uncle Lewis Pintard, commissioner for American prisoners in New York; edited *The Daily Advertiser*; afterward engaged in commerce; was for many years city inspector. He was the founder of the New York historical society; vice-president of the American bible society, and an active member of several other societies. He was distinguished as a philanthropist, and also as a local antiquary in New York. He wrote articles for several periodicals.

PINTOS, a name applied to the people inhabiting the valley of the Mescala, in the state of Guerrero, Mexico, because they are liable to a disease which is produced, as it is thought, by some peculiar properties of the water of the Mescala, and resembles leprosy—the name Pintos (Sp.) signifying spotted. The people being mostly of Indian descent, the mistake has been made of supposing that the name Pintos applied to them as a tribe.

PINTURIC'CHIO, BERNARDINO (BERNADINO BETTI), 1454–1513; b. Italy; supposed to have been a pupil of Perugino. His first work was the decoration of the Belvedere at the Vatican; the most celebrated were his ten frescos in the Sienna cathedral. On these he is said to have had the assistance of Raphael. His "Discovery of the True Cross" was painted for the chapel of the church of Ara Cœli. Alexander VI. employed him in the decoration of the Vatican, 1473–96.

PINZON, FRANCISCO MARTIN, the youngest of three brothers, belonging to a wealthy Spanish family, known as bold navigators, who sailed with Columbus on his first voyage to America. Francisco acted as pilot to the *Pinta*, which was commanded by his brother Martin. Charles V. honored the family by conferring upon them the rank of hidalgos. Admiral Pinzon, who, in 1863, was in command of the Spanish fleet which took possession of the Chincha islands, Peru, is a descendant.

PINZON, MARTIN ALONSO, the head of an Andalusian family of the port of Palos de Moguer. It was chiefly through the influence of the Pinzons that Columbus was able to obtain crews for the vessels provided by the crown. Martin commanded the *Pinta*. After the discovery of San Salvador, he deserted Columbus with the view of obtaining fame by original discovery. He landed at the mouth of a river in Hispaniola, long called by his name, but now known as Porto Caballo, and carried off some of the natives; but was compelled to return them by Columbus, whom he encountered at sea.

Pinzon was parted from his commander by a storm on the return voyage, and reached Bayonne. Believing that the admiral had been shipwrecked, he sent a full account of the discoveries to Ferdinand and Isabella, claiming more than his share of the credit. He arrived at Pinto on the same day as Columbus, was badly received by the court, and died the same year, 1493, it is said from mortification and dejection.

PINZON, VICENTE YAÑEZ, b. Spain; commander of the *Niña* on the first voyage of Columbus. Under the general license granted by Ferdinand and Isabella to go on voyages of discovery, he sailed from Palos, in 1499, with four vessels. Sailing some 700 leagues, he crossed the equinoctial line, and, Jan. 28, 1500, discovered cape St. Augustine. He landed, and formally took possession of the territory in the name of Spain; but, on account of the hostility of the natives, he set sail to the n.w., passed the mouths of the Amazon and Orinoco, and arrived at Hispaniola in June. Two of his ships foundered in a storm, and he finally reached Palos, having spent his entire fortune in the enterprise. In 1501 he obtained the royal consent to settle and rule the territory which he had discovered, from a point n. of the Amazon to cape St. Augustine. He never, however, returned to that country, though he took part in expeditions which were sent out in 1506 and 1508, to discover the passage which Columbus imagined between the Atlantic and a s. ocean. He was the first European who crossed the equator in the western ocean, and the first to discover Brazil.

PIOMBINO, a principality now incorporated in the kingdom of Italy, lies along the Italian coast opposite the island of Elba, the greater part of which belonged to it. Its extent was about 132 English sq. m.; and its population, previous to its incorporation with the rest of Italy, about 25,000. Piombino was originally a fief of the empire, and, at the end of the 14th c., came into the possession of the family of Appiani, which, after ruling it for nearly 300 years, made way for a new dynasty, the family of Buoncompagni. This latter dynasty was mostly under the suzerainty of the neighboring states of Sardinia and Naples alternately. In 1801, the Buoncompagni family were expelled by Napoleon, and the principality given to his sister Elisa, the wife of Felice, prince Baciocchi; but the latter was ejected, and the old dynasty restored, by the congress of Vienna; the principality being then put under the suzerainty of Tuscany, whose grand-duke indemnified the Buoncompagni for their loss of sovereignty. It is now part of the province of Pisa, in the kingdom of Italy. The strait between Piombino and Elba is called the "channel of Piombino."

PIOMBO, FRA SEBASTIANO DEL, 1485-1547; b. Venice; educated for the musical profession, in which he attained great excellence in his youth; afterwards studied the rudiments of painting with Bellini; then became a pupil of Giorgione. For many years he painted after the designs of Michael Angelo, thus enhancing his reputation. His principal works are his "Pieta," in the church of the Conventuale at Viterbo; the "Transfiguration," and "Flagellation," in San Pietro in Montorio; and his "Raising of Lazarus," which is considered his masterpiece. Receiving from pope Clement VII. the office of keeper of the papal signet, he assumed the monk's habit, and the title of Fra, or Frate del Piombo.

PIONEER, a military laborer employed to form roads, dig trenches, and make bridges as an army advances, and to preserve cleanliness in the camp when it halts. Formerly, the pioneers were ordinary laborers of the country in which the army was, impressed for military purposes; but now such persons are only brought in as auxiliaries, a few men being attached to every corps as a permanent body of pioneers. In the British army one man is selected, for his intelligence, from every company. These pioneers march at the head of the regiment, and the senior among them commands as corporal. Instead of a musket each man carries a saw-backed sword, which is at once tool and weapon. Each bears also an axe and two gun-spikes, other necessary tools being distributed among them. There is something rather conflicting between the functions of the pioneers and those of the engineer force.

PIOTRKÓW, a division of Russian Poland, adjoining Prussian Silesia, Warsaw, Kalisz, Kielce, and Radom; drained by the Warta and Pilica; 4,730 sq.m.; pop. '72. 696,007. The surface is level, though somewhat hilly in the s., and the soil fertile.

PIOTRKOW, since 1867 the capital of one of the 10 governments into which Poland was then divided, is near the Warsaw and Vienna railway. It is one of the oldest Polish towns; here, in the 15th and 16th centuries, diets were held, and kings elected. In 1702 Piotrkow was burnt by the Swedes; in 1709 the Russians gained a battle here. Pop. '80, 18,000.

PIOZZI, MRS. (née HESTER LYNCH SALUSBURY), who cannot be forgotten while the great Dr. Samuel Johnson continues to be remembered, was the daughter of John Salusbury, esq., of Bodvel, in Caernarvonshire, where she was born in the year 1739. Early introduced into the fashionable world of London, she charmed by her beauty and her lively manners; and, in 1763, was married to Mr. Henry Thrale, a rich brewer with a recognized position in society, and, at the time, one of the members for the borough of Southwark. Her acquaintance with Dr. Johnson, which speedily became an intimacy of the closest and most affectionate kind, began shortly after. Of all Johnson's many friendships this was perhaps, in certain essential respects, the most

valuable to him To Johnson, widowed and alone, and subject, as he had been throughout, to excesses of a frightful gloomy hypochondria, which made life at times to him an almost intolerable burden, the society of Mrs. Thrale, and of the circle which she gathered round her, was a source of incalculable solace. Mrs. Thrale in particular, with her warm heart, and bright womanly intelligence, was always a comforting presence; and her unfailing cheerfulness and vivacity enlivened for him many an otherwise cloudy hour. Her married life, though prosperous, was not an eminently happy one, Mr. Henry Thrale, though always a pleasant and kindly gentleman, being no miracle of conjugal virtue. If Johnson owed her much, it may be surmised that the benefit was in some sort reciprocal, and that, by her affectionate reverence and solicitude for her sage, she a little consoled herself for the gentlemanly indifference of her husband. On the death, in 1781, of her husband, Mrs. Thrale retired with her four daughters to Bath, where, in 1784, she married Mr. Gabriel Piozzi, an Italian teacher of music. This *mésalliance*—as it was held—was deeply censured by all her friends, and so unreasonably excited the ire of Dr. Johnson in particular, that a rupture of friendly relations was the result. In the correspondence between them on the subject, it must be admitted the lady has much the better of the philosopher, whose tone of unmannerly rudeness gives some countenance to the good-natured suspicion of his friends, that he had an eye to the widow himself. Though the feud was ostensibly healed, the friends never again met; Mrs. Piozzi leaving England for Italy with her husband, and Dr. Johnson dying soon after. Some little time subsequent to his death she published an octavo volume, entitled *Anecdotes of Dr. Samuel Johnson during the last Twenty Years of his Life*, in which it seemed to the indignant Boswell and others, that her main intention was to take her little feminine revenge on the deceased for his outrage in the matter of Piozzi. This work she supplemented in 1788 by a collection of *Letters to and from Dr. Samuel Johnson*, in 2 vols. 8vo. Of works more properly her own may be mentioned *Observations and Reflections made in the Course of a Journey through France, Italy, and Germany* (2 vols. 8vo, 1789); *British Synonymy, or an Attempt at regulating the Choice of Words in Familiar Conversation* (2 vols. 8vo, 1794); and *Retrospection, or a Review of the most striking and important Events, Characters, Situations, and their Consequences, which the last Eighteen Hundred Years have presented to the View of Mankind* (2 vols. 4to, 1801)—books long since utterly forgotten, if ever they were at all read and remembered. Having survived her second husband, her own celebrity, and almost in some sort that of the great Dr. Johnson, with whom her name remains indissolubly connected, Mrs. Piozzi died at Clifton, near Bristol, on May 2, 1821.

PIP, CHIP, or ROUP, a disease of poultry, often very fatal, particularly to chickens and turkey poults. It is very frequent also in young pheasants. Adult birds are, however liable to it; and when it appears in a poultry-yard it often attacks many in rapid succession, so that it is regarded as highly contagious. It most frequently occurs in wet or very cold weather, and is generally described as a kind of catarrh, although perhaps it might more accurately be called a kind of influenza. It begins with a slight hoarseness and catching in the breath, which is followed by an offensive discharge from the nostrils and eyes, rattling in the throat, and an accumulation of mucus in the mouth, forming a "scale" on the tongue. The communication of the disease from one bird to another is supposed to take place through the contamination of the water in their common drinking-vessel, and therefore a bird affected with it should at once be removed from the rest. Castor-oil is freely administered by some poultry-keepers. Mrs. Blair, in *The Henwife*, recommends a table-spoonful, but without saying whether this dose is for a full-grown fowl or a young chicken. She recommends also a medicine composed of half a dram of dried sulphate of iron, and one dram of capsicum, made into 30 pills with extract of licorice, one pill to be given three times a day. This after a certain time is to be followed by another compound, of sulphate of iron, cayenne pepper, and butter. The eyes, nostrils, and mouth are to be washed with vinegar. In a work on poultry published in 1867 (*The Practical Poultry-keeper*, by L. Wright, London), it is especially recommended that the diseased birds should be kept warm; they are to be fed on oatmeal mixed with ale, and to get plenty of green food. In other respects, except as to the castor-oil, the treatment recommended nearly agrees with Mrs. Blair's; but the removal of the "scale" from the tongue is not regarded as necessary, because it will disappear of itself on the cure of the disease.—It is proper to mention that there is considerable confusion of nomenclature as to the disease of fowls, and that, by some writers, the mere symptomatic affection of the tongue is called *pip*, and the disease itself *roup*. The terms, however, are generally used in the same sense.

PIPA, a genus of batrachians, in general form resembling frogs and toads, and characterized by the very broad and triangular head, the sides of which are destitute of the glands (*parotoïds*) so large in the true toads; the eyes small, and situated near the margin of the lower jaw; the ear concealed beneath the skin; the tongue merely rudimentary; the jaws destitute of teeth; the fore-feet not webbed, but divided into four fingers, each of which divides at the extremity into four small points, these again being minutely divided in a similar manner; the hind-feet five-toed and completely webbed; the larynx of the male extremely large—a triangular bony box, within which are two small movable bones for occasionally closing the entrance of the bronchi; the back of the female fur-

nished with numerous cells or pouches, in which the eggs are hatched, and the young undergo all their transformations till they have attained a form similar to that of their parents. These characters are so remarkable as to make the creatures of this genus objects of peculiar interest; but particularly the mode of rearing the young. It was at first supposed that the young were produced in some unusual way in the cells from which they were seen finally to emerge; but this is not the case. The eggs are deposited by the female in the ordinary manner, and are carefully placed by the male in the cells of her back, which close over them. When the young are ready to use their limbs they struggle out of the cells, to which they never afterwards return. The best-known species of pipa is that commonly called the Surinam toad (*P. surinamensis*), a native of Guiana and other warm parts of continental America, where it inhabits swamps and ditches, and is occasionally found in damp and dirty corners of houses. It is sometimes 7 in. long; its color is brownish-olive above, whitish below; the skin covered with small hard granules, mingled with occasional horny tubercles. The whole aspect of the creature is peculiarly hideous.

PIPE, a measure of quantity commonly employed in Portugal, Spain, France, and in some other countries which trade with these. It is used almost exclusively for wine and oil, and has a particular value for almost each locality. The pipe is called in England a butt, and is equal to two hogsheads, or half a tun. The pipe of Oporto is larger than those of Lisbon and of Spain in the proportion of 93 to 76. There are three different measures of this name in France; and there was formerly a pipe, a measure of capacity for dry goods, in use by the Bretons. But the pipe in England varies with the description of wine it contains: a pipe of port contains 114 imperial gallons; of sherry, 108 imperial gallons; and of madeira, 92 imperial gallons; while the common English pipe contains 126 wine gallons, or 105 imperial gallons nearly.

PIPE-CLAY is a fine clay (q. v.), free from iron and other impurities, having a grayish-white color, a greasy feel, and an earthy fracture. It adheres strongly to the tongue, and is very plastic, tenacious, and infusible. It is used for the manufacture of tobacco-pipes and white pottery. The localities where it is chiefly obtained are Devonshire, and the Trough of Poole in Dorsetshire. It is also found in various places in France, Belgium, and Germany.

PIPE-FISH, *Syngnathus*, a genus of osseous fishes of the order *lophobranchii* (q. v.), and of the family *syngnathidæ*. In this family the form is elongated, there is little flesh, and the body is almost covered with partially ossified plates; the head is long; the jaws are elongated so as to form a tubular snout—whence the name pipe-fish and *syngnathus* (Gr. *syn*, together, and *gnathos*, a jaw); and the males have pouches, variously situated, in which they receive the eggs of their mate, and carry them till they are hatched. The family *syngnathidæ* is sometimes restricted to those in which the egg-pouch of the males is on the tail, and is open throughout its whole length, and the tail is not prehensile. Thus restricted, it contains a number of genera, of which one only, *syngnathus*, is British.—One of the most common British species is the GREAT PIPE-FISH (*syngnathus acus*), which is sometimes found in deep water, and sometimes at low tide among the sea-weed in rock-pools. The specimens commonly seen are from 1 ft. to 16 in. in length; but this fish is said to attain a length of 2 or 3 feet. Its food, and that of the other species, is believed to consist of small marine animals and the eggs of fishes; and it may be seen slowly moving about, with curious contortions, poking its long snout into every crevice in search of food, and sometimes assuming a vertical position with the head downward, poking into or stirring the sand. This and the other pipe-fishes show great affection for their young, which are believed to return, on the appearance of danger, to the pouch of their male parent, after they have begun to leave it, and to swim about in the sea.

The name pipe-fish is sometimes also given to the fishes forming the family *fistularidæ* (q. v), or flute-mouths, sometimes called *pipe-mouths*.

PIPE LINES. See page 895.

PIPERA'CEÆ, a natural order of exogenous plants, natives almost exclusively of the hottest part of the globe, particularly of Asia and America. None of them found in cold regions. About 600 species are known, to most of which the name PEPPER is sometimes given, although some are also known by other names, particularly those of which the fruit is not used as a spice, but of which some part is employed for some other purpose, as betel, cubebs, matico, and ava. See these heads. But pepper (q. v.) is the most important product of the order. Of the piperaceæ, a few are almost trees; but they are generally shrubs or herbaceous plants, often climbing. They have jointed stems; opposite whorled or alternate leaves, with or without stipules, and insignificant greenish flowers in slender spikes, unisexual or hermaphrodite, the different kinds generally mingled in the same spike; the flowers without calyx or corolla, but each with a bract, the stamens 2 to 6, the ovary with one cell and one ovule, and crowned with one or three stigmas; the fruit somewhat succulent, containing one seed.

PIPERINE ($C_{34}H_{19}NO_6$) is an alkaloid possessing very weak basic properties, which is found in the pepper tribe. It may be obtained by heating powdered pepper with alcohol, which extracts the piperine and some resinous matter, which may be removed by digestion in a solution of potash. It occurs in colorless well-formed prisms, which are insoluble in cold water, but dissolve readily in alcohol and ether. According to Miller,

piperine "has an acrid taste, resembling that of pepper;" while Gorup-Besanez asserts that "it is devoid of odor or taste, and that, consequently, the well-known properties of pepper are not dependent on it." On heating piperine with soda-lime, a remarkable oily base, *piperidine* ($C_{10}H_{11}N$), is obtained, with a pungent odor, resembling both that of ammonia and pepper.

PIPES, or **TUBES**, are made of various materials and for various purposes. Thus, we have draining-pipes for agricultural and sanitary purposes, made of earthenware, wood, and metal; pipes of various kinds of metals for a great variety of purposes, and tobacco-pipes (q.v.) of various materials. Formerly, wooden pipes were extensively used for conveying water and for draining; but so great an improvement has been effected of late years in the manufacture of metal and earthenware pipes that they have now become exceedingly rare, and will soon disappear. For agricultural purposes, *drain-tiles* are made of ordinary brick-clay; and owing to the use of machinery in their manufacture, they are produced very rapidly and cheaply. They are of various sizes, but the most general is 15 in. in length by $2\frac{1}{2}$ in. diameter. The operation of the drain-tile machine is to squeeze a continuous length of soft plastic clay through a ring-shaped orifice, the center of which is occupied by a core or mandrel of the size of the hollow part of the pipe. Another arrangement of the machine is to cut the pipe to the proper lengths as it passes through, and by means of a traveling-table, to carry them forward to be removed to the sheds, where they are dried, previous to being burned in the kilns.

Earthenware pipes are now made of almost every size, from an inch or two in diameter up to the enormous size of 54 inches. They are usually made of fire-clay, and are glazed like common pottery. See the article POTTERY. They are wider at one end, so as to form a socket to receive the end of another, and thus form a continuous tube. These are greatly used for the drainage of houses, and for sewerage, for which they are admirably adapted: the inner surface being glazed as well as the outer, offers no resistance to sedimentary matters, which are consequently carried away readily. These pipes are of such great strength, that many small towns in England are now sewered with them almost entirely. Another kind has been introduced for chimney flues. They are also made of fire-clay, but unglazed externally, and so thick that there is little fear of breaking. They are placed one on another, and are built into the walls of houses, instead of the ordinary chimneys, and in this way save much labor in building, and afford a much more effective, and easily cleaned flue. *Caoutchouc vulcanized* and *gutta percha* are also extensively used for making pipes for a variety of purposes, their flexibility rendering them very useful. *Leathern pipes* are used chiefly for the conveyance of water temporarily, as in the case of fire-engines: they are generally called *hose*. Metal pipes are made of iron, lead, tin, or an alloy of tin and lead, copper, brass, etc. Iron pipes are usually cast, and the manufacture of such pipes has become of enormous extent, in consequence of the vast works, by which almost all large towns in this kingdom and in many foreign states are now supplied with water and gas, the pipes for which are largely exported from Great Britain. A great proportion of the trade in cast-iron pipes is carried on in Scotland. The water-works which supply the great towns of Lancashire have nearly all been furnished with pipes from Scotland; and the magnitude of the supply can be best understood when it is known that for the Rivington pike works, which supply Liverpool, upwards of 20 m. of iron pipes, nearly 4 ft. in diameter, are required. It would be impossible to make a correct estimate, but it has been stated, with great reason for belief, that in Great Britain the gas and water pipes laid and in use exceed half a million of miles in length.

Pipes made from the ductile metals, such as brass, copper, and tin, are made by first casting an ingot of the metal into the shape shown in fig. 1, with a hole through its length of the same diameter the bore of the pipe is intended to have. Into this is placed an iron rod, called the mandrel (*a*, fig. 2), which exactly fits, and which projects slightly at the tapered end (*b*, fig. 2). It is then brought to the drawing-table, and here the small end with its projecting mandrel is put into a funnel-shaped hole, drilled through a steel post (*a*, fig. 3), so as to allow the point to be gripped on the other side by a pair of

FIG. 1.

FIG. 2.

FIG. 3.

pincers, at the end of a strong chain; the machine-power is then applied to the other end of the chain, and the soft metal and its mandrel are drawn through, the former being extended equally over the surface of the latter, which is then removed, and the length of pipe is complete. Some metals require repeated drawing through holes, getting gradually smaller, and have to be softened or annealed at intervals, as the metal hardens under repeated drawing. In this way, brass, copper, tin, and pewter pipes are made; and

a patent has also been taken out for making steel ones; but lead pipes are made of great lengths by squeezing the soft metal through a hole in a steel plate in which there is a fixed

core or mandrel projecting, which forms and regulates the size of the bore of the pipe. Pipes are also made from copper, brass, and malleable iron by rolling out narrow strips of metal, and then passing them successively through rollers, which are deeply grooved, and which turn up the edges. A mandrel is then laid in it, and it is next passed through double-grooved rollers, which turn the edges in, and thus form a complete tube round the mandrel. The edges, however, require soldering or welding, if of iron. All boiler tubes used to be made in this way; but the method of drawing has lately been so much improved, that copper and brass pipes, or tubes, as they are frequently called, are now drawn of considerable thickness and diameter.

PIPE-STICKS. It is usual to call the wooden tubes used for some tobacco-pipes by this name; and unimportant as it may at first sight appear what the tube is made of, there is great difference of taste in this respect; and great care is taken by some smokers to get what they consider the choicest material. Perhaps the most prized are the agriot or cherry pipe-sticks of Austria. These are the young stems of the mahaleb cherry (*prunus mahaleb*), which is extensively grown for the purpose in the environs of Vienna. An astonishing amount of care is bestowed on the cultivation of these shrubs, which are all raised from seed. When the seedlings are two years old, they are each planted in a small pot, and as they continue to grow, every attempt at branching is stopped by removing the bud. As they increase in size from year to year, they are shifted to larger pots or boxes, and great care is taken to turn them round almost daily, so that every part is equally exposed to the sun. When they have attained a sufficient height, they are allowed to form a small bushy head, and continue to receive the same attention in daily turning, etc., until they are thick enough in the stem. They are then taken up, and the roots and branches removed, and the stem put by to season. Afterwards, they are bored through and are ready for use. These pipe-sticks have an agreeable odor, and are covered with a reddish-brown bark, which is retained. Sometimes they are 5 ft. in length, and as smooth and straight as if turned. When of such a length, they command high prices. In Hungary, pipe-sticks made from the stems of the mock orange (*Philadelphus coronarius*) are much used; and the jessamine sticks of Turkey are in great esteem in all countries. Orange and lemon trees and ebony are also used. The chief recommendation of these materials seems to be in the power of the wood to absorb the oil produced in smoking tobacco, and consequently to render the smoke less acrid. See TOBACCO-PIPES.

PIPESTONE, a co. in s.w. Minnesota, bordering on Dakota, drained by the Rock river and by the Big Sioux and its tributaries; 350 sq.m.; pop. '80, 2,092. The surface is mostly rolling prairie. It is noted for its quarry of red stone, from which the Indians made their pipes, and which was regarded by them as sacred. Co. seat, Pipestone.

PIPI, the name given to the ripe pods of *Cæsalpinia papai* (see CÆSALPINIA), which are used in tanning, and are not unfrequently imported along with dividivi (q.v.), and sometimes separately, but not to any considerable extent, being very inferior to dividivi. They are easily distinguished from the pods of dividivi, not being curved as they are, but straight.

PIPING CROW. See BARITAH.

PIP'IT, **TITLING**, or **TITLARK**, *Anthus*, a genus of birds included by Linnæus among larks (*alauda*); but now regarded as forming even a distinct family, *anthidæ*, which is ranked among the *dentirostres*, whilst the lark family (*alaudidæ*) is ranked among the *conirostres*. The bill is more slender than in larks; the tips of the mandibles slightly bent downwards and notched. The hind-claw is long, although not so long as in larks, and more or less curved. The plumage resembles that of larks; in habits and motion of the tail, there is a greater resemblance to wagtails. The bill is not strong enough for feeding on grain or hard seeds, and insects and worms are the principal food of pipits. The most common British species is the MEADOW PIPIT, COMMON TITLARK, or TITLING (*A. pratensis*), familiarly known in many parts of England and of Scotland as the *moss-cheeper*. It is found in almost all parts of Europe, and the n. of Asia, in western India, in Japan, and in Iceland. It is a small bird, its color brown of various shades. It frequents heaths, mosses, and pastures; and usually makes its nest on a grassy bank, or beside a tuft of grass or heath. Its song is weak and plaintive, and it generally sings in the air. It is gregarious in winter. The cuckoo is said to deposit its eggs more frequently in the nest of the meadow pipit than in that of any other British bird.—A rather larger British species is the TREE PIPIT, or FIELD TITLING, which has a shorter claw, and perches on trees, frequenting inclosed and wooded districts. It is a summer visitant of Britain, and most common in the s. of England. It occurs in most parts of Europe, in Asia, and the n. of Africa.—The rock pipit, or SEA TITLING (*A. petrosus*), is to be found on the shores of all parts of Britain and Ireland. It is rather larger than the tree pipit, and has a long curved hind-claw. It feeds chiefly on small marine animals, seeking its food close to the edge of the retiring tide.

PIPPI. See GIULIO PIPPI, *ante*.

PIPPIN (so called probably because raised from the *pip*, or seed), a name given to many varieties of apple, among which are some of the finest in cultivation, as the *Golden Pippin*, *Ribston Pippin*, etc. The ribston pippin was long supposed to be an originally

English variety, produced at Ribston hall in Yorkshire, but it is proved to have been introduced from Normandy in the beginning of the 18th century.

PIPSISCEWA. See WINTERGREEN, *ante*.

PIQUA, a city in Miami co., Ohio; on the w. bank of the Miami river, on the Miami and Erie canal, and the Cincinnati, Hamilton and Dayton, and the Pittsburg, Cincinnati, and St. Louis railroads; 88 m. n. of Cincinnati, 73 m. w. of Columbus; pop. '80, 6,031. It is situated on a large plain, has broad streets lighted with gas, and has a fine trade from the surrounding country, which is very fertile, the products of which are mostly shipped from this point. The river is here spanned by three bridges; the place is supplied with water-power by the river and canal, and contains various manufactories, schools, churches, a town hall, and banks.

PIQUET, a game of cards played between two persons with 32 cards—viz., the four honors, and the highest four plain cards of each suit. The cards are shuffled and cut as in whist, and then dealt, two by two, till each player has 12; and the remaining 8, called the *talon*, or stock, are then laid on the table. The first player must then discard from one to five of his cards, replacing them with a similar number from the talon; and after him, the younger hand may discard if he pleases, similarly making up his proper number from the remaining cards of the talon. The player who first scores 100 wins the game, and the score is made up by reckoning in the following order—*carte-blanche*, the point, the sequence, the quatorze, the cards, and the capot. *Carte-blanche* is a hand of 12 plain cards, and counts 10 for the player who possesses it. The *point* is the greater number of cards in any suit, or, if the players are equal in this respect, that which is highest in value (the ace counting eleven, each court-card 10, and the plain cards according to the number of pips), and counts a number equal to the number of cards in the suit. The *sequence* is a regular succession of three or more cards in one suit, and the highest sequence (i.e., the one containing the greatest number of cards, or if the players have sequences equal in this respect, the one of the two which begins with the highest card), if of three cards, counts three; of four cards, four; of five cards, fifteen; of six cards, sixteen, etc. The *quatorze* is a set of four equal cards (not lower than tens), as four aces, four queens, etc., and the highest quatorze counts 14 for its holder; but should neither player have a quatorze, then the highest set of three is counted instead, but it reckons only three. The possessor of the highest sequence or the highest quatorze also counts all inferior sequences and quatorzes (including sets of three): while his opponent's sequences and quatorzes go for nothing. The first player reckons his points, and plays a card; the dealer then reckons his points, and follows his opponent's lead, and cards are laid and tricks are taken as in an ordinary card-game. Each player counts one for every card he leads, and the taker of the trick (if second player) counts one for it: the possessor of the greater number of tricks counting 10 in addition (the "cards"), or if he takes all the tricks, he counts 40 in addition (the "capot"). If one player counts 30—i.e., 29 by his various points, and 1 for the card he leads, before his adversary has counted anything, he at once doubles his score, reckoning 60 instead of 30 (this is called the "pique"); and should his score reach thirty before he plays a card, or his adversary begins to count, he mounts at once to 90 (the "re-pique").

PIQUÉ WORK, a very fine kind of inlaying with gold, silver, and other costly materials; it is, in fact, a kind of buhl-work (q.v.), carried out on a very minute scale. It is only applied to articles of small size, such as snuff-boxes, card-cases, and similar articles.

PIRANE'SI, GIOVANNI BATTISTA, 1720-78, b. Italy; studied architecture at Rome. In 1741 he brought out a work on triumphal arches and other antique architectural remains. The engravings in this work gave him a high reputation. He produced, in less than 40 years, nearly 2,000 engravings. His most important works are *Architectura Romana*; *Campus Martius*; a collection of *Ancient Statues and Busts*; and *Antiquities of Herculaneum and Pompeii*. Piranesi drew his subject upon the plate itself, and completed it by etching in aqua fortis.

PIRACY is robbery on the high seas, and is an offense against the law of nations. It is a crime not against any particular state, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas. It is of the essence of piracy that the pirate has no commission from a foreign state, or from one belligerent state at war with another. Pirates being the common enemies of all mankind, and all nations having an equal interest in their apprehension and punishment, they may be lawfully captured on the high seas by the armed vessels of any particular state, and brought with its territorial jurisdiction for trial in its tribunals. The African slave-trade was not considered piracy by the law of nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and since the treaty of 1841 with Great Britain, it is also declared to be so by Austria, Prussia, and Russia.

PIRÆUS (Gr. *Peiræus*), the principal harbor both of ancient and modern Athens (q.v.). Only a few traces remain of the long walls which formerly united it and Munychia with the capital city. The modern Piræus, which has sprung up since 1835, is a regularly laid-out town, with some good houses and shops, and a handsome stone exchange,

built at the expense of the municipality. It was in 1869 connected with Athens by a railway, and it has several spinning factories of recent construction. The harbor, called also Porto Leone or Drakoni, is both safe and deep; but the entrance is narrow. In 1871, the number of vessels which entered the Piræus was 6,206, with a tonnage of 294,338 tons. Pop. '79, 21,055.

PIRANO, a sea-port of Austria, in the market-grafdom of Istria, stands on a peninsula in the bay of Largonè, 15 m. s.w. of Trieste. It contains an old castle, has a port and several dock-yards, commodious roads, in which large vessels find safe anchorage, and is the seat of considerable trade and commerce. Among its more important edifices are an interesting Gothic church, a town-house, and a minorite convent, with a number of good pictures. Wine and oil are made in considerable quantities, and there are salt-works in the neighborhood, which produce upward of 330,000 cwts. of salt annually. Pop. 7,387.

PIRON, ALEXIS, 1689-1773; b. France; studied law at Besançon, but was unable to support himself in that profession. Going to Paris in 1719, he became secretary to Belle-Isle, the grandson of Fouquet. He soon began writing for the stage, and produced comedies and tragedies. Few of the latter have much merit. His best work is his comedy *La Métromaine*, which appeared in 1738. He was chosen a member of the academy in 1753, but the royal sanction was refused on account of a licentious ode which he had written in his 20th year. On this occasion Piron proposed this epitaph for himself:

*Ci-git Piron, qui ne fut rien,
Pas même académicien.*

PIRAYA, or PIRAI, the name given in Guiana to *serrasalmo piraya*, and other species of *serrasalmo*, a genus of fishes of the family *characinidæ*, regarded by many as a section of *salmonidæ* (q.v.). The fishes of this genus, of which numerous species inhabit the rivers and other fresh waters of tropical South America, have a compressed and deep body, the belly keeled and serrated with a double row of hard serratures. They are extremely voracious fishes, and not only consume with great rapidity dead carcasses thrown into the water, but attack living creatures very much larger than themselves, biting off the fins of large fishes, and then devouring them at leisure, often mutilating ducks and geese by depriving them of their feet, and venturing to attack even oxen and human beings. The latter, however, make reprisals on them, and find them very good food. *Serrasalmo piraya* seldom exceed 10 or 12 in. in length, but some of the species attain a considerably larger size. Some of them are very brilliantly colored. The Indians use the teeth for sharpening the arrows, made of the very hard ribs of palm-leaves, which they use for their blow-pipes, and which they sharpen to a very fine point by drawing them across a piraya's jaw, an article with which the Indian of Guiana is always provided; nor does the edge of the the soon begin to be worn. Pirayas are readily taken by a baited hook, and almost any kind of bait will do; but they at once cut through any line, and the line must therefore be cased above the hook in tin-plate. The Indians often shoot them with arrows.

PIRMASENS, a t. of the Bavarian palatinate, and formerly the chief t. of the county of Hanau-Lichtenberg, 22 m. w. of Landau. In 1880 it had 12,039 inhabitants; chief manufactures, shoes and musical instruments.

PIRNA, a small t. of Saxony, stands on the left bank of the Elbe, 11 m. by railway s.e. of Dresden. It is surmounted by a hill, crowned by a castle, now used as a lunatic asylum, contains a beautiful parish church, and a number of important benevolent institutions. The manufacture of stoneware employs many hands. Pop. '80, 11,680.

PISA, a province of Italy, bounded on the n. by the province of Lucca, on the e. by that of Firenze, on the s. by that of Siena, and on the w. by the Mediterranean; drained by the Arno, Serchio, Cecina, and Era; intersected by railroads running to Leghorn, Florence, and Lucca; 1177 sq.m.; pop. '81, 281,269. The surface is varied, crossed in the central and n. parts by branches of the Apennines, and swampy in some other parts. The n. part is a wide plain, on which the city of Pisa is built. Corn, wine, fruits, flax, silk, and hemp are the chief products. Capital, Pisa.

PI'SA, one of the oldest and most beautiful cities of Italy, capital of the province of the same name, which formed part of the late grand duchy of Tuscany is situated on the banks of the river Arno, which intersects the city and is spanned by three noble bridges. Pisa is situated in 43° 43' n. lat., and 11° 24' e. long. The population was, in 1881, 53,957. It has broad, straight, well-paved streets, and several fine squares. Among its 80 churches, the most worthy of notice is the cathedral, or Duomo, begun in 1068, and completed in 1118, with its noble dome, supported by 74 pillars, and its fine paintings, variegated marbles, and painted windows. Near the cathedral stands the round marble belfry known as the leaning tower of Pisa, from the circumstance that it deviates about 14 ft. from the perpendicular. This celebrated building, which is 180 ft. in height, and consists of seven stories divided by rows of columns, and surmounted by a flat roof and an open gallery commanding a splendid view of the surrounding country, was erected in the 12th c. by the German architect Wilhelm of Innsbruck. The baptistery, or church of St. John, opposite the cathedral, an almost equally remarkable structure,

was completed in 1162 by Diotisalvi. The main building, which is circular, and raised on several steps, supports a leaden-roofed dome, having a second dome above it, surmounted by a statue of St. John. The beautifully proportioned interior, noted for its wonderful echo, contains a pulpit, which ranks as the greatest masterpiece of Nicola Pisano, various pieces of sculpture, and a large octagonal marble font. The Campo-Santo, or ancient national cemetery, dates from the year 1228, when the Pisans caused earth to be brought from Jerusalem for the graves of the most distinguished citizens of the republic. In 1283, the ground was surrounded by cloisters, the walls of which were adorned by fresco-paintings, now nearly obliterated, although some of these works of art, which are chiefly by Giotto, Veneziano, Orcagni, and Memmi, still retain traces of their original beauty. Among the other public buildings of Pisa, special notice is due to the churches of La Madonna della Spina and San Stefano, both rich in paintings and sculptures, and the latter famous for its organ, the largest in Italy; the grand ducal and Lanfranchi palaces; the Torre della Fame, so called from its being supposed to have been supposed the spot in which Ugolino Gherardesca and his children were starved to death in 1288; the university, founded in 1330, and restored by Cosmo I. de' Medici, which enjoyed a high reputation in the middle ages, and still possesses claims to consideration in its library, botanical garden, observatory, and affiliated schools and art collections, etc. The population of Pisa, which, in the 13th c., amounted to 150,000, had fallen, in the present c., to less than one-sixth of that number; but of late years, trade and industrial arts have made a rapid advance, and the population has increased in proportion. In the neighborhood of Pisa, at the foot of San Giuliano, lie the mineral baths, whose fame was known to Pliny, and which continued through the middle ages to attract sufferers from every part of Italy. The waters, which are rich in carbonic acid and chloride of sodium, are found efficacious in various arthritic and rheumatic affections.

History.—Ancient Pisa, like other Etruscan cities subject to Rome, retained its municipal government, and enjoyed an almost unlimited freedom while nominally under Roman protection; but, on the decline of the imperial power, it was compelled to submit in turn to the various transalpine nations who successively overran northern Italy. Early in the 11th c., Pisa had risen to the rank of a powerful republic, whose sway included the then fertile district known as the Maremma di Lerici, and which yielded little more than nominal homage to its suzerain lords, the emperors of Germany. Throughout the 11th c. Pisa was at the height of its prosperity, and to this period belong most of the splendid monuments of art that still adorn the city. Its troops took part in all the great events of the Holy Land; and its fleet in turn gave aid to the pope in southern Italy, to the emperor in northern France, chastised the Moors, and exacted its own terms from the eastern emperors. In their wars with the Saracens of Sardinia, the Pisans had conquered Sardinia, Corsica, and the Balearic islands, and for a time maintained their ground against their hereditary enemies, the Genoese; but having sided with the Ghibellines in the long wars which desolated the empire, Pisa suffered severely at the hands of the victorious Guelphic party. Indeed, the rivalry of the Guelphic cities of Florence, Lucca, and Sienna nearly brought Pisa to the brink of ruin at the close of the 13th c.; and after struggling for more than a hundred years against external foes and the internal dissensions between the democratic mob and the Ghibelline nobles, without losing their character for indomitable valor, the Pisans finally threw themselves under the protection of Galeazzo, visconti of Milan. The son of the latter sold the Pisan territory to their greatest enemies, the Florentines, from whose tyrannical rule it was for a time relieved by Charles VIII. of France, who, in 1494, accepted the protectorate of the city. When the French left Italy, the old struggle was renewed; and after a desperate resistance, the Pisans, in 1509, were compelled by hunger to surrender to the Florentine army. The most influential families, as formerly in 1406, emigrated. Pisa, with the rest of Tuscany, became part of the kingdom of Italy in 1860. Since 1868 Pisa has given its name to an Italian province, containing a population of, '81, 283,269.

PISA, COUNCIL OF, one of the councils commonly reputed by Roman Catholics as ecumenical or general, although some, especially of the ultramontane (q.v.) school do not look upon it as such. It was assembled in the time of the great western schism, for the purpose of restoring the peace of the church, and the unity which had been interrupted by the rival claims of two competitors for the papacy. The history of this rival claim will be found under the head **SCHISM, WESTERN**. For our present purpose, it is enough to state that the adherents of both the claimants of the see of Rome—those of Gregory XII., as well as those of Benedict—agreed on the necessity of a general council, as the only means of putting an end to the schism; and the rival popes having themselves either evaded or declined the demand, the cardinals of both united in issuing letters of convocation, and in summoning both the claimants to the council so convened. Neither of them complied with the citation; but the council proceeded, nevertheless, to examine and deliberate upon the cause. It was opened at Pisa, Mar. 25, 1409, there being present 22 cardinals, 4 patriarchs, 12 archbishops, 80 bishops, together with representatives of 12 archbishops and 102 bishops, and a vast body of abbots, doctors in theology, and other eminent ecclesiastics. Of the proceedings, it will be enough to say, that after a formal citation of the rival popes to appear within a

stated period, the council, on the expiration of that period, proceeded to declare them contumacious, and to examine their respective claims as though they had appeared. The result, after a protracted inquiry, was a decree in the 13th session by which they were both declared schismatics, and their conduct heretical, and calculated to lead the people from the faith; wherefore, since they had violated the solemn engagements made at their respective elections, they were deposed from the papal dignity, and their followers released from obedience. In the 17th session, the cardinals having first pledged themselves by oath, each, that, if elected, he would continue the sittings of the council, entered into conclave to the number of 24, and unanimously elected Peter Philargi, one of the cardinal priests, and a member of the Franciscan order. He took the name of Alexander V. The council proceeded after his election to pass a number of decrees, for the purpose of giving validity to the acts done on either side during the schism. A vain attempt was made to obtain the submission of the still recusant rivals, and it was resolved that a new council should be held within three years. The authority of this council, like that of the council of Constance, is alleged, on the Gallican side, as establishing the superiority of a general council over the pope. But the ultramontanes reply that both these councils, and also that of Basel, must be regarded as abnormal assemblies, called to meet the special emergency of a disputed succession and of a doubtful pope, and that these principles cannot by any means be applied to the ordinary circumstances of the church, or form a precedent by which to estimate the normal relations between a pope whose title is certain and undisputed, and a general council regularly assembled at a time of peace, and in the ordinary circumstances of the church. It cannot be doubted, nevertheless, that the spirit of the fathers of Pisa was the same which ran through the succeeding assemblies of Constance and Basel, and found its permanent representation in the Gallicanism (see GALLICAN CHURCH) of later centuries.

PISA'NO, ANDREA. See **ANDREA PISANO.**

PISA'NO, GIOVANNI, 1240-1320; b. Italy; studied with his father Nicola. The fountain near the Perugia cathedral, the church of Santa Maria della Spina, and the Campo Santo at Pisa, and the Neapolitan Castel Nuovo, after which the Paris Bastille was modeled, are his work. He was engaged on the design of the Campo Santo 1278-83. He imitated, or was associated with his father in some of his works. His finest sculptures are the mausoleums which he built for some of the popes, and the shrine for the high altar of the Arezzo cathedral. He is not to be confounded with Donatello's pupil of the same name.

PISANO, NICOLA, 1200-78; studied the antique sculptures, and began the renaissance in Italian statuary. His finest sculptures are the pulpit for the cathedral of Sienna, the pulpit in the baptistery of Pisa, and the marble urn of St. Dominic at Bologna. In architecture he designed the Frari church at Venice, the Santa Trinità at Florence, the basilica of St. Anthony at Padua, and the campanile for the church of San Nicola at Pisa.

PISCATAQUA, a river about 80 m. in length, which forms the southern part of the boundary between Maine and New Hampshire, United States, and empties itself into the Atlantic, forming at its mouth the excellent harbor of Portsmouth.

PISCATAQUIS, a co. in n.e. Maine, intersected by the Bangor and Piscataquis railroad, and drained by the Penobscot and Piscataquis rivers and their branches; 378 sq. m.; pop. '80, 14,873. The northern portion is a vast forest; the southern portion contains fertile lands, and is extensively settled. The surface is generally hilly, and in some parts mountainous, abounding in lakes, the largest of which are Moosehead and Chesuncook. Mount Katahdin, 5,835 ft. high, stands near the center of the county, and is the highest point in the state. The principal products are grain, cattle, wool, cheese, and butter. It contains 22 saw-mills, manufactories of carriages, leather, harness, and woolen goods. Co. seat, Dover.

PISCICULTURE, or **FISH-CULTURE**, the breeding and rearing of fishes, in order to the increase of the supply for food. Hitherto it has been almost entirely limited to fresh-water fishes; nothing having been done as to sea-fishes but by legislation—chiefly in the case of the herring—to prevent the destruction of the very young fish, and that not, apparently, to much advantage. Ponds for sea-fishes have, indeed, been sometimes constructed, advantage being taken of natural circumstances favorable for the purpose. The ancient Romans had such ponds, and some have been made on different parts of the British coast, fishes being caught in the open sea and placed in them to be fed and fattened for the table. Such ponds, however, are of little real utility. That the Romans succeeded in keeping sea-fishes in fresh-water ponds, as has been asserted, must be regarded as mere fable, or as an exaggeration, founded on the power which a few fishes have of adapting themselves both to fresh and salt water. But it may be doubted if in modern times sufficient advantage has been taken of this power.

Ponds for fresh-water fishes have been common from a very remote antiquity. It appears from Isaiah, xix. 10, that they were used in ancient Egypt. In the times of Roman luxury almost every wealthy citizen had fish-ponds. The Chinese have long bestowed more attention on pisciculture than any other nation, and with them it is truly

a branch of economy, tending to the increase of the supply of food and of the national wealth; not merely, as it seems to have been among the Romans, an appliance of the luxury of the great. In some countries of modern Europe this branch of pisciculture is also prosecuted to a very considerable extent, particularly in Germany and Sweden, and of late years in France, in order to the supply of fish for the market. In Britain it has never been systematically prosecuted, or for any important purpose; the country-seats of the nobility and gentry being, indeed, generally provided with fish-ponds, but in most cases rather as ornamental waters than for use. In the northern parts of Britain trout, perch, and pike are almost the only fish kept in ponds; in England they are often stocked with carp and tench, and are turned to much better account than in Scotland. In Germany, ponds carefully attended to are found very productive and remunerative. There can be no doubt that in Britain, also, many a piece of land at present very worthless, might easily be converted into a pond, and made to yield large quantities of excellent fish.

In the construction of ponds, or *stews*, for fish, it is recommended to have, if possible, a succession of three ponds on the same rivulet, with sluices, by which they can be dried, so that the fish may be easily taken when required, the different ponds being in part intended for fish of different ages. But all this must be very much regulated by local circumstances. It is of more importance to note that the margins should be shallow, so that there may be abundance of reeds and other water plants, and that only a small part of the pond should be too deep for the growth of pond-weeds (*potamogeton*). Much depends upon the soil of the neighborhood as to the supply of food, and consequently the growth of fish and productiveness of the pond. A stony bottom is very advantageous to perch and trout ponds; and in designing these, care should be taken to provide places of shelter for the fish, more especially if the pond be a shallow one, as trout and perch are easily killed by the glare of the sunshine. Ponds for pike must be larger than is necessary for any other fish known to British pisciculture; an extent of at least six acres is desirable. A nursery for minnows may be established with great advantage in connection with a fish-pond, as they afford most acceptable food to perch, pike, and trout. But in a pond where carp and tench are expected to spawn, the presence of minnows is very undesirable. It is often impossible to provide a pond with a place suitable for the spawning of trout, for which a gravelly stream with a quick current is necessary; but for perch, pike, carp, or tench, the pond itself is sufficient, and the stock, once introduced, is kept up without replenishing. Indeed, it is recommended that a pond stocked with carp should also be stocked with pike, that the excessive multiplication of the carp may be checked, which would otherwise prevent the fish from growing rapidly or to a good size. Private ponds and stews in which country gentlemen breed fish for the use of their own tables, as well as similar places attached to monasteries and other religious edifices, in which fish were grown for fast-day uses, were at one time common enough throughout Great Britain and Ireland. It is probable that some of our rarest fishes were introduced into this country during the old monastic times, such as the Lochleven trout, the vendace, etc.

The greatest improvement in pisciculture, and a most important branch of it, to which the term is often restricted, is the breeding of fish in artificial breeding places, from which not only ponds, but rivers, may be stocked; or the art of fecundating and hatching fish-eggs, and feeding and protecting the young animals till they are of an age to secure their own food and protect themselves from their numerous enemies.

Modern pisciculture is the revival of an old art well known to the ancient Italians, but which had fallen into abeyance for a number of centuries. The art of breeding and fattening fish was practiced by the luxurious Romans, and many stories are told about the fanciful flavors which were imparted to such pet fishes as were chosen for the sumptuous banquets of Lucullus, Sergius Orata, and others. The art had doubtless been borrowed from the ingenious Chinese, who are understood to have practiced the art of collecting fish-eggs and nursing young fish from a very early period. Fish forms to the Chinese a most important article of diet; and, from the extent of the water-territory of China, and the quantities that can be cultivated, it is very cheap. The plan adopted for procuring fish-eggs in China is to skim off the impregnated ova from the surface of the great rivers at the spawning-season, which are sold for the purpose of being hatched in canals, paddy-fields, etc.; and all that is necessary to insure a large growth of fish is simply to throw into the water a few yolks of eggs, by which means an incredible quantity of the young fry is saved from destruction, as a large percentage of the young of all fish die for want of food. Although all kinds of fish are enormously fecund, it is well known to naturalists that only a small percentage of the eggs ever come to life, and of the young fish, very few ever reach the table as food. So many of the eggs are destroyed by various influences, and so many likewise escape impregnation, that if we are to keep up our fish supplies, pisciculture, or protected breeding, becomes absolutely necessary.

Commercial pisciculture, as at present carried on, owes its origin to the French, the art having been first put in practice by M. Remy, a poor fisherman who gained a living by catching fish in the streams of La Bresse in the Vosges. This re-discovery of the lost art of fish-breeding is understood to have been quite accidental on the part of Remy, although it is thought by some zealous Scotsmen that the Frenchman must have heard of the experiments of Mr. Shaw of Drumlanrig, who, for a few years previous to

Remy's discovery, had been trying to solve some problems in the natural history of the salmon by means of the artificial system. The art had also been partially revived in Germany about the middle of last century by a gentleman of the name of Jacobi, who practiced the artificial breeding of trout. Whether or not Remy had heard of either of these experimenters, it is certain that to him we owe the revival of the art in its larger or commercial sense; the others only used it as an adjunct to their study of the natural history of fishes.

It was the great waste of eggs incidental to the natural system of fish-breeding that led Remy, about 1842, in conjunction with Gehin, a coadjutor whom he assumed as a partner, to try what he could do in the way of re-peopleing the fish-streams of his native district. His plan being at once successful, attracted the favorable notice of many of the French *savans*, and led to rewards and preferment for Remy; the new art was besides taken under the protection of the government. At Huningue, in Alsace, on the Rhine, a gigantic fish-nursery and egg-dépôt for the supply of eggs, and the dissemination of the art, was erected some years ago. Since the cession of Alsace to Germany, the operations of the establishment at Huningue (now known as Hüningen) have been conducted on a still larger scale by a German association.

The course of business at Huningue is as follows: The eggs are chiefly brought from the streams of Switzerland and Germany, and embrace those of the common trout, as well as the Rhine and Danube salmon, and the tender charr or ombre chevalier. People are appointed to capture gravid fish of these various kinds, and having done so, to communicate the fact to Huningue. An expert is at once sent to deprive these fishes of their spawn, and bring it to the breeding or resting-boxes, where it is carefully tended till it is ready to be dispatched to some district in want of it. It is, of course, much more convenient to send the eggs than the young fish, as the former, nicely packed among wet moss in little boxes, can be carried to a distance with greater facility. The mode of artificially spawning a salmon is as follows: It should, of course, be ascertained that the spawn is in a perfectly matured state, and that being the case, the salmon is held under water in a large tub, while the hand is gently passed along its abdomen, when, if the ova be ripe, the eggs will flow out like so many peas. The eggs are then carefully washed, and the water is poured off. The male salmon is then handled in a similar way, when the contact of the milt immediately changes the eggs into a brilliant pink color. After being again washed, they may be ladled out into the breeding-boxes, and left to come to life in due season. The period occupied in hatching is different in different climates. At Stormontfield, where the eggs have no shelter, the usual period is about 135 days; but salmon ova have been known to burst in about half that period, and to yield very healthy fish. Great care is of course necessary in handling the ova. The eggs manipulated at Huningue are all carefully examined on their arrival, when the bad ones are thrown out, and those that are good are counted and entered in a record. The ova are watched with great care, and from day to day all that become addled are removed. The applications for eggs, both from individuals and associations, are always a great deal more numerous than can be supplied; and before second applications can be entertained, it is necessary for the parties to give a detailed account of how their former efforts succeeded. It may be interesting to note, as regards the cost of pisciculture at Huningue, that the most expensive fish is the ombre chevalier. Of some species, as many as 60 or 70 per cent of the eggs are lost. The general calculation, however, is 12 living fish for a penny.

The most sustained effort in British pisciculture has been in connection with the salmon-fisheries of the river Tay. At Stormontfield, near Perth, a series of ponds has been constructed, and a range of breeding-boxes laid down capable of receiving 500,000 eggs. The operations at Stormontfield were begun in 1853, and are still continued. But for years a comparatively small number of fish have been hatched, and probably not 20,000 have for some time past been annually turned out of the ponds there. The annual rental is very high. At several other places in Scotland, the artificial system has been introduced as an adjunct to the natural breeding resources of different rivers. The art of pisciculture was also introduced into Ireland, at the fisheries of Loughs Mask and Carra, by the late Mr. Ashworth, who for a time obtained excellent practical results. These lochs contain an area of water equal to 35,000 acres; and, a communication with the sea having been opened, they now teem with salmon. Several attempts have been made to introduce British fishes into the rivers of Australia, which, in the case of trout, carp, tench, and perch, have been quite successful; but in that of salmon greater difficulty has been experienced. Sir James G. Maitland has erected an extensive fish-rearing establishment near Stirling, England. Each of the hatching boxes contains about 18,000 eggs, which, in addition to the tanks, give a product of 4,000,000 eggs each season. There are nine large ponds, and many smaller ones, each filled with a particular variety of fish.

Pisciculture is largely practiced in America, both by private persons and under the auspices of a commissioner, Mr. Spencer F. Baird, who acts on behalf of the government. Eggs are collected for distribution in the seas and rivers of the United States in enormous quantities, and are transported hither and thither to and from all parts of the country. As one example of what has been lately accomplished, it may be stated on the authority of a recent report to the house of representatives, that the number of eggs of the Californian salmon collected during the season of 1875 at the United States pisci-

cultural establishment on the upper Sacramento, amounted to about 11,000,000, making a bulk of eighty bushels, and weighing with their packing gear nearly ten tons. In the years 1874 and 1875, a total of 26,137,855 eggs of shad and various kinds of salmon were distributed by the U.S. fish commission; and altogether 40,000,000 of fish eggs were handled by the fishery officers of the states during the three years ending in 1875.

In recent years in parts of France, efforts have been made to increase the supply of oysters by means of artificial cultivation. Oysters were cultivated in Italy during the classic ages; but the art of cultivating them seems to have been lost till it was accidentally re-discovered by an artisan of the Ile de Ré, who found out that the chief point in artificial oyster-culture is to insure a supply of spat. The seed of the oyster is too often carried away from the place of its birth by adverse winds acting on the waves, and thus it sometimes falls on an unpropitious growing-place. The spat of the oyster must have a "coign of vantage" to which to cling; if it falls on a muddy bottom it is lost forever. On the foreshores of the Ile de Ré, there are countless oyster-beds of the most simple description, in which the spat is reared and tended during its period of growth. All that is required for a good bottom to an oyster-bed is a rocky surface, which, if not found naturally, can be easily constructed by the laying down of stones and tiles. Oyster-culture, in simple form, has been practiced at Whitstable, on the coast of Kent, for a long period, and the famous "native" oysters are fed on ground at that place. Other experiments are in course of being made, and on some parts of the English coast artificial *parcs* have been laid out on the French plan, in which plentiful supplies of oysters have been grown to maturity. The great difficulty in all experiments connected with oyster-culture is to find the requisite supply of spat from which to rear the mature animal.

Pisciculture is now being practiced to some extent in several countries of Europe, and has been deemed of sufficient importance to demand the attention of governments. It is probable that the attention turned to the whole subject of pisciculture, and the example of the transportation of salmon to Australia, may lead to the introduction of valuable kinds of fishes into waters where they are now unknown. The grayling has thus already been introduced into the Clyde and Tweed. There is no apparent reason why every valuable fresh-water fish of Europe should not be plentiful in Britain.

PISCINA, the large basin (or *pond*) in the Roman thermæ, containing tepid water, in which the bathers might swim.

PISCINA, a shallow stone basin with a drain (usually leading directly to the earth), in Roman Catholic churches, in which the priest washes his hands, and for rinsing the chalice at the celebration of the mass. In England, it is almost invariably placed on the s. side of the choir, at a convenient height.

PISE, a kind of work used instead of brick, etc., for the walls of cottages. It consists of loam or earth hard rammed into framing, which, when dry, forms a wall.

PISE, CHARLES CONSTANTINE, D.D., 1802-66, b. Md.; graduated at Georgetown (D. C.) college, became a member of the society of Jesus, which he left two years later on the death of his father, who was an Italian. He studied in Rome, receiving the degree of D.D., and knighthood, and on his return taught rhetoric in the college of Emmetsburg. In 1825 he was ordained priest in the Roman Catholic church, and called to the cathedral of Baltimore; afterwards he ministered at St. Patrick's, Washington, and was chaplain of the senate; was assistant pastor of St. Peter's, New York; and in 1849 was appointed to St. Charles Borromeo, Brooklyn, where he remained till his death. He published *History of the Church*, 1827; *Father Rowland*, his finest work, 1829; *Aletheia, or Letters on the Truth of the Catholic Doctrines*, 1843; *St. Ignatius and his First Companions*, 1845; and *Christianity and the Church*, 1850.

PISEK (Boh. *Piscek*, sand), a small t. of Bohemia, on the right bank of the Wottawa, an affluent of the Moldau, stands on a sandy plain (from which circumstance it probably received its name) 55 m. s.s.w. of Prague. The town is old, and contains the remains of a royal castle. Among other institutions are a school of arts and a high school. The manufactures are woolen and cotton fabrics, iron wire, and musical instruments. Pop. '80, 10,545.

PISGAH, a range of the mountains of Abarim, of which mount Nebo was the highest; or, as some suppose, the top of mount Nebo itself, from which Moses beheld the promised land, and where he died. It was in the land of Moab, at the n.e. angle of the Dead sea, near Jericho. The view obtained by Moses included "all the land of Gilead unto Dan; all Naphtali; the land of Ephraim, and Manasseh; all the land of Judah unto the utmost sea; the s., and the plain of the valley of Jericho—the city of palm-trees—unto Zoar." Tristram in *Land of Israel* beautifully describes the view which he and his party had, during a clear day, from a spot at, or near, which Moses probably stood. The elevation was about 4,500 ft., yet the ascent was not difficult.

PISID'IA, an ancient division of Asia Minor, bounded on the n. by Phrygia, on the e. and n.e. by Cilicia and Isauria, on the s. by Pamphylia, and on the s.w., and w. by Lycia and Phrygia. It belongs to the modern Turkish vilayet of Konieh. It was drained by the Catarrhactes, Cestus, and other streams emptying into the gulf of Pamphylia. The principal towns were Selge and Antiochia. The wines of Amblada were celebrated,

and salt and olives were chief productions. It was made a separate province by Constantine. Its inhabitants were mountaineers, and never submitted to the Romans.

PISIS'TRATUS (Gr. *Peisistratos*), a famous "tyrant" of Athens, belonged to a family of Attica, which claimed descent from Pylian Nestor, and was b. towards the close of the 7th c. B.C.—certainly not later than 612. His father's name was Hippocrates, and through his mother he was pretty closely related to the great lawgiver, Solon, between whom and Pisistratus a very intimate friendship long existed. He received an excellent education; and the charm of his manners, as well as the generosity of his spirit was so great that (according to Solon) had he not been ambitious, he would have been the best of Athenians; but his passion for the exercise of sovereign power led him to adopt a policy of artifice and dissimulation, for the purpose of attaining his ends, which prevents us from regarding him with the admiration that the beneficent character of his government might seem to demand. At first, Pisistratus co-operated with his kinsman Solon, and in the war against the Megarians, acquired considerable military distinction; but afterwards, when probably his ambitious views had become more matured, he came forward as the leader of one of the three parties into which Attica was then divided. These were, the *Pediæi* (party of the plain), or the landed proprietors; the *Parali* (party of the seaboard), or wealthy merchant classes; and the *Diacrii* (party of the Highlands), chiefly a laboring population, jealous of the rich, and eager for equality of political privileges. It was to the last of these that Pisistratus attached himself; but indeed he assiduously cultivated the good-will of all the poorer citizens, to whom he showed himself a most liberal benefactor. At last Pisistratus took a decided step. Driving into the marketplace of Athens one day, and exhibiting certain self-inflicted wounds, he called upon the people to protect him against his and their enemies, alleging that he had been attacked on account of his patriotism. Solon, who was present, accused him of hypocrisy; but the crowd were, according to Plutarch, ready to take up arms for their favorite: and a general assembly of the citizens being summoned, Ariston, one of Pisistratus's partisans, proposed to allow him a body-guard of fifty men. The measure was carried in spite of the strenuous opposition of Solon. Gradually Pisistratus increased the number, and in 560 B.C., when he felt himself strong enough, seized the Acropolis. The citizens, in general, seem to have tacitly sanctioned this high-handed act. They were sick of the anarchic broils of the different factions, and probably glad to see their champion and favorite usurp supreme authority. Megacles and the Alcmaeonids—the heads of the rich aristocratic party—immediately fled from the city. Solon, who loved neither oligarchic arrogance nor military despotism, but was a thorough constitutionalist, tried, but in vain, to rouse the Athenians against Pisistratus. Pisistratus, who was not at all vindictive in his disposition, did not attempt to molest Solon; he even maintained the legislation of the latter almost intact, and distinguished himself chiefly by the vigor of his administration. Pisistratus himself did not enjoy his first "tyranny" long. The *Pediæi* and the *Parali* rallied under Lycurgus and Megacles, united their forces, and overthrew the usurper, who was forced to go into exile. But the coalition of the two factions was soon broken up. Megacles hereupon made overtures to Pisistratus, inviting him to resume his tyranny, which he did; but a family quarrel with Megacles induced the latter to again ally himself with Lycurgus, and Pisistratus was driven from Attica. He retired to Eubœa, where he remained for ten years, ever keeping an eye, however, on Athens, and making preparations for a forcible return. How he managed to acquire so much influence while only a banished man is difficult to ascertain; but certain it is that many Greek cities, particularly Thebes and Argos, placed the greatest confidence in him, and finally supplied him abundantly with money and troops. Pisistratus at length sailed from Eubœa, landed in Attica at Marathon, and marched on the capital. His partisans hurried to swell his ranks. At Pallene he encountered his opponents, and completely defeated them, but used his victory with admirable moderation. When he entered the city no further resistance was made, and he resumed the sovereignty at once. The date of this event, as of most others in the life of Pisistratus, is very uncertain; perhaps we shall not err far if we place it about 543 B.C. He lived for sixteen years afterwards in undisturbed possession of power, dying 527 B.C., and transmitting his supremacy to his sons, Hippias and Hipparchus, known as the *Pisistratidæ*. His rule was mild and beneficent. Although the precautionary measures that he adopted to establish his authority involved at first a certain resolute and stringent policy (e.g., the seizure of the children of his leading opponents, and the detaining them as hostages); yet no sooner had he placed himself out of danger, than he began to display that wonderful tact, moderation, kindness, and sympathetic appreciation of the wishes of the Athenians, that have won him the praise and esteem of all later ages, in spite of his usurpation. He firmly, but not harshly, enforced obedience to the laws of Solon; emptied the city of its poorest citizens, and made them agriculturists, supplying such as had no resources with cattle and seed; secured provision for old and disabled soldiers; bestowed great care on the celebration of the religious festivals of the Atticans, and even introduced some important changes; encouraged literature more than any Athenian had ever done before—it is to Pisistratus, or to the poets, scholars, and priests about him, that we owe, for example, the first complete edition of Homer (q.v.); and, like his still more brilliant successor in the following century, Pericles, he adorned Athens with many beautiful buildings, such as the Lyceum, a temple to the Pythian Apollo, another to Olympian Zeus. etc.

PISHAMIN. See DATE PLUM.

PI'SOLITE (Gr. pea-stone), a concretionary limestone, differing from oolite in the particles being as large as peas.

PISTA' CIA, a genus of trees of the natural order *anacardiaceæ*, having diœcious flowers without petals, and a dry drupe with a bony stone. The **PISTACIA**, or **PISTACHIO TREE** (*P. vera*), is a small tree of about 20 ft. high, a native of Persia and Syria, but now cultivated in all parts of the s. of Europe and n. of Africa, and in many places naturalized. It has pinnate leaves, with about two pair of ovate leaflets, and an odd one; flowers in racemes; fruit ovate, and about the size of an olive. The stone or nut splits into two valves when ripe; the kernel, which is of a bright green color, is very oleaginous, of a delicate flavor, and in its properties very much resembles the sweet almond. In the s. of Europe and in the east, *pistachio nuts* are much esteemed; but as they very readily become rancid, they are little exported to other countries. They are sometimes called *green almonds*. Oil is expressed from them for culinary and other uses. In cultivation one male tree is allowed to five or six fertile ones. The tree produces flowers and even fruit readily enough in the s. of England, but the summers are not warm enough to ripen the fruit, and the tree is apt to be destroyed by a severe frost.—The **MASTIC TREE**, or **LENTISK** (*P. lentiscus*), yields the gum-resin called mastic (q.v.). It is a native of the countries around the Mediterranean.—The **TURPENTINE TREE** (*P. terebinthus*) yields the turpentine (q.v.) known in commerce as *Cyprus turpentine*, *Chian turpentine*, or *Scio turpentine*, which is of a consistency somewhat like that of honey, a greenish-yellow color, an agreeable odor, and a mild taste, and in its properties resembles the turpentine of the Coniferæ, but is free from acidity. It is obtained by making incisions in the trees, and placing stones for the turpentine to flow upon, from which it is scraped in the morning, before it is liquified again by the heat of the sun. The tree is about 30 or 35 ft. in height, and has pinnate leaves, of about three pair of leaflets and an odd one; the flowers in compound racemes, the fruit nearly globular. The kernel of the fruit is oleaginous and pleasant.—The **BATOUM TREE** (*P. Atlantica*), a round-headed tree of about 40 ft. in height, a native of the n. of Africa, produces a fruit much used by the Arabs; and a gum-resin of pleasant aromatic smell and agreeable taste, which exudes from its stem and branches, is chewed to clean the teeth and impart a pleasant smell to the breath.—The fragrant oil of the kernels of *P. oleosa*, a native of Cochin China, is used by the people of that country to impart a perfume to ointments.

PIS'TIL, in botany, the female organ of fructification in phanerogamous plants; that part of the flower (q.v.) which, after flowering is over, is developed into the fruit. There

PISTILS:

1, Section of flower of a species of primrose, showing the pistil laid open; numerous ovules attached to a free central placenta. 2, Section of flower of comfrey, with corolla removed, showing two of the four ovaries, and the style. 3, Pistil of the barberry, consisting of several carpels combined; the style very short and thick, the stigma shield-like. 4, Section of the ovary of a lily. 5, Section of flower of cherry, showing pistil of two separate carpels, only one of which comes to perfection in fruit. 6, Pistil of pea, opened; *a*, ovule; *b*, placenta; *f*, umbilical cord.—From Balfour's *Class-Book of Botany*.

is sometimes one pistil in a flower, sometimes more; in some flowers, which have numerous pistils, they form a number of whorls, one within another, sometimes on an elevated receptacle or elongated axis, or more rarely, they are spirally arranged. In every case the center of the flower is occupied by the pistil or pistils, if present. See FLOWER. A pistil is either formed of a single carpel (q.v.), as is the case when there are numerous pistils, or of several carpels combined; and the number of carpels of which the pistil is formed is often indicated by the number of the cells of the germen, or by its lobes or angles. The pistil usually consists of a germen (q.v.) or ovary, in which the ovules (q.v.) are contained, and which is surmounted by a *stigma*, either immediately or through the intervention of a *style*; but in gymnogens (q.v.) there is neither germen, style, nor stigma, the female organs of fructification being mere naked ovules. The germen is always the lowest part of the pistil. The stigma exhibits an endless variety of forms, and is adapted to the reception and retention of the pollen grains requisite for fecundation, partly by the roughness of its surface—which is of a somewhat lax cellular tissue, covered with pro-

reception and retention of the pollen grains requisite for fecundation, partly by the roughness of its surface—which is of a somewhat lax cellular tissue, covered with pro-

jecting cells, often in the form of minute warts, and often elongated into hairs—and partly by the secretion of a viscous fluid. The stigma, when not *sessile*—or seated immediately on the germen—is supported by the style, which rises from the germen, and on the top of which the stigma is generally placed. The style is sometimes very long and slender, sometimes very short; the germen sometimes passes imperceptibly into the style, and sometimes the style rises from it abruptly; and similar differences appear in the relations of the style and stigma; the stigma, however, may be regarded as always an expansion of the top of the style, although it is sometimes, but rarely, situated on one or both sides of the style, beneath its summit. In like manner, by peculiar modifications taking place in the growth of the germen, the style sometimes seems to rise from beneath its apex, or even from its base; but it always rises from what is, structurally considered, the real apex of the germen. When several carpels are united to form one germen, they are sometimes again separated in their styles, and more frequently in their stigmas, so that one germen bears several styles, or the style divides at some point above the germen, or one style is crowned by a number of stigmas. The style is usually cylindrical; and when this is not the case it is often owing to the combination of several styles into one, although sometimes the style is flat and even petal-like. It is traversed throughout its whole length by a canal; which, however, is in general filled up by cells projecting from its sides, and often also by very slender tubes extending in the direction of its length; the function of the canal, to which in some way or other the inclosed slender tubes are subservient, being to bring about the connection between the pollen and the ovules for fecundation (q.v.). The length of the style is adapted to the ready fecundation of the ovules, being such that the pollen may most easily reach the stigma; and in erect flowers the styles are usually shorter than the stamens; in drooping flowers they are longer than the stamens. After flowering is over, when fecundation has taken place, the *foramen* of the ovules closes, the germen enlarges and ripens into the fruit, whilst each ovule is developed into a seed. The style and stigma meanwhile either fall off, or remain and dry up, or they increase in size, and are changed into various kinds of appendages of the fruit, as feathery awns, beaks, etc.

PISTILLID'IUM, in botany, a term which, along with *antheridium* (q.v.), must be regarded as provisional, and as expressive of an opinion, probable, but not yet ascertained to be true. The evidence in favor of it, however, seems continually to increase, and its great probability is more and more generally acknowledged. The pistillidium is an organ of cryptogamous plants, supposed to perform functions in fructification analogous to those of the pistil in phanerogamous plants. It consists of a germen-like body—the *sporangium*, *theca*, or *spore-case*—hollow, and containing spores (q.v.), by which the species is propagated. These spore-cases are very various in their forms, and in the situations which they occupy in different orders and genera; being sometimes immersed in the substance of the plant, sometimes distinct from it, sometimes sessile, sometimes stalked, etc. See the articles on the different cryptogamous orders.

PISTO'JA (anc. *Pistorium*), a manufacturing t. of Italy, in the province of Florence, and 21 m. by railway n.w. of the city of that name, stands on a gentle rising ground at the foot of the Apennines. It is well built; its streets are thoroughly Tuscan, and it is surrounded by lofty and well-preserved walls. The chief buildings are the cathedral, built at various times, and containing a number of good pictures; several old and interesting palaces, and a number of churches, some of which are of importance in the history of mediæval architecture and sculpture. The principal manufactures are iron and steel wares, and paper. Pop. '81, 12,224.

PISTOL is the smallest description of fire-arm, and is intended to be used with one hand only. Pistols vary in size from the delicate saloon-pistol, often not six in. long, to the horse-pistol, which may measure eighteen in., and sometimes even two feet. They are carried in holsters at the saddle-bow, in the belt, or in the pocket. Every cavalry soldier should have pistols, for a fire-arm is often of great service for personal defense, and almost indispensable in giving an alarm or signal. Sailors, when boarding an enemy's ship, carry each two in their waist-belts. As early as the reign of Henry VIII. the English cavalry carried clumsy pistols called "dags." The latest improvement on the pistol is the revolver (q.v.).

PISTO'LE, the name formerly given to certain gold coins current in Spain, Italy, and several parts of Germany. The pistole was first used in Spain, and was originally equivalent to about 11 old French livres, but till 1728 it was merely an irregular piece of gold. From this time till 1772 its value was 17s. 1d. sterling. But it was after this date decreased till it reached the value of 80 reals, or 16s. 2d. sterling. The Italian pistoles were also gold coins, and varied considerably in value; that of Rome = 13s. 9d.; of Venice = 16s. 2½d.; of Florence and Parma = 16s. 10½d.; and the old coin of Piedmont = £1, 2s. 7¾d., or 24 old liras. Gold coins of this name used to be current in Hesse-Cassel, Switzerland, Brunswick, and Hamburg, but were in most cases merely convenient multiples of the ordinary thaler and gulden. Of late years, and especially since the introduction of new systems of coinage in Spain and Italy, and of a uniform system in the German empire, the name pistole is scarcely ever used.

PI'SUM. See PEA.

PIT, in gardening, is an excavation in the ground, intended to be covered by a frame (q.v.), and to afford protection to tender plants in winter, or for the forcing of vegetables, fruits, etc. Pits are often walled on all sides, although, in many cottage gardens, excellent use is made of pits which are mere excavations. The walls are often raised above the ground, particularly the back wall, the more readily to give slope to the glazed frame. A pit in which no artificial heat is supplied is called a *cold pit*; but when forcing is intended, flued pits are often used. Artificial heat is sometimes also given by means of fermenting matter. The ventilation of pits, as much as the weather will permit, is of the greatest importance.

PITA-HEMP, one of the names of the agave or aloe fiber. See **AGAVE**.

PIT'AKA (literally "basket") is, with the Buddhists, a term denoting a division of their sacred literature, and occurs especially in combination with *tri*, "three;" *tripit'aka*, meaning the three great divisions of their canonical works, the *vinaya* (discipline), *abhidharma* (metaphysics), and *sūtra* (aphorisms in prose), and collectively, therefore, the whole Buddhistic code. The term "basket" was applied to these divisions, because the palm-leaves on which these works were written were kept in baskets, which thus became a part of the professional utensils of a bhikshu, or religious mendicant.

PITAVAL, FRANÇOIS GAYOT DE, 1673-1743; b. France; entered the army, but afterward studied jurisprudence, and became an advocate at Paris. His chief work is the compilation called *Causes Célèbres et Intéressantes* (20 vols., 1734-43).

PITCAIRN, JOHN, d. 1775; b. Scotland; the only British officer who was accounted fair in his dealings with the people of Boston in their altercations with the British soldiers. He was commissioned capt. of marines, 1765; major, 1771. He was prominent in the battle of Lexington, conducting the expedition to that town, April 19, 1775, and commenced the attack on the militia collected there; but he denied that he ordered the first shot to be fired. He was shot at the battle of Bunker Hill when about to enter the redoubt. His son David, a distinguished physician in London, died 1809.

PITCAIRN ISLAND, a solitary island in the Pacific ocean, lying at the south-eastern corner of the great Polynesian archipelago, in lat. 25° 3' 6" s., and long. 130° 6' west. Its length (2½ m.) is about twice its breadth, and the total content is approximately 1½ sq. m.; so that, except from its being the only station (with the exception of the Gambier islands) between the South American coast and Otaheite at which fresh water can be procured, it would be too insignificant to deserve notice, were it not for the manner in which it was colonized. The island is wholly surrounded by rocks; it has no harbor, and its soil is not very fertile. It was occupied in 1790 by the mutineers of the *Bounty* (see **BLIGH**, **WILLIAM**), who after touching at Toobouai sailed for Tahiti, where they remained for some time. Christian, the leader of the mutineers, however, fearing pursuit, hastened their departure; and after leaving a number of their comrades who preferred to stay on the island, they brought off with them 18 natives and sailed eastward, reaching Pitcairn island, where they took up their residence and burned the *Bounty*. They numbered then 9 British sailors—for 16 of the sailors had preferred to remain at Tahiti, and of these 14 were subsequently captured, and (Sept., 1792) three of them executed—and 6 Tahitian men, with 12 women. It was impossible for concord to subsist in a band of such desperate character; and in the course of the next ten years all the Tahitian men, all the sailors, with the exception of Alexander Smith (who subsequently changed his name to John Adams), and several of the women, had died by violence or disease. From the time of their leaving Tahiti nothing had been heard of them, and their fate was only known when an American, capt. Folger, touched at Pitcairn island in 1808, and on his return reported his discovery to the British government; but no steps appear to have been taken by the latter. On Sept. 17, 1814, a British vessel, the *Britain*, called at the island and found old Adams still alive, commanding the respect and admiration of the whole little colony by his exemplary conduct and fatherly care of them. Solitude had wrought a powerful change in Adams; and his endeavors to instill into the young minds of his old companions' descendants a correct sense of religion had been crowned with complete success, for a more virtuous, amiable, and religious community than these islanders had never been seen. They were visited by British vessels in 1825 and 1830, and the reports transmitted concerning them were fully corroborative of the previous accounts; but in 1831 their numbers (87) had become too great for the island, and at their own request they were transported to Tahiti in the *Lucy Ann* by the British government. But, disgusted at the immorality of their Tahitian friends and relatives, they chartered a vessel, defraying the cost of it in great part with the copper bolts of the *Bounty*, and most of them returned to Pitcairn island at the end of nine months. In 1839, being visited by capt. Elliot of H.M.S. *Fly*, they besought to be taken under the protection of Britain, on account of the annoyances to which they had been subjected by the lawless crews of some whale-ships which had called at the island; and, accordingly, capt. Elliot took possession of it in the name of her majesty, gave them a union jack, and recognized their self-elected magistrate as the responsible governor. He also drew up for them a code of laws, some of which are amusing from the subjects of which they treat, but the code was of great use to the simple islanders. From this time they were frequently visited by European ships; and in 1855, finding their numbers again too

great for the island, they petitioned government to grant them the much more productive Norfolk island, to which they were accordingly removed in 1856. In 1859, however, two families, numbering in all 17, returned to Pitcairn island, reducing the number on Norfolk island to 202, and others have since followed. From their frequent intercourse with Europeans, the Pitcairn islanders have, while still retaining their virtuous simplicity of character and cheerful, hospitable disposition, acquired the manners and polish of civilized life, with its education and taste. They are passionately fond of music and dancing, the latter evidently a legacy from their maternal ancestry. The men are engaged in whaling and herding cattle, or in cultivating their gardens and plantations; while the women (who seem to be the more industrious class) attend to their families, manage the dairies, and take an occasional part in field-labor.

Pitcairn island was first discovered by Carteret in 1767, and was named by him after one of his officers; but it was never visited by Europeans till taken possession of by the mutineers. When admiral de Horsey visited Pitcairn island in 1877, there were in all 16 men, 19 women, 25 boys, and 30 girls on the island. See the account published by him in 1878.

PITCH. The common kind of pitch is the black residue which remains after distilling wood-tar. See **TAR**. It is made extensively in Russia, Norway, and North America. It is a most useful material for protecting wood from the action of water, hence it is used for calking the seams and coating the outsides of ships and boats; it is also applied to the inside of water-casks, and many similar uses. A variety of pitch is now obtained from the distillation of coal-tar, and another from bone-tar; the latter is said to be nearly equal in value to that from wood, but coal-pitch wants the toughness which is one of the more valuable qualities of wood-pitch. It is, however, much used in making artificial asphalt for building and paving purposes, and for the black varnish used for coating iron-work to keep it from rusting. Pitch is solid at the ordinary temperature of our climate, but softens and melts with a small accession of heat.

PITCH, the degree of acuteness of musical sounds. A musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals; the greater the number of vibrations in a given time, the more acute or higher is the pitch. In stringed instruments the pitch is dependent on the length, the thickness, and the degree of tension of the strings; the shorter and thinner a string is, and the greater its tension, the higher is the pitch of the note. In wind instruments, where the notes are produced by the vibration of a column of air, as in the mouth-pipes of an organ, the pitch is dependent on the length of the column set in motion; the shorter the column of air, the higher the pitch becomes.

The pitch of musical instruments is adjusted by means of a tuning-fork, consisting of two prongs springing out of a handle, so adjusted as to length that when struck a

particular note is produced, that note being C  in Britain, and A 

in Germany. It is obviously important to have a recognized standard of pitch by which instruments and voices are to be regulated; but there is, unfortunately, not the uniformity that might be desired in the pitch in actual use. For a long time prior to 1859 concert-pitch had been gradually rising, to the detriment of the voices of public singers. The C tuning-fork, in use in 1699, made 489 vibrations per second, while in 1859 the number of vibrations had increased to 538. Mr. Hullah, in 1842, in the numerous classes instituted by him under the sanction of the committee of council on education, found it necessary to secure a uniform standard of pitch, and adopted 512, which has an especial convenience as being a power of 2. The French imperial government, in 1858, fixed on 522. In 1859 a committee of the society of arts was appointed to consider the subject of a uniform musical pitch. Their deliberations lasted 12 months. Sir John Herschel, in a letter to the committee, strongly recommended the number 512. It was agreed on all hands that the then existing opera-pitch of 546 was too high and painful to the singers of soprano music. The instrumental performers stated that they could lower the pitch to 528, but if they had to lower it to 512 some of them would have to purchase new instruments; and, in consequence apparently of their representation, the committee reported in favor of 528.

PITCH, BURGUNDY. See **BURGUNDY PITCH**.

PITCHBLENDE, a mineral which is essentially oxide of uranium (q.v.), with slight mixtures of other substances. Its color is grayish-black or brownish-black. It is infusible before the blow-pipe, without the addition of borax, with which it fuses into a dull yellow glass.

PITCHER, THOMAS G., b. Ind., 1824; graduated at West Point, and was appointed to the infantry in 1845. He served through the Mexican war, and was promoted capt. in 1858. He was made brig.gen. of volunteers in 1862, and was afterwards assistant provost-marshal-gen. He was appointed col. of the 44th infantry in 1866, was supt. of West Point, 1866-71; gov. of Soldiers' Home, Washington, 1871-7; honorably retired, 1878.

PITCHER PLANT. See **NEPENTHES**.

PITCHSTONE, a name sometimes given to a variety of common opal (q.v.), brown, black, gray, red, or of mixed colors; the luster more resinous than in opal, and the fracture less perfectly conchoidal. It occurs in several localities in the British islands, in Saxony, etc.—The same name is given to another mineral (Ger. *pechstein*), a variety of felspar (q.v.), occurring as a rock in dikes which traverse strata or in overlying masses; compact, slaty, or in concentric slaty concretions. It exhibits great variety of color, and has a somewhat resinous appearance. It often contains numerous imbedded crystals of felspar, and is then called *P. porphyry*.

PITCHURIM BEANS, or SASSAFRAS NUTS, an occasional article of importation from South America, are the seed-lobes of *nectandra puchury*, a tree of the same genus with the greenheart (q.v.), growing on the banks of the Rio Negro and elsewhere in the rich alluvial parts of the basin of the Amazon. They are about 1½ in. long, and half an inch broad. They are much in request among chocolate manufacturers for flavoring chocolate, as a substitute for vanilla. They are sometimes called wild nutmegs, because of a resemblance to nutmeg in flavor. The name sassafras nuts is also due to the flavor, which approaches that of sassafras bark; and the tree belongs to the same natural order with the sassafras tree.

PIT-DWELLERS OF YEZO. See page 895

PITEA, or NORTH BOTHNIA. See NORRBOTTEN.

PITH, *Medulla*, the light cellular substance which occupies the center of the stem and branches in exogenous plants (q.v.). In the earliest stage of a young stem or branch, it is entirely composed of pith and bark, by which alone, therefore, young buds are nourished; the vascular bundles or woody fiber appearing afterwards, and, in trees and shrubs, generally increasing, so as to constitute the greater part of the substance of the stem and branches, whilst the pith is ultimately reduced to a very small column in the center. The pith, however, exists even in the most mature woody stem, and maintains its connection with the bark by means of *medullary rays*, analogous in their character to the pith itself, and which exist even in the most compact wood, although much compressed by the woody layers, and in a transverse section appearing as mere lines. The medullary rays convey to the central parts of the stem the secretions of the bark necessary for their nourishment. Pith is in general entirely composed of cellular tissue; vessels occurring in it only in a few plants. Its cells diminish in size from the center towards the circumference. In a few plants it exhibits cavities which have a regular arrangement; in many herbaceous plants of rank growth large irregular cavities occur in it. The pith is immediately surrounded by a thin vascular layer called the *medullary sheath*, consisting chiefly of spiral vessels, which continue to exercise their functions during the life of the plant.

PITHECIA. See SAKI.

PITHECUS. See ORANG.

PITHOM. See SUCCOTH.

PITKIN, TIMOTHY, LL.D., 1766–1847, b. Conn.; educated at Yale college, and admitted to the bar. He was for 5 years speaker of the lower house of the state legislature, and a member of congress 1806–20. He wrote *A Statistical View of the Commerce of the United States* (1816); and *Political and Civil History of the United States from 1763 to the Close of Washington's Administration*, 2 vols. 1828.

PITMAN, ISAAC, b. England, 1813; educated at the Normal college of the British and foreign school society of London; in 1832 began to teach school at Barton-on-Humber, and was afterwards master of several other schools. He was the inventor of the system of phonetic writing, or short-hand. His first work on the subject was printed in 1837, *Stenographic Sound-hand*. He has since devoted himself entirely to teaching his system, publishing many manuals and treatises, acting as editor of the *Phonetic Journal*, a weekly paper, and printing in short-hand character a number of books, including the Bible. For many years he has been greatly interested in the subject of a reform in English spelling, and has issued a number of pamphlets advocating radical measures. For a description of his system see **SHORT-HAND**. The phonetic society was organized by Pitman in 1843.

PITON BARK. See CARIBBEE BARK.

PITRA, JEAN BAPTISTE, b. France, 1812, educated at Autun, entered the priesthood, and after teaching rhetoric at the Autun seminary became a monk in the Benedictine abbey of Solesme. There he studied ecclesiastical antiquities, and wrote a *History of St. Leger, Bishop of Autun*, 1846; and *Spicilegium Solesmense*, 5 vols., 1852–60, a collection of hitherto unpublished documents in regard to church history. To collect the materials for this work, he visited all the principal European libraries. In 1858 Pius IX. called him to Rome, and directed him to study the ancient and modern canons of the oriental churches. The fruits of this study are found in his *Juris Ecclesiastici Græcorum Historia et Monumenta*. He was appointed a member of the sacred college of the propaganda in 1862, and the next year was created cardinal priest with the title of S. Tommaso in Parione. He is now (1885) librarian of the holy Roman church.

PITRI' (a Sanskrit word literally meaning father = Latin *pater*, in the plural *patras*, but in English translations from the Sanskrit usually Anglicized to *pitris*), a name which, in a general sense, means the deceased ancestors of a man, but in the special sense in

which it occurs in Hindu mythology, denotes an order of divine beings inhabiting celestial regions of their own, and receiving into their society the spirits of those mortals for whom the funeral rites (see SRÂDDHA) have been duly performed. They include, therefore, collectively the names of the deceased ancestors; but the principal members of this order are beings of a different nature and origin. According to Manu, they were the sons of Marîchi, Atri Angiras, and the other rishis or saints produced by Manu, the son of Brahmâ; and from them issued the gods, demons, and men. According to several Purânas (q.v.), however, the first pitris were the sons of the gods; and to reconcile this discrepancy, a legend relates that the gods having offended Brahmâ by neglecting to worship him, were cursed by him to become fools; but, upon their repentance, he directed them to apply to their sons for instruction. Being taught accordingly the rites of expiation and penance by their sons, they addressed the latter as fathers, whence the sons of the gods were the first pitris (fathers). See Wilson's *Vishnu-Purâna*. Manu enumerates various classes of pitris, in defining those who were the ancestors of the gods, those who were the ancestors of the demons, and those from whom proceeded the four castes severally; but he adds, at the same time, that these are merely the principal classes, as their sons and grandsons indefinitely must likewise be considered as pitris. The Purânas divide them generally into seven classes, three of which are without form, or composed of intellectual, not elementary substance, and assuming what forms they please, while the four other classes are corporeal. In the enumeration, however, of these classes the Purânas differ. The pitris reside in a world of their own, called Pitri-loka, which is sometimes supposed to be the moon; according to the Purânas, it is below the paradise of Indra, and is also the abode of the souls of devout Brahmans. The time at which the pitris are to be worshiped, the libations which they are to receive, the benefit which they derive from them, and the boons which they confer on the worshiper, are all minutely described in the Purânas. See SRÂDDHA. A song of the pitris, as given by the *Vishnu-Purâna*, may convey an idea of the importance attributed to this worship, and of the manner in which the Brahmans turn it to their profit. It runs as follows: "That enlightened individual who begrudges not his wealth, but presents us with cakes, shall be born in a distinguished family. Prosperous and affluent shall that man ever be who, in honor of us, gives to the Brahmans, if he is wealthy, jewels, clothes, lands, conveyances, wealth, or any valuable presents; or who, with faith and humility, entertains them with food, according to his means, at proper seasons. If he cannot afford to give them dressed food, he must, in proportion to his ability, present them with unboiled grain, or such gifts, however trifling, as he can bestow. Should he be utterly unable even to do this, he must give to some eminent Brahman, bowing at the same time before him, sesamum seeds adhering to the tips of his fingers, and sprinkle water to us, from the palms of his hands, upon the ground; or he must gather, as he may, fodder for a day, and give it to a cow; by which he will, if firm in faith, yield us satisfaction. If nothing of this kind is practicable, he must go to a forest, and lift up his arms to the sun and other regents of the spheres, and say aloud, 'I have no money, nor property, nor grain, nor anything whatever fit for an ancestral offering; bowing therefore to my ancestors, I hope the progenitors will be satisfied with these arms tossed up in the air in devotion.'" See Wilson's *Vishnu-Purâna*.

PITT, a co. in e. North Carolina, drained by the Tar river, Grindle creek, and the Neuse river; 700 sq.m.; pop. '80, 21,794. The surface is level, and well wooded, and the soil fertile. The principal productions are corn, potatoes, and cotton. Co. seat, Greenville.

PITT, WILLIAM, the second son of the earl of Chatham and of lady Hester Grenville, daughter of the countess Temple, was born on May 28, 1759. His genius and ambition displayed themselves with an almost unexampled precocity. "The fineness of William's mind," his mother writes of him, when he was but twelve years old, "makes him enjoy with the greatest pleasure what would be above the reach of any other creature of his small age." Owing to the excessive delicacy of his constitution, it was found impossible to educate him at a public school. His studies were, however, prosecuted at home with vigor and success. In 1773 he was sent to the university of Cambridge, where his knowledge of the classics seems to have astonished veteran critics. To modern literature he appears to have been utterly indifferent—he knew no continental language except French, and that very imperfectly. Among English poets, he liked Milton best; the debate in pandemonium being his favorite passage. In 1780 Pitt was called to the bar. He took chambers in Lincoln's Inn, and joined the western circuit. A general election having taken place in the autumn of the same year, he stood for the university of Cambridge; but he was at the bottom of the poll. Through the influence, however, of the duke of Rutland, he obtained a seat in parliament as member for Appleby. Lord North was now prime-minister. The opposition consisted of two parties; one being led by Rockingham and Fox, the other by lord Shelburne. The latter consisted chiefly of the old followers of Chatham; and to this party Pitt naturally became attached. On Feb. 26, 1781, he made his first speech in parliament. It was in favor of Burke's plan of economical reform, and was a splendid success. "It is not a chip of the old block," said Burke, "it is the old block himself." Shortly before the meeting of parliament, in the autumn of 1781, the news arrived of the surrender of Cornwallis and his army. In the

debate on the address, Pitt spoke with even more energy and brilliancy than on any former occasion. No one was so loud in eulogy as Henry Dundas, lord advocate of Scotland; and from this night dates a connection between him and Pitt, which was only broken by death. After several defeats, the ministry resigned, and Rockingham was called on to construct a cabinet. Pitt was offered the vice-treasurership of Ireland; but he declined to accept a position which did not confer a seat in the cabinet. On May 7, 1782, he made his first motion for a reform in the representation of the people; which motion was lost by only 20 votes in a house of more than 300 members. The reformers never again had so good a division till 1831. At the end of three months after his accession to office, Rockingham died; lord Shelburne succeeded to the head of the treasury; and Pitt, at the age of 23, became chancellor of the exchequer. In opposition to the government, there was then formed a coalition emphatically known as "the coalition." On lord Shelburne's resignation in 1783, the king himself, who hated the coalition, tried to persuade Pitt to take the helm of affairs; but he resolutely declined. The duke of Portland succeeded, with Fox and North as secretaries of state. Pitt from the opposition benches, brought for a second time the question of parliamentary reform before the house. His motion was lost by 293 votes to 149. On the prorogation, he visited the continent for the first and last time. In 1783, the ministry having been defeated on a motion for transferring the government of India to parliament, Pitt became first lord of the treasury and chancellor of the exchequer. But parliament was dead against him: between Dec. 17, 1783, and March 8, 1784, he was beaten in sixteen divisions. The nation, however, was in his favor; both on account of his policy, and from admiration of his private character. Pecuniary disinterestedness is what all can comprehend; and even when known to be overwhelmed with debt, when millions were passing through his hands, when the greatest men in the land were soliciting him for honors, no one ever dared to accuse him of touching unlawful gain. At the general election in 1784, 160 supporters of the coalition lost their seats, Pitt himself heading the poll for the university of Cambridge. He was now, at 25 years old, the most powerful subject that England had seen for many generations. He ruled absolutely over the cabinet, and was at once the favorite of the sovereign, of the parliament, and of the nation; and from this date, the life of Pitt becomes the history of England and of the world. For seventeen eventful years he held his great position without a break. In 1784 he established a new constitution for the East India company. In 1786 he carried through a commercial treaty with France on liberal principles. In the same year he established a new sinking fund; a scheme which experience has shown to be wrong in principle, though it was long viewed with favor by the nation. To exertions which were now begun for the abolition of the slave-trade, he gave the help of his eloquence and power. In 1788-89 he maintained against Fox the right of parliament to supply the temporary defect of royal authority occasioned by the incapacity of the king. The year 1793 saw the beginning of the great war with France. Authorities differ as to the cause. It is, however, certain that Pitt's military administration was eminently unsuccessful. But no disaster could daunt his spirit. When a new French victory, a rebellion in Ireland, a mutiny in the fleet, and a panic in the city had spread dismay through the nation, Pitt from his place in parliament poured forth the language of inextinguishable hope and inflexible resolution. Disaster abroad was regularly followed by triumph at home, until at last he had no longer an opposition to encounter. In 1799 he effected the union with Ireland. It was part of his scheme to relieve the Roman Catholic laity from civil disabilities, and to grant a public maintenance to their clergy; but the obstinacy of the king frustrated this design. Chagrined by this failure, Pitt resigned office in 1801. He was succeeded by Mr. Addington, to whom for a while he gave his support. In 1804 he returned again to the head of the treasury, which position he continued to hold till his death on Jan. 23, 1806. This event was doubtless hastened by the stupendous success of Napoleon. The peculiar look which he wore during the last ten days of his life was pathetically termed by Wilberforce "the Austerlitz look." The impeachment also of his friend lord Melville is supposed greatly to have hastened his end. It gave him, he said in parliament, a deep pang. His voice quivered as he uttered the word; and it seemed as if the man of iron were about to shed tears. "He was," says Macaulay, "a minister of great talents; honest intentions, and liberal opinions, . . . but unequal to surprising and terrible emergencies, and liable in such emergencies to err grievously, both on the side of weakness and on the side of violence." But what man ever lived, we may ask, who, placed in such circumstances as Pitt, would not often have greatly erred? His policy was liberal beyond his age, at least he wished it to be so, although he was often obliged to yield to the prejudices of his sovereign. He resigned office because he could not carry Catholic emancipation. He laid before the king unanswerable reasons for abolishing the test act. He was more deeply imbued with the doctrines of free-trade than either Fox or Grey. It cannot indeed be denied that he was addicted to port-wine, and that he died overwhelmed with debts; parliament voting £40,000 to his creditors. High as his character stands, it would have stood even higher had he united the virtue of frugality to that of disinterestedness. See *Life of Pitt*, by lord Stanhope (Lond. 1861); also lord Macaulay's *Biographies* (Edin. 1860). In the former work, vol. ii., p. 185, will be found a valuable criticism on Macaulay's memoir.

PITT, WILLIAM, Earl of Chatham. See CHATHAM, EARL OF, *ante*

PITTA, Vicillot's name for a genus of remarkable birds placed by Mr. Swainson among the ant-thrushes, or *myiotherinæ*. Cuvier united the *breves* of Buffon and the typical ant-thrushes. The *breves* are remarkable for their livid plumage, their long legs, and their very short tail. They are found in the Malay islands, while the ant-thrushes belong to America as well as to the old world. The genus *pitta* is of remarkable beauty; they have the gradually curved bill of the true thrushes, but much stronger. *P. gigas*, or giant pitta, is about the size of a magpie, with a short square tail, which is completely covered by the wings. The back, rump, and tops of the wings are of a brilliant azure blue; the quills are black, with azure towards the tips; top of head and collar black; front and side of head, breast, and belly ashy brown; throat, whitish; feet very long, and of a horny, ashy color. Total length from beak to end of tail, 9 inches. Inhabits Sumatra. A sub-genus, *chlorisoma* (green-bodied), is clothed principally in a brilliant celadon-green, with velvety black bands springing from the angle of the bill, passing behind the eye and across the back of the head; tail, deep green; wings, reddish; but the three or four secondary feathers nearest the body are of an opaline bluish-ash color; iris, bill, and feet are colored a very bright vermilion. The males and females have a close resemblance. The young, however, have black feet, rusty-red wings, with all the rest of the plumage a light clear blue. This light blue, as the bird grows older, becomes darker blue, and then passes into a celadon-green. These birds are natives of Java and Sumatra. The sub-genus *grallaria* is a native of South America, especially Brazil and Guiana. It is the king-thrush (*grallaria rex*), and is brown on the back, inclining to red on the sides; lighter beneath; back of head, lead-color; forehead varied with black and white; thighs short, tibia long.

PIT'TACUS, one of the "seven wise men" of ancient Greece, was b. at Mitylene, in the island of Lesbos, about the middle of the 7th c. B.C. The incidents of his life do not perhaps rest on a very secure historical basis, but he is by no means to be regarded as a merely traditionary personage. We may feel quite certain that his career and character were substantially what later history represents them. About 612 B.C., in conjunction with the brothers of Alcæus the poet, he overthrew the "tyrant" Melanchrus, and put him to death. He next figures in the contest between the Lesbians and the Athenians for the possession of Sigeum in the Troad, and displayed as much valor on the battle field as Alcæus did cowardice. His townsmen, the Mitylenæans, were so pleased with his deeds of prowess that they gave him a portion of the city territory, which he dedicated to sacred uses, and which was known long after as the "Pittaceian land." Meanwhile the civic struggles did not cease; the democratic party, however, roughly represented by a series of popular "tyrants," were in the ascendant, and the oligarchic aristocrats, at the head of whom was Alcæus, were finally banished. Pittacus was subsequently chosen dictator, 589 B.C., to prevent the turbulent exiles from returning to Mitylene, and ruled absolutely with great success for ten years, after which he voluntarily resigned his power, and withdrew into honored retirement. He died in 569 B.C. Many of the anecdotes preserved by tradition concerning Pittacus are probably apocryphal; but they all attribute to him the same characteristics—great moral sagacity, a contempt of outward pomp, and a plain practical understanding. His favorite maxim, *Grôthi kairôn* ("Know the fitting moment"), may be recommended to all statesmen and politicians. To Pittacus is also ascribed the saying which has so often been verified in actual history, *Chalepôn esthlôn emmenai* ("It is a misfortune to be eminent"). Of his 600 didactic verses, only four are extant, and these prove that he was strongly impressed with the falsehood and insincerity of men. See Schneidewin's *Delectus Poesis Græcorum Elegiacæ*, etc. (Gott. 1839).

PITTOSPORA'CEÆ, a natural order of exogenous plants, allied to *vitaceæ* (the vine, etc.), and containing nearly 100 known species of trees and shrubs, chiefly Australian, although a few are natives of different parts of Asia, Africa, and the islands of the Pacific. To this order belongs the genus *billardiera* (q.v.). The genus *sollya* also deserves notice, as containing some of our most beautiful green-house climbers.

PITTSBURG, a city of Pennsylvania, at the confluence of the Alleghany and Monongahela rivers, at the head of the Ohio, lat. 40° 26' 34" n., long. 80° 2' 38" west. It is situated among some of the richest deposits of bituminous coal and iron in America, supplying, in 1874, coal to the amount of 135,215,250 bushels. The city possesses 60 iron-foundries, 42 iron and steel works, nearly 600 furnaces, extensive machine-shops, and manufactures of steam-boilers, engines, nails, etc. The annual value of the iron manufactures is about \$30,000,000. There are also copper-smelting and rolling mills, 6 cotton-mills, oil-refining works, white-lead and glass works. The numerous foundries and factories fill the atmosphere with smoke, and have given Pittsburg the name of the Birmingham of America. It is connected by steamboats with the whole Mississippi valley, and by railways and canals with Philadelphia and Cleveland. Among its public buildings are a fine court-house, the largest Roman Catholic cathedral in the country, 141 churches, railway, aqueduct, and other bridges, U. S. arsenal, schools and colleges, western state penitentiary, etc. Nine railways center at this bustling city. It occupies the site of fort Pitt, and the older French fort Duquesne, in an expedition against which the British gen. Braddock was defeated in 1755 by an allied force of French and Indians. It was taken, on a third attempt, by gen. Forbes in 1758.

The city was chartered in 1816; in 1845 it was nearly destroyed by fire. Pop. '40, 21,115; '60, 49,220; '70, 86,076. The annexation of adjacent boroughs and townships raised the population to about 140,000 in 1875. Pop. '80, 156,389.

PITTSBURG (*ante*) is the second city in population and importance in Pennsylvania and the county seat of Alleghany county. Its history dates from about 1754, when a portion of its present limits was taken by the English, and a stockade was built at the junction of the Ohio and Monongahela rivers. After three or four severe struggles with the French and Indians, permanent occupation was established, and about 1759 the place began to be an important trading post. A new fort was built and called fort Pitt in honor of William Pitt, then at the head of the British ministry, from which eventually the town derived the name Pittsburg. The site of the original town was surveyed in 1773, or the following year, by members of the Penn family, and the lower part of the city still retains the streets and general conformation given it by them. In 1816, when the town became a city, the limits were confined to a peninsula of level ground between the two rivers; but these limits have gradually been extended until they now embrace territory far over the adjoining hills and seven miles up both rivers. The city is substantially and compactly built, contains many fine residences in the eastern part, and a large number of the principal avenues are graded and paved. The foreign population is chiefly Irish, German, and English, most of whom were engaged in trade, manufactures, and manual labor. The business of manufacturing, which is a distinguishing characteristic of the city, began at a very early period, and the establishment of rolling mills and foundries began shortly after the close of the second war with Great Britain, and has been going on steadily ever since. The capital invested in 1880 in manufactures was estimated at \$105,000,000, and the annual value of manufactured goods at \$147,000,000. There were at that time within the city 36 iron rolling mills, employing 18,905 hands; capital, \$20,000,000; 16 blast furnaces for the production of pig metal; 35 foundries and machine shops; 59 glass factories, employing 5,000 men; together with manufactories of malt liquors, white lead, leather, tobacco, cotton and woolen goods, pottery, carriages, and brushes. The city is also largely identified with the production of petroleum, and contains numerous refineries. About 90,000 hands are employed. Besides these great interests, Pittsburg also has facilities for traffic in its three rivers, and it is a port of delivery in the district of New Orleans. In 1881 the number of vessels belonging to the port was 214, with an aggregate tonnage of 52,711. The Pennsylvania, the Alleghany Valley, and the Pittsburg Washington and Baltimore railroads afford direct connection with the eastern cities and with nearly every part of Pennsylvania; the Pittsburg Fort Wayne and Chicago railroad and tributary lines connect the city with the west and northwest; and the Pittsburg Cincinnati and St. Louis line furnishes communication with the southwest. There are 25 national banks, with a capital of \$11,000,000; 23 savings banks, with a capital of \$3,250,000; and 19 home insurance companies. The assessed value of property was in 1885, \$250,000,000, and the city debt amounted to about \$15,000,000. The number of graded schools was, in 1880, 53, one of which was a high school; and the western university of Pennsylvania and the Pittsburg female college (Methodist) are also located within the city. The leading denominations are well represented. The finest church edifices are the Rom. Cath. cathedral of St. Paul, and Trinity Prot. Epis. church. Other noteworthy buildings are the U. S. arsenal, the custom-house, and the mercantile library, containing over 15,000 volumes. The city is divided into 37 wards, and is governed by a mayor, a select and a common council. Pittsburg is noted for the excellence of its gas, for the manufacturing and storage of which there are several works. The new reservoir is capable of supplying 1,000,000 inhabitants with water of good quality. The Monongahela river is spanned by five, and the Alleghany by seven, bridges, affording easy access with the city of Alleghany. (The manufacturing statistics given above include Alleghany.)

PITTSBURG LANDING, BATTLE OF. See SHILOH.

PITTSFIELD, a city in Massachusetts, on the Boston and Albany railway, 151 m. w. of Boston, and the terminus of the Housatonic and the Pittsfield and North Adams railways. It has manufactures of cotton and woolen goods, etc.; a medical college, 9 churches, etc. Pop. '70, 11,112.

PITTSFIELD (*ante*) a city in w. Massachusetts, incorporated 1761, named in honor of William Pitt, 50 m. s.e. of Albany by rail, and 53 m. n.w. of Springfield; pop. '80, 13,400. It is on the Boston and Albany railroad, at the terminus of the Pittsfield and North Adams and the Housatonic railroads. The town site is at an elevation of 1000 ft., surrounded by high hills. The Housatonic river, fed by 6 lakes in the vicinity, is divided by this plateau, one branch flowing past it on the e. side, the other on the w., uniting at the s. limit of the town. Pittsfield has the county court-house, built of marble at a cost of \$400,000, overlooking a park in the center of the city, containing a soldiers' monument. There are 12 churches several of considerable beauty, notably the stone church of the First Congregational society, the marble church of St. Joseph, and St. Stephen's (Episcopal). Among other buildings is that of the Berkshire life insurance company. The Berkshire atheneum has a library of 7,000 vols.; and there is a mercantile library. The town has 2 seminaries, one the Maplewood institute for young women, situated on a large estate. Among the charitable institutions is one for the disabled by accident or disease. It has 3 banks, 2 of them national, with an aggregate capital of

\$700,000, and a savings bank with deposits amounting to \$2,000,000. It is lighted by gas, is furnished with water from lake Ashley (the lakes also supplying water-power). Among the manufactures are paper, machinery, silk, tacks, etc.

PITTSTON, a borough in Pittston township Luzerne co., Penn., at the mouth of the Lackawanna river, on the e. bank of the Susquehanna, on the Lehigh Valley, Lackawanna and Bloomsburg and the Lehigh and Susquehanna railroads; pop. '80, 7,472. The chief business is the mining and exportation of coal. It has a bank and two newspapers.

PITTSTOWN, N. Y. See page 895.

PITTSYLVANIA, a co. in s. Virginia, adjoining North Carolina, bounded on the n. by the Staunton river; drained by the Dan and Bannister rivers; traversed by the Richmond and Danville railroad; about 900 sq. m.; pop. '80, 52,589—27,199 colored. The surface is somewhat hilly. The soil is fertile. It raises more tobacco than any other county in the state. Corn, oats, and live stock are the other principal productions. Co. seat, Chatham.

PITUITARY BODY, a small reddish-gray mass of an oval form, weighing from six to ten grains, and situated on the sella turcica of the sphenoid bone, on the floor of the cavity of the skull. It is very vascular, and in its structure it resembles the ductless glands. In the fetus, it is relatively larger than in the adult, and contains a cavity which subsequently disappears. It derives its name from its having been formerly supposed to secrete the fluid which (as we now know) is yielded by the Schneiderian or pituitary membrane of the nostrils. Its function is not known.

PITYRIASIS (from the Greek word *pityron*, bran) is the term given to one of the squamous or scaly diseases of the skin, in which there is a continual throwing off of bran-like scales of epidermis, which are renewed as fast as they are lost. It may occur upon any part of the body, giving rise to brown patches, in which there are sensations of itching, tingling, or pricking. It is more easily cured than the other scaly diseases, and its removal can generally be effected by the frequent use of the warm bath; or, if it fails, recourse may be had to alkaline or sulphur baths; due attention being at the same time paid to the general health. It sometimes occurs on the scalp, when it is known as *dan-driff*, and must be treated with weak alkaline lotions, or, if these fail, with tar ointment, provided there is no inflammation. There is a variety known as *pityriasis versicolor*, which is probably due to the presence of a parasitic fungus, the *microsporon furfurans*; but whether the fungus is the positive cause of the disease, or only an attendant on it, finding a suitable *nidus* in the diseased epidermis, is not certain. This variety may be detected by a microscopic examination of the exfoliated scales, when the spores and filaments of the fungus will be detected. The treatment of this affection must be solely local. Dr. Watson mentions a case which yielded at once to a couple of sulphur baths. Probably the best remedy is the application of a saturated watery solution of sulphurous acid gas, or of one of the sulphites dissolved in diluted vinegar.

PIÙ (in Ital. more), as a musical term, when prefixed to another word, intensifies its meaning—e.g., *più mosso*, with more movement.

PIURA, a city in Peru, founded by Pizarro, 1531; the first city in Peru founded by Europeans, and called originally San Miguel. It is the capital of a province of the same name, on the left bank of the river Piura; pop. about 15,000. It is the largest town in n. Peru, and is built with more regard to permanency than beauty, on a level plain, 20 m. from Payta, and 523 m. n.w. of Lima. Its climate is warm and mild, with a limited rain-fall, and the agricultural products include tobacco, cotton, sugar-cane, and live stock; its mules being considered the best in the country. Sulphur, iron, lead, lime, magnesia, sulphate of soda, and potroleum constitute its mineral wealth. Its leading industries are the manufacture of soap and leather, and it has an extensive transit trade.

PIUS I., SAINT, Pope 90–157; b. Italy; pastor of the Roman Christians 117–42, when he succeeded Hyginus as pontiff. He opposed the heresies of Marcion and Valentinus, and the keeping of the feast of the resurrection on Sunday is said to have been ordered by him. His father's name was Rufinus, and the name Pius was given him by the Christians at Rome. The Latin church gives him the title of martyr, but it is not known that he was actually put to death. His anniversary is kept July 11.

PIUS, the name of nine among the Roman pontiffs, of whom the following only appear to call for particular notice.—**PIUS II.**, originally known as Æneas Sylvius, was a member of the noble family of Piccolomini, and was b. (1405) at Corsignano, in the duchy of Sienna. His early life was not free from serious irregularities, but he made amends by his subsequent decorous conduct; and his eminent abilities as a canonist led to his being employed, when but 26 years of age, as secretary of the cardinal of Fermo, in a post of the highest confidence at the council of Basel (q.v.). He was intrusted by that council—the views of which, in its conflict with the pope, he fully shared—in several commissions of great importance; and on the election of the antipope Felix V., Æneas Sylvius was chosen as his secretary. But having been sent by him as ambassador to the emperor Frederick III., he was induced to accept office in the imperial court, and served on several embassies and other missions of importance on behalf of the emperor. In the difficulties between Frederick and the pope Eugenius IV., which arose after the council of Florence, Æneas conducted so skillfully a negotiation with which he was intrusted that the pope was induced to retain him in his own court, in the capacity

of secretary. His views of church matters having undergone a considerable change, he continued in equal favor under the successor of Eugenius, Nicholas V., 1447; and under Callistus III. he was elevated to the cardinalate. On the death of Callistus in 1458, he was elected pope, and took the name of Pius II. His pontificate was embarrassed by some contests on German affairs, but it is chiefly rendered memorable by the sustained efforts which Pius—the first in this policy of a long line of pontiffs, to whom the public security of Europe owes a deep obligation—made to organize an armed confederation of Christian princes to resist the progress of the Turkish arms. This organization, however, for a long time did not lead to any considerable results. Pius died Aug. 14, 1464. The literary reputation of the scholar Æneas Sylvius has partially eclipsed the historical fame of the pope Pius. He was one of the most eminent scholars of his age. His works were published at Basel (1 vol. fol., 1551), but many of his works are not included in that edition. They consist chiefly of histories, or historical dissertations and materials of history; but the most interesting portion of his collected works are his letters, which are very numerous, and full of details, characteristic as well of the writer as of the age. The same may be said of a biographical commentary, which is in truth an autobiography, being chiefly written from his own dictation, by his secretary, John Gobelinus, published at Frankfort in 1614. See Voight's *Life of Pius* (Berl. 1856).—PIUS IV., Giovanni Angelo Medici, uncle of saint Carlo Borromeo, deserves to be noticed from his connection with the celebrated creed known under his name. He was elected in 1560; and his pontificate is chiefly memorable as that in which the protracted deliberations of the council of Trent (q.v.) were brought to a close. Pius had the duty, in Dec., 1563, of issuing the bull confirmatory of its decrees. The well-known creed called the creed of Pius IV., and sometimes the Tridentine creed, was issued by Pius IV. as an embodiment of all the doctrines defined in that council. Pius died Dec. 8, 1565, in the arms of his nephew, Carlo Borromeo.—PIUS V., a saint of the Roman Catholic church, originally named Michele Ghisleri, was b. of poor parents, in the village of Bosco, near Alessandria, in 1504, and at the age of 14 entered the Dominican order. His eminent merits were recognized by Paul IV., who named him bishop of Satri in 1556, and cardinal in the following year. Of austere and mortified habits, he carried into his administration the same rigor which distinguished his personal conduct; and when appointed inquisitor-general for Lombardy he employed the most rigorous measures in repressing the progress of the reformation, which had begun to effect an entrance. He was afterwards translated to the see of Mondovi; and immediately after the death of Pius IV. he was chosen unanimously as his successor, Jan. 8, 1566. Pius carried into his pontifical life the same personal austerity and administrative rigor which he had evinced as a bishop. Applying to others the same rules which he enforced upon himself, he enacted a number of severe laws for the regulation of public morals, prohibiting bull-fights, suppressing prostitution, and proscribing a variety of popular but demoralizing exhibitions. The Roman inquisition, too, under his government, exercised a severity of which no other pontificate has shown any example. He endeavored to enforce everywhere the disciplinary decrees of the council of Trent; and the whole spirit of his pontificate is most strikingly exhibited in the decree by which he ordered the yearly publication of the celebrated bull, *In Cæna Domini* (q.v.). It was an application to the 16th c. of the principles and the legislation of the Hildebrandine epoch. But the most momentous event of the pontificate of Pius was the expedition which he organized, with Spain and Venice, against the Turks, and which resulted in the great naval engagement of the gulf of Lepanto, on Oct. 7, 1571. Pius died in the following May, 1572. He was canonized by Clement XI. in 1712.—PIUS VI., originally named Angelo Braschi, was b. at Cesena, Dec. 27, 1717. He was selected by Benedict XIV. as his secretary; and under Clement XIII. he was named to several important appointments, which led finally, under Clement XIV., to his elevation to the cardinalate. On the death of Clement XIV. cardinal Braschi was chosen to succeed him, Feb. 15, 1775. The conflict with the civil power in the various states of Europe, in which, from the days of Innocent XI., the Roman see had been almost unceasingly involved to a greater or less degree, assumed under Pius what may be called its complete and scientific development. His relations to the emperor Joseph of Austria and the grand duke Leopold of Tuscany, who persisted in the reformation of the religious orders, etc., were far from amicable. The internal administration of Pius, however, was enlightened and judicious. To him Rome owes the drainage of the Pontine marsh, the improvement of the port of Ancona, the completion of the church of St. Peter's, the foundation of the new museum of the Vatican, and the general improvement and embellishment of the city. These and other similar projects were interrupted by the outbreak of the French revolution. In 1793 a popular tumult at Rome, which was caused by the imprudence of a French political agent named De Basseville, and which resulted in his death, gave the French directory an opportunity of hostile demonstrations against the pope. In 1796 Bonaparte took possession of the legations, and afterwards of the march of Ancona, and by a threatened advance upon Rome extorted from Pius, in the treaty of Tolentino, the surrender of these provinces to the Cisalpine republic, together with a heavy war contribution. The year 1797 was marked by a continuance of the same vexatious measures; and at length the directory ordered the invasion of Rome; Berthier entered the city, Feb. 10, 1798, and took possession of the castle of St. Angelo. Pius was called on to renounce his temporal sovereignty, and on

his refusal was seized, Feb. 20, and carried away to Sienna, and afterwards to the celebrated Certosa, or Carthusian monastery of Florence. On the threatened advance of the Austro-Russian army in the following year, he was transferred to Grenoble, and finally to Valence on the Rhone, where, worn out by age and by the rigor of confinement, he died in Aug., 1799, in the 82d year of his age and the 24th of his pontificate.—PIUS VII., originally Gregory Barnabas Chiaramonte, was b. at Cesena in 1742. He entered the Benedictine order at an early age, and was employed in teaching philosophy and theology at Parma, and afterwards at Rome. He was appointed bishop of Tivoli; and afterwards, being created cardinal, was translated to the see of Imola. After the death of Pius VI., cardinal Chiaramonte was chosen his successor (Mar. 14, 1800). Rome, which, up to this time, had been in the occupation of the French, was now restored to the papal authority, and in the July of that year Pius VII. entered into his capital; and in the following year the French troops were definitively withdrawn from the papal territory, with the exception of the legations. From this time forward Pius, ably seconded by his secretary of state, cardinal Consalvi, was destined to occupy a prominent place in the political as well as the ecclesiastical affairs of Europe. Bonaparte had resolved to restore religion in France on the ancient basis of connection with Rome. With this view, he entered into negotiations with Pius VII. for the establishment of a concordat suited to the new order of things which had arisen. These negotiations were conducted at Paris, and were attended with many difficulties and delays, until at length cardinal Consalvi repaired in person to the conference, and, by his energy and decision, disentangled the complicated embarrassments in which it was involved. It was agreed to at Paris, July 15, 1801; ratified in Rome, Aug. 14; and published in Notre-Dame on Easter Sunday, 1802. But, simultaneously with the concordat, and as if forming part of the same arrangement, was published a code of what were called "organic laws," seriously affecting the discipline of the church on marriage, on the clergy, and on public worship, which had never been submitted to Pius, and to which he not only had not consented, but to which he found himself compelled to offer every opposition. For the first year which succeeded the publication of the concordat, no occasion of difficulty arose; but conflict of principles was in the end inevitable. In 1804, Bonaparte having resolved on assuming the imperial crown, invited Pius to come to Paris for the purpose of crowning him, and the pope, although with much hesitation, consented. He took advantage of his visit to demand the recall or modification of the articles, but without success; and although, during his visit to Paris, he was treated with great distinction and reverence, his relations with Napoleon from that date began to assume a less friendly character. The French emperor now proceeded from one petty outrage to another, until finally, in Feb., 1808, the French troops, under gen. Miollis, entered Rome, and took possession of the castle of St. Angelo; and on the 2d of April, a decree was issued annexing the provinces of Ancona, Fermo, Urbino, and Macerata to the kingdom of Italy. Pius, besides protesting against the usurpation, declared himself a prisoner in the French hands, and confined himself to his palace. The papers of the cardinal secretary were violently seized, and the pope was compelled to appoint a pro-secretary; and finally (May 17, 1809), the usurpation was consummated by a decree annexing Rome and all the remaining papal territory to the French empire. This was the signal for the pope abandoning his lengthened policy of forbearance. On June 10, Pius issued a bull of excommunication, directed (without naming Napoleon) against the perpetrators and abettors of the invasion of the rights and the territory of the holy see. Soon afterwards, the French general ordered the removal of the pope from Rome; and Pius, without offering any resistance beyond the declaration that he yielded to force, was removed, first to Florence, then to Grenoble, thence for a longer time to Savona, whence, in June, 1812, he was finally transferred to Fontainebleau. During this prolonged captivity Pius firmly but quietly resisted every effort to compel or seduce him from his policy. At Fontainebleau he was treated with much external respect; and on Napoleon's return from the Russian campaign, in Dec., 1812, orders were given that the cardinals, with certain exceptions, should be admitted to the presence of the pope. Under much pressure, both from the emperor himself—who is alleged by some to have acted with great rudeness, and even with personal violence—and from the ecclesiastics to whom the emperor confided his plans, Pius was induced to sign a new concordat, an important provision of which was the recognition of the annexation of the Roman states to the empire. Having obtained the concession, Napoleon at once permitted the absent cardinals to return, and of these many remonstrated so earnestly against the concordat, that, on March 24, Pius wrote to revoke his consent. Napoleon took no notice of the revocation; nor was it till after the disasters of 1813 that he began to seek an accommodation. Pius refused to treat until he should be restored to Rome; and on Jan. 22, 1814, orders were sent for his immediate return to his capital. Unattended by his cardinals, he was escorted to Italy, and remained at Cesena until the fatal campaign of the spring of 1814 placed Paris in the hands of the allies, when Pius re-entered Rome amidst the gratulations of the people on May 24, 1814—a day since that time held sacred in the Roman calendar. During the Hundred Days, he was again compelled to leave Rome; but, after the campaign of Waterloo, he finally resumed possession, which was undisturbed for the rest of his life, and which extended to the whole of the ancient territory, including the Legations.

The last years of his pontificate were devoted to measures of internal administration;

and under the enlightened government of cardinal Consalvi, were marked by much wisdom and moderation. But the administration chiefly by ecclesiastics and the secrecy of law procedure were resumed. Pius repressed, too, with great vigor the disorder and brigandage which the long wars had introduced, and a whole village of notorious and incorrigible criminality, that of Somma, was razed to the ground in 1819. He was equally vigorous in repressing secret societies, especially that of the Carbonari (q.v.). The ecclesiastical measures of his later period were also of much importance. In 1814 he formally restored the suppressed order of the Jesuits (q.v.). In 1817 and the following years he concluded concordats with Naples, with Russia, Würtemberg, and other courts of Germany. In this and every other period of his life Pius was a model of gentleness, simplicity, benevolence, and Christian charity. In July, 1823, having reached the patriarchal age of 81, he fell accidentally and broke his thigh. He sank gradually, and died Aug. 20, 1823.

PIUS IX., GIOVANNI MARIA MASTAI FERRETTI, occupant of the papal chair during one of the most eventful periods in the history of the papacy, was born at Sinigaglia, May 13, 1792. He was originally destined for the military profession—the noble guard; but symptoms of an epileptic tendency led to his abandoning his intended profession. He received holy orders, and after exercising his ministry for a time in Rome, was sent as “auditor” of the vicar-apostolic to Chili. Having been successively archbishop of Spoleto and of Imola, nuncio, and cardinal, he was, on the death of Gregory XVI. in 1846, elected “by acclamation” to succeed him. He took the name of Pius IX., and entered at once on a course of reforms, by which he hoped to establish the papal government on a popular, but yet on a firm basis. He resolved to extirpate all abuses of administration, to withdraw the restrictions of personal liberty, to secularize the local administration, and to extend the rights of self-government. His first step to this end was to grant an amnesty; and this measure, however humane and necessary, had the result of drawing together into the Roman states a body of men whom an unhappy experience of foreign exile had embittered against the existing order of things. For a time, the reforming policy of Pius carried with it the affections of the people; but he soon fell short of the expectations which he had created. The outbreak of the French revolution of Feb., 1848, precipitated the crisis of popular discontent. In November of that year, count Rossi, whom the pope had appointed his minister, was assassinated; and violent demonstrations were daily employed to compel the pope’s assent to measures which he repudiated. Having at first confined himself to the Quirinal, he at length fled secretly from Rome to Gaeta, a Neapolitan sea-port near the Roman frontier. A republic was proclaimed in Rome, the provisional heads of which proceeded to a complete and radical remodeling of the civil government of the state. Pius from his exile addressed a remonstrance to the various sovereigns. In April, 1849, a French expedition was sent to Civita Vecchia, which eventually advanced upon Rome, and, after a siege of about thirty days, took possession of the city, and established a French army of occupation within the Roman state. The pope’s government was re-established, but he himself did not return till 1850, when he again entered upon the administration. In consequence of the unsettled condition of Italy and the failure of many of his early measures of improvement, he declared himself unable to proceed with the reformatations which he had contemplated. After that time his authority was maintained without interruption, but the discontent continued. After the war for the unification of Italy, the Legations, Ancona, and a considerable part of the papal territory southward in the direction of Rome, were annexed to the kingdom of Italy, but Pius persistently refused to cede any portion or to enter into any compromise. His ecclesiastical administration continued very active, and proceeded upon the strongest assumption of the right of independent action on the part of the church. In this view he re-established the hierarchy in England, he sanctioned the establishment in Ireland of a Catholic university, and condemned the principles upon which the queen’s colleges in that country were constituted. He concluded with Austria a concordat much more favorable to church authority than the existing ecclesiastical laws had permitted. See CONCORDAT. In 1854 he issued a decree propounding as a doctrine of the church the faith of the Immaculate Conception of the blessed virgin Mary (q.v.). In the internal administration of his states, notwithstanding the embarrassed condition of finances produced by the curtailment of his territory, he introduced many ameliorations, and did much for the advancement and improvement of the city of Rome and of its institutions. In this he was aided by the voluntary contributions of the several churches, as well in special gifts as in the organization of the permanent tribute called Peter-pence (q.v.). In 1864, on occasion of the centenary of the martyrdom of St. Peter, he brought together at Rome a large assemblage of bishops, and subsequently, on occasion of the canonization of the Jesuit martyrs of Japan. But the most important event of his pontificate was the convocation of the Vatican council (see COUNCIL), at which bishops from all parts of the Catholic world assembled in Dec., 1869. For the discussions of this council, see POPE. It was adjourned in July, 1870, after it had proclaimed the celebrated decree of the infallibility of the pope, when on a subject of faith or morals he issues a decree *ex cathedrâ* to the universal church. Soon after the adjournment, the Italian army occupied Rome, and declared it the capital of the kingdom of Italy. Pius renewed with all solemnity his oft-repeated protest, and refusing an

offered donation, and all other proposals of accommodation, from that date declared himself a captive in the Vatican, to which he strictly confined himself. In June, 1871, he completed the 25th year of his pontificate, thus exceeding the term of all previous pontificates except that assigned to St. Peter, and falsifying in his own person the traditional prediction that no pontiff would ever "see the days of Peter." His health was for some years precarious; but, with the exception of occasional interruptions, he continued to attend personally to all the public affairs, civil as well as ecclesiastical, of his office. He died Feb. 7, 1878.

PIUTE, a co. in Utah, adjoining Colorado, drained by the Grand, Green, and Colorado rivers; about 6,000 sq. m.; pop., '80, 1651—1337 of American birth. The Wahsatch mountains traverse the w. part. The soil is sterile. Co. seat, Junction.

PI-UTES, an Indian tribe of the Shoshone family. They are a migratory tribe of hunters, wandering about New Mexico, Nevada, Utah, and Colorado. They are divided into several tribes and number some 15,000.

PIVOT, the point on which a body revolves, has a like signification in military affairs—the pivotman being that soldier who marks the center while a line is wheeling.

PIYĀDASI, one of the names of the celebrated king Asoka. See **BUDDHISM**, India. He is often designated by this name in inscriptions.

PIZARRO, FRANCISCO, the conqueror of Peru, was an illegitimate son of Gonzalo Pizarro, a col. of infantry, and a soldier of some distinction. He was born at Truxillo, in Estremadura, Spain, about 1471. Of his youth, little is known, but it appears that he was wholly neglected by his parents, was taught neither to read nor write, and that in his youth his principal occupation was that of a swineherd. Abandoning this uncongenial employment, he sought the port of Seville, and there embarked to seek fortune in the new world. He was in Hispaniola in 1510; later, he joined Balboa, and was with that cavalier when he crossed the isthmus of Panama, and discovered the Pacific. In 1515 he was engaged in traffic with the natives on the shores of the newly discovered ocean, but was afterward chiefly employed in military service, in which he showed great bravery, resource, and power of endurance. About this time, when a fresh and powerful impulse was given to adventure by the splendid achievement of Cortes, rumors of a country far s., in which gold and silver were said to be as abundant as iron in Spain, reached Panama, and kindled Pizarro's ambition. He formed a sort of copartnery with Diego de Almagro, an adventurer and a foundling like himself, and Hernando Luque, an ecclesiastic; and with the funds which the three friends amassed, they were enabled to fit out a small expedition, of which Pizarro took command. In Nov., 1524, he set sail southward, but went no further than Quemada point. Making an agreement (dated Mar. 1, 1526), that all lands, treasures, vassals, etc., that should be discovered, were to be equally divided between them, the three friends, Pizarro, Almagro, and Luque, organized a second expedition, consisting of two ships, which set sail for the south seas. Having reached the port of Santa, lat. about 9° s., and having really discovered Peru, Pizarro returned to Panama, carrying with him, however, many beautiful and valuable ornaments in gold, and silver, which he had obtained from the friendly and generous natives, as well as specimens of woolen cloths of silky texture and brilliant hue, and some llamas or alpacas. Unable to find in Panama a sufficient number of volunteers for the invasion of the newly discovered country, the indomitable adventurer returned to Spain in 1528, narrated the story of his discoveries before Charles V. and his ministers, described the wealth of the territories, and showed, as proof the gold ornaments and utensils, the manufactures, etc., which he had brought with him. The result of his representations was, that the right of the discovery and conquest of Peru was secured to him, and honorable titles—among others, those of governor and capt.gen. of Peru—were conferred on him. On his side, he agreed to raise a certain number of followers, and to send to the crown of Spain a fifth of all the treasures he should obtain. Returning to Panama, he set sail for Peru for the third and last time, with a well equipped but small force, the number being not more than 180 men, of whom 27 were cavalry. The chief events of the conquest of Peru are detailed at sufficient length in the article **PERU**, and also the articles **ALMAGRO** and **ATAHUALPA**. Within 10 years the great *conquistador* made the empire of Peru his own; but he who had surmounted so many stupendous difficulties, who had broken through the lofty barrier of the Andes, and, with his group of followers, been a victor in so many fields, fell a victim to a conspiracy, June 26, 1541.

Pizarro was a soldier of the most undoubted courage, inflexible constancy of purpose, and infinite resource; yet his success in Peru appears to have been more the result of chance than of calculation. His boldest stroke was the seizure of the Inca Atahualpa (q.v.), when surrounded by thousands of his followers; but in doing so, he deserved credit neither for originality nor policy, because the idea was borrowed from Cortes, and the step itself was so foolhardy and desperate, that its success can be regarded only as luck. Although on many occasions he appears to have been guided by noble and generous impulses, he was eminently selfish, perfidious, and relentless. His conquest of Peru is a drama in every act of which there is bloodshed; but the drama is at least consistent to the end. Pizarro lived a life of violence, and died a violent and bloody death.

PIZARRO, GONZALO, threw in his fortunes with those of his brother Francisco, on the occasion when that leader returned to Spain in 1528. He was, like the great conqueror, illegitimate. He became a soldier at an early age, distinguished himself, before he joined his brother's expedition, by his skill in martial exercises, and when he reached Peru, was esteemed the best lance in the Spanish troop. The territory of Quito was assigned to him by Francisco, and he was enjoined to undertake an exploring expedition to the e., where a land, reputed to be extremely rich in spices, was said to lie. At the head of 350 Spaniards and a great concourse of Indians, Pizarro set out on his famous journey in the beginning of 1540. Marching e., they reached a country traversed by lofty branches of the Andes. Here the icy winds benumbed the limbs of the adventurers as they rose to the higher plateaux, and, rendered helpless by the cold, many of them sank and died. Descending the eastern slopes of the Andes, they reached the "land of cinnamon;" but as they could not transport the trees across the mountains, their discovery was almost valueless. Hearing of a land abounding in gold at the distance of ten days' journey, the leader resolved to reach it. Pushing forward, the Spaniards entered great forests, where often they had to hew a passage with their axes. Their clothes were now torn to shreds, and their provisions had been long exhausted. They killed and ate the dogs they had brought with them, after which they lived on the herbs and dangerous roots of the forest. At length they struck the broad but desolate waters of the Napo, an important affluent of the Amazon. On the surface of this broad river no vessel floated, and it ran amid gloomy woods, the silence of which was undisturbed save by the sound of the rushing waters. Here Pizarro caused a rude bark to be constructed for the transport of the baggage and of the weaker travelers. Francisco de Orellana was intrusted with the command of the vessel. Pizarro, hearing of a populous nation at the distance of a few days' journey, who dwelt near the confluence of the Napo with a larger river, sent forward Orellana to obtain and bring back supplies for the starving travelers, who had eaten the last of their horses, and were now reduced to the leather of their saddles and belts. Orellana reached the Amazon; but, unable either to obtain supplies, or to return against the current of the river, abandoned the expedition, and with his fifty followers resolved to sail down the Amazon, reach the Atlantic, and make for Spain. This wonderful design was successfully carried out. Pizarro, after waiting in vain for the return of the bark, resolved to return to Quito, which, after enduring terrible sufferings, and seeking fruitlessly for the rich regions of which he had heard so much, he reached in June, 1542, after an absence of more than two years. The fatal character of this expedition may be inferred from the appearance the travelers presented on their return. Half of the 4,000 Indians had perished, and of the Spaniards, only 80 remained; and these, clad in skins, blackened by the sun, and wasted by hunger and fatigue, with long matted locks, seemed like a troop of spectral savages. This expedition stands unmatched in the annals of American discovery for its dangers and sufferings, for the length of their duration, and for the heroic fortitude with which they were endured. For the fate of Gonzalo Pizarro, see article PERU.

PIZZICA'TO (Ital. twitched), abbreviated *pizz.*, a phrase used in music for the violin or violoncello, to denote that the strings, instead of being played as usual by the bow, are to be twitched with the fingers in the manner of a harp or guitar. The pizzicato is much used in accompaniments, as sounds thus produced do not cover the voice; it is also used in symphonic effects. The ordinary mode of playing is restored by the letters *e. a.* (*col arco*, with the bow).

PIZZO, a sea-port of south Italy, in the province of Catanzaro, 24 m. w.s.w. from Catanzaro, on the gulf of Santa Eufemia. It was at Pizzo that Murat (q.v.), the ex-king of Naples, was taken, tried, and shot. He was buried in one of the common vaults of a church to the erection of which he had largely contributed. Pop. 6,402.

PLACENTA, or **AFTER-BIRTH**, a temporary organ that is developed within the uterus during pregnancy, and is, as its popular name implies, expelled from the maternal organism shortly after the birth of the child or young animal. It is a spongy vascular mass, existing in some form or other in all mammals, excepting the *Marsupialia* and *Monotremata*, as an appendage to the fetal membrane called the *chorion*. In the human subject, it is of considerable size at the period of delivery, being of a rounded or oval form, with a diameter of 6 or 8 in., and a thickness of somewhat more than an inch. Its outer surface, which, till the period of its detachment and expulsion, is attached to the walls of the uterus, is uniform and level (unless it has been morbidly adherent), being covered by a membrane, shortly to be noticed, called the *decidua serotina*; and on peeling off this membrane, the various lobes of which the placenta is composed are apparent. The internal or free surface is smooth and shining, and gives attachment to the umbilical cord or navel-string, which connects it with the fetus. To render the mode of formation of the placenta clear, we must premise that the impregnated ovum, when it reaches the uterus, is invested with an outer membrane, the *chorion*, which forms a shut sac, externally covered with short villi. As the ovum advances in age, these villi diminish in number, until few remain, except at that part of the chorion which is in contact with the uterus; and here, about the second month (in the human subject), they divide into branches. While these changes are going on in the membrane of the ovum, the uterus is also undergoing modification; and it is on the nature and extent of these uterine

changes that the character or type of the placenta depends. There are two such types, the first of which is best represented by the human placenta, and the latter by that of the pig.

In animals exhibiting the first type of placental structure, the mucous membrane lining the uterus undergoes a rapid growth and modification of texture, becoming connected with the *membrana decidua*, which is so called from its being thrown off at each parturition. For brevity, it is usually termed the *decidua*. This decidua is from an early period separable into three portions—the *decidua vera*, or *decidua uteri*, which lines the general cavity of the uterus: the *decidua reflexa*, which immediately invests the ovum; and the *decidua serotina*, which is merely a special development of a part of the decidua vera at the part where the villi of the chorion are becoming converted into the fetal portion of the placenta. At first, the villi of the chorion lie loosely in the corresponding depressions of the decidua; but subsequently, the fetal and maternal structures (the villi and the decidua vera) become closely united, so as to form one inseparable mass, by the following means: the deeper substance of the uterine mucous membrane in the region of the placenta is traversed by vessels which enlarge into what, in the case of the veins, are termed *sinuses*, dip down between the villi, “and at last swell round and between them, so that finally the villi are completely bound up or covered by the membrane which constitutes the walls of the vessels, this membrane following the contour of all the villi, and even passing, to a certain extent, over the branches and stems of the tufts.”—Goodsir’s *Anatomical and Pathological Observations*, p. 60.

The pure maternal blood is conveyed to the placenta by what are termed, from their tortuous course, “the curling arteries” of the uterus, and is returned by the large veins termed sinuses. “The fetal vessels,” says Dr. Carpenter, “being bathed in this blood, as the branchiæ of aquatic animals are in the water that surrounds them, not only enable the fetal blood to exchange its venous character for the arterial, by parting with its carbonic acid to the maternal blood, and receiving oxygen from it, but they also serve as rootlets, by which certain nutritious elements of the maternal blood (probably those composing the liquor sanguinis) are taken into the system of the fetus. It is probable, too, that the placenta is to be regarded as an excretory organ, serving for the removal, through the maternal blood, of excrementitious matter, whose continued circulation through the blood of the fetus would be prejudicial to the latter.”—*Human Physiology*, 3d ed., pp. 1013, 1014. Moreover, the recent investigations of Bernard show that the placenta secretes, like the liver, the saccharine matter known as glycogen (q.v.), which probably takes part in keeping up the animal heat. The vascular connection between the fetus and the placenta is effected by the umbilical vein (containing arterial blood) and the two umbilical arteries (containing venous blood), all of which lie in the umbilical cord which connects the fetus (q.v.) with the placenta. The placenta may be formed at any point of the uterus, but is most commonly on the left side. Occasionally (in 11 cases out of 600, according to Nægele), it is situated partially or entirely over the mouth of the womb (*os uteri*), in which case dangerous flooding takes place previous to or at the period of labor. This condition is known as *placenta prævia*, and under ordinary management, “one in three of the mothers are lost, and more than 65 per cent of the children.”—Churchill, *Theory and Practice of Midwifery*, 3d ed., p. 473. By substituting the detachment and extraction of the placenta for the old method of turning the child *in utero*, prof. Simpson finds that the mortality sinks to 1 in 14 of the mothers, but slightly rises (to 69 per cent) in the case of the children.

Another difficulty in midwifery practice, but far less serious than the preceding, is undue retention of the placenta. In ordinary cases, the average interval between the birth of the child and the expulsion of the after-birth is a quarter of an hour. When the expulsion does not take place within an hour or an hour and a half, the case is regarded as coming under the head of “retained placenta.” It occurs in about 1 case in 400, and in these cases is fatal to about one mother in five; the cause of death being hemorrhage. The principal causes of retention are either imperfect and insufficient, or irregular contraction of the womb after the birth of the child. In the first of these cases, if the uterus cannot be excited to sufficient action, the placenta must be withdrawn by steady traction of the umbilical cord, and if it fail, extraction by the introduction of the hand (an operation always to be avoided if possible) must be resorted to; in the latter case, manual extraction is commonly necessary. Sometimes, in consequence of inflammatory or other affections of the placenta, there may be adhesion between its outer surface and the inner surface of the womb. This is the most dangerous form of retention, there being usually excessive flooding, and additionally the peril arising from the decomposition of any portion that cannot be removed without undue violence.

The placenta acquires its proper character, in the human subject, during the third month, and it subsequently goes on increasing to the full period of gestation. At about the fourth month, the blood, moving through the enlarged uterine vessels, produces a peculiar murmur, which is known as the *placental bruit*, resembling the sound made by blowing gently over the lip of a wide-mouthed phial, and increasing in intensity and strength as pregnancy (of which it is one of the characteristic signs) advances.

In animals exhibiting the second type of placental structure—as, for example, the pig—the placenta is comparatively simple in its structure. “No *decidua* is developed;

the elevations and depressions of the unimpregnated uterus simply acquire a greater size and vascularity during pregnancy, and cohere closely with the chorionic villi, which do not become restricted to one spot, but are developed from all parts of the chorion, except its poles, and remain persistent in the broad zone thus formed throughout fetal life. The cohesion of the fetal and maternal placenta, however, is overcome by slight maceration or post-mortem change; and at parturition, the fetal villi are simply drawn out like fingers from a glove, no vascular substance of the mother being thrown off." Prof. Huxley, from whose *Elements of Comparative Anatomy* (1864, p. 103) the preceding extract is borrowed, follows the opinion adopted by De Blainville, Von Baer, Eschricht, Milne-Edwards, Gervais, and Vögt in regarding "the features of the placenta as affording the best characters which have yet been proposed for classifying the monodelphous [or placental] mammals." He proposes to apply the term *deciduate* to those animals whose placenta presents the human type, and which throw off a *decidua*; and to term those animals *non-deciduate* in which the placenta is constructed on the same plan as that of the pig. "Thus," he observes, "man; the apes, or so-called *quadrumanæ*; the *insectivora*; the *chiroptera*; the *rodentia*, to which the lowest apes present so many remarkable approximations; and the *carnivora*, are all as closely connected by their placental structure as they are by their general affinities. With the pig, on the other hand, the ungulate quadrupeds, and the *cetacea* which have been studied, agree in developing no decidua, or, in other words, in the fact that no vascular maternal parts are thrown off during parturition. But considerable differences are observed in the details of the disposition of the fetal villi, and of the parts of the uterus which receive them. Thus, in the horse, camel, and *cetacea*, the villi are scattered as in the pig, and the placenta is said to be *diffuse*; while in almost all true *ruminants*, the fetal villi are gathered into bundles or cotyledons, which in the sheep are convex, and are received into cups of the mucous membrane of the uterus; while in the cow, on the contrary, they are concave, and fit upon corresponding convexities of the uterus."

The remarks which have been made on the functions of the human placenta, are equally applicable to all placental mammals generally.

The *diseases* of the human placenta had not been studied with any accuracy, until the subject was taken up by prof. Simpson. This distinguished physician and subsequent observers have ascertained that the placenta is liable to (1) congestion, ending in the effusion of blood into the substance of the organ upon its surfaces, or between the membranes; (2) inflammation, giving rise to adhesions, or terminating in suppuration, which may occasion very serious constitutional disturbances; (3) partial or entire hypertrophy or atrophy; and (4), fatty degeneration, affecting its small vessels. Whatever be the form of disease by which the placenta is attacked, the result is usually fatal to the fetus.

PLACENTA, in botany, a membrane of the interior of the germen (q.v.) or ovary, to which the ovules are attached either immediately or by umbilical cords (q.v.). The placenta sometimes appears as a mere thickening of the walls of the germen. In many cases, it is a more decided projection from the walls of the germen. When thus connected with the walls of the germen, the placenta are described as *parietal* (Lat. *paries*, a wall). But in some plants, the placenta of the different cells of the germen are united together in a column in its axis, and they are then described as *axile*. This distinction is of great importance as characterizing different natural orders. Parietal placenta are formed where the edges of carpellary leaves unite; but great difficulty has been experienced by vegetable physiologists in explaining the formation of axile placenta; some regarding them as also originally formed in this manner, and others as formed in a quite different manner from the axis itself; nor is it impossible that both theories may be correct as to different orders of plants. It is certain that in many cases in which the placenta appear as axile, they are formed from the edges of the carpellary leaves which fold in to meet in the axis, and form *dissepiments* (q.v.) between the cells of the germen. The number of placenta corresponds with the number of carpels in the germen, or appears to be the double of it, each carpel producing two rows of ovules instead of one. See article PISTIL.

PLACENZA. See PIACENZA.

PLACER, a co. in e. California, adjoining Nevada, bounded on the e. by lake Tahoe, on the s. by the middle fork of the American river, on the n.w. by Bear river, drained by the n. fork of the American river, traversed by the Central Pacific, and the Oregon division of that railroad; about 1500 sq.m.; pop. '80, 14,226—9,015 of American birth. The surface is uneven, crossed in the e. by the Sierra Nevada, and covered with great forests of pine. The rivers flow in deep, narrow canyons. The valley soil is fertile. The principal productions are barley, wool, wheat, and wine. Quartz, slate, granite, and serpentine are found. Placer-mining is extensively carried on, and gold is the principal export. Co. seat, Auburn.

PLACETUM REGIUM, called also PLACET, EXEVUATUR, LETTRES PATENTES, is an act or instrument executed in virtue of the privilege claimed by the government in certain kingdoms to exercise a supervision over the communications of the Roman pontiff with the clergy and people of those kingdoms, and to suspend or prevent the publication of any brief, bull, or other papal instrument which may appear to contravene the laws of the

kingdom, or to compromise the public interest. The early Christian emperors, it is well known, freely stretched their legislation into the affairs of the church; and one constant cause of conflict between church and state in the mediæval period was the attempt, on the part of the sovereigns, to control the free intercourse of the pope with the several churches. In the pragmatic sanction in France, and in the similar legislation of Spain, Portugal, Sicily, and the Low Countries during the 15th c., the claims of the state on the same head are more than once asserted; and among the so-called "liberties" of the later Gallican church was a certain though not a complete subjection to the state in this particular; but it was in the German states that this claim was most distinctly asserted, and most formally embodied in the constitutional law. The principle upon which the peace of Westphalia, so far as regards its religious provisions, is based, is that the will of the sovereign of the state is supreme and final in all the concerns of religion. *Cujus regio illius et religio* ("Whose the territory, his also the religion") became the maxim of church government; and, of course, within certain limits, the Catholic sovereigns acted as freely upon it as the Protestant. This intermixture of the spiritual and the temporal prevailed especially in the mixed governments of the ecclesiastical sovereigns of Germany, the prince-bishops of the Rhine; but without the same foundation, the system was carried to its height in Austria under Joseph II. (see FEBRONIANISM, PIUS VI.), the excessive minuteness of whose ecclesiastical ordinances procured for him the sobriquet of "The Sacristan." Under him all pontifical bulls, briefs, and constitutions, and all the ordinances of the local bishops, were made subject to the imperial censorship, and it was forbidden to publish any of them without its receiving the *placet* of the emperor. The only exception, in the case of pontifical decrees, regarded those emanating from the Roman penitentiary (q.v.), which, as being of their nature secret, were not held subject to revision. In Prussia the same law was enforced, as also in Baden and Saxony, no less than in the Protestant governments of Würtemberg, Saxe-Gotha, Saxe-Weimar, etc. These claims of the state had always been the subject of protest on the part of the Roman see, but the church, nevertheless, had been compelled to acquiesce silently in the enforcement. In many cases, however, they have led to serious disputes, of which the mixed-marriage question in Prussia furnished a few years ago a very remarkable example. And since the ascendancy obtained by Prussia in the German empire at the close of the Franco-German war, the system of church legislation has undergone a complete change, the details of church government being largely taken into the control of the state, and obedience to the new code of church laws being exacted from the clergy under penalty of forfeiture of income, of deprivation of office, and in some cases of exile.

PLA'COID FISHES, an order of fishes, in the classification proposed by Agassiz, characterized by having *placoid* (Gr. *plax*, a broad plate) scales, irregular plates of hard bone, not imbricated, but placed near together in the skin. These scales or plates are of considerable size in some fishes, but in others they are very small tubercles, as in the dog-fish, of which the skin forms fine-grained shagreen. Agassiz includes among the placoid fishes those cartilaginous fishes which have no scales. The order is exclusively composed of *cartilaginous fishes* (q.v.). The existing placoid fishes are few in comparison with the fossil genera and species. Placoid scales are often elevated in the middle, the center sometimes rising into a strongly projecting point or spine. They exhibit great variety of forms, sometimes even in different parts of the same fish.

PLA'GAL, a musical term, principally applicable to *canto fermo* and signifying collateral. Gregory the great, in revising the labors of Ambrose, and remodeling the plain-song (q.v.) of the church, added to the scales of Ambrose, which he distinguished as authentic, certain other collateral scales, which he called plagal, possessing the peculiarity of having the octave so divided that the fourth was above the fifth. Melodies are now known as plagal which have their principal notes contained between the fifth of the key and its octave or twelfth. The cadence, consisting of the subdominant harmony followed by the tonic, is called the plagal cadence—

PLA'GIOSTOMI (Gr. transverse-mouthed), an order of fishes, in the system of Müller, containing the cartilaginous fishes with placoid (q.v.) scales, and divided into two sub-orders, one containing sharks, and the other rays. The plagiostomi have five or six more gill-openings. They have no air-bladder. Impregnation takes place before the eggs are deposited, and the males are furnished with *claspers*.

PLAGUE, a very malignant kind of contagious fever prevailing at certain times and places epidemically, characterized by buboes, or swellings of the lymphatic glands, by carbuncles and petechiæ, and not apparently furnishing any security against its recurrence in the same individual. For a history of the origin of the plague in the far east (China), and its gradual spread, under the name of the *black death* (q.v.), through Asia and Europe, in the 14th c., the reader is referred to Hecker's *Epidemics of the Middle Ages* (1844, published by the Sydenham society). Its true and permanent home seems to be in the regions bordering upon the eastern extremity of the Mediterranean. At different periods of the 15th, 16th, and 17th centuries, it visited western Europe. It last

attacked London and almost all England in the years 1663-65; while so late as 1720, it destroyed nearly half the population of Marseilles; and seventy years afterwards, prevailed in Russia and Poland, since which time it has been almost unknown in western Europe. It is now limited chiefly to Egypt, Syria, Anatolia, Greece, and Turkey, occasionally extending northward towards Russia, and westward as far as Malta.

The disease usually commences with a sensation of intense weariness and fatigue, slight shivering, nausea and sickness, confusion of ideas, giddiness, and pain in the loins. These symptoms are rapidly followed by increased mental disturbance, with occasional stupor and delirium, by alternate pallor and flushing of the face, by suffusion of the eyes, and a feeling of intense constriction in the region of the heart. Darting pains are felt in the groins, armpits, and other parts of the body, which are soon followed by enlargements of the lymphatic glands, or *buboes* (which sometimes appear on the first and second day, sometimes not till near the close of the disease, and sometimes are altogether absent), and by the formation of *carbuncles* on various parts of the body. As the disease advances, the tongue becomes dry and brown, while the gums, teeth, and lips are covered with a dark fur; the bowels, at first constipated, become relaxed, the stools being dark, offensive, and sometimes bloody. The power of the will on the muscles is much impaired; and altogether the patient resembles a person under the influence of intoxication. Throughout the disease, there is more or less tendency to faintness; and usually about the second or third day, petechial spots, livid patches like bruises, and dark stripes (called *vibices*), appear upon the skin, especially in severe cases. These discolorations are owing to the extravasation of blood, and are often accompanied with hemorrhagic discharges from the mucous membranes. In severe cases, the pulse gradually sinks, the surface becomes cold and clammy, blood oozes from the mucous surfaces, there is coma, or low delirium; and death occurs usually in five or six days, either without a struggle, or preceded by convulsions.

Great difference of opinion exists as to the cause of plague. Some maintain that it is propagated exclusively by a peculiar contagion; others, while admitting its contagious nature, maintain that it may also be spontaneously engendered by endemic or epidemic influences; while others, again, reject the contagion view altogether, and assert that it originates exclusively in local causes or epidemic influences. Of these three views, the great mass of evidence goes to show that the second is the correct one. Whatever may be the cause of the disease, temperature appears to exert a considerable influence over it. In tropical climates, the disease is unknown, and the cold weather of northern climates has been observed to check its ravages. In Europe, it has always been most fatal in the summer and autumn, especially in September. Thus, in the plague of London in 1665, the deaths from the plague were, in June, 590; in July, 4,129; in August, 20,046; in September, 26,230; in October, 14,373; in November, 3,449; while in December, they were less than 1000.

The exact nature of the disease is unknown. A poison whose characters evade all chemical and microscopical examination is absorbed and alters at once, or after a short stage of incubation, the composition of the blood and the condition of the tissues.

With respect to treatment, little can be done to arrest the progress of the disease in any individual case. The patient should, if possible, be removed at once from the source of the disease; he should be exposed freely to fresh air; his secretions should be duly regulated, and his strength supported as far as possible. Friction with olive oil has been strongly recommended, but subsequent experience has not confirmed the first reports in its favor. But although treatment is comparatively valueless, much may be done toward guarding against the attacks of the disease. There can be little doubt that it is in consequence of the free external use of cold water, perfect cleanliness, moderate habits of life, and superior ventilation that European (especially English) residents in the infected cities of the Levant are comparatively exempt from this disease. It is very possible that inunction of the body with olive oil may be (as has been asserted) a useful prophylactic agent, although it fails to cure the disease. It is almost needless to add that all unnecessary communication with the sick, or contact with clothes or other matter that may have been infected with the poison, should be as much as possible avoided.

PLAGUE, SOUTHERN CATTLE. See TEXAS CATTLE DISEASE.

PLAICE, *Platessa vulgaris*, a species of flounder (q.v.), much resembling the common flounder, but rather broader in proportion to its length: the upper surface of the body and the fins olive-brown, marked with large bright orange spots; a row of similar spots on the dorsal fin and on the anal fin; no tubercular asperities on any part of the body, but a curved row of bony tubercles on the eye-side of the head. The plaice inhabits sandy and muddy banks, not in very deep water, and is very abundant on most parts of the British coasts, as well as on those of continental Europe. Like the common flounder, it often ascends slow rivers to some distance from the sea, and it has even been found to thrive well when transferred to fresh-water ponds. It feeds on worms, mollusks, small crustaceans, and young fishes. It has been known to attain the weight of fifteen pounds, but a plaice of seven or eight pounds is accounted large. It is taken both by lines and trawl-nets. It is in considerable esteem for the table, although so plentiful in the British markets that it is in general very cheap.

PLAID, a woolen garment, in the form of a large scarf, to wrap round the body, and used chiefly among the rural population of Scotland. See TARTAN.

PLAIN, in geography, is an extensive tract of country which, on the whole, preserves a nearly uniform elevation. When referred to the level of the sea, plains may be distinguished into low plains or lowlands, and elevated plains called plateaux or *table-lands* (q.v.). Plains differ much in appearance, according to the nature of their soil and climate, from the frightful sandy wastes of Africa, to the luxuriant fertility of the South American silvas. They are occasionally crossed by hills of moderate altitude, which, however, are generally detached, and exhibit no connection with any neighboring mountain system. These hills often, as in the North American plains, degenerate into mere undulations, perfectly uniform in structure. The term "plains" is, in a limited sense, confined to the plains of western Europe; those of other parts of the world receiving special designations, and differing from each other in many important points; thus, we have the *steppes* (q.v.) of eastern Europe and Asia; the *deserts* (q.v.) of Arabia and Africa; the *savannahs* (q.v.) and *prairies* (q.v.) of North America; and the *llanos* (q.v.), *pampas* (q.v.), and *silvas* (q.v.) of South America. The chief plains of Europe are, the country stretching from the foot of the Carpathians in Galicia to the Ural mountains (including Poland and Russia, the drainage-area of the Danube in Hungary, and the portion of Europe which is bounded by the Elbe, the Harz mountains, France, and the sea. Plains of comparatively small extent, but presenting the necessary characteristics in perfection, are found in almost all countries.

PLAINFIELD, a city in n.e. New Jersey incorporated 1869; on the Central railroad of New Jersey in Union co.; pop. '80, 8,126. It is 24 m. from New York, 11 m. from New Brunswick, and 12 m. from Elizabeth. It has many costly residences, chiefly occupied by persons doing business in New York, 9 churches, public schools, an institute, and a seminary for young ladies. It supports 3 weekly newspapers, a hotel, and has 4 national banks. Its industries include the manufacture of machinery, clothing, etc.

PLAINFIELD, Conn. See page 895.

PLAINS, Penn. See page 895.

PLAINS, Va. See page 895.

PLAIN'-SONG, or CANTO FERMO (Ital.), a name given by the church of Rome to the ecclesiastical chant. It is an extremely simple melody, admitting only notes of equal value, rarely extending beyond the compass of an octave, and never exceeding nine notes, the staff on which the notes are placed consisting of only four lines. The clefs are C and F. St. Ambrose is considered to have been the inventor or systematizer of plain-song. His labors consisted in selecting from the extremely complicated system of the Greeks a set of scales sufficiently few and simple for a very rude people. During the two centuries succeeding the death of Ambrose, his institutions fell into utter confusion. Gregory the great revived and perfected them, recasting them into an *antiphony*, or authorized body of ecclesiastical music, and brought plain-song into the state in which it is yet used in the Roman church. See AMBROSIAN CHANT and GREGORIAN CHANT.

PLAIN'TIFF, in English and Irish law, is the name given to the person who institutes and maintains a civil action or suit against another, who is called the defendant. In Scotland a plaintiff is called a pursuer. But in both countries many proceedings and applications of a civil nature are commenced by petition; and hence the party taking the initiative is called the petitioner.

PLAIN'TIFF (*ante*) corresponds to the complainant in equity proceedings, the libellant in admiralty suits, and the complainant in the old "real actions." A distinction exists at common law between the legal and equitable plaintiff; the former is the man in whom the legal right of action is vested; the latter he who is equitably entitled to the relief or damages sued for. Thus if A brings an action for the use or benefit of B, A is the legal and B the equitable plaintiff. In the system of pleading and procedure now in use in most states, the name of the party really interested is inserted in the declaration and the old distinction abolished. The plaintiff in error is the party suing out a writ of error for the purpose of appealing to a higher court and may be either the plaintiff or defendant in the original suit. A plaintiff *ad litem* is one appointed to represent an insane person or minor for the purpose of prosecuting the suit.

PLAISTED, HARRIS M. See page 895.

PLAN, a word frequently applied to all kinds of architectural drawings, but which ought to be limited to those which represent the horizontal sections of the various floors of buildings. Plans show the disposition of the apartments and walls, with the situation of the fire-places, cupboards, doors, etc.; they, in fact, represent the different stories as they actually appear as seen from above, when the walls are built two or three feet above the level of each floor.

PLANA, GIOVANNI ANTONIO AMADEO DE, Baron 1781-1864; b. Italy; educated at the Paris polytechnic school. He held the chair of mathematics at the Alessandria artillery school 1803-11, when he became prof. of astronomy at the univ. of Turin. In 1813 he was made director of the Turin observatory. His most important works are a treatise *On the Theory of the Attraction of Elliptical Spheroids*, 1810; and *Theory of the Movement of the Moon*, 1832. He was made baron and senator, and elected to the French academy.

PLANA'RIA, a genus of worms placed by Cuvier among *entozoa*, although not parasites, but inhabitants of stagnant waters, because of their great resemblance to some of the entozoic parasites, and particularly to flukes. The species are numerous. Some inhabit fresh, and others salt water; they feed on small annelids, mollusks, etc. They are generally found creeping among confervæ, or on the stems of plants. Many of the larger marine species are able to swim freely by flappings of the broad margins of their bodies. The body of a planaria seems to be entirely gelatinous; but M. de Quatrefages has detected under the skin an arrangement of muscular fibers. Two red specks in the fore-part of the body of many species have been supposed to be eyes; but there is no proof of it. Planariæ are hermaphrodite, but copulate for mutual impregnation. Their power of multiplication by division is very great; if an individual be cut in pieces, each piece continues to live and feel, and "even if it be the end of the tail, as soon as the first moment of pain and irritation has passed, begins to move in the same direction as that in which the entire animal was advancing, as if the body was actuated throughout by the same impulse; and, moreover, every division, even if it is not more than the eighth or tenth part of the creature, will become complete and perfect in all its organs."—*Rymer Jones*.

PLANCHÉ, JAMES ROBINSON, 1796-1880; b. London; was successful as a writer of more than 200 pieces for the stage; some of which were translations from the French. His first work was a burlesque called *Amoroso, King of Little Britain*. In 1826, having traveled on the continent, he published *Lays and Legends of the Rhine*; 1827, *Descent of the Danube*; 1828, *Charles XII.*, one of his best works: In 1830 he was chosen a member of the antiquarian society; and appointed Somerset herald, 1866. Among his numerous publications are: *History of British Costume*; *Regal Records*; *The Pursuivant of Arms, or Heraldry founded upon Truth*; *King Nut-Cracker, a Fairy Tale*; *Popular Fairy Tales Illustrated*; *Recollections and Reflections, a Professional Autobiography*; *The Conqueror and his Companions*.

PLANCHE, JEAN BAPTISTE GUSTAVE, 1808-57; b. Paris; educated at the Bourbon college. He was a contributor to the *Revue des Deux Mondes*, an associate of Balzac on the *Chronique de Paris*, and a writer on Italian art.

PLANCHETTE (a little board) is, as the name implies, a French invention, but its popularity in America has induced the belief of its being of American origin. It consists of a heart-shaped board seven or eight inches at its greatest breadth and length, mounted on two pentagraph wheels, about two inches high, at its widest part, while a pencil fastened at the apex forms its third support. Placed upon a table with a sheet of paper under it, and one or two persons with the necessary qualifications having their hands upon its tablet, setting it in motion, it is found to return answers to questions sometimes of a puzzling character. These answers are asserted by believers in spiritualism to be communications from the spirit-world.

PLANCUS, LUCIUS MUNATIUS, b. at Tibur near Rome; in youth one of Cicero's pupils and later an officer of Cæsar in the Gallic wars. After the assassination of Cæsar, Plancus at first favored Brutus, but soon went over with four legions to Antony. In B.C. 42 he was consul with Lepidus. In the contest between Antony and Octavius, he sided with the latter, and proposed in the senate the title of Augustus. Plancus was a man of some literary taste and to him one of Horace's odes is addressed.

PLANE, in geometry, is a surface without curvature, and the test of it is, that any two points whatever being taken in the surface, the straight line which joins them lies wholly in the surface. When two planes cross or intersect one another, their common section is a straight line; and the inclination of the planes to each other is measured by taking any point in their common section, and drawing from it two straight lines, one in each plane, perpendicular to the common section; the angle contained by these lines is the angle of inclination of the planes. When the angle is a right angle, the planes are perpendicular to each other.

PLANE, *Platanus*, the sole genus of trees of the natural order *platanaceæ*, regarded by many as a suborder of *amentaceæ* (q.v.). The flowers are in globose, small, pendulous, long stalked catkins, which give the tree a peculiar appearance in winter; the ovary is one-celled, and contains one or two pendulous ovules. The species of plane are very few; natives of temperate climates in the northern hemisphere; tall trees, with deciduous large palmate leaves, and smooth whitish bark, which annually scales off in large pieces. The **ORIENTAL PLANE** (*P. orientalis*), a native of Greece and the east, was planted by the Greeks and the Romans as an ornamental tree; no other tree, indeed, commanding equal admiration; and, for centuries, the youth of Greece assembled under its shade in the groves of Academus, to receive lessons in philosophy. The plane is still planted for shade and ornament in the south of Europe. Many fine trees exist in England, but they were at one time much more numerous, great part having died in the end of last century. The spring frosts, and the insufficient duration of the summer for the proper ripening of the wood, render Scotland less suitable for its cultivation; yet there is a tree at Gordon castle 66 ft. high. No tree better endures the atmosphere of a large city, and there are no finer trees within the precincts of London than its plane trees. In the east the plane

attains an immense size. One tree, in the meadow of Buyukdere on the banks of the Bosphorus, is 141 ft. in circumference at the base, extends its branches 45 ft. from the trunk, and is believed to be more than 2,000 years old. The wood of the plane, when young, is yellowish-white; when old, it is brownish, fine grained, takes a high polish, and is esteemed for cabinet-making. A rich alluvial soil and the vicinity of water are most suitable to this tree.—The NORTH AMERICAN PLANE, or BUTTONWOOD (*P. occidentalis*), is a very similar tree. It is the largest deciduous tree of the United States, and abounds on the banks of the great rivers of the middle states. Its timber is not very valuable, and is very liable to decay. A tree of this species on the bank of the Thames, in Chelsea hospital gardens, is 115 ft. high, with a trunk five ft. in diameter. The name plane-tree is commonly given in Scotland to the sycamore (*acer pseudo-platanus*), which resembles the true planes in its foliage.

PLANE, a tool used for rendering the surface of wood smooth and level. It consists of an oblong block of wood or metal (the latter has only recently come into use), with an opening through the center; this opening is square on the upper side, and is always large enough to admit the cutting instrument; it diminishes down to a mere slit on the under side, just wide enough to allow the cutting edge of the plane-iron and the shaving of wood which it cuts off to pass through. The essential part of the tool is the plane-iron, a piece of steel with a chisel-shaped edge, and a slot in its center for a large-headed screw to work and to attach to it a strengthening plate. They are held in place by the hard-wood wedge. By driving in the wedge, the irons are held very firmly in their place, and they are so adjusted that only the fine sharp chisel-edge of the cutting-tool projects through the slit in the bottom of the body of the plane, so that when the tool is pushed forward by the force of the hand, the cutting edge pares off all irregularities, until the wood is as smooth as the under surface of the plane. There are many modifications in this tool, which can have its cutting edge and under surface made to almost any contour, so that moldings of all kinds may be made. The two commonest are the jack-plane for rough work, and the smoothing-plane for finishing off plane surfaces.

PLANING-MACHINES have lately been much in use, by which both wood and metal are planed. In the case of those intended for wood, the cutting instruments are moved forward over the wood by machinery in the same manner as in the hand-plane. The precision and rapidity with which these machines work have given great facilities for building, as one machine will do as much work as sixty men. The planing-machines used for metal are different in principle. A well-tempered, chisel-edged steel cutter is held in a fixed position, pressing downwards upon the metal plate, which is moved forward by powerful machinery. The action of this movement is that a groove is plowed into the metal of the size of the steel cutter; when the metal has traveled its full length, and has made the groove complete, the downward pressure of the tool is removed, and by the action of the double screw which has carried it forward, it is returned, and readjusted for another groove to be formed by the side of the first; and this is repeated until the whole surface of the plate is reduced to the required level. However tedious this process may appear, it offers such facilities for metal working as were previously unknown.

PLANER TREE, found on swampy lands in the southern states, is like the elm in general appearance, but has a different flower and fruit; of moderate size, and supplies hard timber, useful for various purposes. A species found in the Levant has aromatic wood—the Cretan false sandal-wood mentioned by old writers. A third species, a native of Persia and the Caucasus, has been introduced into Europe; it is tall and handsome, and furnishes excellent timber.

PLANET, INTRA-MERCURIAL, THE. See page 895.

PLANE'TA, the Greek name of the vestment called by the Latins *casula*, and in English “chasuble,” which is worn by priests in the celebration of mass. The form of this vestment in the modern Roman church differs both from the ancient form and from that in use in the Greek church. The change appears to date from the 9th c., but has been gradual. A certain modification of the Roman *planeta* was recently introduced in England under the inspiration of the late Mr. Pugin, the great reviver of Gothic architecture and ecclesiastical costume and decoration. But its use has been only partial even in England.

PLANETA'RIUM, a machine much employed by astronomers in the 17th and 18th c., and first constructed by Huyghens and Römer, for the purpose of exhibiting clearly the motion of the heavenly bodies in conformity with the Copernican doctrine. The planetarium exhibited only the orbital motions of the planets about the sun, either in circles or ellipses, and with constant or varying motions, according to the perfection of the machine. It was subsequently supplemented by the *combined tellurian and lunarian*, which exhibited at one and the same time the motion of the moon about the earth and that of the latter round the sun, with the principal phenomena (such as the succession of day and night, the varying length of each, eclipses, and the motion of the moon's apogee and nodes) which accompany these motions. A *satellite machine* was also invented to illustrate the motions of Jupiter's satellites. All these machines are now combined in the Orrery (q.v.), which exhibits in the best manner possible the varied motions and phenomena of the bodies in the solar system.

***PLANETOIDS**, or **ASTEROIDS**, the name given to that numerous group of very small planets which are situated in the solar system between Mars and Jupiter. Till the present century they remained undiscovered; but for some years before, their existence had been suspected, mainly owing to the remarkable hiatus in the series of the planetary distances when compared with the law of Bode (q.v.). On the first day of the present century the first of them was detected by Piazzi of Palermo, and his success roused his brother astronomers to search for more planets. Their search was successful, for Olbers (q.v.) discovered two in 1802 and 1807, and Harding one in 1804; but as all researches for some time subsequent to 1807 were unavailing, astronomers gradually allowed themselves to settle down into the belief that no more planetoids remained to be discovered, when the detection of a fifth by Hencke in 1845 revived the hope of fresh discoveries, and from this period no year (excepting 1846) has passed without adding to the list. The number now known is more than 170. This remarkable success of the astronomers of our time is due to the systematic manner in which the zodiacal belt has been explored, and the place and apparent size of every star of this region distinctly determined; so that the presence of a wandering body can at once be detected.

The magnitudes of these celestial bodies have not been accurately ascertained, but it is certain that they are exceedingly small as compared even with Mercury, the least of the other planets; the diameter of the largest among them being generally believed not to exceed 450 miles, while most of the others are very much smaller than this. They also differ, generally speaking, from the rest of the planets in other respects; their orbits are of greater eccentricity, are inclined to the ecliptic at a greater angle, and are interlaced in a most intricate manner, crossing each other so frequently as to form, when viewed perpendicularly, a kind of net-work. The consequence of this is that a planetoid which is nearest the sun at one part of its orbit is, when at another part of its orbit, further from it than are several of the others, and a mutual eclipsing of the sun at different periods by two planetoids must be of very frequent occurrence. Of the planetoids, of which the elements had in 1876 been satisfactorily calculated, Flora has the shortest period of revolution, 1193 days, and Sylvia the longest, 2,374 days. The corresponding mean distances from the sun, expressed in parts of the earth's mean distance, are respectively 2.201 and 3.484. [But it is now known that Hilda has a period of 2,868 days and a mean distance of 3.947.] The nearest approach to the sun is made by Phocæa (perihelion distance, 1.787). Freia recedes furthest from him (aphelion distance, 4.002). Polyhymnia's orbit has the greatest excentricity, amounting to 0.33998; Lomia's, the least, 0.2176. Massalia's orbit makes a smaller angle—only 41' 7"—with the ecliptic than that of any other planet in the solar system, while the inclination of the orbit of Pallas is no less than 34° 42' 41". After the first two or three of these bodies had been discovered, the opinion was propounded by Olbers that they were but the fragments of some large planet; and this hypothesis received corroboration from the intimate connection which was shown to subsist among them; but of late years it has fallen out of favor with astronomers. Some infer that the planetoids are best accounted for by the nebular hypothesis. It has been calculated that the combined mass of all the planetoids cannot exceed one-fourth of the earth's mass. The number of planetoids discovered now amounts to 200; the following is a table of those known in Feb., 1877:

Name.	Date of Discovery.	Discoverer.	Name.	Date of Discovery.	Discoverer.
1. Ceres	1801, Jan. 1	Piazzi, Palermo.	87. Sylvia	1866, May 16	Pogson, Madras.
2. Pallas	1802, Mar. 28	Olbers, Bremen.	88. Thisbe	" June 15	Peters.
3. Juno	1804, Sept. 1	Harding, Bremen.	89. Julia	" Aug. 6	Stéphan, Marseille.
4. Vesta	1807, Mar. 29	Olbers. [(Prussia).]	90. Antiope	" Oct. 1	Luther.
5. Astræa	1845, Dec. 8	Hencke, Driesen	91. Ægina	" Nov. 4	Stéphan.
6. Hebe	1847, July 1	Hencke.	92. Undina	1867, July 7	Peters.
7. Iris	" Aug. 13	Hind, London.	93. Minerva	" Aug. 24	Watson.
8. Flora	" Oct. 18	Hind.	94. Aurora	" Sept. 26	Watson.
9. Metis	1848, Apr. 25	Graham, Sligo.	95. Arethusa	" Nov. 23	Luther.
10. Hygieia	1849, Apr. 12	De Gasparis, Naples.	96. Ægle	1868, Feb. 17	Coggia, Marseille.
11. Parthenope	1850, May 11	De Gasparis.	97. Clotho	" Feb. 17	Tempel.
12. Victoria	" Sept. 13	Hind.	98. Ianthe	" Apr. 18	Peters.
13. Egeria	" Nov. 2	De Gasparis.	99. Dike	" May 29	Borelly, Marseille.
14. Irene	1851, May 19	Hind.	100. Hecate	" July 11	Watson.
15. Eunomia	" July 29	De Gasparis.	101. Helena	" Aug. 16	Watson.
16. Psyche	1852, Mar. 17	De Gasparis. [dorf].	102. Miriam	" Aug. 22	Peters.
17. Thetis	" Apr. 17	Luther, Bilk (Düssel-)	103. Hera	" Sept. 7	Watson.
18. Melpomene	" June 24	Hind.	104. Clymene	" Sept. 13	Watson.
19. Fortuna	" Aug. 22	Hind.	105. Artemis	" Sept. 16	Watson.
20. Massalia	" Sept. 19	De Gasparis.	106. Dione	" Oct. 10	Watson.
21. Lutetia	" Nov. 15	Goldschmidt, Paris.	107. Camilla	" Nov. 17	Pogson, Madras.
22. Calliope	" Nov. 16	Hind.	108. Hecuba	1869, Apr. 2	Luther.
23. Thalia	" Dec. 15	Hind.	109. Felicitas	" Oct. 9	Peters.
24. Themis	1853, Apr. 5	De Gasparis.	110. Lydia	1870, Apr. 19	Borelly.
25. Phocæa	" Apr. 7	Chacornac, Marseille	111. Ate	" Aug. 14	Peters.
26. Proserpine	" May 5	Luther.	112. Iphigenia	" Sept. 19	Peters.
27. Euterpe	" Nov. 8	Hind.	113. Amalthea	1871, Mar. 12	Luther.
28. Bellona	1854, Mar. 1	Luther.	114. Cassandra	" July 24	Peters.
29. Amphitrite	" Mar. 1	Marth, London.	115. Thyra	" Aug. 6	Watson.

See Supp., page 895.

PLANETS (Gr. *planētes*, "a wanderer") are those heavenly bodies (including the earth) which belong to our solar system, and revolve in elliptic orbits round the sun. They are often denominated *primary planets*, to distinguish them from their moons or satellites, which are called *secondary planets*. The name planet is of considerable antiquity, and was applied to these dependants of the sun to distinguish them from the myriads of luminous bodies which stud the sky, and which present to the naked eye no indication of change of place (see STARS). The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the earth, Mars, the planetoids (q.v.), Jupiter, Saturn, Uranus, and Neptune. Six of these, Mercury, Venus, the earth (which was not, however, then reckoned a planet), Mars, Jupiter, and Saturn, were known to the ancients; Uranus was discovered by sir William Herschel (q.v.) in 1781; and Neptune, after having its position and elements determined theoretically by Leverrier and Adams, was discovered by M. Challis, and afterwards by Dr. Galle, in 1846. The planetoids, of which more than 180 are now known, have all been discovered during the present century. Five of the planets, the earth, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, almost the whole of the planetoids, and all the satellites except the moon, are invisible to the naked eye. The visible planets can be at once distinguished from the fixed stars by their clear steady light, while the latter have a sparkling or twinkling appearance. The comparative proximity of the planets may be proved by examining them through a telescope of moderate power, when they appear as round luminous disks, while the fixed stars exhibit no increase of magnitude. The planets, as observed from the earth, move some-

Planets.

times from w. to e., sometimes from e. to w., and for some time remain stationary at the point where progression ends and retrogression commences. This irregularity in their movements was very puzzling to the ancient astronomers, who invented various hypotheses to account for it. See PTOLEMAIC SYSTEM and EPICYCLE. The system of Copernicus, by assuming the sun, and not the earth, as the center of the system, explained with admirable simplicity what seemed before a maze of confusion.

The planetary orbits differ considerably in their degrees of eccentricity, the planetoids, Mars, and Mercury being most, and the larger planets least eccentric. No two planets move exactly in the same plane, though, as a general rule, the planes of the larger planets most nearly coincide with that of the ecliptic. The latter are consequently always to be found within a small strip of the heavens extending on both sides of the ecliptic; while the others have a far wider range, Pallas, one of them, having the angular elevation of its orbit no less than $34^{\circ} 42''$ above the ecliptic. According to Kepler's laws (q.v.), the nearer a planet is to the sun the shorter is the time of its revolution. The arrangement of the planets in the solar system bears no known relation to their relative size or weight, for though Mercury, Venus, and the earth follow the same order in size and distance from the sun, yet Mars, which is further from the sun, is much less than either the earth or Venus, and the planetoids, which are still further off, are the least of all. Jupiter, which is next in order, is by far the largest, being about $1\frac{1}{2}$ times as large as all the others together; and as we proceed further outwards, the planets become smaller and smaller, Saturn being less than Jupiter, Uranus than Saturn, and Neptune, than Uranus.

With reference to their distance from the sun, as compared with that of the earth, the planets are divided into *superior* and *inferior*; Mercury and Venus are consequently the only "inferior" planets, all the others being "superior." The inferior planets must always be on the same side of the earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a *transit* (see SUN) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight. The time which elapses from one conjunction to its corresponding conjunction is called the *synodic period* of a planet, and in the case of the inferior planets must always be greater than the true period of revolution.

Mercury, the planet which is nearest the sun, is also, with the exception of the planetoids, the smallest (being only 3 times the size of the moon), and performs its revolution round the sun in the shortest time. Its greatest elongation is never more than $28^{\circ} 45'$, and consequently it is never above the horizon more than two hours after sunset, or the same time before sunrise; on this account, and from its small apparent size ($5''$ to $12''$), it is seldom distinctly observable by the naked eye. It shines with a peculiarly vivid white or rose-colored light, and exhibits no spots.

Venus, the next in order of distance and period, is to us the most brilliant of all the planets. Its orbit is more nearly a circle than any of the others, and when at its inferior conjunction, it approaches nearer the earth than any other planet. Its apparent angular dimensions thence vary from $10''$ at the superior, to $70''$ at the inferior conjunction. Its greatest elongation varies from 45° to $47^{\circ} 12'$, and therefore it can never be above the horizon for much more than three hours after sunset, or the same time before sunrise. While moving from the inferior to the superior conjunction, Venus is a *morning star*; and during the other half of its synodic period, an *evening star*. When this planet is at an elongation of 40° , its brilliancy is greatest, far surpassing that of the other planets, and rendering a minute examination through the telescope impossible. At this period it sometimes becomes visible in the day-time, and after sunset is so bright as to throw a distinct shadow. Astronomers have repeatedly attempted to ascertain the nature and characteristics of its surface, but its brightness so dazzles the eyes as to render the correctness of their observations at best doubtful. From the changes in the position of dusky patches on its surface, which have been frequently noticed, it is concluded that it revolves on its axis, and that its equator is inclined to the plane of its orbit at an angle of 75° ; but many astronomers (sir John Herschel included) profess to doubt these conclusions. Both Venus and Mercury necessarily exhibit phases like the moon.

The *Earth*, the next planet in order, will be found under its own name; it has a single satellite, the *moon* (q.v.).

Mars, the first of the superior planets, is much inferior in size to the two previous, its volume being about $\frac{1}{7}$ of the earth's, and, after Mercury, its orbit is much more eccentric than those of the other planets. When it is nearest to the earth (i.e., in opposition), its apparent angular diameter is $30''$; but when furthest from it (i.e., in conjunction), its diameter is not more than $4''$. Mars is less known than the rest of the superior planets, owing to its not possessing a satellite, by the motions of which its attractive force (and hence its mass and density) could be estimated. It shines with a fiery red light, and is a brilliant object in the heavens at midnight when near opposition; when seen through the telescope its surface appears to be covered with irregular blotches, some of them of a reddish, others of a greenish color, while at each pole is a spot of dazzling white. The red spots are surmised to be land; the green, water; while the white spots at the poles are

with some reason supposed to be snow, since they decrease when most exposed to the sun, and increase under the contrary circumstances. The phases (q.v.) of Mars range between full, half, full (in conjunction, if visible), and half.

The Planetoids.—After Mars in order come the *planetoids* (q.v.), formerly but improperly called asteroids.

Jupiter, the next in order, is the largest of all the planets, its bulk being more than 1400 times that of the earth, though, from its small density, its mass is only 338 times more. After Venus it is the brightest of the planets and the largest in apparent size, its angular diameter varying from 30" to 45". When looked at through a telescope, it is seen to be considerably flattened at the poles, owing to its rapid revolution on its own axis; and its surface is crossed in a direction parallel to its equator by three or four distinct and strongly-marked belts, and a few others of a varying nature. Spots also appear and remain for some time on its surface, by means of which its revolution on its axis has been ascertained. This planet is attended by four satellites, which are easily observable through an ordinary telescope, and which have rendered immense service in the determination of longitudes at sea, and of the motion and velocity of light. The satellites, which were discovered by Galileo, were proved by sir William Herschel to revolve on their own axes in the same time that they revolve round their primary. The smallest is about the same size as our moon, the others are considerably larger.

Saturn, next in position, is about 735 times larger in volume, though only about 100 times greater in mass than the earth. Its apparent diameter when in opposition is 18", and there is a considerable flattening toward the poles. Its surface is traversed by dusky belts much less distinctly marked than those of Jupiter, owing doubtless in great part to its inferior brightness; its general color is a dull white or yellowish, but the shaded portions, when seen distinctly, are of a glaucous color. The most remarkable peculiarity of Saturn is its ring, or series of concentric rings, each one parallel and in the same plane with the others and with the planet's equator; the rings are at present supposed to be three in number, the two outermost are bright like the planet itself, while the innermost is of a purplish color, and is only discernible through a powerful telescope. The rings are not always visible when Saturn is in the "opposite" half of its orbit, for when the plane of the rings is intermediate between that of the earth's orbit and of the ecliptic, their dark surface is turned toward us, and when the sun is in their plane only the narrow edge is illumined; in both of these cases the ring is invisible from the earth. Its plane being inclined at an angle of 28° to the ecliptic, we see the two surfaces of the ring alternately for periods of 15 years at a time; and at the middle of each period, the rings attain their maximum obliquity to the ecliptic, and are then best seen from the earth. It is hardly necessary to remark that at the end of each period they become invisible. Saturn has also no less than eight satellites, seven of which revolve round it in orbits little removed from the plane of the ring, while the eighth, which is the second in size, is considerably inclined to it. Two of the satellites were discovered by Herschel in 1787 and 1789, four by Cassini in 1672–84, one by Huyghens in 1655, one by Mr. Lassell in England and prof. Bond in America in 1848. The satellites are all situated outside of the ring, and the largest of them is nearly equal to the planet Mars in size.

Uranus, the next planet in position, was discovered accidentally by the elder Herschel on Mar. 13, 1781, and was named "the Georgium Sidus" and "Herschel," but these names soon fell into disuse. It is about 96 (some astronomers say 82) times greater than the earth in volume, and 20 (according to others, 15) times in mass; but though so large, its distance is so much greater in proportion that astronomers have been unable to gain much information concerning it. No spots or belts have hitherto been discovered on its surface, and consequently its time of rotation and the position of its axis are unknown. It is attended by a number of satellites, but so minute do these bodies appear, that astronomers hitherto have been unable to agree as to their exact number; sir William Herschel reckoned six, while other astronomers believe in the existence of four, five, and eight respectively. That there are at least four is without doubt.

Neptune is the next and outermost member of the solar system, and, at a distance of nearly 3,000 millions of miles from the center of the system, slowly performs its revolution round the sun, accomplishing the complete circuit in about 165 solar years. It is about 84 times larger than the earth, but from its extreme remoteness is of almost inappreciable magnitude when seen through an ordinary telescope. It was the disturbance in the motion of Uranus caused by the attractive force of this planet which led Leverrier and Adams to a calculation of its size and position, on the supposition of its existence; and the directions which were given by the former to Dr. Galle of Berlin, specifying its exact position in the heavens, led that astronomer to its discovery on Sept. 23, 1846. Mr. Lassell of Liverpool has discovered that Neptune is attended by one satellite. The satellites of Uranus and Neptune differ from the other planets, primary and secondary, in the direction of their motion, which is from e. to w., and in the case of the former, in planes nearly perpendicular to the ecliptic. Both Uranus and Neptune were observed long before the times of Herschel and Leverrier, but they were always supposed to be stars. Uranus is known to have been observed by Flamsteed between 1690 and 1715, and Neptune by Lalande in 1795.

In astronomical tables, almanacs, etc., the planets are for convenience denoted by

symbols instead of their names, as follows: Mercury, ☿; Venus, ♀; earth, ♂; Mars, ♂; the planetoids, in the order of their discovery, ①, ②, ③, etc.; Jupiter, ♃; Saturn, ♄ or ♅; Uranus, ♅; Neptune, ♆; the sun, ☉; the moon, ☾.

For a TABLE of the periods, distances, size, density, etc., of the planets, see SOLAR SYSTEM.

PLANT, a living organic being, destitute of any indication of mind or feeling, and sometimes defined as essentially differing from an animal in the want of voluntary motion. Plants are the organisms which form the *vegetable kingdom*; the science which treats of them is botany (q.v.). Plants of higher organization can never be mistaken for animals, nor animals of higher organization for plants. But there is no regular ascending and descending scale of organisms, from the highest animal to the lowest plant; instead we find a widely extended base from which the ascent seems to begin at once in both the organic kingdoms, with many ramifications in each; and in the case of the lowest groups of either kingdom, it is sometimes difficult to discern the difference between plants and animals. The difficulty may be owing to our ignorance and incapacity of proper observation.

Something which resembles the voluntary motion of animals is to be seen in some plants, in various phenomena of irritability (q.v.); and there is even locomotion in the vegetable kingdom wonderfully simulating voluntary locomotion, a provision of nature for the diffusion of some of the lower vegetable organisms; the *gonidia* (q.v.) of algæ and the *spermatozoidia* (q.v.) of some other cryptogamous orders moving in a surrounding fluid by means of cilia, so that they have often been mistaken for animalcules. But no motion which can really be deemed voluntary takes place in the vegetable kingdom; and no animal, certainly to be pronounced such, fails to exhibit it—even when there is no power whatever of locomotion—in the prehension of food, or for some of the purposes of life.

The general laws which govern life prevail in plants as in animals. There are organs of nutrition and organs of reproduction; the whole being made up of organs, and every organ destined to maintain the existence either of the individual or of the race. But there is nothing in plants corresponding to the mouth, stomach, and alimentary canal of animals. Nutrition takes place in a different manner; assimilation being effected by a process very unlike that of digestion in animals. There are, however, animals destitute of a mouth, stomach, and alimentary canal; so that the distinction between plants and animals cannot be stated so absolutely in this respect as in respect to voluntary motion; and as there are many plants which have no roots, nutrition by means of roots, although peculiar to the vegetable kingdom, is not its distinguishing characteristic. The nutriment of plants is derived either by their roots from the soil (see *Root*), or through the integuments of their other parts from the air or water in which they live; and all their nutriment is either liquid or gaseous, being taken up in the former case by endosmose (q.v.), and in the latter case through *stomata* (q.v.). Many plants, and among them the greater number of phanerogamous plants, owe their nourishment both to the soil and to the atmosphere, their roots deriving it from the former, and the leaves (q.v.) of plants that have leaves being the principal organs by which they derive it from the latter. When leaves are wanting, the integument of the parts exposed to the air performs the functions ordinarily assigned to them. Solid matter cannot be appropriated by plants until it has been dissolved in water, or decomposed. See *MANURE* and *SOIL*.—The nutriment appropriated by the plant is not assimilated until it has undergone chemical changes, which sometimes take place entirely within the very cell through the integument of which it has entered, some of the lowest kinds of plants consisting altogether only of a single cell, but which, in other plants of higher and more complex organization, depend upon a circulation of the sap (q.v.), and a very various action of many different organs, each formed of a multitude of cells. These processes are still very imperfectly understood. By them, not only is the plant nourished, but vegetable products of every kind are elaborated, in which, throughout the wide domains of the vegetable kingdom, there is such wonderful variety, and often great diversity in different parts of the same plant.

Whatever the source from which plants derive their nutriment, no organic substance is appropriated by them; but in order to their use, it must first undergo decomposition. Their food consists wholly of inorganic matter, and the value of organic substances as manures depends not only on the abundance which they contain of the proper elements, but of the readiness with which they undergo decomposition so as to present these elements in the most suitable form; which is not, however, as elements uncombined, but in various combinations with each other. Thus carbon and oxygen enter plants together in the form of carbonic acid, oxygen and hydrogen together in the form of water, hydrogen and nitrogen in the form of ammonia. Carbonic acid absorbed by the leaves from the air is decomposed within the plant, under the influence of light, and particularly of the direct rays of the sun, and its carbon enters into new combinations to form vegetable substances, whilst its oxygen is exhaled again into the atmosphere, which is thus maintained in a state fit for the support both of vegetable and animal life by the opposite and balanced action of animals and plants. Of the elements which enter into the composition of vegetable substances, carbon is the most abundant; and, along with it, oxygen,

hydrogen, and nitrogen constitute the chief part of every plant. Other elements, both metallic and non-metallic, are found in comparatively small quantity, although some of them are very generally present in plants, as calcium, potassium, sodium, sulphur, phosphorus, silicon, iron, aluminium, magnesium, chlorine, and iodine. Among the elements found in plants are also to be enumerated bromine, manganese, and copper, which occur only in minute quantities, and copper very rarely.

There is no circulation in plants like that of the blood in animals, nor any organ at all analogous to a heart; although there is a constant motion or circulation of their juices, both throughout the whole organism and within individual cells. And although the term *respiration* has been often employed with reference to plants, and particularly to leaves, yet there is not only no action analogous to that of lungs, but no oxygenation of the juices by their being brought into contact with the air; carbonic acid and ammonia—not oxygen—being imbibed from it for nutrition. And there is nothing in the vegetable kingdom having the slightest resemblance to a brain or a nervous system. In the possession of sexual organs, however, there is a wonderful agreement, where it might least have been expected, between plants—or at least all phanerogamous plants—and animals. As to this and other important points concerning the life of plants, see **VEGETABLE PHYSIOLOGY**. See also the article **FLOWER**, and those on the different organs of which the flower is made up; the articles **FRUIT**, **SEED**, **SPORE**; **CELLS**, **CELLULAR TISSUE**, **VASCULAR TISSUE**; **METAMORPHOSIS OF ORGANS**; **LEAVES**, **STEM**, etc. The great divisions of the vegetable kingdom are noticed in the article **BOTANY**, in connection with the subject of classification, and in separate articles. The **GEOGRAPHICAL DISTRIBUTION OF PLANTS**, and the **DISEASES OF PLANTS**, are noticed under these heads.

Besides the relations of the animal and vegetable kingdoms already noticed in this article, in their joint and balanced action, keeping the constitution of the atmosphere such as is fit both for animal and vegetable life, reference may be here made, in conclusion, to similar relations subsisting in plants and animals as to temperature and as to their mutually providing food for one another. “It would almost seem as if plants possessed a power of producing cold analogous to that exhibited by animals in producing heat, and of this beneficent arrangement man enjoys the benefit in the luxurious coolness of the fruit which nature lavishes on the tropics” (sir J. E. Tennent). Flowers indeed produce heat; but the juices of plants are colder than the soil or surrounding atmosphere during the time of active vegetation: and the coolness of groves is owing not only to shade, but to the transpiration of moisture by the innumerable leaves.—Inorganic substances are appropriated by plants, as food, and converted by a “high and mysterious” chemistry into organic substances of many kinds, many of them suitable food for animals, which feed on organic substances alone. But the excrements of animals again furnish food for plants; and when animals die, their bodies undergo a series of changes by decomposition, which terminate in the production of the substances most suitable for the nourishment of plants. There is, moreover, not only this conversion of the same matter into animal and vegetable substances alternately; but there is also a continual transformation of matter which has remained inorganic throughout long geologic periods into organic substances, and in this some of the lowest kinds of plants are particularly employed, as lichens, which decompose and feed upon the very rocks on which they grow; whilst, on the other hand, the fossil remains of remote periods, and all the products of decomposition, exhibit matter which once formed part of living organisms returned to an inorganic state.

PLANTAGENET, the surname of the French family of Anjou, which, in 1154, succeeded to the throne of England on the extinction of the Norman dynasty in the male line, and reigned till 1485, when it was supplanted by the family of **TUDOR** (q. v.). The name Plantagenet belonged originally to the house of Anjou, and is said by antiquarians to have been derived from the circumstance of the first count of this house having caused himself to be scourged with branches of broom (*planta-genista*), as a penance for some crime he had committed. On the extinction of the male line of the Norman dynasty in the person of Henry I., the crown of England was claimed by Stephen, count of Blois, the son of Henry's sister Adela, or Adeliza, and by Henry's own daughter Matilda (“the empress Maud”), then the wife of Geoffrey Plantagenet, count of Anjou, for her son Henry Plantagenet. Stephen, by favor of the nobles, was the successful competitor, on the condition that Henry should succeed him; and accordingly on Stephen's death, in 1154, the son of Geoffrey Plantagenet ascended the throne of England as Henry II. His sons, Richard I. and John, succeeded him, and the descendants of the latter in the direct male line—viz., Henry III., Edward I., Edward II., Edward III., and (Edward III.'s eldest son, the Black Prince, having died before his father, leaving an only son, who as) Richard II.—succeeded without interruption. The eldest male line now became extinct, and it was necessary to choose the rightful heir to the throne from among the descendants of Edward III.'s other sons. His second son had died without heirs, but Lionel, duke of Clarence; John of Gaunt, duke of Lancaster; and Edmund Langley, duke of York, his third, fourth, and fifth sons respectively, were still represented by legitimate issue. Of these, Edmund Mortimer, earl of March, and Anne Mortimer, the wife of Richard, earl of Cambridge (who was the eldest son and heir of Edmund Langley, duke of York), the lineal descendants of Lionel of Clarence, possessed the prior claim to the

throne; but Edmund was put in prison by Henry IV., the eldest son of John of Gaunt, duke of Lancaster, who usurped the crown in 1399, and transmitted it to his lineal descendants Henry V. and Henry VI. By this time Edmund Mortimer had died without heirs, and the descendants of the marriage of his sister Anne (the heiress of Clarence) with Richard, earl of Cambridge (the heir of York), uniting the claims of the *third* and *fifth* sons, had, through their maternal ancestress, a superior claim to the throne over Henry VI. the Lancastrian monarch, who only represented the *fourth* son of Edward III. Richard, duke of York, the son of Richard of Cambridge, and Anne Mortimer, attempted to obtain the crown, but he was taken and executed, leaving to his sons the task of avenging his death, and asserting the claims of the combined house of York and Clarence to the throne, in which they were ably assisted by Richard Neville, earl of Warwick ("the king-maker"). The result was a long and desolating civil war (1455-85) between the partisans of York and Lancaster, which is known in history as the "Wars of the Roses" (the Lancastrians having chosen for their emblem a *red* and the Yorkists a *white* rose), in which more than 100,000 persons perished, and many noble families were either extirpated on the field and the scaffold, or completely ruined. During this dreadful contest, in which the Yorkists generally had the advantage, Edward IV. (the eldest son of the duke of York who had been executed), his son Edward V., and his brother Richard III. (q.v.) successively swayed the scepter. But Richard's cruel and tyrannical government added new vigor to the reviving Lancastrians, and Henry Tudor (see HENRY VII.), the representative of their claims, defeated the Yorkist tyrant on the field of Bosworth; and then, by his marriage with Elizabeth, the eldest daughter of Edward IV., and the representative of the Yorkist claims, reunited in his family the conflicting pretensions to the throne, which he transmitted in peace to his descendants. See TUDOR; and, for the events of this contest, see ROSES, WARS OF THE.

PLANTAGINEÆ, or **PLANTAGINA'CEÆ**, a natural order of exogenous plants, mostly herbaceous and without stems; the leaves forming rosettes, flat and ribbed, or taper and fleshy; the flowers generally in spikes, and generally hermaphrodite; the calyx 4-parted, persistent; the corolla hypogynous, membranous, persistent, its limb 4-parted; the stamens four, inserted into the corolla, with long filaments; the ovary free, of a single carpel, 1 to 4-celled; the cells containing one, two, or many ovules; the fruit, a membranous capsule with a lid. The *testa* of the seeds abounds in mucilage, which is easily extracted by boiling water. The order is allied to *plumbagineæ* and *primulaceæ*. There are about 120 known species, diffused over all parts of the globe, but most abundant in temperate and cold countries. The most important genus is *plantago*, the species of which often receive the English name **PLANTAIN**. Five of this genus are found in the United Kingdom, the chief of which are the following: the **GREATER PLANTAIN**, or **WAYBREAD** (*P. major*), one of the most common of British plants; a perennial, with broad ovate-stalked leaves and long cylindrical spikes, growing in pastures, waysides, etc. It is very widely diffused over the world. Its seeds are a favorite food of birds, and the gathering of the spikes to feed cage-birds is familiar to every one. The leaves are applied to wounds by the peasantry in many districts. They are said also to be a useful application to ulcers and indolent scrofulous tumors.—The **RIBWORT PLANTAIN**, or **RIBGRASS** (*P. lanceolata*), is another very common British plant, forming no small part of the herbage of many meadows and pastures, and sometimes sown by farmers, because its foliage is produced early in the season, and is then acceptable to oxen, sheep, and horses; but deemed most suitable for poor soils, as its spreading leaves occupy too much of the ground, and choke better grasses in rich land. Its leaves are lanceolate, and taper at both ends; its spikes are short, ovate, or cylindrical, and placed on long angular stalks. Its seed is acceptable to cage-birds. This is the plant, commonly known as "bullies," or "sodgers," the striking off the heads (or spikes) of which is such a favorite amusement of children.—The mucilage of the seeds of *plantago ispaghula* and of *P. psyllium* is much used in India in catarrhs and other complaints; and *P. psyllium*—called **FLEAWORT**, and its seed **FLEA-SEED**—is cultivated in France for the sake of this mucilage, which is used by paper-stainers in preference to that obtained from linseed, and is also extensively used by muslin manufacturers for stiffening their goods. The plant has a branched spreading stem, and recurved leaves.

PLANTAIN, *Musa paradisaica*, a most important food-plant of tropical countries, and one of the largest of herbaceous plants, belongs to the natural order *musaceæ* (q.v.), and is a native of the East Indies, where numberless varieties of it have been cultivated for thousands of years. It is now diffused over all the tropical and subtropical regions of the globe. It must have been carried to America soon after or during the days of Columbus; for its fruit was a principal article of food there in the first half of the 16th c.; but there is nothing to support the conjecture of Humboldt that there may be different species cultivated under the name of plantain, and some of them natives of America. The plantain is now, however, cultivated to the furthest depths of the primeval American forests, accompanies the Indians in their frequent changes of residence, forms the wealth of many occupiers of land in the vicinity of great towns, where large plantations of it are made, and is a true staff of life to the population of all colors and classes in tropical countries. In many regions it is the principal article of food.

In the genus *musa* there arise from the midst of the leaves—or apparently from the

top of the stem, the sheathing bases of the leaves forming a tree-like false stem—stalks which bear great spikes of flowers, each inclosed in a large bract or spathe; the flowers, and afterwards the fruit, are arranged in clusters or almost in whorls on the stalk; the flowers have a perianth of six segments, five of which cohere as a tube slit at the back, and the sixth is small and concave; there are six stamens, one or more of them imperfect; the germen is inferior, 3-celled, with two rows of ovules in each cell; the fruit is fleshy, and has many seeds imbedded in its pulp. The name *musa* is from the Arabic *moz*, a plantain; the plantain seems to be described by Pliny under the name *pala*, a name probably derived from an eastern root, from which also comes the name *plantain*. The specific name *paradisaica* alludes either to a fancy that the plantain was the forbidden fruit of Eden, or to a legend that the aprons which our first parents made for themselves were of plantain leaves.

The stem of the plantain is usually 15 or 20 ft. high, although there are varieties having a stem of only 6 feet. The leaves are very large, the blade being sometimes 10 ft. long and three ft. broad, undivided, of a beautiful shining green; the midrib strong and fleshy. The fruit is oblong, varying from its usual long shape to an almost spherical one, obscurely angular, 8 in. to a foot long in the varieties commonly known by the name plantain, of which the fruit is usually cooked or prepared in some way in order to be eaten, and very often forms a substitute for bread; whilst the smaller fruited varieties, of which the fruit is eaten raw, are generally known by the name banana (q.v.), these names, however, being somewhat variously used.

The plantain is generally propagated by suckers; and a sucker attains maturity in about eight months or a year after being planted. The stem is cut down after fruiting, but the plantation does not require renewal for 15 or 20 years. Plantains ought to be at least 10 ft. apart in plantations of them, or 6 ft. in single rows around fields or gardens. The plantain has been sometimes cultivated with success in hot-houses.

With the exception of two or three palms, it would not be easy to name, in the whole vegetable kingdom, any plant which is applied to a greater number of uses than the plantain. The fruit is sometimes eaten raw, although more generally—except that of the banana—boiled or roasted, and variously prepared. It is both farinaceous and saccharine. In most of the varieties it has a sweetish taste, in some it is mealy, and in some it is sub-acid or austere. It is as much used before being perfectly ripe as when it is so. In the West Indies the plantain boiled and beaten in a mortar is a common food of the negroes. Plantains baked in their skins, or fried in slices with butter and powdered over with sugar, are favorite dishes in some tropical countries. They are preserved by drying in the sun or in ovens, and pressed into masses, in which state they keep for years, and furnish a wholesome article of food. The unripe fruit, peeled, sliced, dried, and powdered, is called *P. meal*, and in Guiana *conquin-tay*; it is whitish with dark-red specks, a fragrance like orris-root, and a taste like wheat-flour; and is made into excellent and nourishing dishes. A good and wholesome starch is obtained from the plantain by rasping and washing.—A decoction of the fruit is a common beverage, and a kind of wine is obtained from it by fermentation.—The top of the stalk is a good boiled vegetable.—The leaves are much used for packing, and many other purposes; the fiber of their stalks is used for textile purposes and for cordage, and it is probable that it might be used for paper-making; but hitherto the leaves and stems of plantains have been generally burned or left to rot.

So great is the food produce of the plantain, that, according to Humboldt's calculation, it is to that of the potato as 44 to 1, and to that of wheat as 133 to 1. The plantain requires little attention.

The name plantain is frequently extended to the whole genus *musa*. Wild species, with austere fruit, are found in many parts of the east. One ascends the Himalayas to an elevation of 6,500 feet. A species found in the South sea islands (*M. troglodytarum*) is remarkable for bearing its clusters of fruit erect, not pendent like the other species. Its fruit is eatable, as is that of *M. Cavendishii* and of *M. chinensis*, species or varieties smaller than the common plantain.—The *musa*, which is extensively cultivated in the Philippine islands for its fiber, *abaca* or *Manilla hemp*, is very similar to the common plantain, but has a green, hard, and austere fruit. It is generally cut when about a year and a half old, before flowering. The outer layers of the stem yield the coarsest fiber; that of the inner is so fine that a garment made of it may be inclosed in the hollow of the hand.—The young stems of *M. ensete*, the ENSETE of Abyssinia, are used in that country as a boiled esculent.

PLANTAIN-EATER, *Musophaga*, a genus of birds of the family *musophagidæ*, to the whole of which the same English name is often extended. The *musophagidæ* are tropical birds, African and South American, of the order *insessores*, and tribe *conirostres*, allied to finches, but many of them large, and more like gallinaceous birds than finches. They are birds of beautiful plumage. They have strong thick bills, more or less curved on the top, the cutting edges jagged or finely serrated, so as to render them very efficient instruments for cutting soft vegetable substances, on which they feed, as the plantain and other fruits, and for dividing the succulent stems of plants, which they cut off close to the ground. They live much among the boughs of trees, and are active and wary birds. The true plantain-eaters (*musophaga*) have the base of the bill extending upon the forehead; the TOURACOS (*corythaix*) have a smaller bill, and the head crested.

PLANTAMOUR, EMILE. See page 896.

PLANTATION, a term sometimes applied to places where timber trees have been planted. In that sense, as a general rule, whoever is the owner of the soil, is entitled to the trees which are planted in such soil. When land is let by lease to a tenant, the tenant does not become the owner of the trees, and cannot cut them down. But he is in England and Ireland entitled to reasonable estovers; that is, to cut sufficient wood to repair or build the houses, or make implements of husbandry. The common law of England was very defective in protecting plantations, for it was held that, as the trees were part of the realty, or soil, and nobody could steal the soil, hence nobody could be punished for larceny of trees. But this defect was cured by statute. Whoever cuts, breaks, roots up, or otherwise destroys or damages, with intent to steal, the whole or any part of a tree, sapling, or shrub, if the damage is of the amount of one shilling, may be convicted summarily, before justices of the peace, and fined £5; for a second offense, he may be committed to the house of correction for 12 months or less; and for a third offense, he is guilty of felony, and may be punished as for larceny. So, whoever steals or damages a live fence, may be fined by justices a sum of £5; and for a second offense, may be committed to the house of correction for 12 months. Moreover, if any person is found in possession of a piece of a tree or live fence, and do not give a proper account of his coming into lawful possession of the same, he may be fined £2.—In Scotland, various acts of the Scotch parliament were directed against offenses of damaging trees, which are punishable as malicious mischief; the penalty being £10 Scots for each tree less than 10 years old, and £20 Scots for each older tree. Tenants may also be fined for such offenses. In case of injuries to fences, old Scotch statutes also provide a punishment.

PLANTATION AND PLANTING OF TREES. See ARBORICULTURE.

PLANT CUTTER, *Phytoma rara*, a conirostral bird nearly related to the finches. In the single genus *phytoma* the bill is of the conirostral type, short, strong, conical, with lateral margins finely serrated. The intestine is short, an unusual condition in vegetable-eating birds. They live in pairs or in small flocks and commit depredations in orchards by cutting off plants, buds, and fruits. They also catch insects. The best-known species is *phytotoma rara*, of Chili, of the size of the common thrush; back brown, each feather having a lighter edge. The top of the head is of a reddish-brown color; breast a dull reddish-white, rather more deeply colored on the belly and thighs. The wings are dark brown, the primaries having a white bar, the wing coverts also edged with white. The tail is brownish-red with a terminal dark brown bar. It has a short low flight, and a disagreeable rough note.

PLANTIGRADA, in Cuvier's zoological system, a tribe of *carnivora* (q.v.), characterized by placing the whole sole of the foot on the ground in walking. The sole is generally destitute of hair. Both fore and hind feet are five-toed in all the plantigrada. The plantigrada are generally more or less nocturnal in their mode of life, and their movements are slower and their gait more clumsy than those of the *digitigrada*. They are also, in general, less carnivorous; many of them feed in part or occasionally on vegetable food. The conformation of their limbs and feet gives them a power of standing erect on their hind-feet, which none of the *digitigrada* naturally possess, and of which advantage is taken in tame bears for the amusement of spectators.

PLANTIN, CHRISTOPHE, an eminent printer, was b. at St. Avertin, near Tours, in 1514, and set up a printing-establishment at Antwerp in 1550, which soon became the greatest and most celebrated of the time. He had often 20 presses or more in active operation. Guicciardini mentions his printing-establishment as the finest ornament of the city of Antwerp, and as one of the wonders of Europe, and the learned agreed in regarding him as the first printer of his time, although he was the contemporary of Aldus and Estienne (Stephens); but this is true only as regards the number of works which issued from his establishment, and the beauty of their typography; for the services which the others have rendered to classic literature are far beyond those of Plantin. Plantin was nevertheless himself a man of varied, though probably not very profound learning. He superintended the publication of works in several languages, and was extremely careful of their accuracy, employing able and learned correctors of the press, whom he remunerated liberally, and publicly offering rewards for the discovery of errors. The most noted of all his publications is the *Biblia Polyglotta* (8 vols. 1569-72), which was printed under the personal superintendence of Arias Montanus, the court chaplain of Philip II. of Spain, and towards which Philip gave 6,000 ducats for the purchase of paper. But the oldest book known to have proceeded from the press of Plantin is the *Institution d'une Fille de Noble Maison, traduite de Langue Toscane en François*, by Jean Beller (Ant. 1555). Plantin died at Antwerp in 1589. He had set up printing-establishments in Leyden and Paris, and these, with that in Antwerp, were carried on by the husbands of his three daughters.

PLANT LOUSE. See APHIS, *ante*.

PLANTS, in point of law, when put in a garden or other ground let to a tenant, belong to the landlord, and not to the tenant, for they become part of the soil. Hence, a tenant cannot dig them up and remove them at the termination of his lease. This right of the landlord, however, is seldom enforced with much strictness, partly because the tenant

may alter and remove the plants at discretion during his lease, and thus can evade the rule of law. In the case of nursery-grounds, however, the above rule does not apply, as between landlord and tenant, for the plants are considered the stock-in-trade of the nurseryman, who puts them in the ground, not with a view to let them grow permanently, but as a convenient mode of keeping them for sale. Hence, at the termination of his lease, the tenant can remove them all.

PLANU'DES, MAXIMUS. See ANTHOLOGY.

PLAQUEMINES, a parish in s.e. Louisiana, on the gulf of Mexico, drained by the Mississippi; about 1,000 sq.m.; pop. '80, 11,575—7,324 colored. The surface is regular and low, including part of the delta of the Mississippi. The soil is fertile. The principal productions are molasses, sugar, and rice. The county produces the most rice of any in the state. Co. seat, Point à la Hache.

PLASEN'CIA, an ancient and much-decayed, but most picturesque t. of Spain, in Estremadura, 43 m. n.e. of Caceres, stands on a steep hill, with beautiful and fertile valleys extending on the n.w. and s.e. sides. It is almost wholly girdled by the clear waters of the Jerte; and the surrounding scenery, embracing city, castle, river, rock, and mountain, and overarched by a sunny and unclouded sky, is remarkably beautiful. The city contains the picturesque remains of an ancient castle, and is surrounded by crumbling walls, surmounted by 68 towers, and pierced by 6 gates. Water is brought to the town by an aqueduct of 80 arches. There are 7 Gothic churches, an episcopal and several other palaces, and the cathedral, an ornate Gothic edifice, begun in 1498, and some portions of which are still unfinished, while others have been altered and disfigured. The cathedral contains many noble tombs, with effigies. Plasencia once a flourishing and important city, was founded in 1190. It now carries on some minor manufactures of cotton, woolen, and hemp fabrics, and of hats and leather. Pop. about 7,000.

PLASMA, a silicious mineral, a variety of quartz or chalcedony, of a dark-green color, black when unpolished and seen by reflected light, but very translucent when held between the eye and the light. It is very nearly allied to heliotrope or bloodstone, but has no red spots, is more translucent, and is not susceptible of so brilliant a polish. It is never found crystallized. It is a rare mineral, and the finest specimens are brought from India and China. It was highly prized by the ancient Romans, who wrought it into ornaments of various kinds; and very fine engraved specimens have been found among the ruins of ancient Rome. The ancients are said to have obtained their plasma from Mount Olympus, in Asia Minor. The name plasma is supposed to be identical with the Greek *prason*, a leek, the *r* having passed into *l*.

PLAS'SEY, a small t. of British India, in the presidency and province of Bengal, and in the district of Nuddea, 96 m. n. from Calcutta, on the left bank of the Bhagirathi, a river which derives its waters from the Ganges, and pours them into the Hooghly, or rather may be said to become the Hooghly. Plassey is celebrated in the history of India for the great victory gained by Clive (q.v.) over Suraja Dowlah, subahdar of Bengal, June 23, 1757, a victory the immediate effect of which was to transfer the subahdarship to Meer Jaffier, but which really laid the foundation of British supremacy in India. The British force at the battle of Plassey consisted of not much more than 3,000 men; and the only British troops were about 650 foot and 150 artillerymen, the remainder being sepoys. The subahdar's force consisted of 15,000 cavalry and 35,000 infantry, with 40 or 50 French artillerymen, 50 large cannon, and 4 pieces of light artillery. On the evening before the battle, Clive held a council of war, at which it was resolved to decline battle, on account of inferiority of force; but Clive himself afterwards adopting a different resolution, crossed the river, and won a most brilliant victory.

PLASTERING, the art of covering walls, partitions, ceilings, etc., with a composition of lime mixed with sand and hair. It is usually done in three coats. The first coat is the solid foundation on which the rest is placed; it is therefore of a good thickness, and is hatched or crossed with lines, so as to give a bond for the next coat. The first coat is allowed to dry thoroughly; then the second coat is floated over the first, and rubbed well in with a flat board, about 12 in. sq., so as to bring it all to a fair and equal surface (in Scotland this is called the "straightening"); and before the second coat has thoroughly dried, the third or finishing coat is applied in finer materials, and in a more liquid state. In the case of ceiling cornices, moldings, etc., plaster of Paris or stucco is generally used. This sets or hardens more rapidly than lime, and has a finer and whiter surface. Ornaments (called enrichments) are generally composed of plaster of Paris, and cast in molds. They are then set in their places after the cornice has been made, or *run*.

PLASTER OF PARIS. See GYPSUM.

PLASTERS are a class of medicinal agents which are employed externally with various objects. They are solid and tenacious compounds, adhesive at ordinary temperature of the body, and owing their consistency—1. To the chemical combination of oxide of lead, with one or more fatty acids; or 2, to a due admixture of wax, or fat, and resin; or 3, to the chemical action of the component parts of the plaster on each other. Strictly speaking, the term *plaster* should be restricted to the first class of compounds; viz., to combination of oxide of lead with fatty acids. In the British Pharmacopœia, there are directions for making 12 plasters, viz., ammoniac and mercury plaster, belladonna

plaster, cantharides plaster, chalybeate plaster, galbanum plaster, litharge (or lead) plaster, mercurial plaster, opium plaster, pitch plaster, resin plaster, soap plaster, and warm plaster. The litharge (or lead) plaster, directly or indirectly, enters into the composition of all the twelve officinal plasters, excepting those of ammoniac and mercury, cantharides, and pitch. *Lead plaster*, which is usually sold under the name of *diachylon*, in combination with resin, constitutes the ordinary *adhesive plaster*. The best plaster of this kind for strapping is composed of a mixture of six drams of resin with a pound of lead plaster. The *cantharides plaster* and the *ammoniac and mercury plaster*, are examples of the second and third varieties.

Plasters are generally kept in rolls; and when they are to be used, they are melted at a temperature of not more than 212°, and spread on soft leather. They are employed to answer two distinct indications, namely, to act *mechanically*, as by affording artificial support to weak muscular structures, by preventing threatened or tedious excoriations, by protecting parts already excoriated from the action of the air, etc.; and to act *medicinally* as stimulant, discutient, alterative, anodyne, etc.

PLATA, LA. See ARGENTINE REPUBLIC.

PLATA, RIO DE LA, a wide estuary of South America, between Uruguay on the n. and the Argentine Confederation on the s., forms the mouth of the Parana (q.v.) and the Uruguay (q.v.). It is 200 m. long, 29 m. broad at Buenos Ayres, and 140 m. broad at its mouth, between Maldonado and cape San Antonio. At its mouth it is, on an average, only about 10 fathoms deep; at Montevideo it is only 3⁺ fathoms; and at Buenos Ayres about 16 ft. deep. Some conception of the vast volume of water which this estuary carries to the Atlantic may be had when it is remembered that with its affluents it drains an area of 1,250,000 sq. miles. The strong and irregular currents, and the sudden tempests of the La Plata, render its navigation extremely dangerous. It is estimated that through this estuary about one-fourth of the produce of South America is brought to market. For the navigation of its affluents, see PARAGUAY, PARANA, and URUGUAY.

PLATÆA, or PLATÆÆ, a city in the western part of Beotia, on the borders of Attica, and at the foot of Mount Cithæron. It was about 6½ m. from Thebes. In 480 B.C., it was destroyed by the Persians because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year, it was the scene of the glorious victory won by the Lacedæmonian Greeks, under Pausanias and Aristides, over the Persian hordes commanded by Mardonius—a victory that finally delivered Greece from the threatened yoke of the invader. In the third year of the Peloponnesian war (429 B.C.), it was attacked by a Theban-Lacedæmonian force—for the Plataeans were firm friends of Athens—and heroically defended itself for more than two years, until it was starved into surrender. The little garrison of about 200 men were put to the sword, and the city was razed to the ground. Such of the Plataeans as escaped were hospitably received at Athens. By the treaty of Antalcidas (387 B.C.), their children were allowed to go back again, and rebuild their city, after an exile of 40 years; but they were again driven out by their implacable enemies, the Thebans; and half a century elapsed before the victory of Philip of Macedon at Chæroneia enabled the Plataeans to finally return to their homes. After this, the city remained inhabited, probably till the latest days of the empire. It is mentioned in the 6th c. A.D. Some ruins of Plataea are still visible near the village of *Kokhla*.

PLATA'LEA. See SPOONBILL.

PLAT-BAND, in architecture, a flat fascia or band, with less projection than breadth.

PLATE, in heraldry, a roundle (q.v.) argent. It is represented flat, and in the heraldry of Scotland is known as a *bezant argent*.

PLATE-MARKS are legal impressions made on articles of gold or silver at the various assay offices, for the purpose of indicating the true value of the metal of which the articles are made. The marks are a series of symbols, which are embossed in a line of about three-quarters of an in. in length, and usually on every separate piece of which an article is composed. These symbols are—1. The maker's own mark or initials. 2. The standard or assay mark; viz., *for gold*, a crown, and figures denoting the number of carats fine. This means that pure gold is reckoned at 24 carats, and every part of alloy added reduces that standard number (see CARAT); so that if a piece of gold-plate jewelry is marked with a crown and 18, it indicates that it consists of 18 parts of pure gold, and 6 parts of some other metal alloyed with it. Gold of nine carats is now legal, but as it is marked by the assay office, there can be no deception, if the public understand the plate-marks. If not, they may pay for pure gold, relying upon the hall-mark, when they only receive about a third part gold. *For silver*—England, a lion passant; Ireland, a harp crowned; Edinburgh, a thistle; Glasgow, a lion rampant. 3. The hall-mark of the district office—London, a leopard's head crowned; York, three lions and a cross; Exeter, a castle with two wings; Chester, three wheat-sheaves or a dagger; Newcastle, three castles; Birmingham, an anchor; Sheffield, a crown; Edinburgh, a castle and lion; Glasgow, a tree, salmon, and ring; Dublin, the figure of Hibernia. 4. The duty-mark, indicating the payment of duty, viz., the head of the reigning sovereign. 5. Each office has also its alphabetical date-mark. In London, the assay year, which commences

on May 30, is indicated by one of the first twenty letters of the alphabet. The Goldsmiths' company of London have marked thus:

- From 1716 to 1756, Roman capital letters.
 " 1756 " 1776, Roman small letters.
 " 1776 " 1796, Old English letters.
 " 1796 " 1816, Roman capital letters A to U.
 " 1816 " 1836, Roman small letters a to u.
 " 1836 " 1856, Old English letters A to U.
 " 1856 " 1876, Small black letters a to u.
 " 1876 onwards, Roman capitals, distinguished from former series by shape of shield on which they are imprinted.

Thus, E S A S would represent the mark of Elkington's plate made in the year 1874.

PLATEN-HALLERMÜN'DE VON, AUGUST, Count, 1796-1835; b. Germany. After participating as Bavarian lieutenant in the war against Napoleon I., he studied at Würzburg and Erlangen, devoting himself to philology and philosophy. In 1826 he went to Italy, only returning to Germany for a short time in 1832 and in 1833. In 1835 he fled to Sicily to escape the cholera which was raging in Naples, but succumbed to a violent fever in Syracuse the same year. He is best known by his *Polenlieder* and by his dramas *Die verhängniss volle Gabel* and *Der romantische Oedipus*. A complete edition of his works was published at Stuttgart in 1847, and his *Poetischer und Litterarischer Nachlass*, edited by Minckwitz, appeared in 1852.

PLATE-POWDER, a composition used for cleaning gold and silver plate and plated articles. It is also called rouge-powder (see ROUGE). It is made by levigating rouge with three times its weight of prepared chalk, until they are thoroughly mixed into an almost impalpable powder. Sometimes putty-powder (q.v.) is used instead of rouge, and a little rose-pink added to color it. A plate-powder is also sometimes made by levigating quicksilver with twelve times its weight of prepared chalk, until it is thoroughly incorporated, and forms a gray powder. It puts a remarkable brilliancy on silver-plate, but is very injurious to it.

PLATER, GEORGE, 1736-92; b. Md.; graduated at William and Mary college, 1753; studied and practiced law, and eventually became one of the judges of the Maryland court of appeals. In 1778 he was president of the Maryland state convention which ratified the constitution of the United States; and from that year until 1781 he represented the state in congress. During the year of his death he was governor of Maryland.

PLATING signifies the covering of an inferior metal with one of the precious metals, the object being to give the appearance of silver or gold to articles chiefly intended for table use. At present the articles are generally made of German silver, or some of the similar white-metal alloys; but formerly, copper, or an alloy of that metal with brass, was used; the disadvantage of which was that, as the coating of silver wore off, the red color of the copper became disagreeably apparent through the thin covering of silver. Gold is rarely plated on any other metal than silver, except for purposes of deception. Previous to the introduction of electro-plating, the method generally pursued was that which has acquired the name of *Sheffield-plating*, from the large extent to which it was carried on in that town. It consists in soldering on to one or both sides of an ingot of the baser metal a thin plate of silver. The ingot is always of an oblong shape, and is most carefully prepared on the surfaces which are to receive the silver, so that nothing shall prevent the complete union of the two. The soldering is a process requiring much care and nicety; the plates of silver are thinly coated with a concentrated solution of borax, and are then applied to the prepared surfaces of the ingot, to which they are firmly bound with iron wire, and then placed in the *plating-furnace*, and subjected to a strong heat. This furnace is so arranged that the interior can be constantly watched, and when the proper temperature is attained the workman knows the exact instant to withdraw it. The act of soldering is almost instantaneous, and fusion would immediately follow if the ingot was not quickly withdrawn. When cooled, the wire is taken off, and the ingot is taken to the rolling-mill, where it is passed backwards and forwards, of course with the silver above and below, until it is rolled out into a sheet of the exact thickness required. However thin it may be made, it is found that the relative thickness between the ingot and its layers of silver is always the same. As usual in all cases of rolling or striking metal, annealing from time to time is necessary, to remove the brittleness which these operations cause.

This method does not admit of the manufacture of any portions such as ornamental molded borders, etc.; these had, therefore, to be formed separately of copper, and were coated by the process called *silvering* (q.v.). Now, however, it is found better to make them of silver rolled thin, and fill them inside with lead, to give them solidity; by this plan is avoided the annoyance of the silver rubbing off, and exposing the copper. Sheffield-plating is still made extensively, but the manufacture is rapidly declining in presence of the newer art of electro-plating. See GALVANISM.

Within a very recent period, and since the subject of electro-plating was treated under the article GALVANISM, some very remarkable applications of the process have

been discovered; for instance, it is no longer confined to the deposit of silver and gold; aluminium, silicium, titanium, tungsten, molybdenum, tin, cadmium, lead, bismuth, palladium, rhodium, iridium, and the alloys, brass and bronze, are all now deposited under patent processes. Of all these, by far the most important is the deposit of the alloys, and a very large trade has sprung up in manufactures of iron coated with brass. The importance of being able to cover a metal so cheap, yet so easily corroded as cast iron, with so ornamental an alloy as brass or bronze, can hardly be overrated. Consequently the process is carried on very extensively and satisfactorily.

PLATINUM (symb. Pt, equiv. 99—new system, 198—sp. gr. 21.5) is one of the “noble metals,” which may be obtained in more forms than one. It is only found in the native state, usually occurring in small glistening granules of a steel-gray color, which always contain an admixture, in varying proportions, of several metals, most of which are rarely found except in association with platinum. Sometimes, however, it is found in masses of the size of a pigeon’s egg, and pieces weighing ten or even twenty pounds have occasionally been found. The following table shows the composition of crude platinum ore as obtained from different parts of the globe. The analyses were conducted by Messrs. Deville and Debray:

	Columbia.	California.	Oregon.	Spain.	Australia.	Russia.
Platinum.....	80.00	79.85	51.45	45.70	59.80	77.50
Iridium.....	1.55	4.20	0.40	0.95	2.20	1.45
Rhodium.....	2.50	0.65	0.65	2.65	1.50	2.80
Palladium.....	1.00	1.95	0.15	0.85	1.50	0.85
Gold.....	1.50	0.55	0.85	3.15	2.40
Copper.....	0.65	0.75	2.15	1.05	1.10	2.15
Iron.....	7.20	4.45	4.30	6.80	4.30	9.60
Osmide of iridium.....	1.40	4.95	37.30	2.85	25.00	2.35
Sand.....	4.35	2.60	3.00	35.95	1.20	1.00
Osmium and loss.....	0.65	0.05	0.80	2.30

Ruthenium is also almost always present, and in the above analysis is probably included with the iridium, which it closely resembles.

There are two modes of obtaining platinum in the form of ingots from the ore, both of which require notice. The method which has been universally employed, till within the last five years, was that discovered by Wollaston, the leading steps of which were as follows: After the removal of the metals associated with the platinum, by the successive action of nitric and hydrochloric acids, the platinum itself is dissolved in aqua regia, from which it is precipitated by a solution of sal ammoniac in the form of a sparingly soluble double salt, the chloride of ammonium and platinum, represented by the formula $H_4NCl, PtCl_2$. This salt is washed and heated to redness, by which means the chlorine and ammonia are expelled, leaving the metal in the form of a gray, spongy, soft mass, known to chemists as *spongy platinum*. In this form it is very finely powdered under water, is next shaped by intense pressure into a mass, and is then exposed to an intense heat in a wind-furnace, the ingot being formed by hammering it upon its two ends. (If hammered on its sides, it splits.) This heating and forging must be repeated till the metal becomes homogeneous and ductile.

Deville and Debray have introduced an entirely new method for the extraction of platinum from its ores. They first form a fusible alloy of this metal with lead, by exposing the platinum ore—2 cwt. being used in a single experiment, with equal weights of galena and litharge gradually added, and a little glass to act as a flux—to full redness in a reverberatory furnace lined with clay. The sulphur of the galena is oxidized and expelled, and the liquid alloy of lead and platinum is allowed to rest for some time, to allow the osmide of iridium, which is not affected by the preceding operations, to sink to the bottom. The upper portions of the alloy are then decanted, and cast into ingot-molds, which are submitted to cupellation; and the metallic platinum which is left after the cupellation is melted and refined in a furnace of lime—which is employed in consequence of its being a very bad conductor of heat—by means of the oxyhydrogen blow-pipe. The platinum obtained in this manner is nearly pure, and very ductile and malleable. For details regarding this process, which has been patented both in France and in this country, the reader is referred to the memoir “On Platinum and the Metals which accompany it,” in the *Annales de Chimie et de Physique* for August, 1859.

Platinum, as obtained by either of the above processes, exhibits a bluish-white metallic luster; it is exceedingly malleable and ductile, and is very infusible, melting only before the oxyhydrogen blow-pipe, or in a very powerful blast-furnace, such as that used by Deville and Debray. It expands less by heat than any other metal, and it is usually regarded as the heaviest form of matter yet known; but, according to Deville and Debray, osmium and iridium are about equally dense. It is unaffected by atmospheric action, and does not undergo oxidization in the air at even the highest temperatures. It is not acted on by nitric, hydrochloric, sulphuric, or hydrofluoric acid, or in short, by any single acid; but in aqua regia it slowly dissolves, and forms a soluble bichloride. In consequence of its power of resisting the action of acids, it is of great service in experimental and manufacturing chemical processes, platinum spatulas, cap-

sules, crucibles, etc., being employed in every laboratory; while platinum stills, weighing sometimes as much as 1000 ounces, are frequently used for concentrating oil of vitriol. Platinum is, however, corroded if heated with the alkalies or alkaline earths, and especially with a mixture of nitrate of potash and hydrated potash, an oxide being formed which combines with the alkaline bases.

The form of the metal known as *spongy platinum* has been already noticed. The metal may, however, be obtained in a state of subdivision much finer than that in which it is left on heating the double chloride of platinum and ammonium—namely, in the state known as *platinum black*. In this form it resembles soot. It may be prepared in various ways, of which one of the simplest is to boil a solution of bichloride of platinum, to which an excess of carbonate of soda and a quantity of sugar have been added, until the precipitate formed after a little time becomes perfectly black, and the supernatant liquid colorless. The black powder is then collected on a filter, washed, and dried by a gentle heat. In its finely comminuted state, either as spongy platinum or platinum black, it possesses a remarkable power of condensing and absorbing gasses, one volume of platinum black being able to absorb more than 100 volumes of oxygen. This absorption appears to be accompanied by a conversion of some or all of the oxygen into the modification known as ozone (q.v.), since the metal becomes capable of exerting the most energetic oxidizing action, even at ordinary temperatures. For example, it can cause the combustion of a jet of hydrogen, can oxidize sulphurous acid into sulphuric acid, ammonia into nitric acid, and alcohol into acetic acid, the rise of temperature in the last case being often sufficiently great to cause inflammation. Platinum in the compact form, as foil or wire, possesses similar powers, but in a far lower degree.

Platinum may be easily alloyed with most of the metals, the alloys being in general much more fusible than pure platinum. Hence care must be taken not to heat the oxides of metals of easy reduction, such as lead and bismuth, in platinum crucibles, as, if any reduction took place, the crucible would be destroyed by the fusion of the resulting alloy. An alloy of platinum, iridium, and rhodium is found, by the investigations of Deville and Debray, to be harder, and capable of resisting a higher temperature than the pure metal; and hence is admirably adapted for the formation of crucibles, etc.

There are 2 *oxides* of platinum, a protoxide, PtO , and a binoxide, PtO_2 , neither of which can be formed by the direct union of the elements. Excepting that the change which platinum vessels undergo when containing the caustic alkalies, etc., and exposed to a red heat, is due to the formation of a superficial layer of oxide (probably binoxide), these compounds are of little interest. The *sulphides* and *chlorides* correspond in number and composition to the oxides. Of these compounds, the bichloride ($PtCl_2$) alone requires notice. It is formed by dissolving platinum in aqua regia, and evaporating the solution to dryness; and it is obtained as a deliquescent, reddish-brown mass, which forms an orange-colored solution in water, from which, on evaporation, it crystallizes in prisms. It is also freely soluble in alcohol and ether. A solution of this salt is much used for the recognition and determination of potash and ammonia.

By the action of ammonia on protochloride of platinum (which is obtained by heating a solution of the bichloride to a temperature of 450°), several remarkable compounds are formed, which possess strong basic characters, and are of great interest in a theoretical point of view, such as platosamine (PtH_3NO), platinamine (PtH_3NO_2), etc.

PLATO, who, along with Aristotle, represents to modern Europe the whole compass of Greek speculation, was born at Athens in the year 429 B.C., shortly after the commencement of the Peloponnesian war, and the same year in which Pericles died. He was of a good family—being connected on the mother's side with Solon, and on the father's side with Codrus, one of the ancient kings of Athens. He received a good education, according to the common practice of the Greeks, in music, gymnastics, and literature. His rich and gorgeous imagination is said at first to have essayed its powers in poetry; but when about 20 years of age, having become acquainted with Socrates, he threw all his verses into the fire, and consecrated his great intellect to philosophy. When he was 20 years old the political troubles, of which the death of Socrates was only one terrible symptom, forced him to leave Athens for a season, and he resided at Megara, with Euclid, the founder of the Megaric sect. The disturbed state of his native country, doubtless, also was one cause of the frequent travels which he is reported to have made. Of these, his three visits to Sicily, during the time of the elder and younger Dionysius, are the most celebrated and the best authenticated. That he visited Italy is extremely probable; at all events, he was most closely connected with Archytas and the Pythagorean philosophers; though, as Aristotle (*Metaph.* i. 6) justly-remarks, he borrowed from Heraclitus as well as from Pythagoras, and put a stamp of freshness and originality on all that he borrowed. After returning from his first visit to Sicily, being then in his fortieth year, he commenced teaching philosophy publicly, in the Academia, a pleasant garden in the most beautiful suburb of Athens, and there gathered around him a large school of distinguished followers, who maintained a regular succession after his death, under the name of the philosophers of the academy. He lived to the age of 82; was never married, and must have possessed some independent property, as he expresses himself strongly against teaching philosophy for fees, and we nowhere read of his having held any public office from which he could have derived emolument. Such are the few reliable facts known as to the life of Plato.

The principles of his philosophy are happily better known; for all his great works have been preserved, and have always been extensively read wherever the Greek language was known. The only danger to which the students of his philosophy have been exposed is the confusion of the doctrines distinctly taught by him with the exaggeration of these as afterwards worked out by the Neoplatonists of Alexandria; but this is a danger which the exact critical scholarship of modern times has put out of the way for all persons who exercise common precaution in the acquisition of knowledge. The distinctive character of the Platonic philosophy is expressed by the word idealism, as opposed to realism, materialism, or sensationalism, using these words in their most general and least technical sense, the capacity of forming and using ideas being taken as an essential virtue or quality of mind, as contrasted with matter; of thought as contrasted with sensation, of the internal forces of individuals and of the universe, as contrasted with the external forms by which these forces are manifested. As such, the ideal philosophy stands generally opposed to that kind of mental action which draws its stores principally from without, and is not strongly determined to mold the materials thus received by any type of thought or hue of emotion derived from within. In other words, the philosophy of Plato is essentially a poetical and an artistical philosophy; for poetry, painting, and music all grow out of idealism, or those lofty inborn conceptions by which genius is distinguished from talent. It is also, at the same time, a scientific philosophy, for the purest science, as mathematics—on which Plato is well known to have placed the highest value—is a science of mere ideas or forms conditioned by the intellect which deduces their laws; and, above all, it is essentially a moral and a theological philosophy; for practice, or action is the highest aim of man, and morality is the ideal of action; and God, as cause of all, is the ideal of ideals, the supreme power, virtue, and excellence to which all contemplation recurs, and from which all action and original energy proceed. The distinctive excellence of the Platonic philosophy is identical with its distinctive character, and consists in that grand union of abstract thought, imaginative decoration, emotional purity, and noble activity, which is the model of a complete and richly endowed humanity. The poetical element in Plato, so wonderfully combined with the analytical, shows itself not only in those gorgeous myths which form the peroration of some of his profoundest dialogues, but in that very dialogic form itself, of which the situation is often extremely dramatic; though this form of philosophic discussion perhaps owes its existence more to the lively temper and out-of-door habits of the Greeks, than to the special dramatic talent of Plato. On the other hand, the defects of the Platonic philosophy arise from its essential one-sidedness, as a polemical assertion of the rights of thought against the claims of the mere senses, of the stability of the eternal type against the constant change that characterizes the ephemeral form. In his zeal to submit all that is external to the imperatorial power of internal conception, the philosopher of ideas is apt to forget the obstinate and unpliant nature of that external world which he would regulate, and after projecting a grand new scheme of society, according to what appears a perfect model, shows like the architect who, after drawing out the model of a marble temple, finds he has only bricks to build it with. For this reason, extremely practical men, and those who are compelled to reason chiefly by an extensive induction from external facts, have ever felt an instinctive aversion to the Platonic philosophy; and Plato himself, by some of the strange and startling conclusions, in matters of social science, to which his ideal philosophy led, has, it must be confessed, put into the hands of his adversaries the most efficient weapons by which his ideal system may be combated.

The starting-point of the Platonic philosophy, as, indeed, it must be of all philosophy, properly so called, is the theory of knowledge. This is set forth in the *Theætetus*, the *Sophistes*, and the *Parmenides*; and in the *Cratylus*, the foundations are laid for a science of language, as the necessary product of a creature energizing by ideas. The Platonic theory of knowledge, as developed in the *Theætetus*, will be most readily understood by imagining the very reverse of that which is vulgarly attributed to Locke; viz., by drawing a strong and well-marked line between the province of thought and that of sensation in the production of ideas, and taking care that, in the process of forming conceptions, the mind shall always stand out as the dominant factor. In other words, the hackneyed simile of the sheet of blank paper, applied to the mind by extreme sensational philosophers, must either be thrown away altogether or inverted; the more active part of the operation must always be assigned to the mind. The formation of knowledge, according to Plato, may be looked on as the gradual and systematic elimination of the accidental and fleeting in the phenomenon from the necessary and permanent; and the process by which the mind performs this elimination—and it can be performed only by mind—is called *dialectics*. This word, from *dialégomai*, originally signifies only conversational discussion; thence, that discussion conducted in such scientific fashion as to lead to reliable results, i.e., strictly logical. The product of dialectics is ideas, and these ideas being the *éidé*, forms or types of things which are common to all the individuals of a species, all the species of a genus, all the genera of a family, and all the families of a class, generate classification—that is, knowledge of the permanent in phenomena—and definition, which is merely the articulate verbal expression of this permanency. The construction of the confused results of observation into the orderly array of clear conceptions, by a sort of cross-examination of the phenomena, performed by minds impassioned for truth, is exhibited as the great characteristic of the teaching of Socrates, in the

Memorabilia of Xenophon. In the dialogues of Plato, the same purification of the reason, so to speak, from the clouds of indistinct sensuousness, is exhibited on a higher platform, and with more comprehensive results. For between Socrates and Plato, notwithstanding a deep internal identity, there was this striking difference in outward attitude—that the one used logic as a practical instrument in the hands of a great social missionary and preacher of virtue; while the other used it as the architect of a great intellectual system of the universe, first and chiefly for his own time and his own place; but, as the event has proved, in some fashion also for all times and all places.

We should err greatly, however, if we looked on Plato as a man of mere speculation, and a writer of metaphysical books, like certain German professors. Neither Plato nor any of the great Greeks looked on their intellectual exercises and recreations as an end in themselves. With them, philosophy did not mean mere knowledge or mere speculation, but it meant wisdom, and wisdom meant wise action, and wise action meant virtue. The philosophy of Plato, therefore, with all its transcendental flights, of which we hear so much, was essentially a practical philosophy; all his discussions on the theory of knowledge and the nature of ideas are undertaken mainly that a system of eternal divine types, as the only reliable knowledge, may serve as a foundation for a virtuous life, as the only consistent course of action. Virtue, with Socrates and Plato, is only practical reason. As in the Proverbs of Solomon, all vice is folly, so in the philosophy of Plato, the imperial virtue is *phronēsis*—i.e., “wisdom” or practical “insight.” The other two great Greek and Platonic virtues—*sōphrosynē*, “moderation” or “sound-mindedness,” and *dikaïosynē*, “justice,” or the assigning to every act and every function its proper place—are equally exemplifications of a reasonable order applied to action—such an order as alone and everywhere testifies the presence of mind. The theory of morals as worked out from such principles is, of course, as certain as the necessary laws of the reason which it expresses; and accordingly, the Platonic morality, like the Christian, is of that high order which admits of no compromise with ephemeral prejudice or local usage. The contrast between the low moral standard of local respectability and that which is congruous with the universal laws of pure reason, stands out as strikingly in Plato as the morality of the Sermon on the Mount in the Gospels does against the morality of the Scribes and Pharisees. Splendid passages to this effect occurs in various parts of Plato’s writings, particularly in the *Republic* and the *Gorgias*. In perfect harmony with the Platonic theory of noble action, is his doctrine with regard to pure emotion and elevated passion. Love with Plato is a transcendental admiration of excellence—an admiration of which the soul is capable by its own high origination and the germs of god-like excellence, which are implanted into it from above. The philosophy of love is set forth with imaginative grandeur in the *Phædrus*, and with rich dramatic variety in the *Banquet*, of which dialogue there is an English translation by Shelley. The philosophy of beauty and the theory of pleasure are set forth with great analytic acuteness in the *Philebus*. With Plato, the foundation of beauty is a reasonable order, addressed to the imagination through the senses—i.e., symmetry in form, and harmony in sounds, the principles of which are as certain as the laws of logic, mathematics, and morals—all equally necessary products of eternal intellect, acting by the creation and by the comprehension of well-ordered forms, and well-harmonized forces, in rich and various play through the living frame of the universe; and the ultimate ground of this lofty and coherent doctrine of intellectual, moral, and æsthetical harmonies lies with Plato, where alone it can lie, in the unity of a supreme, reasonable, self-existent intelligence, whom we call God, the fountain of all force, and the creator of all order in the universe; the sum of whose most exalted attributes, and the substantial essence of whose perfection may, as contrasted with our finite and partial aspects of things, be expressed by the simple term *tò agathón*—the Good. From this supreme and all-excellent intelligence, human souls are offshoots, emanations, or sparks, in such a fashion that they partake essentially of the essential nature of the source from which they proceed, and accordingly possess unity as their most characteristic quality, attest their presence everywhere by a unifying force which acts by impressing a type on whatever materials are submitted to it, and is filled with a native joy in the perception of such types, the product of the same divine principle of unity, wheresoever presented. The undivided unity and unifying force which we call the soul is immortal, being from its nature altogether unaffected by the changes of decay and dissolution to which the complex structure of the material human body is exposed. The doctrine of the immortality of the soul is most fully set forth in the *Phædo*, a dialogue which combines with the abstract philosophical discussion a graphic narrative of the last hours of Socrates, which, for simple pathos and unaffected dignity, is unsurpassed by any human composition.

The most complete and systematic exhibition of the opinions of Plato will be found in the *Republic*, or ideal commonwealth, of which an excellent English translation has been recently made by Davies and Vaughan. The *Republic* is not, as the title would lead us to suppose, a political work, like the *Politics* of Aristotle. It is, as baron Bunsen well remarked, not so much a state as a church with which this great work has to do; or at least, both a state and a church; and the church is the superior and dominating element. In the *Republic*, accordingly, we find the necessity of virtue to the very idea of social life proved in the first book; then the whole process of a complete moral and scientific education is set forth with such fullness as to throw the strictly political part

of the book, including the germs of what is now called political economy, very much into the shade. The principles and government of an ideal moral organism, of which the rulers shall be types of fully developed and perfectly educated men, is the real subject of the *Republic*, which accordingly forms a remarkable contrast to the inductive results of the thoroughly practical work of Aristotle on the same subject. Plato's commonwealth is a theoretical construction of a perfect ideal state of society; Aristotle's is a practical discussion on the best form of political government possible under existing conditions. Of the value of Plato's work, both suggestively in the world of politics, and dogmatically in the region of moral and religious speculation, there can be no doubt; but as a practical treatise on politics, it is vitiated throughout, both by its original scheme and by an inherent vice in the author's mind, which prevented him from recognizing the force of the actual in that degree which necessarily belongs to such a complex art as human government. Of this fault, the author was himself sufficiently conscious, and has accordingly, in another large political treatise, the *Laws*, endeavored, for practical purposes, to make some sort of compromise between the transcendental scheme of his *Commonwealth* and the conditions of existing society. But, however he might modify individual opinions, there was a one-sidedness about Plato's mind which rendered it impossible for him to struggle successfully with the difficulties of complex practical politics. He was too much possessed with the idea of order, and, moreover, had planted himself with too manifest a polemical attitude against Athenian democracy, to give due weight to the opposite principle of freedom, proved by experience to be so indispensable to every healthy and vigorous political development.

Physical science, in the days of Plato, stood on no basis sufficiently sure or broad to authorize a philosophy of the material universe with any prospect of success. Nevertheless; in his *Timæus*, the great philosopher of ideas has attempted this; and it is a work which, however valueless in the face of the grand results of modern chemical and kinetic research, will ever be consulted with advantage, as a grand constructive summary of the most important facts and theories of nature, known to the Greeks, before the accurate observations of Aristotle, and the extended mathematics of the Alexandrian school. The great question as to what matter is, and whence, Plato nowhere seems to settle very clearly; but the general tendency of ancient thought was towards a dualism, which recognized the independent existence of a not very tractable element called matter, in which Plato seems to have acquiesced.

The works of Plato were extensively studied by the church fathers, one of whom joyfully recognizes, in the great teacher of the academy, the schoolmaster who, in the fullness of time, was destined to educate the heathen for Christ, as Moses did the Jews. A lofty passion for Plato likewise seized the literary circle of the Medici at the period of the revival of letters in Italy. Since that time, the tyrannous sway of Aristotle, characteristic of the middle ages, has always been kept in check by a strong band of enthusiastic Platonists in various parts of Europe. Since the French revolution particularly, the study of Plato has been pursued with renewed vigor in Germany, France, and England; and many of our distinguished authors, without expressly professing Platonism—as Coleridge, Wordsworth, Mrs. Browning, Ruskin, etc.—have formed a strong and a growing party of adherents, who could find no common banner under which they could at once so conveniently and so honorably muster as that of Plato. The amount of learned labor expended on the text of Plato during the present century, has been in proportion; and in this department the names of Bekker, Ast, and Stallbaum stand pre-eminent. Prof. Jowett also, in Oxford, has made Plato his standard author for many years; from his hand we had, in 1871, his translation of the *Dialogues of Plato*. Mr. Grote, the historian of Greece, published his *Plato and the other Companions of Socrates* in 1864. One of the best accounts of the Platonic philosophy is given in Zeller's *Phil. der Griechen*, of which the part on *Plato and the Older Academy* was translated in 1876.

PLATOFF, MATVEI IVANOVITCH, Count, the hetman of the Cossacks of the Don, and a Russian cavalry gen., was b. on the banks of the Don. Aug. 6. 1757, and was descended from an ancient and noble family, which had emigrated from Greece. Having acquired a considerable reputation for wisdom and bravery, he was appointed by the czar Alexander I. hetman of the Cossacks; and subsequently, as a lieut.gen. in the Russian army, and afterwards as commander of the Russian irregular cavalry, he took a prominent part in the wars both with France and Turkey. After the French had evacuated Moscow, and retreated, Platoff hung upon their rear with the utmost pertinacity, wearying them out by incessant attacks, cutting off straggling parties, capturing their convoys of provisions, and keeping them in a state of continual terror and apprehension. The French historians state that Napoleon's army suffered more loss from the attacks of Platoff's Cossacks than from privation and exhaustion. He defeated Lefebvre at Altenburg. After the rout of the French at Leipzig, he inflicted great loss upon them in their retreat, and subsequently gained a victory over them at Laon. The inhabitants of Seine-et-Marne will long remember him by the devastations and pillage committed by his undisciplined bands. He was enthusiastically welcomed by the Parisians (to their shame), and also by the English, who presented him with a sword of honor on the occasion of his visit to London in company with marshal Blücher. The allied monarchs loaded him with honors and decorations, and the czar gave him the title of count. He

retired to his own country, there to mourn the death of his only son, who had been killed in the campaign of 1812, and died near Tcherkask in 1818. No other Russian gen. ever exercised such an influence over the men under his command, and their awe of him was not greater than their affection; but this was doubtless owing to the inflexible and speedy justice which he administered to them, and to the freedom with which he left them to rob and pillage.

PLATON'IC LOVE, the name given to an affection subsisting between two persons of different sex, which is presumed to be unaccompanied by any sensuous emotions, and to be based on moral or intellectual affinities. The expression has originated in the view of Plato, who held that the common sexual love of the race, harassed and afflicted with fleshly longings, is only a subordinate form of that perfect and ideal love of truth which the soul should cultivate. Whether such a sentiment as Platonic love can really subsist between persons of different sex has been frequently disputed; but without pronouncing positively on a point so delicate, and depending so much on differences in our spiritual organization, it may be safely affirmed that wherever a feeling calling itself by this name exists, it has undoubtedly a tendency to develop into something more definite and passionate.

PLATOON (probably from the French *peloton*) was a term formerly used to designate a body of troops who fired together. A battalion was commonly divided into 16 platoons, and each company into two platoons, the platoon thus corresponding to the present subdivision. The word is obsolete in this its original sense; but it survives in the expression "platoon exercise," which is the course of motions in connection with handling, loading, and firing the musket or rifle.

PLATT, ORVILLE H. See page 896.

PLATT, THOMAS C., b. N. Y., 1833; educated at the Owego academy; a member of the class of 1853 in Yale college, withdrawing in his junior year on account of ill health. He went into mercantile business, became president of the Tioga national bank, and was heavily engaged in lumbering in Michigan. He was clerk of Tioga co. 1859-61, and a member of congress from the 29th district for two terms, 1872-76. In 1879 Mr. Platt was made general manager, secretary, and director of the U. S. express company; and in 1880 was appointed a quarantine commissioner at the port of New York. Jan. 13, 1881, after a serious struggle, he was nominated for U. S. senator from the state of New York, and took his seat at the opening of the session, which he resigned 1881, May.

PLATTE. See NEBRASKA.

PLATTE, a co. in n.w. Missouri, adjoining Kansas, bounded on the s.w. and s. by the Missouri, drained also by Platte river, and Smith's fork of the Platte; traversed by the s.w. branch of the Chicago, Rock Island and Pacific, and the Kansas City, St. Joseph and Council Bluffs railroads; about 400 sq.m.; pop. '80, 17,366—16,637 of American birth. The surface is rolling and heavily wooded, the soil fertile; principal productions, corn, wheat, oats, and live stock. Co. seat, Platte City.

PLATTE, a co. in e. Nebraska, bounded on the s. by the Platte river, drained by Shell creek and the Loup fork of the Platte, traversed by the Union Pacific railroad; about 675 sq.m.; pop. '80, 9,511—5,690 of American birth. The surface is rolling, and the soil fertile. Corn, hay, oats, and wheat are the principal productions. Co. seat, Columbus.

PLATTEN-SEE. See BALATON.

PLATTE RIVER is formed by its n. and s. forks, which rise in Colorado among the Rocky mountains, and join in Lincoln co., Nebraska. Its general course is e., and it empties into the Missouri in lat. 41° 3' n. after a course of about 450 miles. Including the n. fork, its length is 1250 m., and it drains an area estimated by prof. Hayden at 300,000 sq. miles. It is very shallow and unnavigable even for small vessels.

PLATTS'BURG, a village of New York, on the w. shore of lake Champlain, at the mouth of the river Saranac, which furnishes water-power to several mills and factories. It has a custom-house, academy, and six churches. In Plattsburg bay was fought the naval battle of Champlain, in which the British flotilla, under commodore Downie, was defeated by the American commodore McDonough, Sept. 11, 1814; while the land forces, amounting to 14,000 men, under sir George Prevost, were defeated by gen. Macomb. Pop. '70, 5,139.

PLATTSBURG (*ante*), the capital of Clinton co., N. Y., and port of entry for the Champlain district; on the w. shore of lake Champlain, at the mouth of the Saranac river; pop. '80, town, 8,283; village, 5,245. One of the first naval battles of the revolutionary war was fought here Oct. 11, 1776, the American vessels being commanded by Benedict Arnold. During the second war with Great Britain it was the United States headquarters for the northern frontier and the scene of the brilliant naval and land battles in both of which the Americans were victorious. The town was settled in 1785 chiefly by emigrants from Dutchess co. and Long Island. In 1849 and 1867 it was visited by disastrous fires that destroyed the chief business portion of the town. It now contains numerous mills and manufactories, several banks, 5 public schools and a high school, 6 churches, a library, court-house and jail, custom-house and post-office, and barracks for United States soldiers. It is lighted with gas, has a well-organized fire department, and draws its water supply from springs

7 m. distant. It is on the line of the New York and Canada railroad, a branch of which, extending 20 m. s.w. to Au Sable forks, gives access to the Adirondack region, and to the remarkable Au Sable chasm. Large quantities of logs are floated down the Saranac river, producing annually about 25,000,000 ft. of lumber; and the product of more than 50 iron bloom forges is brought to the town for shipment. The annual aggregate of entrances and clearances in the commerce with Canada is nearly 4,000; and of clearances in the coast-wise trade about 1000. Nearly 1000 vessels, the larger part of which are canal boats, are owned in the district.

PLATTSMOUTH CITY, Neb. See page 896.

PLATYPUS. See DUCK-BILL.

PLATYS'TOMA (Gr. broad-mouth), a genus of fishes of the family *siluridæ*, having a very flat (depressed) snout, and a very large mouth with six long barbels; the skin quite destitute of scales; two dorsal fins; the eyes lateral, level with the nostrils. The species are numerous, some of them attaining a large size, many of them notable for their distinct and conspicuous markings. Several are natives of the rivers of the n.e. of South America; and among these are some of the most beautiful and delicious of fresh-water fishes, as *P. tigrinum*, known among different tribes of Indians by various names—*corutto*, *colite*, *oronni*, etc., which has an elongated body, light blue, transversely streaked with black and white, and a spreading forked tail. It is both taken by baited hooks and shot with arrows by Indians, as are several other species, some of which are found as far s. as Buenos Ayres.

PLAU'EN, an important manufacturing t. of Saxony, in a beautiful valley on the White Elster, 74 m. s. of Leipsic by railway. It was the chief town of the Saxon Voigtland, and its castle was at one time the residence of the voigt, or imperial commissioner, but is now used as the seat of justice and other courts. Plauen contains a gymnasium, a royal palace, and numerous educational and benevolent institutions. It carries on extensive manufactures of muslin, cambric, and jaconet goods, as well as embroidered fabrics and cotton goods. In Sept. 1844, 150 buildings were destroyed by fire, and after that event, the town was almost wholly rebuilt. Pop. '80, 35,078.

PLAU'TUS, M. ACCIUS, or, more correctly, T. MACCIUS, the great comic poet of Rome, was b. about 254 B.C. at Sarsina, a village of Umbria. We have no knowledge of his early life and education; but it is probable that he came to Rome while still a youth, and there acquired a complete mastery of the Latin language in its most idiomatic form, as well as an extensive familiarity with Greek literature. It is uncertain whether he ever obtained the Roman franchise. His first employment was with the actors, in whose service he saved an amount of money sufficient to enable him to leave Rome and commence business on his own account. What the nature of this business was, or where he carried it on, we are not informed; we know, however, that he failed in it, and returned to Rome, where he had to earn his livelihood in the service of a baker, with whom he was engaged in turning a hand-mill. At this time—a few years before the outbreak of the second Punic war—he was probably about 30 years of age; and while employed in his humble occupation, he composed three plays, which he sold to the managers of the public games, and from the proceeds of which he was enabled to leave the mill, and turn his hand to more congenial work. The commencement of his literary career may, therefore, be fixed about 224 B.C., from which date he continued to produce comedies with wonderful fertility, till 184, when he died in his 70th year. He was at first contemporary with Livius Andronicus and Nævius: subsequently with Ennius and Cæcilius.

Of his numerous plays—130 of which bore his name in the last century of the republic—only 20 have come down to us. Many of them, however, were regarded as spurious by the Roman critics, among whom Varro in his treatise (*Quæstiones Plautinæ*) limits the genuine comedies of the poet to 21. With the exception of the 21st, these Varronian comedies are the same as those we now possess. Their titles, arranged (with the exception of the *Bacchides*) in alphabetical order, are as follows: 1, *Amphitryo*; 2, *Asinaria*; 3, *Aulularia*; 4, *Captivi*; 5, *Circulio*; 6, *Casina*; 7, *Cistellaria*; 8, *Epidicus*; 9, *Bacchides*; 10, *Mostellaria*; 11, *Menæchmi*; 12, *Miles*; 13, *Mercator*; 13, *Pseudolus*; 15, *Pænulus*; 16, *Persa*; 17, *Rudens*; 18, *Stichus*; 19, *Trinummus*; 20, *Truculentus*; 21, *Vidularia*. As a comic writer, Plautus enjoyed immense popularity among the Romans, and held possession of the stage down to the time of Diocletian. The vivacity, the humor, and the rapid action of his plays, as well as his skill in constructing plots, commanded the admiration of the educated no less than of the unlettered Romans; while the fact that he was a national poet prepossessed his audiences in his favor. Although he laid the Greek comic drama under heavy contributions, and “adapted” the plots of Menander, Diphilus, and Philemon with all the license of a modern playwright, he always preserved the style and character native to the Romans, and reproduced the life and intellectual tone of the people in a way that at once conciliated their sympathies. The admiration in which he was held by his contemporaries descended to Cicero and St. Jerome; while he has found imitators in Shakespeare, Molière, Dryden, Addison, and Lessing, and translators in most European countries. The only complete translation of his works into English is that by Thornton and Warner (5 vols., 1767–74). Unfortunately the text of his plays, as they have come down to us, is in such a very corrupt state, so defective from lacunæ, and so filled with interpolations, that much yet remains to be done by the grammarian and the commentator before they can be read with full appreciation or

comfort. The *editio princeps* was printed at Venice in 1742. Weise and Fleckeisen have given us good modern editions; but that of Ritschl (1st ed. 1848-54; 2d ed. 1871) shows such admirable acuteness and learning as to have superseded all others.

PLAYFAIR, JOHN, a Scottish mathematician and natural philosopher, was b. at Benvie in Forfarshire, March 10, 1748. His father, who was minister of the united parishes of Liff and Benvie, sent him to the university of St. Andrews at the age of 14, to study with a view to the ministry; and here Playfair gained great reputation as a diligent and successful student, especially in mathematics and natural philosophy; so much so that, while a student, he for some time discharged the duties of the natural philosophy chair during the illness of the professor. In 1773 he entered the ministry, and succeeded his father in the parish of Liff and Benvie. During his leisure hours, he still prosecuted his favorite studies, the fruits of these labors being two memoirs, *On the Arithmetic of Impossible Quantities* and *Account of the Lithological Survey of Schihallion*, which were communicated to the royal society of London. In 1782 he resigned his parochial charge to superintend the education of the sons of Mr. Ferguson of Raith; and in 1785 he became joint-professor of mathematics along with Adam Ferguson in the university of Edinburgh; but exchanged his chair for that of natural philosophy in 1805. He took the part of Mr. (afterwards sir John) Leslie (q.v.), his successor in the mathematical chair, and published a pamphlet full of biting satire against the "new-sprung zeal for orthodoxy." He became a strenuous supporter of the "Huttonian theory" in geology, and after publishing his *Illustrations of the Huttonian Theory of the Earth* (Edin. 1802), he made many journeys for the sake of more extensive observations, particularly in 1815, when he visited France, Switzerland, and Italy. He died at Edinburgh, July 19, 1819. Playfair, according to Jeffrey (*Annual Biography*, 1820), "possessed in the highest degree all the characteristics both of a fine and a powerful understanding; at once penetrating and vigilant, but more distinguished, perhaps, by the caution and success of its march, than by the brilliancy or rapidity of its movements." Playfair was, during the later part of his life, secretary to the royal society of Edinburgh. From 1804 he was a frequent contributor to the *Edinburgh Review*, criticising the works of Laplace, Zach, and Kater, and the great trigonometrical surveys, both French and English, which had just been completed. He also wrote the articles "Æpinus" and "Physical Astronomy," and an incomplete "Dissertation on the Progress of Mathematical and Physical Science" for the *Encyclopædia Britannica*. His contributions to the *Transactions of the Royal Society of Edinburgh* are numerous and exceedingly varied, a treatise on "Naval Tactics" even appearing among them. His separate works are the *Elements of Geometry* (Edin. 1795), containing the first six books of Euclid, with supplementary articles on trigonometry, solid geometry, and the quadrature of the circle; and his *Outlines of Natural Philosophy* (Edin. 1812 and 1816), being the heads of his lectures delivered in the university on that subject. A third volume of the *Outlines*, completing the work, was promised, but never appeared.

PLAYFAIR, LYON, LL.D.; b. Bengal, India, 1819; educated at St. Andrews college; at an early age (in 1834) took a course in chemistry at Glasgow. In 1837 he revisited India for his health; returned the next year, and after studying under the celebrated German chemist Liebig, became the manager of large calico mills at Clitheroe, Scotland. In 1843 he was appointed professor of chemistry at the Manchester royal institution. In the world's exhibition in London he was at the head of the department of juries, and for his valuable services was made a companion of the Bath. At the exhibition of 1856 he held the same position. The chemical society of London elected him president in 1857, and in 1858 he was appointed to the chair of chemistry in Edinburgh university. He has been a member of several royal commissions for examining into questions concerning science or health. In 1868 Dr. Playfair was returned to parliament as a liberal from the Scotch universities, and has since been prominent in political matters. In 1873 he was appointed postmaster-general and became a privy-councilor. He has been made the recipient of several foreign orders. Dr. Playfair has edited and written many treatises on scientific and technical topics, and has published several lectures and addresses on universities and education and one on the progress of sanitary reform.

PLEA is a technical term in the law of the United Kingdom. In England it had a very restricted meaning, being confined to the pleading of a defendant to an action at common law. Now in all actions in the high court it is called the "statement of defense."—In Scotland it is not used in the same sense, but denotes the short legal ground on which a party, whether pursuer or defender, bases his case or pleading. Hence the pleas in law are only short propositions of law. Pleas are subdivided according to their subject-matter, into pleas dilatory and peremptory, pleas of abatement, pleas to the jurisdiction. Pleas in bar are the same as peremptory pleas; but in criminal cases in England, special pleas in bar are pleas stating some ground for not proceeding with the indictment, such as a plea of formal acquittal or autrefois acquit; or of conviction, or autrefois convict; or a plea of pardon.—In Scotland a "plea of panel" means a plea of guilty or not guilty. Pleas of the crown was an expression anciently used to denote the divisions of criminal offenses generally, as in the well-known work called *Pleas of the Crown*, by sir Matthew Hale and other writers. The phrase was so used because the sovereign was supposed in law to be the person injured by

every wrong done to the community, and therefore was the prosecutor for every such offense.

PLEADING, as a legal term, has two meanings—a restricted and a general meaning. In the former sense, it is a generic term to denote the written formula containing the subject-matter of a litigant's demand, or claim, or of his defense or answer thereto. In its general sense, it denotes that system of rules on which the particular pleadings of litigants are framed. In the practice of English common law, the pleadings in an action were called the declaration, plea, replication, rejoinder, surrejoinder, rebutter, surrebutter, etc.—the first being a statement of the plaintiff's demand; the second, the defense thereto, and so on, each alternately answering the other, until the parties arrive at a stop, called an issue, which means a proposition of fact, which the one affirms, and the other denies. When an issue is arrived at, the parties can go no further; and the next step is to send the issue before a jury, that they may decide it. When the parties differ, not on a question of fact, but on one of law, it is called a demurrer, which must be decided by the court. These technical names have, however, been recently much changed. In the high court of justice, the plaintiff's pleading is called his "statement of claim;" then follow the "statement of defense," the reply, etc., there being no further pleadings.—In Scotland, the pleadings of the parties are called the summons (including the condescendence), the defenses or answers, the revised condescendence, the revised answers, etc. The peculiar technical rules to which the pleadings of parties must conform are capable of being understood only by lawyers.

PLEADING (*ante*), in the common-law system until recently followed in most of the states, differed greatly from the equity pleading and that employed in the admiralty courts. In the last the "libel" of the complainant or "libelant" corresponds to the "declaration" in common law and to the "bill" in equity proceedings, and each subsequent step was set forth in an "allegation." In equity, the plea responding to the bill is called the "answer," and subsequent pleadings were less formal and technical than in common law. At common law pleas subsequent to the declaration were either of the nature of a traverse, directly contradicting the allegations of the plea next preceding, and thus offering an opportunity to close the issue; or in the nature of confession and avoidance, not denying the truth of the facts claimed by the declaration, but setting up new matter to show the plaintiff not entitled to his action, and to avoid the effect of his allegations. Pleas may be peremptory or dilatory; the former altogether denies a right of action; the latter sets out that the suit has been brought in improper form, or against the wrong party, or before a court lacking jurisdiction. A *special plea in bar* differs from the *general issue* in that the latter denies all the material allegations of the preceding plea; and from a *special issue*, which does not set up new matter but denies some part which, it is claimed, goes to the *gist* of the action. The issue finally reached may be either one of law, raised by a demurrer; or of fact, as on the acceptance of a traverse. A plea *puis darrein continuance* sets out that new matter of defense has come to the knowledge of the party presenting the plea, since the last continuance of the case, or the last stage of the suit. The system of common-law pleading was extremely technical and formal, required great accuracy and precision, and the pleas were cumbered with obsolete and redundant phraseology. In England the old system has been greatly improved by acts of parliament, and in the United States the codes of procedure of a majority of the states have abolished the common-law pleadings, and have done away with the distinction between legal and equitable suits, admitting equitable defenses in all suits. The "complaint" usually takes the place of the declaration, the demurrer is retained, the response of the defendant is termed the "answer," and the pleadings never extend beyond the plaintiff's "reply" to the answer. The one point insisted upon is that the conflicting claims of the parties shall be clearly and distinctly set out, and the points in dispute brought within the jurisdiction and cognizance of the court. The rules of pleading in criminal practice are similar to those in civil practice. The pleas are of five kinds: plea of guilty; to the jurisdiction; in abatement; in demurrer, and pleas in bar. Pleas in bar (in criminal cases) may be of four kinds: former conviction; former acquittal; pardon; and "not guilty." On refusal of an accused to plead, the court may order a plea of "not guilty" to be entered. A plea of "nolo contendere" allows an inferior court to give verdict on an *ex-parte* hearing, and is made for the purpose of at once taking the case to a higher court. In England a prisoner accused of felony who refused to plead, was formerly subjected to the pressure of heavy weights until he yielded or died. The last application of this *peine forte et dure* was in 1741.

PLEASANTON, ALFRED, b. in the district of Columbia, 1823; graduated at West Point, 1844, and brevetted 2d lieut. 1st dragoons; maj. 2d cavalry, 1862; served in the Mexican war and brevetted 1st lieut. for bravery at Palo Alto and Resaca de la Palma; afterward on frontier duty as acting assistant adj.gen.; in the war of the rebellion commanded his regiment from Utah to Washington and served with it through the peninsular campaign, 1862; during which he was appointed brig.gen. of volunteers; commanded a division of cavalry in the army of the Potomac that followed Lee's army into Maryland; was engaged at Boonsboro', South Mountain, Antietam, and in the pursuit afterward; at Fredericksburg steadily engaged the enemy's cavalry; at Chancellorsville

arrested the advance of Stonewall Jackson's corps when it seemed about to drive all before it. Having been made maj. gen. he took part in numerous actions preceding the battle of Gettysburg, in which also he was commander-in-chief of the cavalry; transferred to Missouri, 1864, he drove gen. Price out of the state; was mustered out of the volunteer service, 1866; resigned his commission in the regular army, 1868; and for several years afterward was a collector of internal revenue.

PLEASANTS, a co. in n. w. West Virginia, bounded on the n. w. by the Ohio; about 225 sq. m.; pop. '80, 6,255—25 colored. The surface is rolling or hilly, and heavily wooded. The soil is fairly fertile. The principal productions are corn, wheat, oats, potatoes, and grass. Much petroleum is exported. Co. seat, St. Mary's.

PLEBEIANS (Lat. *plebs*, from the same root as Lat. *impleo*, to fill: and Gr. *plethos*, multitude), the common people of Rome; one of the two elements of which the Roman nation consisted. Their origin, as a separate class, is to be traced partly to natural, and partly to artificial causes. The foundation of Rome, probably as a frontier-emporium of Latin traffic (according to Mommsen's suggestion), would bring about the place a number of inferior employees, clients, or hangers-on, of the enterprising commercial agriculturists who laid the primitive basis of the material and moral prosperity of the city. These hangers-on were the original plebeians, or non-burgesses of Rome, whose numbers were constantly increased by the subjugation of the surrounding cities and states. Thus, tradition states that, on the capture of Alba, while the most distinguished citizens of that town were received among the Roman patricians, the greater part of the inhabitants, likewise transferred to Rome, were kept in submission to the *populus* or patricians of Rome—in other words, swelled the ranks of the plebeians. Similar transfers of some of the inhabitants of conquered towns are assigned to the reign of Ancus Martius. The order of plebeians thus gradually formed soon exceeded the patricians in numbers, partly inhabiting Rome, and partly the adjoining country. Though citizens, they were neither comprehended in the three tribes, nor in the *curiæ*, nor in the patrician *gentes*, and were therefore excluded from the comitia, the senate, and all the civil and priestly offices of the state. They could not intermarry with the patricians.

The first step (according to traditionary belief) towards breaking down the barrier between the two classes was the admission, under Tarquinius Priscus, of some of the more considerable plebeian families into the three tribes. Servius Tullius divided the part of the city and the adjacent country which was inhabited by plebeians, into regions or local tribes, assigning land to those plebeians who were yet without it. The plebeian tribes, with tribunes at their head, formed an organization similar to that of the patricians. The same king further extended the rights of the plebeians by dividing the whole body of citizens, patrician and plebeian, into five classes, according to their wealth, and forming a great national assembly called the *comitia centuriata*, in which the plebeians met the patricians on a footing of equality; but the patricians continued to be alone eligible to the senate, the highest magistracy, and the priestly offices. These newly acquired privileges were lost in the reign of Tarquinius Superbus, but restored on the establishment of the republic. Soon afterwards, the vacancies which had occurred in the senate during the reign of the last king, were filled up by the most distinguished of the plebeian equites, and the plebeians acquired a variety of new privileges by the laws of Valerius Publicola. The encroachments on those privileges on the part of the patricians, began the long-continued struggle between the two orders, which eventually led to the plebeians gaining access to all the civil and religious offices, acquiring for their decrees (*plebiscita*) the force of law. Under the Hortensian law (286 B. C.), the two hostile classes were at last amalgamated in one general body of Roman citizens with equal rights. Henceforth, the term *populus* is sometimes applied to the plebeians alone, sometimes to the whole body of citizens assembled in the *comitia centuriata* or *tributa*, and *plebs* is occasionally used in a loose way for the multitude or populace, in opposition to the senatorial party. See PATRICIAN.

PLEBISCITE, the name given, in the political phraseology of modern France, to a decree of the nation obtained by an appeal to universal suffrage. Thus, Louis Napoleon, for example, was chosen president, and subsequently emperor, by a plebiscite. The word is borrowed from the Latin; but the *plebiscitum* of the Romans properly meant only a law passed at the *comitia tributa*, i. e., assembly of the *plebs*, or "commons," as distinguished from the *populus*, or the "nobles;" and although it was ultimately obligatory on both classes of the community, it, of course, could only refer to such matters as it was within the province of the *comitia tributa* to legislate upon, and could not fundamentally alter or destroy the constitution.

PLECTOG'NATHI, in the system of Cuvier, and also in that of Müller, an order of osseous fishes, but having the skeleton less perfectly ossified than osseous fishes generally; the skin furnished with ganoid scales or spines; and particularly characterized by having the maxillary and premaxillary bones ankylosed or soldered together. The gill-lid and rays are concealed under the thick skin, with only a small opening. The ribs are very short, and there are no distinctly developed ventral fins. The fishes belonging to this order are not many. They are regarded as a connecting link between the osseous and the cartilaginous fishes.

PLEDGE is the depositing of a chattel or movable with a creditor in security of a debt, and is a contract between the parties that the pledgee shall keep the chattel till the debt is paid. In England when A pledges property with B for a debt, and other debts are incurred, B cannot retain the pledge for the additional debts; but in Scotland this can be done. When chattels are pledged in England for debt the pledgee may sell the goods if the debt is not paid at the time agreed, or within a reasonable time after notice given; but in Scotland this can only be done by getting the authority of the sheriff and a warrant to sell the goods. Owing to the frequent occasions of poor and needy persons to pledge their goods in order to procure advances of money for temporary purposes, the legislature has enacted a code of special laws to regulate these contracts. See PAWN-BROKING.

PLEIADÉS, in Greek mythology, were, according to the most general account, the seven daughters of Atlas and Pleione, the daughter of Oceanus. Their history is differently related by the Greek mythologists: according to some authorities they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of their father, Atlas (q.v.); according to others they were companions of Artemis (Diana), and being pursued by Orion (q.v.), were rescued from him by the gods by being translated to the sky; all authorities, however, agree that, after their death or translation, they were transformed into stars. Only six of these stars are visible to the naked eye, and the ancients believed that the seventh hid herself from shame that she alone of the Pleiades had married a mortal, while her six sisters were the spouses of different gods. Their names are Electra, Maia, Taygete, Alcyone, Celæno, Sterope (the invisible one), and Merope.

In astronomy a group or constellation of six stars placed on the shoulder of Taurus, the second sign of the Zodiac, and forming, with the pole-star and the twin Castor and Pollux, the three angular points of a figure which is nearly an equilateral triangle. Many believe, from the uniform agreement that the Pleiades were "seven" in number, that the constellation at an early period contained "seven" stars, but that one has since disappeared; not a very uncommon occurrence.

The name *Poetical Pleiades* is frequently applied to reunions of poets in septenary groups; and this use of the word dates from the time of the Ptolemies—the originator of the first being Ptolemy Philadelphus, who, from the number of the Greek poets that flocked to Alexandria, chose out seven, whom he treated with special distinction, and denominated his *pleiad*. His example was followed by Charlemagne; and the same system was kept up by the "Compagnie des Sept Mantenadors del gay Saber," or the "Compagnie des Sept Troubadours de Toulouse," down till the 17th century. Such associations were valuable as promoting an interchange of ideas and opinions by the most eminent in the same department of letters, and creating a kind of *esprit du corps* among them.

PLEISTOCENE (Gr. most recent), or **NEWER PLEIOCENE**, terms introduced by sir Charles Lyell to designate the most recent tertiary deposits, the organic remains of which belong almost exclusively to existing species. Within the last few years, no section of the earth's crust has received so much attention as the strata included under this name. The obscurity arising from great antiquity and metamorphic changes in deposits, and the consequent necessity of calling to some extent on the imagination in investigations into the older strata, have always thrown a peculiar charm round geology; but the examination of the little-changed newer deposits, containing animals scarcely differing in genera from, and many of them the same even in species as, those now living, being based on simple observation, has been overlooked, although the best method in all obscure inquiries is that which starts from the known, and gradually proceeds to the unknown. The paleozoic rocks have been carefully grouped and classified, and the fossils described and figured; while the order and contents of the pleistocene deposits are little known. Their isolated nature to some extent accounts for this: but, on the other hand, as they exhibit the changes that have immediately preceded the present order of things, and so give us the first sure footing in our progress downward, they deserve the most careful attention.

Not only in organic contents, but in physical conditions under which they were deposited, the pleistocene strata show that the earth, as regards its general temperature, was, at the time of their deposition, in a condition nearly approaching to its present. There is consequently a considerable difference in the deposits and fossils of this period in the different regions of the world. The alluvial pampas of South America and the gravels of Australia exhibit, by their structure and contents, a temperature of some warmth; while corresponding deposits of Britain and the continent show a state of cold that is scarcely conceivable at so recent a period. The whole of northern Europe must have been under ice like the interior of Greenland at the present day. Perhaps the best classification of the deposits is one based on the relation which they bear to the temperature of the period when they were formed. The oldest pleistocene deposits represent a time of intense cold. They were formed at the bottom of a sea into which immense glaciers forced their way. The fine mud in which the organic remains are buried was obtained from the melting glaciers. All the shells belong to species now living in arctic or boreal seas. The Bridlington beds, near Flamborough Head, consisting of sand, clay,

and pebbles, with numerous marine shells, belong to this period. Of the 63 species determined by Dr. Woodward, one-half are at present living only in seas n. of Britain. The clay deposits on the e. of Scotland, at Elie and Errol, lately described by the rev. Thomas Brown, contain fossils that have a similar arctic facies. The shells of the Bridlington, Elie, and Errol deposits differ from those of the other pleistocene strata in being much more arctic, and they consequently show that the cold had reached its climax at the time of their formation. To this period most probably belongs the boulder-clay of the s. of England, which contains erratics from Scandinavia. Both the clay and the boulders seem to have been transported to their present position by floating icebergs.

The temperature, however, after a time improved, reducing the extent of the ice-covering, and driving the arctic fauna northward from our shores. In the Norwich Crag we find a larger proportion of southern species, only one-sixth of these being truly arctic. This deposit, found in the neighborhood of Norwich, consists of beds of sand and gravel which contain fresh-water and marine shells, and the bones of large mammalia. Contemporaneous with the Norwich Crag are the marine deposits of the Clyde, at least the older of them, for though the fossils of all the beds have hitherto been grouped together, they certainly represent two periods, which differ from each other by reason of the increasing temperature. While these beds were being deposited around the shores, the ice was disappearing from the land. The glaciers were gradually creeping inward, leaving an ever-increasing margin of bare land between the glaciers and the sea, which they covered with a continuous layer of mud and rubbed stones—the materials taken up in their progress over the surface—and so forming the boulder-clay of Scotland and the n. of England. This is a remarkable deposit of unstratified mud, the character and color of which is influenced by the rocks on which it rests, and from which it was derived. It contains numerous rounded and polished blocks of stone of various sizes, promiscuously scattered through it, the whole seeming to be the result of an irregular pell-mell hurrying forward and deposition of the materials. It has been always a puzzle to geologists (see BOULDER-CLAY); but Mr. Geikie, in his recently published memoir, by showing it to be the terminal moraine formed by the slowly retreating sheet of glacier-ice, has given an explanation which meets all the singular phenomena connected with it. Connected with the disappearance of glaciers, are the lateral moraines which exist on many hillsides; and perhaps a little later, the long ridges of gravel which are called kames in Scotland, and eskers in Ireland. The loamy deposits of the valleys of the Rhine and the Danube, known as the loess, were formed at this time by the fine mud from the glaciers, with which every torrent rushing from the icy caverns at the termination of a glacier is charged, and which is now forming a similar deposit in some places on the coast of Greenland.

When the glaciers began to disappear, mammalia again occupied the land; their remains, we have already seen, occur in the Norwich Crag. They continued to increase as the conditions for their existence improved. The caves of the British islands and the continent were inhabited by hyenas, bears, and other wild beasts, which have left their remains buried in the mud at the bottom of the caves. The raised sea-beaches of this period contain the shells of mollusca now living in the neighboring seas. In many places around the shores of Britain and Ireland, submarine forests are met with dipping down under low water, and exhibiting the stumps and roots of trees, in the position of growth belonging to species now living in Britain. Some of the older peat-bogs require to be placed also among the later pleistocene deposits.

The classification, then, of these strata, which we propose, from the light thrown on them by recent observation, may be put into the following tabular form. The subdivisions are the names of recognized deposits, and though arranged in tabular series, the order is not one of strict sequence, representing the superposition of the different beds; they are all very local deposits, and many of them, though differing in character, were formed contemporaneously:

Post-glacial.....	}	Peat-bogs.
		Submarine forests.
		Modern raised sea-beeches.
		Cave deposits.
Glacial.....	}	Loess.
		Kames and eskers.
		Lateral moraines.
		Boulder-clay.
	}	Newer Clyde beds.
		Older Clyde beds.
Arctic.....		Elie, Errol, and Tirie clay beds.
	}	Bridlington beds.

Many speculations have been made as to the cause of the remarkable change of temperature, from the comparatively warm period of the pleiocene deposits, to the extreme cold of the early pleistocene strata, and the subsequent gradual return to the warmer temperature of the present period. The most probable is that it resulted from an extensive depression of the land of the northern hemisphere in some parts, and its elevation in others during the period. Deposits of glacial shells have been found more than 1000 ft.

above the sea-level in Wales. A depression much less than this, in the isthmus of Panama, would give a different direction to the gulf stream, and so deprive western Europe of its benignant influences. It would also put the immense sandy Sahara under water; and that it has been so at a comparatively recent period has been clearly established by the discovery lately of existing marine shells (including *cardium edule*) over an extensive district of the desert. Without the Sahara the s. of Europe would have no burning dry sirocco, which now melts the glaciers of the Alps; but instead, a comparatively cold sea-breeze, laden with moisture, which would to a large extent feed them. The existence of a greater quantity and a higher elevation of land near the north pole would also depress the temperature. These and similar causes would do much, if they were not in themselves sufficient, to produce the extreme cold of the arctic period.

The classification of the British strata will suit, in a general way, the whole of the north temperate zone, for throughout the whole of the northern regions of Europe, Asia, and America similar conditions existed, producing similar physical changes, and the whole region formed one zoological province inhabited by the mammoth, mastodon, and their contemporaries. A warmer climate prevailed at this period in South America, and the fossil animals there belong to types still peculiar to that continent, though of a size immensely greater than their living representatives. The megatherium, mylodon, and megalonyx were the gigantic forerunners of the living sloth; and the small armadilloes were anticipated by the glyptodon. The llamas, opossums, tapirs, and prehensile-tailed monkeys are the diminutive representatives of similar forms in the pleistocene period. The peculiar marsupial fauna of Australia had also its gigantic forerunners during this period. The skull of one species (diprotodon, an animal between the kangaroo and the wombat), now in the British museum, measures 3 ft. in length. The huge wingless dinornis, and its allies of New Zealand, were nearly allied to the small wingless apteryx, now living in that island.

The question of the antiquity of man is intimately associated with the pleistocene deposits. Whatever be the age of the beds in which either the remains of man or works of art have been found, it is certain that none of them pass the horizon of the boulder-clay. It is, however, equally certain that undoubted evidences of his existence contemporaneously with the mammoth and woolly rhinoceros, with the cave-lion and hyena, have been found in Britain; and setting aside the various French and Belgian caves and gravel deposits about which geologists are, with good cause, so divided, there is evidence in the knives, pins, etc., manufactured from the bones of the large reindeer, found in caves at Bruniquel and elsewhere, that man hunted this huge extinct animal. Its contemporaries, as far as the associated remains from these caves have been determined, yet survive: these were the chamois, ibex, horse, fox, wolf, hare, raven, partridge, and salmon. However far, when measured by years, this carries back the first appearance of man on the globe, geologically speaking, the time is insignificant as compared with the vast lapse of ages represented by even a single formation; still it represents a period in which many remarkable changes have taken place, both in the climatal condition of Europe and in its animal inhabitants.

PLENISHING, in the law of Scotland, denotes the furniture of a house or stocking of a farm. The term is now seldom used, except in the law relating to heirship movables (q.v.).

PLEONASM (Gr. *pleon*, more), a term employed in rhetoric to denote superfluity of expression.

PLESIOSAURUS (Gr. near to a lizard), a remarkable genus of fossil sea-reptiles, the species of which are found in the lias, oolite, and cretaceous measures. Its remains are so abundant and so perfectly preserved, that we are as well acquainted with skeletons of many of its species as we are with those of any living animals. These represent a strange animal, the structure of which Cuvier considers to be the most singular, and its character the most anomalous, that had been discovered 'mid the ruins of former worlds. In the words of Buckland, "To the head of a lizard, it united the teeth of a crocodile, a neck of enormous length, resembling the body of a serpent, a trunk and tail having the proportions of an ordinary quadruped, the ribs of a chameleon, and the paddles of a whale."

The skull is small and depressed. From the nostrils backward, it is quadrate; it suddenly contracts at the nostrils, and is continued into a parallel-sided apex, which is sometimes slightly swollen at the point. No sclerotic plates have been found in the orbits. The rami of the lower jaw are remarkably expanded at their anterior ankylosed extremity. No intervening vacuity separates the angular and surangular pieces, as in the crocodiles, but they are joined throughout, as in the lizards. The teeth occupy distinct cavities; they are sharp-pointed, long, slender, circular in cross-section, and with fine longitudinal ridges on the enamel. The most striking peculiarity of the vertebræ is the great length of the neck-portion, which is composed of from 20 to 40 vertebræ. The articular surfaces of the bodies of the vertebræ are either flat or slightly convex in the center, with a concavity round the periphery. The cervical vertebræ consist of a centrum, neural arch, and two ribs, which articulate into two pits on the sides of the centrum. In the dorsal vertebræ, the ribs are articulated to diapophyses from the neural arch; and in the tail, they gradually descend again to the sides of the centrum. The

tail is much shorter than in the ichthyosaur. In the abdominal region the extremities of each pair of ribs are connected below by the development of the hæmal spine.

The two pair of limbs were equal in size and shape, with probably a single exception. The bones of the hind-limbs closely correspond in number, arrangement, and form with those of the fore-limbs, so that the descriptions of the one set answer to the corresponding bones of the other. The humerus is a stout and moderately long bone, curved slightly backwards, rounded at its proximal extremity, and flattened as it approaches the elbow joints. The radius and ulna are short and flat bones—the former straight, the latter reniform, with the concavity towards the radius. The carpus consists of six to eight flat round bones in a double row. The five metacarpals are long, slender, and slightly expanded at both ends. The numerous phalanges are alike in form, but progressively decrease in size. The radial digit has generally three; the second from five to seven; the third, eight or nine; the fourth, eight; and the fifth, five or six phalanges. The limbs were covered with integument, so as to form simple undivided paddles, as in the turtle.

The supposed habits of the plesiosaur are thus described by Conybeare: “That it was an aquatic, is evident from the form of its paddles; that it was marine, is almost equally so, from the remains with which it is universally associated; that it may have occasionally visited the shore, the resemblance of its extremities to those of the turtle may lead us to conjecture; its motion must have, however, been very awkward on land; its long neck must have impeded its progress through the water, presenting a striking contrast to the organization which so admirably fits the ichthyosaur to cut through the waves. May it not, therefore, be concluded—since, in addition to these circumstances, its respiration must have required frequent access to the air—that it swam upon or near the surface, arching back its long neck like the swan, and occasionally darting it down at the fish which happened to float within its reach? It may perhaps have lurked in shoal-water along the coast, concealed among the sea-weed, and, raising its nostrils to the surface from a considerable depth, may have found a secure retreat from the assaults of dangerous enemies; while the length and flexibility of its neck may have compensated for the want of strength in its jaws, and its incapacity for swift motion through the water, by the suddenness and agility of the attack which they enabled it to make on every animal fitted for its prey which came within its reach.”

The first remains of this animal were discovered at Lyme Regis in 1822. Since then 22 species have been described, the specific differences chiefly resting on peculiarities in the form and structure of the vertebræ.

PLESKOV. See PSKOV, *ante*.

PLESSIS, JOSEPH OCTAVE, 1762–1825; b. Montreal; entered the priesthood, and was appointed rector of Quebec cathedral, and secretary to the bishop. In 1797 he was chosen coadjutor to bishop Denaud, but the death of Pius VI. prevented the ratification of the election till 1800. He was then given the title of bishop of Canada. His election caused a dispute with the British government, which claimed the right of presentation to all bishoprics; but its claim was successfully contested by the bishop. He founded the college of Nicolet, and greatly increased the facilities for both primary and secondary instruction. In 1818 he became, by royal appointment, a member of the legislative council of Canada. In 1819 he visited Rome, and sought to have all British North America made one ecclesiastical district, with an archbishop at Quebec, and suffragan bishops in the other dioceses.

PLETH'ORA (Gr. “fullness” or “excess”), designates a general excess of blood in the system. It may arise either from too much blood being made, or from too little being expended. The persons who become plethoric are usually those in thorough health, who eat heartily and digest readily, but who do not take sufficient bodily exercise, and do not duly attend to the action of the excreting organs. With them the process of blood-making is always on the increase, and the vessels become more and more filled, as is seen in the red face, distended veins, and full pulse. The heart is excited and overworked, and hence palpitation, shortness of breath, and probably a sleepy feeling, may arise; but these symptoms, instead of acting as a warning, too often cause the abandonment of all exercise, by which the morbid condition is aggravated. The state of plethora thus gradually induced may be extreme without any functions materially failing, and yet the subject is on the verge of some dangerous malady, such as apoplexy, or structural disease of the heart or great vessels, or of the lungs, kidneys, or liver.

Plethora is said to be *sthenic* when the strength and irritability of the muscular fibers (especially of the heart and arteries) are fully or excessively developed. This form commonly affects the young and active, and those of sanguineous nature. The blood is rich in red cells and fibrine; and there is a tendency to general febrile excitement, active hemorrhages, fluxes, and inflammation. A natural cure is thus often effected by the super-vention of an attack of bleeding from the nostrils or from piles, or mucous or bilious diarrhea. The plethora is said to be *asthenic* (Gr. *a*, not, and *asthenos*, strength) when there is a deficiency of contractility and tone in the muscular fiber. In this case, the heart and vessels, instead of being excited (as in *sthenic* plethora) by the augmented quantity of blood, are oppressed by its load, and cannot duly expel their accumulated contents. The face is purple instead of red; the extremities cold, and the excreting

organs sluggish. This form affects persons weakened by age, excesses, or previous disease. It tends to produce congestions and passive hemorrhages, fluxes, and dropsies; and, if continued, structural changes, such as dilatation of the heart, enlarged liver, varicose veins, etc.

In *sthenic* plethora, blood-letting is the first remedy, and this, with the continued use of aperient medicine and a sparing diet, is often sufficient to complete the cure. If these means fail, recourse must be had to antimonials, salines, digitalis, and sometimes mercury or colchicum. In the *asthenic* form, Dr. Williams (to whose article on "plethora," in his *Principles of Medicine*, we refer our readers for further details) observes that "the continued use of alterative aperients and diuretics, such as mild mercurials, with rhubarb, aloes, or senna, salines and taraxacum, nitric acid, iodide of potassium, etc., may prepare the way for various tonics, such as calumba, bark, and iron." He also recommends the use of the Cheltenham, Leamington, and Llandrindod waters; first the saline, which are aperient and diuretic; and afterward the chalybeate, which, although tonic, usually contain enough of saline matter to keep the secretions free. Food may be taken more freely than in the *sthenic* form; and in both varieties, as much exercise in the open air should be taken as can be borne without causing exhaustion.

PLEURÆ. Each lung is invested externally by a very delicate serous membrane termed the *pleura*, which, after inclosing the whole organ, except at its root, where the great vessels enter it, is reflected upon the inner surface of the thorax or chest. That portion of the pleura which is in contact with the surface of the lung is called the *pleura pulmonalis*, or visceral layer; whilst that which lines the interior of the chest is called the *pleura costalis*, or parietal layer; while the space intervening between these two layers is called the *cavity of the pleura*. Each pleura is a closed sac, and quite independent of the other. The interspace between the pleuræ on the right and left side is termed the *mediastinum*, and contains all the viscera of the thorax excepting the lungs. The inner surface of each pleura is smooth, glistening, and moistened by a serous fluid; the outer surface is closely adherent to the surface of the lung, to the roots of the pulmonary vessels as they enter the lung, to the upper surface of the diaphragm, and to the walls of the chest. The lobes of the lungs are separated from one another by involutions or in-foldings of the visceral layer. The use of these serous sacs is much the same as that of the *peritoneum* (q.v.); each pleura retains the lung and, to a certain extent, the greater vessels in position, while it at the same time facilitates, within certain limits, the movements of those parts which are essential to the due performance of the act of respiration.

PLEURISY, or inflammation of the investing membrane of the lung, is one of the most serious diseases of the chest. It is very often, but by no means invariably, associated with inflammation of the *substance* of the lung, commonly known as *pneumonia* (q.v.). Pleurisy without pneumonia is much more common than pneumonia without pleurisy. When both are present, but pneumonia preponderates, the correct term for the affection is *pleuro-pneumonia*, although it is frequently spoken of simply as pneumonia, probably in consequence of the remedies being applied mainly to it, as the more important of the two elements in the compound malady.

The pleura being a serous membrane, its inflammation is attended with the same course of events as have been already described in our remarks on the two allied diseases, *pericarditis* and *peritonitis*. The inflammation is of the adhesive kind, and is accompanied by pain, and by the effusion of serum, of fibrinous exudation (the *coagulable lymph* of the older writers), or of pus, into the pleural cavity. In consequence of the anatomical relations of the pleura—one part of the membrane (the parietal) lining the firm walls of the chest, while the other part (the visceral) envelops the soft and compressible lung; and these opposed surfaces being freely movable on one another—it follows that very different effects may be produced by its inflammation. For example, the visceral layer may be glued to the parietal layer, so as to prevent all gliding movement between them, and to obliterate the pleural cavity (similarly to what often happens in *pericarditis*, q.v.); or the two surfaces which are naturally in contact, may be abnormally separated by an infusion of serum between them; or from a combination of these results, the opposite surfaces of the pleuræ may be abnormally united at some points, and abnormally separated at others.

The general symptoms of pleurisy are rigors, pain in the side, fever, difficulty and rapidity of breathing, cough, and an impossibility of assuming certain positions; and of these the most marked is the pain or *stitch in the side*, the *point de côté* of the French writers. From the prominence of this pain, which occupies a single spot, and is of a sharp, stabbing character, the Latin writers term pleurisy *morbus lateris*. This spot is usually about the center of the mamma of the affected side, or just below it; but why the pain should be usually restricted to that one small spot, when the inflammation pervades a considerable extent of surface, is a question that has never received any satisfactory answer. The pain is, however, occasionally felt in other parts—as in the shoulders, in the hollow of the armpit, beneath the collar-bone, along the breast-bone, etc. Cruveilhier observes that the pain sometimes affects the loins, and simulates lumbago; while Andral and Dr. Watson have directed attention to the fact that the pain often affects the hypochondrium, and may be readily mistaken for a symptom of peritonitis, or (if occurring on the right side) of hepatitis. The pain is increased by percus-

sion, by pressure between the ribs, by a deep inspiration, by cough, etc.; and the patient is often observed to suppress a natural desire to cough, or never to draw more than a short and imperfect inspiration. The cough is not invariably present, although it is an ordinary symptom. It is small, suppressed as far as possible by the patient, and is either dry, or accompanied by the expectoration of slight catarrh. If much frothy mucus is brought up, it is a sign that bronchitis (q. v.) is also present, and the appearance of rust-colored sputa indicates the co-existence of pneumonia. Although the above-named symptoms, especially when most of them occur together, afford almost certain evidence of the existence of pleurisy, yet to the physician the physical signs are still more valuable, especially those furnished by percussion and auscultation.

Pleurisy far more commonly arises from exposure to cold than from any other cause, especially if a poisoned condition of the blood, predisposing to inflammation of the serous membrane, is present; but it may be occasioned by mechanical violence (as by a penetrating wound of the thorax by the splintered ends of a broken rib, etc.), or by the accidental extension of disease from adjacent parts. The disease may terminate in resolution and complete recovery; or in adhesion, which often only causes slight embarrassment of breathing; or it may end with such a retraction of one side of the chest as to render the corresponding lung almost or totally useless: or it may cause death either directly by actual suffocation, if the effusion is very copious, and is not removed by tapping; or indirectly, by exhaustion. It is seldom, however, that simple pleurisy proves fatal.

In acute pleurisy, occurring in a robust and previously healthy subject, free blood-letting should be at once resorted to. If there is a sharp stitch in the side, and the respiration is short, quick, and restrained, the patient should be bled, in the upright position, from a large orifice in the vein, until the pain is relieved, and he can draw a full breath without discomfort, or until he is about to faint; and if the pain and difficult breathing should return, and the pulse continue firm and hard, either the venesection must be repeated, or leeches must be freely applied to the painful side. The bowels should be freely evacuated, after which calomel should be given, guarded with a little opium, to the extent of producing *slight* mercurialization, with the view of checking the effusion of fluid. The more rapidly the system can be thus affected, the better, and hence it has been recommended (by Dr. Walsh) that during the first six hours a grain and a half of calomel, combined with a sixth of a grain of opium (or more, if the pain continues acute), should be given every half-hour; while mercurial ointment is rubbed into the skin of the affected side, near the arm-pit, every fourth hour. Care must be taken that neither decided salivation nor narcotism is induced; and as soon as there is any evidence from the breath, or from the appearance of the gums, that the mercurial action has been established, the further administration of the calomel and the ointment must be suspended. After the pain and fever have ceased, we must facilitate the absorption of the fluid by diuretics. A pill composed of half a grain of digitalis, a grain of squills, and three grains of blue pill taken twice a day, usually acts efficiently; and the compound tincture of iodine of the London (*not* the British) Pharmacopœia, in doses of twenty minims, taken, largely diluted, three times a day, has been strongly recommended.

There has been considerable discussion of late years as to how far the operation of tapping the chest, and letting out the fluid, is justifiable in this disease. The best authorities are of opinion that in simple pleurisy it ought never to be performed unless (1) the life of the patient is in immediate danger from the continued pressure of the fluid in the sack; (2) unless all other means of getting rid of the fluid having failed, the patient is evidently losing strength daily; and (3) unless there is good reason to believe that the fluid consists of pus, in which case it should be let out. In all cases in which the operation is contemplated, a grooved needle should be introduced into the pleura. By this means, we not only ascertain the actual presence of fluid, but we discover its nature. If it be serious, it will flow readily along the groove, and trickle down the patient's side; if it be purulent and thick, a drop or two will probably be visible at the external orifice, and when the needle is withdrawn, its groove will be found to contain pus. The puncture thus made is quite harmless, and inflicts very little pain.

PLEURISY-ROOT. See BUTTERFLY WEED.

PLEURODY'NIA is a rheumatic affection of the intercostal muscles, and is characterized by acute pain in the side upon taking a full breath or coughing, and by great tenderness on pressure. If it happens to be attended by slight febrile excitement, or by a cough, it is impossible to distinguish it from pleurisy, except by attending to the physical signs which characterize the latter disease. Cruveilhier maintains that "pleurodynia is nothing more than adhesive pleurisy;" and in many cases of assumed pleurodynia, there is little doubt that the pain is due to old adhesions. The disease generally yields to local measures, such as blistering, or counter-irritation in a milder form by rubefacient liniments. A mixture of soap-liniment and chloroform rubbed over the affected part two or three times a day, often gives relief. In the more persistent cases, leeches may be applied with benefit.

PLEURONECTIDÆ, a family of fishes included in Cuvier's *malacopterygii*, but belonging to the order *anacanthini* of Müller's system (see MALACOPTERYGII), and remarkable for a character to which there is nothing similar in any other vertebrate animals, a want of symmetry in the head, and for swimming not with the back uppermost, like other

fishes, but with one side uppermost. The peculiar structure of the head adapts it to this mode of swimming, both eyes being on that side which is uppermost. Some of the bones of the head are distorted to a very considerable degree, but there is no want of symmetry in those of the body. The sides of the mouth are unequal. The body is extremely compressed, whence the pleuronectidæ are popularly termed *flat fish*, the back and belly being mere edges fringed by the dorsal and anal fins. The pectoral fins are generally unequal, also the ventral fins, those of the lower side being smaller than those of the upper. The upper side is often brown, or of some darkish color, and variously marked; the lower side whitish. The color of the upper side generally corresponds so much with that of the bottom, close to which these fishes swim, that they readily escape observation; and on this they seem chiefly to depend for safety, although, when hard pressed, they raise themselves in a vertical position, and suddenly throw themselves upward and forward to some distance, but then resume their ordinary posture, and as close to the bottom as possible. Their ordinary swimming is by a kind of undulating movement. They swim with great activity. They have no air-bladder. They abound chiefly where the bottom is smooth, either muddy or sandy. All of them are sea-fishes, but some are very common in brackish water, ascend rivers, and can be kept in fresh-water ponds. Many of them are in great esteem for the table. The turbot, halibut, brill, plaice, and flounder are examples of this family.

PLEURO-PNEUMONIA, in an epizootic form, first appeared amongst the horned cattle of Great Britain and Ireland in 1841. From time immemorial it had, however, been known in the great cattle-breeding plains of central and northern Europe. It consists in a sub-acute inflammation of the structure of the lungs and their investing membrane, shows a great tendency to early exudation, and is accompanied by low fever. It is contagious, but, like many other contagious disorders, it occasionally occurs independently of contagion, and is fostered by overcrowding, exposure to cold and wet, damp, dirty hovels, and other such causes, which depress the vital powers. The symptoms come on insidiously, appetite and rumination are irregular, there is fever, dullness, a short, half-involuntary cough, with quickened breathing and pulse. In cows, the yield of milk is early diminished. After three or four days, large portions of the lungs become filled with the products of inflammation, hence the labored breathing, quick indistinct pulse, wasting, and fatal weakness. Death generally occurs in from ten to twenty days. When pleuro-pneumonia first appeared in this country, it was greatly more fatal than it has since become, and fully four-fifths of the cattle attacked died; with prompt and rational treatment, more than one-half of the affected cases now recover. But as a favorable result is uncertain, and much flesh is lost even during a slight attack, it is still advisable, when pleuro-pneumonia breaks out in a herd, to consign to the shambles any of the cattle in good condition that have mixed with those diseased. The best treatment consists in avoiding bleeding and all reducing remedies, supporting the strength, and keeping up the action of the skin, bowels, and kidneys, in order that the poisonous products of the disease may be rapidly got rid of. For this end, the patient should be provided with a cool comfortable house, clothing to the body, bandages to the legs, a daily dose of two ounces each of niter and common salt given in treacle and water. When the bowels are costive, gentle laxatives are required. By the second or third day, counter-irritants may be applied to one or both sides, which should first be bathed with hot water and thin mustard paste, or a mixture of cantharides and euphorbium ointments well rubbed in. By the third or fourth day, or earlier, if there is weakness, arrested secretion, and coldness of the skin, give several times daily some stimulant, such as a quart of warm ale, with an ounce or two of ginger or other stomachic, some good whisky-toddy, three-ounce doses of sweet spirit of niter, or of spirit of ammonia. Whilst the disease continues, and even during early convalescence, all food requiring rumination must be interdicted, and mashes, flour and treacle, bruised grain, or any light digestible articles substituted for the ordinary hay, straw, or roots. As pleuro-pneumonia is in many cases propagated by contagion, the sick should be separated from the sound stock; and any premises they have occupied carefully cleansed by whitewashing, and the use of McDougall's, Condy's, or other effectual disinfectants. When pleuro-pneumonia prevails in a neighborhood, all fresh purchases should be placed in quarantine, and kept perfectly away from the home-stock for at least three weeks. Attention to this simple precaution has preserved many farmers from pleuro-pneumonia, even while it has raged all around them.

PLEURO-PNEUMONIA (*ante*). Prof. James Law, of Cornell university, in a recent work gives much valuable information on the pleuro-pneumonia of cattle, or, as he thinks it should be called, contagious lung plague of cattle, which answers to the German name *lungenseuche* (lung contagion). He gives as a definition of the malady, a specific contagious disease, peculiar to cattle, and manifested by a long period of incubation—ten days to three months—by a slow, insidious onset, by a low type of fever, and by the occurrence of inflammation in the air passages, lungs, and their coverings, with an extensive exudation into the lungs and pleuræ. He says that the nature of the disease has been misapprehended by many authorities, especially among English veterinarians, and that there is no proof that, like other inflammations of the organs within the chest, it is caused by exposure, inclement weather, changes of climate and

season, imperfect ventilation, overcrowding, etc. He says that the malady "is always and only the result of contagion or infection," therefore he proposes the name above given. He has, however, no objection to the old name, *pulmonary murrain*. After giving an account of the disease as it has appeared on the eastern continent, in which he makes the statement that Great Britain alone has, since 1842, lost not less than \$10,000,000 per annum by the ravages of the disease, he gives a brief notice of its introduction into the United States. It was brought into Brooklyn in 1843, by means of a ship cow, bought by Peter Dunn of the capt. of an English vessel. From this cow it spread rapidly over the whole w. end of Long Island. The plague was introduced into Massachusetts in 1859, by four Dutch cows, imported by Mr. Chenery, of Belmont, near Boston. They were brought from the infected port of Rotterdam, and were forty-seven days at sea, during the last twenty of which they were sick, one of them being unable to stand. On landing, two walked to the farm, while the other two had to be carried. One recovered, and three died, the last one the 10th of June. On August 20, another cow of the herd took the disease and died in a few days. Several others followed in rapid succession. Then Mr. Chenery became convinced that he was dealing with the bovine plague of Europe. He had unfortunately sold some calves to a neighbor on the 23d of June. The disease spread, and during the next four years infected many counties. In 1860 a state act was passed to provide for the extirpation of the disease, which empowered the commissioners to cause all cattle in herds where the disease was known or suspected to exist to be killed. The commission was kept in existence six years, when the last member resigned, the disease having been exterminated. The malady was imported into New Jersey in 1847, by Mr. Richardson, who, as soon as he ascertained the fact, had his whole herd, valued at \$10,000, slaughtered. But others who had diseased cattle were not so public-spirited, and the pest was carried into Pennsylvania and Delaware, spreading into Maryland and Virginia, where it still prevails. The disease may be communicated by immediate contact, through the atmosphere for a considerable distance, by the inhalation of pulmonary exudation when placed in the nostrils, from the impregnated clothing of attendants, infected buildings, infected manure, pastures, fodder, etc. Pastures grazed three months previously have communicated the infection, and it has been spread by the flesh of diseased animals. In buildings which contain piles of lumber, litter, and hay, the virus may be preserved some considerable time. The distance through which the infection will pass between separated cattle varies. Herds separated not more than 15 yards, with a tight board fence 7 ft. high between them, have been known to be unaffected for over six months, while the infection has been conveyed much greater distances. The disease is confined to the bovine genus, and all its members, irrespective of age or sex, appear to be equally liable to its attacks, and, as in many other contagious diseases, those animals which have once had the disease are exempt from future attacks. The period of incubation is variable, ranging, according to authorities, from five days to three months; and it is this insidiousness which renders the disease so dangerous. It, however, develops much more rapidly in hot than in cool weather, and in the s. than in the north. The work of exterminating the disease in New York by gen. Patrick and prof. Law was, at the commencement of 1880, as follows: In the preceding ten months the inspectors in New York had examined 40,000 head of cattle, many of them several times. They had paid the owners for 500 head of slaughtered cattle, which nearly eradicated the disease from seven counties. At that time the center of the plague was in Kings co., and the adjacent border of Queens county. In all the country districts where the cattle were kept on inclosed farms, the work of exterminating the disease was comparatively easy. In the suburbs of cities, where cattle were allowed to graze on open lots, the greatest difficulties were met. More difficulty was found in Brooklyn than in New York, because of the greater opposition to the work of the inspectors. In Putnam co., where the disease had been smoldering for more than a year, the county authorities authorized the extermination of every herd known to be infected.

PLEXIM'ETER. See PERCUSSION.

PLEYEL, IGNAZ, a musical composer of some note, b. in 1757 at Rupperstahl, near Vienna. He studied music under Vanhall and Haydn, and made in early life an extensive tour in Italy, to hear the works of the best composers. In 1783 he was made *capellmeister* of Strasburg cathedral, and during the succeeding ten years composed most of the works on which his popularity rests. In 1791 he visited London, and composed there three symphonies. Two years afterward, during the frenzy of the French revolution, he fell under suspicion, and in proof of his acquiescence in the new order of things, had to compose a musical drama for the anniversary of the 10th of August, which saved his life. After a long career in Paris as a publisher of music and pianoforte manufacturer he retired to an estate which he had purchased near Paris, and died in 1831. His compositions, consisting of quartettes, concertantes, and sonatas, are full of agreeable melodies, sometimes light and trivial, but occasionally vigorous.

PLICA POLONICA is the name given to a disease of the scalp, in which the hairs become matted together, by an adhesive and often fetid secretion, and which is especially prevalent in Poland, although it occasionally occurs in other countries. The hair is found, on microscopic investigation, to be infested with a fungus of the genus *trichophyton*.

The only treatment that is beneficial is the removal of the hair, and strict attention to cleanliness; but, as it is popularly believed in Poland that this affection affords a security from all other sickness and misfortune, it is often difficult to persuade patients to have recourse to these means. For an account of the parasitic fungus that attacks the hair in this disease, and of the changes of structure which it induces, see Küchenmeister's *Manual of Parasites*, vol. ii. pp. 148-152.

PLINLIMMON, or **PLYNLIMMON**, a mountain of Wales, on the boundary between the counties of Montgomery and Cardigan, 11 m. n.w. from Llanidloes. It is 2,481 ft. in height. The name Plinlimmon is said to be a corruption of the Celtic *pumlumon*, signifying five rivers, and to be due to the fact that five rivers have their source in this mountain: one of them is the Severn, and another the Wye. Plinlimmon is a huge mountain mass with three chief summits. Although not above 12 m. from the coast, it is in the midst of a wide waste of muir and bog. Spurs or subordinate mountain-ranges spread out from it in all directions. The view from the summit is very extensive. It was in the fastnesses of Plinlimmon that Owen Glendower took his stand, in 1401, at the outset of his career, issuing thence with a few determined followers to make inroads on the English borders.

PLINTH, the square member at the bottom of the base of a column. Also the plain projecting band forming a base of a wall.

PLINY, C. **PLINIUS SECUNDUS**, often called Pliny the elder, and author of the celebrated *Historia Naturalis*, was b. in the n. of Italy, either at Novum Comum (*Como*) or Verona, 23 A.D. Whether it was his birthplace or not the former town was certainly his family's place of residence, since he had estates in its neighborhood; his nephew, the younger Pliny, was born there, and inscriptions relating to members of his family have been found near it. While still young he was sent to Rome, where his ample means and high connections secured him the best education. At the age of 23 he entered the army, and served in Germany as commander of a troop of cavalry under L. Pomponius Secundus, of whom, in later life, he wrote a memoir. He traveled over nearly all the frontier of that extensive province, visited the Cauci and the sources of the Danube, composed during the intervals of military duty his treatise *De Jaculatione Equestri*, and commenced a history (afterward completed in twenty books) of the Germanic wars. On his return to Rome in 52 with Pomponius, he entered on the study of jurisprudence; but his practice as a pleader proved him to have no great capacity for the legal profession; and, accordingly, he retired to his native place, where he spent the greater part of the reign of Nero in miscellaneous authorship. It was during this period that he wrote his *Studiosus*, a treatise in three books on the training of a young orator from the nursery to his entrance on public life, and apparently intended to guide the education of his nephew; also his grammatical work, *Dubius Sermo*, in eight books. Shortly before Nero's death we find him a procurator in Spain, where, in 71, he heard of his brother-in-law's decease, and of his being intrusted with the guardianship of his nephew, Pliny the younger, whom he adopted on his return to Rome before 73. Vespasian, the reigning emperor, whom he had known while serving in Germany, received him as one of his most intimate friends; and it was at this period that he completed, in 31 books, and brought down to his own time the Roman history of Aufidius Bassus. His mode of study at this time was a model of systematic assiduity. When living in the busy world of Rome, he would begin his studies by candle-light in autumn at a late hour of the night, and in winter at one or two in the morning. Before daybreak he would call on the emperor, for whom he would proceed to execute various commissions; this done he would return home and resume his studies. A slender meal would follow; after which he would, in summer weather, lie in the sunshine, and take notes or extracts from the books which were read to him. The practice of jotting down important facts or observations was habitual with him, and he was often heard to say that there was no book, however bad, from which some good could not be got. A cold bath, followed by a light meal and a short sleep occupied another interval, after which he would study till the *cæna*, or dinner-time. Even at this meal some book was read to him on which he would make comments. When in his country residence he studied nearly all the time, except when in the bath; and even then, while his attendants were performing the duties incident to that luxury, he would be listening to some one who read to him, or he would be dictating to his amanuensis. When on a journey, again, he was never without a secretary at his elbow, provided with a book and tablets. By this mode of life he collected an immense mass of materials, from which he compiled his great *Historia Naturalis*, published about 77. No fewer than 160 *volumina* of notes were found at his death, two years afterward. The great eruption which, in 79, submerged Herculaneum and Pompeii was at its height when he was stationed off Misenum, in command of the Roman fleet. Eager to examine the phenomenon more closely, he landed at Stabiæ, where he was suffocated by the vapors caused by the eruption. He was, as his nephew tells us, corpulent and asthmatic, and sank the more readily. None of his attendants shared his fate.

Of all his works, only his *Historia Naturalis* has come down to us. It comprehends a greater variety of subjects than we now regard as included under that title. Astron-

omy, meteorology, geography, mineralogy, zoology, botany, everything, in short, which is a natural or non-artificial product, finds a place in Pliny's Natural History. Even to this elastic interpretation of the term he by no means rigidly adheres, the work being interspersed with digressions on such subjects as human institutions and inventions, and the history of the fine arts. It is divided into 37 books—the first of them being a dedicatory epistle to Titus, with a table of contents of the remaining books, and embraces, as we are told in the preface, 20,000 matters of importance, extracted from about 2,000 volumes. Its scientific merit is not great. There is little attempt at philosophical arrangement; the observations are nearly all taken at second-hand, and show small discrimination in separating the true from the false, or the probable from the marvelous. His meaning is often obscure, from his writing of things with which he was personally unacquainted, and from his having missed the true sense of the authors whom he cites or translates. But it cannot be denied that the work is a great monument of industry and research—most praiseworthy as having been constructed and completed amid the labor of other onerous undertakings, and amid the distractions of a life engaged in an active official employment; and most valuable as supplying us with details on a great variety of subjects, as to which we have no other means of information. The best critical editions of the text are those of Sillig (8 vols., 1851–57), Ian (1854–63; new ed., 1875), and Detlefsen (1867–75). There are several editions of the text with French notes, one by Grandsagne, with notes by Cuvier and others (1829), and one by Littré (1848–50). Pliny's work has been translated into almost all European languages.

PLINY, C. PLINIUS CÆCILIUS SECUNDUS, nephew of the preceding, and son of C. Cæcilius, frequently called Pliny the younger, was b. at Novum Comum, 61 A.D. He was still young when he lost his father, and was adopted by his uncle, under whose care, and that of his mother, Plinia, and his tutor, Virginius Rufus, his education was prosecuted. Passionately devoted to literature, he wrote a Greek tragedy at the age of 13; studied eloquence under Quintilian, and became so famous for his literary accomplishments that he acquired the reputation of being one of the most learned men of the age. His oratorical powers were also considerable; in his 19th year he began to speak in the forum, and his services as an advocate before the court of the centumviri and the Roman senate were in frequent request. He held numerous official appointments; served, while a young man, as *tribunus militum* in Syria, where he listened to the teaching of Euphrates the stoic, and Artemidorus; was afterwards *quæstor Cæsaris*; was prætor about 93, and consul in 100, when he wrote his *Panegyricus*, an adulatory eulogium of the emperor Trajan, and containing little information as to the author and his times. He was appointed, in 103, proprætor of the province Pontica, an office which he vacated in less than two years; and he also discharged the function of curator of the banks and channel of the Tiber. He was twice married, his second wife being Calpurnia, granddaughter of Calpurnius Fabatus, and considerably younger than her husband, by whom she was much beloved for her accomplishments and amiability. He had no issue by either marriage.

Our knowledge of Pliny the younger is mainly derived from his letters or *Epistolæ*, of which there are 10 books. He collected them himself, and probably wrote many of them with a view to publication. They hold a high place in epistolary literature, and give us many interesting glimpses into the life of their author and his contemporaries. Pliny himself appears in them to considerable advantage, as a genial and philanthropic man, enamored of literary studies, and fond of improving his estates by architectural ornament. His ample fortune was liberally bestowed, and his slaves always found in him an indulgent master. Infirm health impaired throughout life his constitution, which was naturally weak; but of the time or cause of his death we know nothing. Of the facts contained in his letters, however, the most interesting to us are those relating to the punishment of the Christians. Death appears to have been the penalty attached even to the confession of being a Christian; although the adherents of the faith admitted no other acts, on examination, than those of meeting on a fixed day before dawn, when a hymn to Christ was sung, and taking an oath to avoid theft, adultery, breach of faith, and denial of a deposit. Nothing more unfavorable to them than this could be extorted by Pliny from two female slaves, reputed to be deaconesses, whom he put to the torture. Pliny having asked Trajan how he was to stop the spreading superstition, the emperor replied that no general rule could be laid down; that he ought not to institute a search after persons supposed to be Christians; but if any were brought before him, and the charge was proved, such were to be punished, if still impenitent. The best edition of Pliny's *Panegyricus* and *Epistolæ* together is that of Schæfer; of the *Epistolæ* alone, that of Gierig.

PLIOCENE (Gr. more recent), the name given by sir Charles Lyell to a section of the upper tertiaries, because the organic remains found in it contain between 60 and 70 per cent of living species; a greater proportion than exists in the older miocene, but not so great as that found in the succeeding pleistocene.

The beds belonging to this period are very local. They have been noticed in several places in Europe, but have been chiefly studied in Suffolk, the only locality in which they occur in Britain. Here they cover the upper beds of the London clay; and being composed of shelly sand, they have, like similar deposits, been used for fertilizing lands

deficient in calcareous matter, and have received the local name of "crag." They are divided into the (1) red crag, 50 ft.; (2) coralline crag, 50 ft.

The red crag consists of beds of quartzose sands and gravel with a mixture of shells, for the most part rolled, and sometimes broken up into sand. The whole deposit, with the contained fossils, has a deep ferruginous or ochreous color. It seems to have been formed in shallow water, the currents of which have given it a very variable character, and frequently confused the stratification, as in some modern sandbanks. The fossils have a somewhat boreal character. They consist chiefly of mollusca; but there have been also found the bones and teeth of large sharks, skates, and other fish, and the ear-bones of one or more true whales.

The coralline crag is generally calcareous and marly, consisting of a mass of shells and polyzoa, separated in some places by thin layers of hard limestone, and coral-like masses, which occupy the position in which they lived. It is easily separated from the red crag by its white color. It has been formed at a greater depth and in more tranquil water than the newer deposit. The fossils have a more southern facies than those of the red crag, and indicate that they lived in an ocean with a higher temperature. Among these southern forms may be mentioned species of the genera *conus*, *oliva*, *mitra*, *voluta*, and *pyrula*. The calcareous polyzoa are abundant and very beautiful; and several interesting forms of echini have been described. A few fossils of the same species as those occurring in the London clay have been found in this and the red crag, but these are believed to have been washed out of the inferior deposits.

Mr. Searles Wood has obtained 345 species of testacea from the coralline crag, and 230 from the red crag, of which about 150 are common to both; about 70 per cent of the newer division are also recent, and about 60 per cent of the older.

Pliocene deposits have been observed in the neighborhood of Antwerp and on the banks of the Scheldt, from which 200 species of shells have been obtained, two-thirds of which were already known from Suffolk. More than a half are recent species found in the northern seas, and a few are still living in the Mediterranean. Similar deposits occur in Normandy. The low hills between the Apennines and the sea on each side of Italy are formed to a considerable extent of beds belonging to this period; and the marine strata of the seven hills of Rome are of the same age. Beds of a brackish-water origin, observed on the shores of the Caspian, Aral, Azof, and Black seas, have been referred to this period.

PLIOSAU'RUS (Gr. literally "more a lizard," i.e., than the *plesiosaurus*), a genus of fossil sea-reptiles nearly allied to the plesiosaurus, but having a very short neck, and comparatively a larger head. The jaws also are furnished with stronger teeth, which are subtriangular in cross section, with one side flattened, and bounded by prominent lateral ridges on the more convex sides. Three species have been described. They are peculiar to the Oxford and Kimmeridge clays of the upper oolite period.

PLOCA'RIA, a genus of *algæ*, of the order or suborder *ceramiaceæ*, having a cartilaginous frond, composed of large cells, as if jointed, and dividing into slender, tufted, and densely aggregated branches. *P. helminthochorton* is the CORSICAN MOSS of the apothecaries' shops, once of some reputation as a vermifuge, but now little used, and believed to be of little efficacy. It is a small plant with a filiform entangled frond, and grows on the shores of the Mediterranean. It has a strong marine odor and a salt taste. It consists in great part of a vegetable jelly or mucilage, which renders it nutritious, and contains much chloride of sodium, sulphate of lime, and carbonate of lime. As sold in the shops, it is always much mixed with other *algæ*.—*P. tenax* is a small plant with filiform, branched, and somewhat gelatinous frond, much used by the Chinese as a glue. It is also used in China as an article of food.—*P. candida* is used to a considerable extent as an article of food in the east. It is popularly called CEYLON MOSS. The frond is whitish and much branched, the branches long and somewhat clustered. It is exported to China from the islands of the Indian archipelago, forming a portion of the cargo of almost every junk. The Chinese make it into a jelly with sugar, and use it as a sweetmeat. It consists in great part of a vegetable jelly, with a considerable quantity of starch. It has been introduced into Britain as a light and nourishing food for children and invalids, and is found particularly suitable in cases of irritation of the mucous surfaces.

PLOCE'US. See WEAVER BIRD.

PLOCK (Russ. Plotzk), a government in the n. of Poland, bounded on the n. by Prussia, and on the s.w. by Warsaw. Area, 3,520 sq.m.; pop. '80, 522,006, 80 per cent of whom are Poles. Hills occur in the n. and on the banks of the Narew and Vistula, which with the Bug are the chief rivers. One-third of the surface is covered with forests, and there are many marshes and lakes. The inhabitants are engaged chiefly in agriculture, and in cattle and sheep breeding.

PLOCK (Russ. Plotzk), a t. of Poland, capital of the government of the same name, occupies an elevation on the right bank of the river Vistula, 78 m. w.n.w. of Warsaw. Its principal buildings are the cathedral, built in 961, the bishop's palace, theater, etc. Agriculture, and the export of grain to Dantzic and other ports, are the chief employments. Pop. '80, 22,127.

PLOJE'SHTI, or **PLOYESTI**, a t. of Wallachia, 35 m. n. by e. from Bucharest, on the Dimbow, a feeder of the Jalomniza. It is a place of considerable trade, and has a great annual wool-fair. Pop. '80, 33,000.

PLOMBIÈRES, a t. and watering place in the department of Vosges in France; pop. 1750. It has for ages been celebrated for its medicinal springs of three sorts, viz., ferruginous, soapy, and thermal. The former are cold, the second tepid, the latter hot. Each possesses peculiar mineral properties. Bathers make principal use of the two latter, and the former is used to drink. Superb accommodations for those who take the baths or drink the waters were made during the reign of Louis Napoleon, in addition to all which had previously been done to make the place attractive. The waters, as drink or in baths, are considered good for the cure of dyspepsia, gout, urinary affections, paralysis, and diseases of the skin. The baths were improved by the Romans. In 1292 the duke of Lorraine built a chateau there "to defend the bathers against the bad," according to the Chronicles. Montaigne was a visitor there in 1580; in 1682 it was shaken by an earthquake; about 1722 king Stanislaus of Poland and the duke of Lorraine built the palais royal, founded a hospital there, and made beautiful promenades. Royal treasures have since flowed in constant streams to decorate the classic grounds, but most of all under the orders of Louis Napoleon, whose engineers made it one of the most admirable health resorts in the world, with all the conveniences and comforts of modern art. Among recent works on the baths are *Eaux de Plombières, clinique médicale du Rheumatisme et de son Traitement*, by L. Heritier, 1857; *Essai sur les Bains Tiède*, by Turck, 1861; and *Traité des Généreaux, et Guides des Eaux*, by Hutin, Bourdon, etc.

PLONGÉE, in artillery and fortification, means a slope toward the front. Thus, in speaking of the course of a shell through the air, its plongée is from the point of greatest altitude to the point at which it strikes the earth. So, in fortification, the plongée is the top of the parapet sloping gently toward the front. This slope is ordinarily 1 in 6; but a deviation is permissible of from 1 in 9 to 1 in 4: the sharper the slope, however, the more liable is the crest of the parapet to be destroyed by an enemy's fire. Moreover, as flat a plongée as possible is desirable, that sandbags may, when required, be laid upon it to form a cover for riflemen. See **FORTIFICATION**.

PLOTINUS, the most original and important philosopher of the Neoplatonic school, was born at Lycopolis in Egypt 205 A.D.; but such was his utter indifference to things human, "being ashamed almost to live in a body," that he never would divulge even his parentage. He would never allow his birthday to be celebrated, although he gave feasts on those of Socrates and Plato; nor would he ever permit a painter or sculptor to perpetuate his features, or, as he called it, to produce the image of an image—the body being to him only a faint image of existence. He deemed it tedious enough already to have to drag about this image whithersoever he went in this life. His body was altogether contemptible in his eyes; he would see no physician in his illness, and was very sparing in the use of food, refraining from meat, often even from bread. Strangely enough, his desire for the study of philosophy did not arise within him before his 28th year, when he repaired to Alexandria, and there, after having sat at the feet of the great masters for some time without feeling satisfied with their teachings, he at last became acquainted with Ammonius Saccas, and in him found the desired teacher. For 10 years he zealously attended his lectures, and although he had agreed, with two of his fellow-students, never to make known aught of Ammonius's teachings to the world, he yet became the chief representative and author of that school, less as a pupil than as an independent thinker, who taking his stand upon its theorems, developed them to their full extent. In 242 he joined Gordianus's expedition to Persia, in order to devote himself to the philosophy of India and Persia; but the emperor being murdered in Mesopotamia, he had to repair hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended not only by crowds of eager youths, but men and women of the highest circles flocked to hear him. Not only Platonic wisdom, in Neoplatonic garb, but asceticism and the charm of a purely contemplative life, were the themes on which he, in ever-new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impression his earnestness made upon his hearers, that several of them really gave up their fortunes to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. Dying parents intrusted their children and money to him, well knowing that an honest guardian, and one more anxious for his charges, could not be found. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. Sixty years old, he thought of realizing Plato's dream, by founding an aristocratical and communistic commonwealth like the latter's "republic;" and the emperor Gallienus was ready to grant the site of two cities in Campania for his "Platonopolis;" but his courtiers prevented the fulfillment of this promise. Plotinus died from a complication of diseases, in 270, at Puteoli, 66 years of age.

Although he began to write very late in life, he yet left 54 books of very different size and contents. His MS. being very carelessly written, he asked his pupil Porphyry to revise and correct it for him. The latter also divided it into six principal divisions, each subdivided again into nine books or *enneads*. The most important parts are those which treat of beauty, fate, immortality of soul, the good, or one, the three original substances, of free will, against gnostics, of providence, of the genesis of ideas, of the influ-

ence of the stars, of the supreme good, etc. The language is very unequal in the different portions, according to the mood and circumstances to which they individually owe their existence; but it always is original, compact, and graphic in the extreme.

Plotinus's system was based chiefly on Plato's theorem of the ideas; only that while Plato assumed the ideas to be the link between the visible and the invisible, or between the supreme Deity and the world, Plotinus held the doctrine of emanation, that is, the constant transmission of powers from the absolute to the creation, through several agencies, the first of which is "pure intelligence," whence flows the "soul of the world," whence, again, the souls of "men" and "animals," and finally "matter" itself. (For a fuller account of this part of Plotinus's system in its historical connection, see NEO-PLATONISTS.) Men thus belong to two worlds, that of the senses and that of pure intelligence. It depends upon ourselves, however, to which of the two worlds we direct our thoughts most and belong to finally. The ordinary virtues, as justice, moderation, valor, and the like, are only the beginning and very first preparation to our elevation into the spiritual realm; purification, or the exercise of *purifying* virtues, is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation is the nearest approach to the goal. The higher our soul rises in this sphere of intellect, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and ecstasies which pervade it. These are a few snatches of Plotinus's philosophical rhapsodies, to which may be further added his mysterious belief in a kind of metempsychosis, by which souls, not sufficiently purified during life, return after death, and inhabit, according to their bent, men, animals, and even plants. He further held views of his own respecting gods and demons, whom he divided into different classes, according to their degrees; and professed faith in mantic, astrology, and magic, the conviction of the truth of which sciences he derived from his theory of the harmony in the intellectual world reflected by the material world. Yet it is clear from his dicta on these subjects that he did not believe in these so-called sciences in the gross sense of the herd, but that he had a vague knowledge of those mysterious laws of attraction and repulsion which go through nature. Plotinus's philosophy, which, as it were, tried to combine all the systems of Anaxagoras, Parmenides, the Pythagoreans, Plato, and Socrates, and the Stoa into one, was the last and boldest attempt of the ancient Greek world to explain the mystery of the creation and of existence. Its influence upon modern philosophy is remarkable. From Spinoza to Schelling, the reminiscences of Plotinus, irrespective of the drift of particular parts of their systems, recur constantly.

Plotinus's works were well-nigh forgotten, when Marsilius Ficinus first published a Latin paraphrase of them (Florence, 1492), which was followed by the *Ed. Pr.* of the original (Basel, 1580 and 1615). The first critical edition, however, is due to Creuzer (Oxford, 1835, 3 vols.). Others are those of Dübner (Paris, 1855) and Kirchhoff (1856). Parts of his works were translated into German by Engelhard (1820); into English by Taylor (1794 and 1817); into French by Bouillet (1861, 3 vols.). See Kirchner, *Die Philosophie des Plotinus* (1854).

PLOTUS. See DARTER.

PLOVER, *Charadrius*, a genus of birds of the family *charadriadæ* (q.v.), having a straight compressed bill; the upper mandible alone slightly inflated and slightly bent at the point; the nasal groove extending about two-thirds of the length of the bill, the nostrils longitudinally cleft near the base; the legs not very long, naked a little above the tarsal joint; no hinder toe; the wings rather long and pointed, the first quill-feather the longest. The species are numerous, and are found in every quarter of the globe; many of them are birds of passage. They chiefly frequent low moist grounds, where they congregate in large flocks, and feed on worms, mollusks, insects, etc.; but some of them visit mountainous regions in the breeding-season. They fly with great strength and rapidity, and run with much swiftness. The flesh and eggs of many of them are esteemed delicacies. One of the British species is the dotterel (q.v.). Another is the GOLDEN or YELLOW PLOVER (*C. plumialis*), a rather larger bird, of a blackish color, speckled with yellow at the tips and edges of the feathers; the throat, breast, and belly black in summer, whitish in winter. The golden plover is a bird of passage, visiting, in summer, the northern parts of Europe, of the west of Asia, and of North America; and migrating to the south in winter. It is known in almost all parts of Europe, and is common in many parts of Britain, breeding in the northern parts. Great numbers frequent the sandy pastures and shores of the Hebrides and of the Orkney and Shetland islands. It makes an artless nest, little more than a slight depression of the ground, and lays four eggs. The parent birds show great anxiety for the protection of their young, and use various stratagems to divert the attention of an enemy. The golden plover exhibits great restlessness on the approach of wet and stormy weather, whence its specific name *plumialis*.—The RINGED PLOVER (*C. hiaticula*), a much smaller bird, not so large as a song-thrush, is found at almost all seasons on the shores of the British islands, frequenting sandy and shingly flats, from which the sea retires at ebb-tide. It is often to be seen also on the banks of large rivers, and not unfrequently of lakes and ponds. It is found in most of the northern parts of Europe and Asia, and in Iceland and Greenland. It is grayish-brown above, whitish beneath, with a collar of white round the neck, and

below it a black—in winter, a brown—collar; the head marked with black and white; a white bar on the wing. Very similar, but smaller, is the KENTISH PLOVER (*C. cantianus*); and also similar and of similar habits is the smallest of the British species, the LITTLE RINGED PLOVER (*C. minor*). Both of these are rare in Britain.—North America has a number of species of plover, one of which, the AMERICAN GOLDEN PLOVER (*C. Virginianus*), very closely resembles the golden plover of Europe; and another, the KILDEER PLOVER (*C. vociferus*), abundant on the great western prairies, and not unfrequent in the Atlantic states, utters, when approached by man, a querulous or plaintive cry, like the lapwing.—The name plover is often extended to species of *charadriadæ* belonging to other genera, as *squatarola*, in which the nasal grooves are short, the tip of the bill is tumid, and there is a rudimentary hind-toe. To this genus belongs the GRAY PLOVER (*S. cinerea*) of Britain, a species rather larger than the golden plover, and chiefly known as a winter visitant. Its geographic distribution extends over most of the northern parts of the world.

***PLOW, PLOWING.** The first in order and importance of agricultural operations is the breaking up of the soil, and this is accomplished, in all countries where agriculture is in an advanced state, by inverting the upper stratum of earth upon which the plants grow. Such a mode also buries and destroys all weeds, leaving the surface clean and unencumbered. The inversion of the upper stratum is effected by turning over successive sods or slices, of the length of the field, and of varying thickness and depth, according to the nature of the succeeding crop, and the nature of the soil; and the implement employed for this purpose is the *plow*. The general form of the plow is known to every one, and to the unobservant eye it appears to be a very simple and even primitive tool; nevertheless, much mechanical skill and ingenuity have been expended in perfectly adapting it to its work. It is a combination of instruments (fig. 1) fastened to a beam, GBL; the *coulter*, K, is an iron knife-blade for cutting the sod vertically; the *share*, CFD, which is merely a socket fitted on and not fastened to the body of the plow, has a sharp point, C, and a projecting horizontal edge, CO, on its right-hand side, its part of the work being to separate the under-surface of the sod from the subsoil; by means of the *mold-board*, H, the slice, now wholly separated from the firm ground, is raised up and turned over by the forward motion of the plow; and the *stilts*, or handles, one of which, BL, is a continuation of the beam, the other, M, being fastened partly to the former by rods, and partly to the lower portion of the framework, are for the purpose of guiding the implement. The front part of the beam is formed with an upward curve; at its extremity is placed the *bridle*, N, to which the horses are attached by means of swing-trees and chains or traces, and the object of which is to enable the workman to elevate or depress the line of draught, or move it to the right hand or the left, as may be found necessary. The left sides of the coulter, share, and framework, ADEB, should evidently be in the same vertical plane. The form of the mold-board is of the utmost importance, and has chiefly attracted the attention of agricultural machinists since the time when improvements on the plow were first projected. Its office being to raise and turn the sod, it is necessary that the surface should slope upward and outward from the front, so as to apply a pressure in both directions, and, accordingly, the surface is so shaped that from the point of the share, where it is horizontal, it gradually curves upward, till, at the extremity, P, it inclines over away from the body of the plow. The gradual change produced on the position of the furrow-slice is seen in fig. 2, where ABCD, on the left-hand side, represents the slice untouched by the plow, AD being the line of section by the coulter; DC, by the share; BC, the open side from which the previous furrow (E) to the right-hand side has been separated; and the four successive rectangles, ABCD to the right, illustrate the successive changes of position of the furrow as the mold-board is pushed forward under and on its left side, till it is finally left, as represented in ABCD, on the right hand; E, F, G are furrows which have previously been laid in their proper position. The advantages of laying the furrows in the position shown are these: in the first place, the weedy side of each furrow being closely applied to the previous furrow, and kept pressed against it by its own weight and the pressure of the mold-board, the weeds are completely buried; secondly, the ridged surface thus presented affords the means of covering the seed by harrowing; and lastly, the openings below increase the amount of surface accessible to air, and drain off superfluous water. The modern plow is wholly formed of iron; the share and the framework of malleable, and the mold-board of cast iron, or sometimes of steel; while the coulter is frequently welded with steel on the right-hand side, the better to resist attrition. In most of the

English (as distinguished from the Scotch) plows, wheels are attached at or near the front end of the beam, a contrivance which renders the implement more steady in its motion, more easily managed, and capable of doing better work in the hands of an inferior workman; but it is generally believed, in Scotland at least, that the plow without wheels, or *swing-plow*, as it is technically termed, is greatly more efficient in the hands of a thoroughly-skilled plowman. The usual dimensions of the furrow-slice in lea or hay-stubble are 8 or 9 in. in breadth by 6 in depth; and in land for green crop, 10 in. in breadth, and 7 or 8 in depth. Shallower plowing is not unfrequently adopted, especially on thin soils, and in various parts of England. Nor is it uncommon to plow stubble-land 10 in. or more in depth.

Other kinds of plows are used for special purposes, such as *trench-plows*, which are made on the same principle as the common plow, but larger and stronger, so as to bring up a portion of the subsoil to the surface; *subsoil plows* which have no mold-board, and merely stir and break up the subsoil, thus facilitating drainage; *double mold-board plows*, which are merely common plows with a mold-board on each side, and are employed for drilling turnip or potato land, for water-furrowing, and for earthing up potatoes, etc. Of each of these plows there are many varieties, each maker having generally some peculiar views regarding the form and proportion of some parts of the instrument. For those who wish to study minutely the best form of plow, it will be necessary to consult works on agriculture and agricultural implements. There is, however, one very peculiar form of plow sometimes used in various parts of England, which deserves more particular notice; this is the *turn-wrest plow*. Its chief peculiarity is, that instead of one, it has two mold-boards, one on each side, and these are alternately brought into operation, so that the furrow is always turned over in the same direction. The mold-boards are firmly fastened together in front, and kept at a constant distance from each other behind by means of struts, while the handles are movable with reference to them; the mold-board which is intended to be used being pushed away from, and the other (which for the time does the same work as the vertical surface ADEB in Fig. 1) brought nearer to the line of the beam; of course, when the next furrow is plowed, the mold-boards exchange adjustments. This form of plow is useful in plowing along a hillside, as by it all the furrows can be turned over towards the hill, thus preventing the natural tendency of the soil to work itself downwards, leaving the upper portions bare. Some years ago the *double-furrow* plow was introduced. It consists of an iron frame, similar in some respects to that of a grubber or cultivator, with two breast-plates, mold-boards, and shares; the one set a little back from the other, and so far distant as it is desired should be the width of the furrow. Two or three wheels bear the implements—one in front running in the bed of the last excavated furrow, and the other one or two behind. There is a directing-rod, but no stilts. The double-furrow plow was at first singularly popular, and after a few years was found on almost every farm. It was, however, soon found that, generally speaking, the weight was too much for the draught of a pair of horses, and that, even on light land, three horses were required. In fact, the depth of tillage is in practice gradually increasing; so that, unless for a grain crop after either turnips or potatoes, these plows have been nearly laid aside.

The operation of plowing can only be briefly referred to. Wherever the soil has been efficiently drained, the ridges can be made wider and plowed on the flat, high ridges being no longer necessary for carrying off the water. There are advantages in plowing the land in uniform ridges of 18 ft. wide, or with an open furrow not more than 72 ft. apart, made as flat as possible. But the effects of cultivation by steam show that the fewer the open furrows the better, particularly when the land is intended for a grain crop which is to be sown by drill or broadcast with machinery, and when the crop is to be cut with a reaping-machine, as is now almost universally the case. It is curious to notice how one improvement in farm practice leads on to another. The most common mode of plowing with horses is now simply by casting the soil two ridges in and the next two out, beginning always with the two ridges where last time was left the open furrow.

The term *feering* is applied to the commencement of a wide ridge. The process of feering differs according to the state of the land to be turned over. If there exists an old furrow or hollow, as is generally the case in lea, two shallow furrows are turned, the one against the other, and so on; along each side of this commencement the plow moves, adding furrow after furrow, and increasing in depth until the third or fourth round is reached. This constitutes what is technically called the gathering system. In newly cleaned land, or where a hollow does not appear to turn the first furrows into, two furrows are thrown out and then turned lightly in. The most common system, however, is what is known as *casting* or *cleaving*. That is, after one feering is accomplished, another is made at the other side of the ridge, and furrow after furrow is turned towards the inside of each of these feerings until the whole ridge is plowed, and then in the center is formed the *finish* or *mids*—a furrow or trench into which the feering is turned the next time the land is plowed.

The plow is one of the most ancient of implements, and is mentioned in the Old Testament at a very early period, iron shares being also incidentally noticed more than seven centuries B.C. The ancient Egyptian plow was wholly of wood, and in some

instances consisted of little more than a pointed stick, which was forced into the ground as it was drawn forward. In fact, the earliest plows were neither more nor less than varieties of the *hoe* (q.v.), worked by pressing the point into the ground instead of by percussion. The earliest form of the Greek plow, the *autoguon*, is an example of this; it was merely the trunk of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the *pekton*, in use among the Greeks, was not substantially different from the modern form in use in Mysia. The ancient Egyptian plow in one of its early stages, like the two forms above described, is devoid of all apparatus enabling the laborer to guide it, all that he can do being to press (by his weight applied to the handle) the share into the earth. The Egyptians, however, gradually improved the form, till it assumed the appearance of a hollow wedge formed by the two handles joined at the bottom, and with the beam fastened between the handles a little above their point of junction. The Romans, an essentially practical nation, largely improved on the plow, adding to it the coulter and mold-board, and occasionally attaching wheels to the beam to prevent the share from going too deep into the earth. The plow was almost unknown among the American aborigines, though Prescott describes a mode of plowing practiced among the Peruvians, which consisted in the dragging forward of a sharp-pointed stake by six or eight men, its sharp point, which was in front, being kept down in the ground by the pressure of the foot of another man who directed it. Britain and America, and their colonies are the only countries in which the plow has been brought to a state worthy of being considered effective, and even in Britain the most important amendments on it are not two centuries old. England took the lead in improvement by rendering the form more neat and effective, and by attaching wheels to aid in keeping the plow in a proper upright position. In Scotland, for some time after this, the plow was extremely rude and cumbrous, and usually drawn by 8 oxen, and some wooden plows are in use yet in the highlands of Scotland. In the middle of the 18th c., some Dutch plows were imported, and being found more effective, an impetus was thus given to attempts at improvement. James Small, who may justly be regarded as the real inventor of the Scotch or swing-plow, made great and important changes in the form and efficiency of the coulter, share, and mold-board, producing an implement at once lighter and vastly more efficient. All the swing-plows of successive makers are founded upon the basis of Small's plow. Wilkie of Uddingston (Lanarkshire) formed it wholly of iron, and his modification has been universally adopted in the modern plows. Among the various improvers of this form of cultivator may be mentioned, besides Wilkie of Uddingston, Gray of the same place, Clarke of Stirling, Cunningham, Barrowman, Ponton, Sellars, Huntly (who have sent many of the swing-plows, for which their firm has long been famous, to Australia). In England, the improvers have chiefly been Ransomes of Ipswich (the patentee in 1785 of the cast-iron share), Howard of Bedford, Hornsby of Grantham (Lincolnshire), and Busby of Bedale, the last of whom gained a medal for his mold-boards at the great exhibition of 1851. For further information concerning the plow and the mode of using it, see Morton's *Cyclopædia of Agriculture* (1856), Stephens's *Book of the Farm, Book of Farm Implements*, by Henry Stephens and R. Scott Burn, and other works.

Steam-plowing.—Although it is not yet a quarter of a century since cultivation of the land by steam came into successful operation, it is about two centuries and a half ago since it was foreseen to be possible. So long ago as 1618 David Ramsey and Thomas Wildgosse took out letters-patent for engines and machinery to plow the ground without the aid of oxen or horses; and nine years afterwards, other ingenious men obtained letters-patent for machines to effect a similar purpose. It is the opinion of Mr. Woodcroft of the patent office, who compiled the *Abridgments of the Specifications Relating to Steam-culture*, that steam was the motive power intended to be employed; but, as the first patent was taken out nearly 40 years before the Marquis of Worcester described the steam-engine in his *Century of Inventions*, the grounds for such an opinion do not seem quite satisfactory. In 1769, however, after the steam-engine had been applied to other purposes, there was lodged in the patent office a specification for a new machine or engine, to plow, harrow, and do every other branch of husbandry, without the aid of horses. The patentee was Francis Moore; and so confident was he of the merits of his plan, that he sold all his own horses, and persuaded his friends to do the same; "because the price of that noble and useful animal will be so affected by the new invention, that its value will not be one-fourth of what it is at present." Moore, however, was much too sanguine; his method of cultivating the land without the aid of animal power failed, as those of others before him had done.

The next invention necessary to mention was one by maj. Pratt, patented in 1810. His plan was to have two engines, one on each headland, drawing, by means of an endless rope, an implement between them. In order to save the labor and loss of time in turning the plow at the ends, he attached two plows, back to back, making them work upon a fulcrum in the center of a frame, so that one could be raised out of the ground when the other was working. This was the first adoption of the balance-principle, now employed in most implements used in steam-cultivation. Maj. Pratt's apparatus, like those of his predecessors, never came into practical operation.

In the interval between 1810 and 1832, when Mr. Heathcoat, M.P., a Tiverton laco-

merchant, patented the first steam-plowing machinery that ever wrought successfully in the field, there were many inventions, but these being of little utility, need not be particularized. Mr. Heathcoat's machinery was principally intended for drainage and breaking up of soft or swampy land. It consisted of a locomotive steam-engine, with a broad, endless, flexible floor or railway attached to the wheels, so as to prevent them from sinking in the boggy soil. Opposite to this engine an auxiliary carriage was placed, and between the two the plow was drawn backward and forward by an endless chain or band—engine and carriage moving along as the work proceeded. In 1836 this plow worked with tolerable success in red moss in Lancashire, and in 1837 it was tried near Dumfries, under the auspices of the highland and agricultural society of Scotland; but here its performance, though in some degree satisfactory, was not sufficiently so to warrant the judges in awarding to it the prize of £500, which had been offered for the first successful application of steam-power to the cultivation of the soil by the society. The apparatus was very cumbersome and expensive to work, the engine being 25 horse-power, and the number of men and boys employed in the operation no less than ten. The amount of work done was at the rate of $8\frac{3}{4}$ acres per day. Mr. Heathcoat abandoned the machine after having spent about £12,000 on it.

After Mr. Heathcoat, the inventors specially worthy of mention are Alexander M'Rae, who, arranging his motive-power in the same manner as maj. Pratt, made the important addition of a barrel to the plow-frame upon which the slack-rope was to be wound up; Mr. Hannam of Burcote, who, in 1849, designed an apparatus to be driven by an ordinary portable engine, to be stationed at the corner of the field, which was surrounded with wire-ropes in the same way as will be afterwards described in Howard's method; and Mr. Tulloh Osborn, who, in 1846, patented a plan for two engines running opposite each other on the headlands, having two drums fixed to them, one for the winding of the tight, and the other for letting out the slack, gear. This apparatus was tried by the marquis of Tweeddale for some time at Yester; but it was found, in consequence of the great power required, and other defects in detail, to be very expensive, and was ultimately given up. To the marquis of Tweeddale, therefore, belongs the honor of being the pioneer of steam-cultivation in Scotland.

In 1855, the Messrs. Fisker of Stamfordham, Newcastle-upon-Tyne, took out a patent for a much more perfect apparatus for cultivating the land by steam than any that had previously appeared. The power was transmitted by a stationary engine to a hempen rope (the Messrs. Fisker being anxious to dispense with wire-ropes), which was worked at a high velocity, and, passing round pulleys on two self-moving anchors, turned a drum upon the plow, whose revolution imparted motion to the implement upon which it was fixed. The important features in this system were the self-propelling anchors, the arrangement of the plows on the balance-principle, and the mode of steering. This plow was exhibited at the annual show of the royal agricultural society of England in the year the patent was taken out, and excited great interest, but failed to obtain any award. Three years before this, the highland and agricultural society of Scotland had thought so hopefully of the idea, that a grant was voted out of its funds to assist the author in maturing his project.

In 1854 Mr. Fowler exhibited his patent steam-draining apparatus at the Lincoln meeting of the royal agricultural society of England; and from this time may be dated the practical history of cultivation of the land by steam; for the idea that such an apparatus could be wrought advantageously in other field-operations entered the mind of a practical farmer, Mr. Smith of Woolston, near Bletchley; and, under the direction of Mr. Fowler, he got constructed an apparatus, which, with modifications, he worked successfully.

The inventions since that time need not be enumerated. It may be stated generally that they have included plans for engines traveling over the surface of the ground, drawing plows or other cultivating implements along with them; engines working on tramways, and drawing implements after them; engines moving along opposite headlands, and working implements between them by means of wire-ropes, and stationary engines driving implements also by means of wire-ropes. The first two principles have been mostly abandoned—the one on account of the great consumption of fuel, and the large amount of wear and tear occasioned to move the engine over uneven and soft ground; and the other, on account of the expense necessary to lay down rails over a farm. The only two systems in practical operation are what are called the direct and round-about—the former where the pull of the implement is directly to and from the engine; and the latter where the implement is drawn at right angles.

The best known of these methods are Fowler's and Howard's, though, perhaps, Smith should be credited with the round-about system, but Howard's name is now much more generally given to it.

In Fowler's system the principal elements are an engine, an anchor, a wire-rope, and a balance-plow. In commencing operations, the engine is placed at the end of one of the headlands of the field, and directly opposite it on the other headland is placed the anchor. Beneath the engine there is a large sheave or drum, 5 ft. in diameter, the groove of which drum is composed of a series of small leaf-like pieces of chilled cast-iron, each moving independently upon its own axis. The object of these is to prevent the rope from slipping (which it is apt to do in a plain groove under great strain), and

this they do in a very ingenious manner, by closing on the rope as soon as it takes the bend—that is, as soon as the rope presses upon them—and they in the same manner open and release it immediately on the pressure being removed, or, in other words, as soon as the rope resumes the straight on the other side of the sheave. The anchor is a massive square framework of wood, mounted on six sharp disk wheels, each about 2 ft. in diameter, which cut deep into the ground, and on the lightest land they take such hold as effectually to resist the pull of the rope which is passed round the sheave beneath. The anchor has a self-acting motion—the power being communicated from the engine through the medium of the plowing-rope—which enables it to move along the headland, and keep opposite to the engine. The plow is a framework of iron, balanced upon two large wheels. To each side of this framework there are attached four plow-bodies and coulter, so that four furrows are cut at one “bout,” and the headland on which the anchor is stationed being reached, the end of the beam that was out of the ground is depressed (the other, of course, being raised), and the four plow-bodies that were out of the ground, and which point in the opposite direction, are inserted in the soil, and turn up the furrows on the way back to the engine. By altering the position of the plow-bodies along the frame-work, a broad or a narrow furrow can be cut at pleasure. In ordinary working, an acre an hour is accomplished. The wire-rope, by which the plow is dragged through the land, passes round the sheaves on the anchor and the engine, the ends are attached to two drums upon the plow; and, by a nice mechanical arrangement, the plowman who rides upon the implement is enabled to wind up, or let out slack if necessary, without loss of time. The wire-rope is made in lengths, which are easily disjoined, in order that it may be adjusted to irregularly shaped fields, or rather to fields that are not exact squares or parallelograms; for Fowler’s method is not well adapted to such irregularities as prevent the engine and anchor being opposite each other. The rope is borne off the ground—a very necessary precaution, without which the wear and tear would be alike annoying and expensive—by a number of pulleys, or “rope-porters,” as they are called, mounted on frames. The outside ones, that is, those furthest from the work, are moved along by the action of the rope; those in front of the plow are removed by boys, and placed behind the implement as it proceeds. The *modus operandi* will be patent at a glance, from the annexed plan of working (fig. 3). To man-

FIG. 3.—Fowler’s Anchor, Engine, and Plow at work.

age this apparatus three men and two boys are required—namely, a man at the engine, another on the plow, a third at the anchor, and the lads to look after the rope-porters. The water and coals needed for the engine must be brought by other men.

The plow-bodies can be removed from the frame, and in their place “digging-breasts” be attached, by means of which the land is thrown up in a somewhat similar manner to that in which it is turned over by the spade. The price of the plowing and cultivating apparatus is about £900.

At the Newcastle show of the royal agricultural society, in July, 1864, Mr. Fowler introduced two engines of 7-horse power, working simultaneously on opposing headlands. The expedition with which these engines were set down to and completed their work was a matter of admiration to all present, and the subject of special remark by the judges. These gentlemen say: “The engines worked smoothly; and so far as we could ascertain, appeared to bear an equal share of work in either direction.” They got up steam in nearly half an hour less time than the 14-horse engine, and working with them, much less time was required to arrange the tackle. “The engines were masters of their work; and acting in combination, appeared to possess more power than the large engine and anchor. . . . The advantages of this system appear to be, that horses are not required to move tackle; that there is a saving of time in setting down, taking up, and removing from field to field [no unimportant consideration]; and that the two small engines are both available for ordinary farm-work, such as thrashing, driving, barn-work, etc.” The cost of the two engines, with the whole apparatus, ranges from £1200 to about £1500, according to the power of the engines, etc. The number of hands employed is the same as at the large anchor and engine; but as a skilled laborer is necessary, where only an unskilled laborer is needed in the latter case, the cost per day is 2s. more. Fowler has been very successful in gaining prizes for steam-plows, having won several thousand pounds in this way since 1856.

Howard’s earliest system consists in a stationary engine driving a windlass, having two winding drums, with direct and reverse action, placed in front of it, round which is coiled about 1600 yards of wire-rope. By a simple lever movement, the man can drop the winding drums out of gear in an instant, a contrivance which enables him to

attend to the proper coiling of the rope, and also to arrest, in case of accident, the plow in a moment, without stopping the engine. The engine is usually placed at the corner of the plot to be plowed, the rope is carried round the field on rope-porters, and fixed at the corners by light anchors. A snatch-block placed in front of the windlass prevents the slack-rope running out too fast, and trailing on the ground. The plow is composed of two strong iron frames balanced upon four wheels, and crossing each other at their inner ends, thereby decreasing the length of the plow, and, as a matter of course, the breadth of the headland. The frames are raised and lowered in such a manner that the set of plows out of work is independent of, and has no tendency to weigh or raise out of the ground the set in work. The frames are made for two, three, or four furrows, and "diggers" or scarifiers can be attached as in the case of Fowler's. The latest improvements of a material character on the Bedford firm's steam-plowing tackle consist of a patent self-coiling windlass and universal joint, 1600 yards of steel rope, patent 5-tined self-lifting cultivator, 2 self-moving anchors, etc. Two men and two boys are sufficient to work the set with a 12-horse-power patent plowing and traction engine; the cost of the set is £1000. This recently introduced apparatus is very popular, and promises to be extensively employed.

Howard's double-engine system is specially adapted for letting out on hire, for large farms, and for use on the great foreign plains. The engines are placed on opposite headlands, and work a plow, grubber, or cultivator between them, similar to the principle on which Fowler's double-engine system operates. Three men and two boys are required to the working of this set. The price of a pair of 12-horse patent plowing and traction engines, each with winding drum, together with 800 yards of steel wire rope, and 6 rope-porters, is £1350.

In the course of the last few years, the Messrs. Howard have issued several hundred sets of steam-cultivating tackle. The Messrs. Howard's cultivator was more generally used for some time than the plow, but the mere digging of much of the land for corn, as a substitute for plowing, was attended with disappointment; so the plow has been all but universally adopted for soil intended for grain crops.

The Fisken tackle is used to a considerable extent in various parts of the country, generally with the plow emanating under that name, and sometimes attached to three-furrow plows made by local manufacturers. Several of the other famed firms dispose of parts of the complete set separately. In other words, those who buy the engines and gearing do not in every case purchase the plow from the same company.

In Coleman's system, the drums upon which the rope is wound are attached to the sides of the engine, and give out and take on rope alternately. The engine moves along the headland; and the anchor, upon which there is very little strain, and which is, therefore, a very light, portable article, is shifted opposite to it by a man as the work is performed; direct action being obtained here, as in the case of Fowler's. The peculiarity of the plan consists in having two implements instead of one at work, the implements being grubbers, which smash up the ground—a practice adopted by some farmers in England, in preference to turning the sod over with the plow. On commencing operations on this plan, the field is divided into two equal parts. The cultivators or grubbers work only one way—*toward* the engine. They are attached by the front to each end of a strong wire-rope, while a smaller wire-rope is fastened to their rear. The one cultivator is placed at the far side of the field, where its teeth or "tines" are inserted in the ground; and it is pulled toward the center of the field, tearing up the soil as it comes, the other meanwhile going out empty to meet it. When the latter reaches the middle of the field, the action of the engine is reversed, and it is dragged back to the engine, cultivating the land as it travels, while the other goes back to the headland empty. The pull out empty and working in is, of course, continued until the whole land has been tilled.

There are some other systems of steam cultivation before the public, but in various respects they resemble those already enumerated. With Coleman's method there may be a slight saving of time at the ends, but there is, on the other hand, a trifling loss of power. In every sense of the term, the systems of the Messrs. Howard, and Fowler and Co., are the most popular. Each of these leading systems has its advocates and its advantages. It is certainly a much more expensive plan to have two engines, but yet for letting for hire it may be the best and cheapest, as they take the apparatus from one place to another, and set to work again more rapidly. It is, however, easy enough to keep one steam-engine always running at full speed, and there seems little reason to keep one engine simply to look at the other, seeing the expense is the drawback which prevents their universal adoption. Besides, the single engine on the round-about system is decidedly best for the working up of corners of fields, and as it does not move along headlands, it does not destroy them; but can continue working while the locomotive remains idle. On soil where there are many stones, it is better first to grub the land thoroughly, and remove the stones, before using the plow.

Where the fields are pretty large, stones not abundant, and the soil heavy, the odds are all in favor of steam cultivation. Not only is the tillage more thorough than could be otherwise accomplished, but there is a greater chance of getting the land worked in better condition. That is to say, the great speed by which the soil can be turned—on an average, about three-fourths of an acre per hour—enables the advantages of weather and

seasonable soil to be more extensively embraced. Then every farmer knows, or should know, the benefits of deep cultivation, where the soil admits; and by steam-power, more than in any other way, this great desideratum is likely to be obtained. There is a danger, however, arising from deep plowing, provided the increased depth is not gradually affected. For instance, if three or four inches of fresh soil is suddenly brought to the surface, and the manuring applied in the usual way, the succeeding crop, if not even crops, is often disappointing. The fresh excavation, in short, has not been fertilized unless very special treatment is bestowed. The best time to introduce the deep furrow is preparatory to the green crop, as with the bulk of the ordinary farming (Scotch especially) that is the rotation which is accompanied by the heaviest manuring of the course. Stunted crops do not now follow the introduction of steam-power, or rather deepened cultivation, to any material extent, but when the causes and cures were not so well known in the earlier days of steam-plowing history, failures for a year or two were more notable. The high price of horses, lately developed into extravagance, together with the growing and already high rate of farm-servants' wages, have stimulated considerably the application of steam-power to the tillage of the soil of Britain. The two principal firms at Leeds and Bedford, already referred to, have an enormous demand just now from all quarters for steam-cultivating apparatus. In Britain, it is computed there are considerably over 1000 steam-tackles at work, and the exports to the continent, to some parts of America, to the East and West Indies, and to Egypt, is considerable and growing. See Supp., page 897.

PLOWDEN, EDMUND, 1518-85; b. England; at first studied medicine and surgery at Cambridge and Oxford, and according to Anthony-à-Wood did not take up the study of the common law till his 36th year. Plowden himself, however, says, in the preface to his *Commentaries*, that he began to study law in his 20th year, and the 30th of the reign of Henry VIII. He was twice a reader of the middle temple, and near the close of Mary's reign was made sergeant-at-law. He wrote *Commentaries, or Reports of Divers Cases in the Reigns of Edward VI.*, etc., in Norman-French; and *Queries, or a Moot-Book of Cases*.

PLOWGATE OF LAND, in the law of Scotland, is an expression denoting a quantity of land of the extent of 100 acres Scots. No person is qualified to kill game in Scotland who has not a plowgate of land, and this is still the law.—Paterson's *Game-laws of United Kingdom*, p. 158.

PLUM, *Prunus*, a genus of trees and shrubs of the natural order *rosaceæ*, suborder *amygdalæ* (q.v.) or *drupaceæ*; the species of which have the stone of the fruit sharp-pointed at each end, with a longitudinal furrow passing all round, and a smooth surface; the fruit covered with a fine bloom, and the young leaves rolled up. The common plum, the bullace, and the sloe, are generally reckoned by botanists as distinct species, but with much doubt if they are really distinct, as the plum passes into the bullace, and the bullace into the sloe by insensible gradations; although there is so wide a difference in general appearance, size of leaves, and size as well as quality of fruit, between the best cultivated plums and the sloe, that it is not without an effort we can imagine them to have sprung from a common stock. The **COMMON PLUM** (*P. domestica*) appears in a wild state in woods and hedges in many parts of England and on the continent of Europe; probably, however, often derived from the seeds of cultivated trees. It is commonly described as destitute of spines, and as further differing from the bullace in having the under-side of the leaves smooth except when they are very young; but if these characters are adopted, many of the cultivated plums must be referred to the bullace (*P. insititia*) as their original; nor does the ovate fruit afford a more certain character, some of the finest garden plums being globose or nearly so, like the bullace. The varieties called damson (q.v.) are particularly like the bullace, except in the form of the fruit. Cultivated plums vary greatly in the size, form, color, and flavor of the fruit. The fruit of some varieties, as the *white magnum bonum*, is 2 in. long; while damsons of the same shape are not quite 1 in., and a single fruit of the one is equal to at least 8 or 10 of the other. The best varieties of plum are among the most delicious dessert fruits; among these, the *green gage* (*reine claud*e of the French) is one of the most esteemed both in Britain and on the continent of Europe, and is unsurpassed both in sweetness and flavor. The inferior varieties are used in pies, conserves, and sweetmeats. Some of them are very austere. In moderate quantity plums are wholesome enough; but excess in the use of them is very apt to produce colic, diarrhoea, and cholera. The danger is greater if they are eaten before being perfectly ripe. A very pleasant wine is made from plums; and in some parts of Europe a strong spirit is distilled from them after fermentation; but for this purpose they are mixed in the s. of France with honey and flour, and in Hungary with apples.—The dried fruit, variously known as *dried plums*, or *French plums*, and *prunes* (q.v.), is much used for the dessert; and the somewhat austere fruit of the *St. Julien plum*, cultivated in the s. of France, becomes, when dried, the medicinal prune, used as a mild laxative. The drying of plums is effected very slowly in ovens, by a heat which is gradually increased. The process requires great care. The prunes called *brignoles* are the produce of a variety grown principally near the little town of Brignole in Provence. The plum has been in cultivation from ancient times, and the first fine varieties were probably introduced into Europe from the east. The finer

varieties are propagated chiefly by budding on stocks of the coarser kinds, which are procured either from seed or as suckers from the roots of plum-trees. The coarser varieties are propagated by suckers, without budding. A free loamy soil is best for plums. They are grown as standard, espalier, or wall trees. As standards, some of the varieties attain a height of more than 20 ft., with a moderately spreading head. The fruit is mostly produced on spurs, but some of the finest fruit on the shoots of the former year. Among the varieties of plum are some which ripen their fruit early, and others which ripen late in the season. The blossom of some of the finer kinds is often protected by gardeners, like that of peaches and apricots.—The wood of the plum-tree is hard and fine-grained, and is used in cabinet-work, in turnery, and for making musical instruments.—The CASHMERE PLUM (*P. Bokharensis*), cultivated in Cashmere and Bokhara, is regarded as a distinct species.—The CHERRY PLUM, or MYROBALAN PLUM (*P. cerasifera* or *myrobalanus*), is a bush very similar to the sloe, with pendulous globular red fruit. It is a native of North America, but is often cultivated for its fruit on the continent of Europe. In Britain it seldom produces fruit.—*P. maritima* is a shrub, indigenous to sandy soils on the sea-coast of North America from New Jersey to Carolina. It has a dark purple agreeable fruit, about the size of a pigeon's egg.

The COCOA PLUM or ICACO of the West Indies is the fruit of *chrysobalanus icaco*, a tree of the natural order *rosaceæ*, suborder *chrysobalaneæ*. The fruit resembles a plum, has a sweet although slightly austere taste, and is eaten both raw and preserved.—The fruit of *parinariûm excelsum*, another of the *chrysobalaneæ*, is called gray plum at Sierra Leone.

PLUM, DATE. See DATE PLUM.

PLUMAGE OF BIRDS. See BIRDS AND FEATHERS.

PLUMAS, a co. in n.e. California, watered by the Middle and North forks of Feather river, about 2,100 sq. m. ; pop. '80, 6,180—3,697, of American birth. The surface consists of fertile valleys, great forests, and lofty cañons. The Sierra Nevada crosses it. The valleys are adapted to grazing. Slate and marble are found. Much gold is mined. Co. seat, Quincy.

PLUMATELLA, a genus of zoophytes (*polyzoa*), having the polypidom fixed, membranaceous, conferva-like, and branched; the polypes issuing from the extremities of the branches, with a crescent-shaped disk surrounded by a single series of many tentacles. The species are found in fresh water, attached to stones, etc. *P. repens* is a common British species, sometimes spreading over a square foot, and having branches 3 in. long, which adhere to some surface throughout almost their whole length. The tentacles are beautifully feathered with cilia on two opposite sides.

PLUMB, JOSEPH, 1791–1870, one of the first to settle in the w. part of New York state. He bought land, acquired a large fortune, and for many years lived in Erie co. near the Seneca reservation. He owned the land on which the village of Cattaraugus now stands. In 1840 he was prominent in organizing the "liberty" party, and was candidate for lieut. gov. in 1844. Edward L. Plumb, his son, has been consul-general at Havana, and has occupied several other diplomatic positions.

PLUMB, PRESTON B. See page 897.

PLUMBAGINEÆ, or **PLUMBAGINACEÆ**, a natural order of exogenous plants, herbaceous or half-shrubby; with leaves somewhat sheathing at the base, and often clustered; flowers in panicles or in heads; calyx tubular, persistent, plaited; corolla very thin, of one or five petals; stamens five; ovary superior, one-celled, with a solitary ovule; styles generally five; fruit a utricle (q.v.). There are about 160 known species, chiefly found on the sea-shores and in the salt marshes of temperate regions. Some are found also in elevated regions, in all zones. Many have flowers of great beauty, and are therefore favorites in gardens. Some are occasionally used in medicine as tonics and astringents; others, being exceedingly acrid, as vesicants, particularly species of *plumbago*. Thrift, or sea-pink (q.v.), is the most familiar British example of the order.

PLUMBAGO. See BLACK LEAD.

PLUMBING. See SANITARY ENGINEERING.

PLUME-BIRD, *Epimachus*, a genus of birds of the family *upupidæ* (see HOOPŒ), but exhibiting points of resemblance both to honey-suckers and to birds of paradise. The bill is slender and arched. The plumage is magnificent and gorgeous, scarcely excelled even by that of birds of paradise. The plume-birds are natives of New Guinea and New Holland. They are variously adorned with enormously long tail-feathers, great shoulder-tufts of broad feathers, loose downy plumes, etc. One species, *E. albus*, has remarkable thread-like prolongations of the shaft of some of its plumes.

PLUMED MOTH, the popular name of a group of "*nocturnal lepidoptera*," known to entomologists as *fissipennæ* and *pterophorites*; remarkable for having at least a pair of the wings, and often all the wings, longitudinally cleft into two or more—sometimes six—divisions, which are beautifully fringed at the edges. The wings are similar to those of other moths in their nervures, but the membrane which usually connects the nervures is interrupted. The plumed moths are extremely beautiful, but often pass unobserved in consequence of their small size. Some of them have the power of folding up the wing like a fan. Although they are ranked among the *nocturnal lepidoptera*, some of them fly about during the brightest part of the day.

PLUMER, WILLIAM, 1759-1850; b. Mass.; entered on the practice of law at Epping, N. H., 1787, and was for many years an active politician. He was elected eight times to the lower house of the state legislature, of which he was speaker for two years; and was afterward a member, and for two years president of the senate. In 1792 he was a member of the convention that revised the constitution of the state; was elected United States senator 1802; four times governor of the state 1812-18; and presidential elector 1820. Having a vigorous mind and being very industrious he became learned in the law and accomplished in general literature. He wrote much for the periodical press and left many unpublished manuscripts. His life, written by his son and edited by rev. A. P. Peabody, was published at Boston, 1856.

PLUMER, WILLIAM SWAN, D.D., LL.D., 1802-80; b. Penn.; graduated at Washington college, Va., in 1825; studied theology at Princeton; was licensed to preach in 1827; organized a Presbyterian church in that year in Danville, Va.; subsequently organized another church at Warrenton, N. C., and preached at Raleigh, Washington, and New Berne in that state; became pastor of a church in Richmond, Va., in 1834, and editor of the *Watchman of the South* in 1837-45; removed to Baltimore in 1847, where a church was built for him. In 1854 he became prof. of theology at the Western seminary, Allegheny, Penn.; and in 1866 was called to the professorship of didactic and polemical theology in the Presbyterian theological seminary at Columbia, S. C. The circulation of his numerous volumes and tracts for the American tract society has been more than 5,000,000 copies. Some of the volumes have been printed in foreign languages. A still larger number of distinct works were published by other houses, and his contributions to the newspapers were numerous. He was the author of commentaries on the *Psalms*, *Romans*, and *Hebrews*. He was prominent in the Presbyterian church courts, moderator of the general assembly, O. S., in 1838; delegate from the southern church to the first general council held in Edinburgh in 1877.

PLUMMET, a weight of lead hung on a string, and attached to a frame, for the purpose of showing the vertical line.

PLUMPTRE, EDWARD HAYES; b. Eng., 1821; educated at University college, Oxford; became fellow of Brasenose in 1844; was chaplain at King's college, London, in 1847; prof. of pastoral theology there in 1853; prebendary of St. Paul's in 1863; prof. of the exegesis of the New Testament in 1864; assistant preacher at Lincoln's Inn, 1851-58; Boyle lecturer, 1866-67; rector of Pluckley, 1869, and vicar of Bickley, 1873. He has been since 1875 one of Old Testament company of revisers appointed by the convocation. He has published *Sermons*; *Lazarus and other Poems*; *Master and Scholar*; etc. (poems); *Christ and Christendom*; *Boyle Lectures*; *Translations of Sophocles and Æschylus*; *Biblical Studies*; notes on the Book of Proverbs in the *Speaker's Commentary*; papers in the *Biblical Educator*, of which he was editor; and notes on the first three Gospels in *Ellicott's New Testament for English Readers*. He has also contributed articles to *Dr. Smith's Dictionary of the Bible*, the *Quarterly*, *Edinburgh*, and *Contemporary Reviews*, the *Expositor*, *Good Words*, and the *Sunday Magazine*.

PLUMULA'RIA, a genus of zoophytes (*anthozoa*); plant-like, rooted, simple, or branched; with feathery shoots and offsets; and having hydra-like polypes in small cells arranged on one side of the shoot or branch, usually in the axil of a horny spine. The species are numerous, inhabitants of the sea, some of them very common on the British coasts, attached to stones, shells, sea-weeds, etc. They are very beautiful objects, even as seen by the naked eye, and still more when examined by the microscope; combining great delicacy with the utmost elegance. The polypes in a single plumularia are often exceedingly numerous; those of *P. falcata*, a very common British species, often to be found at low-water mark, have been calculated as 80,000 or 100,000 in number.

PLU'MULE. See SEED.

PLU'RALISM, in canon law, means the possession by the same person of two or more ecclesiastical offices, whether of dignity or of emolument. Pluralism has been held unlawful from the earliest times, and is forbidden by many ancient councils, as Chalcedon, c. x. (451 A.D.), 2d Nicæa, c. xv. (787 A.D.). This prohibition, however, was not regarded as absolute and admitting no possible exception; the natural ground of the prohibition being the impossibility, in ordinary cases, of the same individual adequately discharging the duties of more than one office. It has been held, therefore, that in cases in which this impossibility does not really exist, the union of two or more offices in the hands of one person might, speaking absolutely, be permitted without infringing the divine law. Canonists therefore distinguish "compatible" and "incompatible" benefices or dignities. Two benefices may be incompatible in three ways—(1) if each requires residence (*ratione residentie*); (2) if the duties of both fall to be discharged at one and the same time (*ratione servitii*); or (3), if the revenue of either fully suffices for the becoming maintenance of the incumbent (*ratione sustentationis*). In other cases benefices or dignities are considered compatible, and with the due dispensation may be held by the same person. The rule by which dispensations from the law of residence are to be regulated, as well as the penalties for its violation, whether on the part of the patron or on that of the recipient, have formed the subject of frequent legislation, as in the 3d and 4th councils of the Lateran, in the decretals of Innocent III. and many other popes, and especially in

those of the council of Trent. In general, it may be said that the canon law regards as incompatible (1) two benefices each having the cure of souls; (2) two "dignities;" (3) a "dignity" and a cure of souls; (4) a cure of souls and a simple benefice requiring residence. In other cases than these the pope is held to have the power of dispensing. There is no department of discipline, however, in which the tendency to relaxation has been greater or more persistent; and one of the gravest of the abuses of the church was the prevalence of pluralism of "incompatible" benefices, even of bishoprics; and although a constant effort was made to prevent this abuse, the evasions of the law were not only frequent, but even screened from punishment. In later times the evil has in great measure disappeared in the Roman Catholic church.

The English law, before the reformation, in the main coincided with the canon law; and the legislation of Henry VIII. preserved the same general spirit, only substituting the dispensing power of the crown for that of the pope.

By 13 and 14 Vict., c. 98, it is provided that no incumbent of a benefice shall take and hold together with it another benefice, unless the churches are within three miles of one another by the nearest road, and the annual value of one of them does not exceed £100. Nor can two benefices be held together if the population of one exceeds 3,000, and that of the other exceeds 500. The word benefice in this sense includes any perpetual curacy, endowed public chapel, parochial chapelry, or district chapelry. But a dispensation or license can be obtained from the archbishop, so as to allow two benefices to be held together; and if the archbishop refuse his license, the party may appeal to the privy council. A special provision is also contained whereby the head ruler of any college or hall in the universities of Oxford or Cambridge, or warden of Durham university, is prohibited from taking any cathedral preferment or any other benefice. If any spiritual person holding a benefice shall accept another benefice contrary to the statute, the first benefice shall *ipso facto* become void. At the same time, provision is made by statutes for uniting benefices where the aggregate population does not exceed 1500, and the aggregate yearly value does not exceed £500.—In Ireland no faculty or dispensation could be granted to any spiritual person to hold two or more benefices.—In Scotland it is contrary to an old Scotch statute for a minister of the established church to hold two or more charges; but the question has arisen almost exclusively with reference to clergymen appointed professors before or after an appointment to a country charge, in which case a resignation is necessary of one of the offices within a certain time after the appointment; but this disqualification does not apply to city charges.

PLUSH (Fr. *peluche*), a variety of woven cloth, having a long shaggy pile on the upper surface. Although woven like velvet, it differs from it in the greater length of the pile, and in its not being clipped or shorn to a uniform length. Formerly it was made of a double warp, one thread being usually double worsted yarn, the other, intended to form the pile, of goat's hair, and the weft of worsted; occasionally only worsted was used. Now it is made very extensively of silk and cotton, the silk taking the place of the goat's hair to form the pile. This silk plush is the material now almost universally used for making gentlemen's hats, instead of beaver-hair, as formerly. It is also worked in colored silks, for many articles of ladies' attire. See WEAVING.

PLU'TARCH (*Ploutarchos*), the biographer and moralist, was b. at Chæroneia in Bœotia. We can only approximate to the year of his birth. He tells us himself that he was a student of philosophy at Delphi, under Ammonius, when Nero was making his progress through Greece in 66 A.D.; and we may safely infer, therefore, that in that year he was beyond the age of puberty. He lived for some years in Rome, and in other towns of Italy, where he seems to have been much occupied with public business, and with giving lessons in philosophy—a circumstance to which he attributes his having failed to learn the Latin language in Italy, and his having to postpone his studies in Roman literature till late in life. During the reign of Domitian he was delivering lectures on philosophy at Rome; but we have not sufficient evidence for the statement that he was preceptor to Trajan, or that that emperor raised him to consular rank. The later years of his life he spent at Chæroneia, where he discharged the duties of archon and priest of Apollo. He lived down to 106, the eighth year of the reign of Trajan; but how much longer is not known. He was married to an amiable wife of the name of Timoxena, by whom he had several sons, who reached manhood, and left descendants.

The work by which Plutarch is best known is his *Parallel Lives* of 46 Greeks and Romans. These are arranged in pairs, each pair forming one book (*biblion*), consisting of the life of a Greek and a Roman, and followed by a comparison between the two men. In a few cases, the comparison is omitted or lost. The heroes of these biographies are the following: 1. Theseus and Romulus; 2. Lycurgus and Numa; 3. Solon and Valerius Publicola; 4. Themistocles and Camillus; 5. Pericles and Q. Fabius Maximus; 6. Alcibiades and Coriolanus; 7. Timoleon and Æmilius Paulus; 8. Pelopidas and Marcellus; 9. Aristides and Cato the elder; 10. Philopœmen and Flaminius; 11. Pyrrhus and Marius; 12. Lysander and Sulla; 13. Cimon and Lucullus; 14. Nicias and Crassus; 15. Eumenes and Sertorius; 16. Agesilaus and Pompeius; 17. Alexander and Cæsar; 18. Phocion and Cato the younger; 19. Agis and Cleomenes, and Tiberius and Caius Gracchus; 20. Demosthenes and Cicero; 21. Demetrius Poliorcetes and M. Antonius; 22.

Dion and M. Junius Brutus. In addition to these are placed in the editions after the 46th *Parallel Lives*, the biographies of Artaxerxes Mnemon, Aratus, Galba, and Otho. Plutarch has no equal in ancient, and few in modern times, as a writer of "lives." His power lies in his felicitous grasp of the character as a whole, and his skill in keeping minor details in subordination. It is not till the reader has seen the portrait in its completeness that his attention is attracted to accessory points. "There are biographers (says an admirable writer in the *Quarterly Review*) who deal with the hero, and biographers who deal with the man. But Plutarch is the representative of ideal biography, for he delineates both in one." Yet with all their artistic harmony, his lives abound with anecdotes and *bon-mots* in such profusion that they form one of our chief authorities for the table-talk of the Greeks and Romans. Their popularity in ancient, mediæval, and modern times, with readers of every rank and age, is something extraordinary, and they have in consequence exerted a very powerful and a very salutary influence on the art of biography, as subsequently practiced. The other writings of Plutarch, more than 60 in number, are included under the general title of *Moralia*, or ethical works. Several of these are not purely ethical in their tenor; while many of them are probably not by him, or if they are, do him small credit. Even in the best of the *Moralia*, there is no philosophical system to be found; their merits are not speculative, but practical; and their value consists mainly in their good sense, in the justness of their views on the ordinary affairs of human life; and in the benevolence of tone diffused throughout them. The best text of the lives is that of Immanuel Bekker; the best translation in English is that of Dryden and others, as re-edited by Clough. The best edition of the *Moralia* is by Wyttenbach (Oxford, 1795-1800); and of the entire works, the editions of Reiske (Leip. 1774-82) and Hutten (Tübingen, 1791-1805).

PLU'TEUS, in classical architecture, a wall filling up the space between two columns. Also the space between two, orders, placed over one another, as in the amphitheater, etc.

PLU'TO (Gr. *Ploutōn*, from *Plouteo*, to be rich), originally only a surname of HADES, as the giver or possessor of riches, is, in the mythology of Greece, the third son of Kronos and Rhea, and the brother of Zeus and Poseidon. On the tripartite division of the universe, he obtained the sovereignty of the under-world—the realm of darkness and ghostly shades, where he sits enthroned as a "subterranean Zeus"—to use the expression of Homer, and rules the spirits of the dead. His dwelling-place, however, is not far from the surface of the earth. Pluto is inexorable in disposition, not to be moved either by prayers or flatteries. He is borne on a car, drawn by four black steeds, whom he guides with golden reins. His helmet makes him invisible, whence, according to some scholars, his name of *Hades* (from *a*, priv., and *idein*, to see); although others, with at least equal probability, derive Hades from *hado* or *chado*, to receive or embrace, and translate the word the "all-receiver." In Homer, Hades never means a place, but always a person. Moreover, it is to be noticed that the poet does not divide the realm of the shades into two separate regions. All the souls of the dead—good and bad alike—mingle together. Subsequently, however, when the ethical conception of future retribution became more widely developed, the kingdom of the dead was divided into Elysium (q.v.), the abode of the good, and Tartarus (q.v.), the place of the wicked. This change also exercised an important influence on the conception of Pluto. The ruler of the under-world not only acquired additional power and majesty, but the very idea of his character was essentially modified. He was now regarded as a beneficent deity, who held the keys of the earth in his hand, and possessed its metallic treasures (whence his new name *Pluto* or *Plutus*), and who blessed the year with fruits, for out of the darkness underground come all the riches and swelling fullness of the soil. Hence, in later times, mortals prayed to him before proceeding to dig for the wealth hidden in the bowels of the earth.

Pluto married Persephone (Proserpina), the daughter of Demeter (Ceres), after carrying her off from the plains of Enna. He assisted his brothers—according to the mythological story—in their war against the Titans, and received from the Cyclops, as a reward for delivering them from Tartarus, the helmet that makes him invisible, which he lent to Hermes (Mercury) in the aforesaid war, to Perseus in his combat with the Gorgons, and which ultimately came to Meriones. The Erinnyes and Charon obey his behests. He sits in judgment on every open and secret act, and is assisted by three subordinate judges, Æacus, Minos, and Rhadamanthus. The worship of Pluto was widely spread both among the Greeks and Romans. Temples were erected to his honor at Athens, Elis, and Olympia. Among trees and flowers, the cypress, boxwood, narcissus, and maidenhair were sacred to him; bulls and goats were also sacrificed to him amid the shadows of night, and his priests had their brows garlanded with cypress wreaths. In works of art, he resembles his brothers Zeus and Poseidon; only his hair hangs down somewhat wildly and fiercely over his brow, and his appearance, though majestic, as becomes so mighty a god, has something gloomy and terrible about it. There can be little doubt that he, as well as Pan (q.v.), helped to trick out the conception of the devil prevalent during the middle ages, and not yet extinct. If it was from Pan that the devil derived those physical characteristics alluded to in the famous *Address to the Devil* by the poet Burns:

O thou, whatever title suit thee,
Auld Hornie, Satan, Nick, or Clootie,

it is no less certain that it is to Pluto he owes his position as "king of hell," "his blackness," and many of the insignia of his infernal royalty.

PLUTON'IC ROCKS, the name given by Lyell to the granitic rocks, from the supposition that they were formed at considerable depth in the earth, and were cooled and crystallized slowly under great pressure. They were so designated in contradistinction to the volcanic rocks, which, though they have risen up from below, have cooled from a melted state more rapidly upon or near the surface. See **GRANITE**.

PLUTUS, in ancient mythology, the god of riches, son of Ceres and of Iasius. He was reared by the goddess of peace, and in Athens there was a statue of Pax holding Plutus in her arms. He was represented as blind, and as distributing his gifts among good and bad indiscriminately. A legend assigned the caves of Spain to him as a residence, that country being noted for its deposits of precious metals.

PLYMOUTH, a co. in n.w. Iowa, adjoining Dakota, bounded on the w. by the Sioux river, drained by Floyd's river and the w. fork of the Little Sioux; on the Sioux City and St. Paul, and the Iowa division of the Illinois Central railroads; about 850 sq.m.; pop. '80, 8,567—6,122 of American birth. The surface is diversified, and the soil fertile. Corn, oats, and wheat are the principal productions. Co. seat, Lemars.

PLYMOUTH, a co. in s.e. Massachusetts, having the Atlantic ocean and Cape Cod bay for its e. boundary, Buzzard's bay for its s., and Massachusetts bay for its n.; drained by the Namasket river and other small streams forming the head-waters of the Taunton river; 700 sq.m.; pop. '80, 74,024—66,081 of American birth, 562 colored. Its surface is hilly, and wooded with forests of oak, pine, maple, birch, hickory, walnut, ash, elm, and poplar trees. It is drained by several large inland lakes; Monponsett, in Halifax, 743 acres; Arsawampsett, in Lakeville, 2,220 acres; Long, 1760 acres; Great Quitticas, 1255 acres; and others of less area. It has many good harbors, and its coast for the most part is well protected. It is intersected by several divisions of the Old Colony railroad. In the s.e. section a neck of land between Cape Cod bay and Buzzard's bay connects this co. with the co. of Barnstable, Cape Cod district. It is through this neck of land that it is proposed to cut a canal, to provide safe and rapid transit for ships to and from Boston. Its soil is sandy and rocky in many portions, but in all is susceptible of cultivation. Much attention is paid to farming and market gardening, an agricultural fair being held annually in the town of Bridgewater. Its industries include the manufacture of boots, shoes, and brogans, boxes, nails, iron in various forms, hardware, harnesses, cotton gins, furniture, cotton, woolen, and straw goods, shovels, metallic wares, cordage, lumber, rolled zinc, etc. It has always held commercial relations with the extreme south in connection with cotton and its manufacture. Co. seat Plymouth.

PLYMOUTH, a t. in Massachusetts, on Plymouth bay, 37 m. s.e. of Boston, famous as the landing-place of the "pilgrim fathers" from the *Mayflower*, Dec. 11, 1620, o.s. Plymouth rock is a granite boulder at the water's edge on which they landed. It is covered by a handsome granite canopy, and there is also a national monument to the pilgrims, completed in 1875. In pilgrim hall are preserved many relics of the first settlement of the country, among which are gov. Carver's chair and the sword of Miles Standish. The town has a good harbor and flourishing trade. Pop. '70, 6,238.

PLYMOUTH (*ante*), a t. in s.e. Massachusetts, a port of entry in Cape Cod bay, the landing-place of the Pilgrim fathers from the *Mayflower* Dec. 21, 1620, where they founded the first settlement in New England; pop. '80, 7,094. It is 37 m. s.e. of Boston, at the terminus of a division of the Old Colony railroad, and stretches along the coast for 18 m., from 5 to 9 m. in width. The principal village is built on several hills rising gradually from the beach, the houses standing compactly on beautifully shaded streets, with concrete walks. It has a fine harbor, protected by a beach with a sea-wall 3 m. long, running n. and s., separating the harbor from Cape Cod bay. The depth of the water at high tide will admit vessels of 12 ft. draught, at low tide those drawing 6 feet. The sea-wall was built by the Plymouth beach lottery, the last lottery tolerated in the state. Adjacent to the breakwater is Clark's island, where the Pilgrims spent their first sabbath; now becoming popular as a summer residence. Near by is the Gurnet light, and opposite this is Manomet bluff and hills, and the Manomet house, a resort for sportsmen. The Clifford house is at the head of Plymouth beach. The court house contains the registry of deeds, with the earliest records of the colony, the original patent to the company granted 1629, from the earl of Warwick, the plan of the town, the order for the first jury, trial, etc. It has a house of correction, a town hall, 12 churches, a soldiers' monument, an odd fellows' hall, masonic and good templars lodges, and a grand army post. It has private schools, public schools, and a public library; 2 national banks with an aggregate capital of \$450,000; 2 savings banks with deposits amounting to \$2,500,000; and 2 weekly newspapers. The leading industries, besides a number of vessels employed in the fisheries, and some commercial business, are the manufacture of woolen goods, iron, boots and shoes, cotton goods, duck, stoves, iron and zinc plate, nails and tacks, steel shanks, kegs, boxes, barrels, etc. The manufactories utilize the extensive water-power which the river affords. The national monument to the Pilgrims is still unfinished; the corner-stone was laid in 1859, the base placed in

position, 1876. In 1877 Oliver Ames, of Easton, Mass., gave \$30,000 for the statue of "Faith," cut out of granite from Hallowell, Me., by Italian workmen, the largest granite figure in the world, being 36 ft. in height, and 216 times life-size. The statue of "Morality," given by the state of Massachusetts, costing \$10,000, occupies one of the wing pedestals, and one of "Education" with an appropriate tablet, presented to the Pilgrim society by a gentlemen of Hartford, is approaching completion. The monument stands on an eminence surrounded by 9 acres of land, constituting the monument park. Plymouth has a fire department with 50 hydrants, and water-works, completed 1855; conveying water from Little South pond $3\frac{1}{2}$ m., having a receiving reservoir capable of holding 1,500,000 gallons of water; total cost, \$175,000. Pilgrim hall contains valuable relics, books, furniture, pictures, etc. The portion of the rock which, having been accidentally split off in 1774, was inclosed by an iron railing in front of the hole, in 1834, has been replaced on the original boulder beneath the canopy, on the beach, a granite structure supported by 4 columns, completed in 1867, in the top of which are the bones of the original settlers, removed from Coles's hill, now ascended by broad flights of steps, the site of a battery in 1742, and a fort in 1775, followed by another in 1814. The railing which once inclosed the fragment of rock, now guards a tablet on which is cut the compact; the names of the signers having been long inscribed on the "heraldic curtains" at the tops of the iron bars. Within the hall are Edgar Parker's copy of Weir's "Embarkation;" "The Landing," by Henry Sargent; and portraits of the early settlers, among them Ephraim Spooner, town clerk 51 years, and Aleoek's copy of the portrait of sir Walter Raleigh, 1775. A recent addition is the gift by hon. A. H. Rice, of a representation of the ship lying at Delfthaven awaiting the departure on July 22, 1620, painted by Charles Luey, 1846, which received in 1848 the prize of £1000 given by the British government at the Westminster exhibition. On Burial hill are the graves of Carver, Bradford, etc., and the stones which mark the site of the old forts and the brick watch-tower, 1643.

PLYMOUTH, an English sea-port and market t., and a parliamentary and municipal borough in the s.w. of Devonshire, 246 m. w.s.w. of London. It stands in the bight of Plymouth sound (q.v.), between the estuaries of the Plym and Tamar. To the w. of it is Stonehouse (q.v.), a township and coast-guard station, and still further w. is Devonport (q.v.), the great naval and military station. The two former places, however, having become united by continuous lines of houses, have lost their individuality, and are (with Devonport, which is walled, fortified, and surrounded by a moat) now generally considered as one great town. Of this great center of fashion, trade, and naval and military preparation, Plymouth proper, which covers an area of 1 sq.m., may be called the city, and Devonport the west end; while Stonehouse is an intermediate district, containing chiefly factories, barracks, victualing yards, hospitals, and other institutions. Plymouth proper extends from Mill bay on the w. to the mouth of the Plym on the east. Its site is somewhat rugged and uneven; an eminence forming the suburbs runs along its n. side, and another eminence, partly occupied by the citadel, fronts the sound. The chief buildings are the Royal hotel, comprising an immense inn, assembly-rooms, a theater, and the athenæum, all partially destroyed by fire in 1862, and rebuilt in 1863; public library, containing in its Cottonian collection 300 sketches by the old Italian masters; St. Andrew's church, the tower of which dates from 1490; and Charles church (1646-58), dedicated, with fervent loyalty, at the restoration, to "St. Charles the Martyr." There are also several important educational establishments, some of which are endowed, as well as many charitable institutions. Mill bay and Sutton pool are two small inlets of the sound, in which lie all the merchant-vessels bound for Plymouth proper. Between these inlets, and running along the shore, is the eminence or high plateau of land called the Hoe. From this ridge, whence the approach of the Spanish Armada is said to have been first descried, magnificent shore and sea views may be obtained. Its eastern end is occupied by the citadel, a fortress mounting 150 guns, which commands the entrance of the Cutwater (the lower estuary of the Plym), and of Sutton pool. Mill bay, on the w., is so deep that vessels of 3,000 tons can lie at the pier at low-water. Here are the important Great Western docks, covering an area of 14 acres, and having a depth of 22 ft., constructed about the years 1855-58. Close to these docks, and connected with them by a tram-line, are the termini of the South Devon, Tavistock, and Cornwall railways. In 1877, 6,069 vessels, of 1,213,328 tons, entered and cleared the port. Commerce is carried on to a considerable extent with the cape of Good Hope, the West Indies, and the Mediterranean; the coasting trade is also important, and the fisheries are productive. Pop. '81, 77,401.

Plymouth, described by Leland as being, in the reign of Henry II., "a mene thing, an inhabitation of fishars," was called by the Saxons Tameorworth (town on the Tamar); after the conquest it was called Sutton (south town); and it was not till the reign of Henry VI. that it received the name of Plymouth (mouth of the Plym). During the 14th and 15th c. it was frequently attacked and set on fire by the French, and in 1512 an act was passed for the strengthening of its defenses, which since then have greatly increased, until now the whole shores of the sound are well defended by cannon, and a cordon of inland forts has been of late years constructed at immense cost, surrounding the three towns at a distance of from two to three miles.

PLYMOUTH, Pa. See page 897.

PLYMOUTH BRETHREN, a religious sect which sprang into existence about 1830-35 in Plymouth, Dublin, and other places in the British islands, and which has extended itself considerably throughout the British dominions and in some parts of the continent of Europe, particularly among the Protestants of France, Switzerland, and Italy, and also in the United States of America. It seems to have originated in a reaction against exclusive high church principles, as maintained in the church of England, with everything of a kindred nature in other churches, and against a dead formalism associated with "unevangelical" doctrine. Many of the first members of the new religious communities formed in Plymouth and elsewhere were retired Anglo-Indian officers, men of unquestionable zeal and piety; and these communities began to appear almost simultaneously in a number of places. Their origin is, however, very much to be ascribed to the labors and influence of Mr. Darby, from whom the Plymouth brethren on the continent of Europe are very generally known as *Darbyites*. Mr. Darby was a barrister, moving in the highest circles of society; and under deeply religious impressions, became a clergyman of the church of England, and lived for some time in a mud hovel in the county Wicklow, devoting himself to his work; but afterward left the church of England from conscientious scruples, and became an evangelist unconnected with any church. In this character, he labored both in England and on the continent of Europe, preaching in French, English, and German. He also gave utterance to his opinions in numerous pamphlets, and in a quarterly periodical called *The Christian Witness*, which for a number of years was the "organ" of the Plymouth brethren. He continues to visit from time to time the communities or meetings of Plymouth brethren. His tenets, and those of the Plymouth brethren in general, are strictly Calvinistic: original sin and predestination, the efficacy of Christ's sacrifice, the merit of his obedience, the power of his intercession, the gracious operations of the Holy Spirit in regeneration and sanctification, are prominent points. Millenarian views are also generally entertained by the Plymouth brethren; and they usually practice the baptism of adults without regard to previous infant baptism. They acknowledge the sacrament of the Lord's-supper, and administer it to one another in their meetings, usually on every Sunday, or "first day of the week;" in this, as in everything else, refusing to acknowledge any special ministers. They utterly reject confirmation. Their most distinctive peculiarity, when contrasted with other Calvinistic churches, is their complete rejection of ecclesiastical organization. They suppose the whole Christian body in the world to have declined from truth and duty, like Israel of old, and, therefore, to have been "corporately rejected of God," and believe the true church to consist of themselves and of other chosen ones in the various Christian churches. They refuse to recognize any form of church government, or any office of the ministry; they insist much on the equal right of every *male* member of the church to prophesy or preach; and in their meetings, after each hymn or prayer, there is usually a pause, that any one, moved by the spirit, may undertake this office. They exclude persons known to have been guilty of gross sins from participation with them in the Lord's-supper, until proof is afforded of repentance. The Plymouth brethren reject every distinctive appellation but that of Christians; although a special denomination is found necessary to designate them; and, in fact, no one not holding their views could remain associated with them. A great schism took place among them in consequence of doctrines preached at Plymouth and Bristol concerning the human nature of Christ; Mr. Darby vigorously opposing what he deemed a dangerous error, and he and his adherents utterly separating from the fellowship of those who maintained or even refused to condemn it. One of the most noted (if not notable) converts to the principles of the sect was the revivalist Guinness, who was baptized in 1860 by another Plymouth brother, lord Congleton. There are about 100 meetings in the U. S., and 100 in Canada.

On the continent of Europe, the Plymouth brethren have in many places given great trouble to the Protestant churches, by their opposition to all ecclesiastical order or organization. See Mrs. H. Grattan Guinness's *Answer to the Question: Who are the Plymouth Brethren?* (Philadelphia, 1861.) For hostile criticisms, see Carson, Reid, and Croskery.

PLYMOUTH SOUND, a well-known roadstead on the s.w. of Devonshire, important as a naval station, has considerable claims to the distinction of being called, as it frequently has been, the most beautiful estuary on the English coast. Its position at the entrance of the English channel is much in its favor. It is two and a half miles wide, and extends inland for three miles. It penetrates into the country by means of the harbors of Hamoaze and Catwater, the estuaries of the Tamar and Plym respectively. On its w. side is Cawsand bay. The shores, which present many beautiful views, rise in hills of from 100 to 400 ft., and are dotted over with woods and with villages, and bound by coasts which are generally rocky and abrupt. Mount Edgecombe park, the beautiful seat of the earl of Mount Edgecombe, occupies the w. shore of the sound. At the mouth of the Tamar is the small island of St. Nicholas, or Drake's island, a pyramidal rock strongly fortified. The sound is open to the s.w., from which direction strong winds frequently blow, and violent surges are thrown in from the Atlantic. In order to protect the shipping in the harbor, a massive stone breakwater, 1700 yards in length, was constructed at a cost of about £1,500,000, and completed in 1841. See **BREAKWATER**. On a sunken rock just inside the breakwater and at its center, a strong stone fort has been within recent years erected; and an extensive series of stone batteries has been erected

at Bovisand and Picklecombe on the mainland, on either side of the entrance to the harbor. Fourteen m. s.s.w. of Plymouth is Eddystone light-house. See EDDYSTONE.

PNEUMATIC DISPATCH. This name is given to a mode of sending parcels, mail-bags, or telegram papers through a tube by atmospheric pressure, or by a partial vacuum. Early in the present century, Mr. Medhurst conceived the idea of some such contrivance. He proposed to construct air-tight tunnels, with carriages moving through them on rails; and these carriages were to be propelled by compressed air from behind, or else by suction in virtue of a vacuum formed in front of them. Medhurst was laughed at by his contemporaries as a visionary; but his speculations were called to mind in later years, and led to the attempts noticed under ATMOSPHERIC RAILWAY.

In 1861 was announced a *pneumatic dispatch* project, based on a reconsideration of the causes of failure in the earlier schemes. The conveyance of passengers and of bulky goods was not here contemplated; parcels and mail-bags were the articles held chiefly in view. To test the theory, a quarter of a mile of iron tube was experimentally laid down near Battersea, with a fair average of gradients and curves purposely given to it. The tube was about 30 in. in diameter; and it was found easy to propel a train through the tube consisting of two iron carriages of 7 cwt. each, at a rate of 30 m. an hour.

After many financial discouragements, a *pneumatic dispatch company* obtained capital in 1862, and began operations in 1863. The experimental tube was removed to London, and laid down beneath the roadway of Seymour street, Euston square, from the Euston station of the London and North-western railway to the n.w. district post-office in Eversholt street—a distance of one-third of a mile. Mail-bags being successfully transmitted in this way, the company commenced in 1864 the construction of a tube on a larger scale, and this has since been completed. The tube is laid down from Euston square to St. Martin's-le-Grand, by way of Tottenham court road, Holborn, and Newgate street—a distance of $2\frac{1}{4}$ miles. The tube is of large size, nearly $4\frac{1}{2}$ ft. in diameter, laid down at as small a depth beneath the carriage-way of the several streets as the water and gas pipes will permit. It is chiefly of cast-iron; but some portions on a sharp curve are of brick. There is a large engine-house on the s. side of Holborn, near Lincoln's Inn Fields, to supply all the power for working the whole tube in both directions. Rarefied air in one-half of the tube draws a train of iron carriages, laden with parcels and mail-bags, from Euston station to Holborn; and compressed air drives them through the other length of tube from Holborn to the general post-office—there being suction in the one case, and pressure in the other. A reverse action brings trains in the other direction. The necessary amount of rarefaction in the one case, and of compression in the other, was determined by experiment; but both are produced by means of a revolving fan of peculiar construction and large dimensions worked by a powerful steam-engine at the Holborn station. If this mode of transmission were to come into general use, there would be great saving of time in the delivery of letters and parcels, and a material lessening of the number of parcels and mail vans and carts in the overcrowded streets of the metropolis. It is to be regretted that a work so successful in a scientific and engineering point of view should still remain undeveloped in a commercial sense. The postmaster-general, the railway companies, and the great carriers, have made no practical working engagements with the pneumatic dispatch company; and this costly tube, with the engine-house in Holborn, has now remained silent and unused for several years. This of course has checked any extension of the system into other districts. We cannot resist the conviction that a better result will present itself sooner or later.

The problem of *passenger* conveyance within a pneumatic tube was shown to be practicable by Mr. Rammell, in an experiment tried at the crystal palace in 1864; but nothing further has been done in the matter.

More success has attended the introduction of a system for transmitting small rolls of paper through tubes of a few inches diameter, by pneumatic pressure. Mr. Siemens introduced it at Berlin; it was next tried with success at Paris; Mr. Latimer Clark constructed similar apparatus in London; and the plan is now in regular use in the telegraph department of the new buildings connected with the general post-office in St. Martin's-le-Grand, while it is also used in some of the chief provincial cities and towns. In 1875 the number of tubes in London was 24, with an aggregate length of nearly 18 m.; there were 4 tubes in Liverpool; 3 in Dublin; 5 in Manchester; 3 in Birmingham; and 1 in Glasgow. Small tubes, two or three inches in diameter, are arranged for the reception of telegraph forms or papers, made up into a roll, and put into a felt cylinder. The purpose is to economize time and expense in conducting the government postal telegraph business by *blowing* along the telegraph forms at a rate of 30 m. an hour, instead of sending them by street conveyance. Two parallel tubes have been laid down beneath the pavements of the streets from the general post-office to various parts of London, and also in some of our large provincial cities and towns; additions being made to the length of tube according as the system becomes practically developed. One tube in each pair may be called the down line, the other the up; the two are placed in connection at each end, and one steam-engine works them both. The felt cylinder very nearly fills up the tube, but still moves easily along it; this movement is brought about either by the formation of a partial vacuum in front of the cylinder, or by compressing the air behind it; and the steam-power is so applied as to produce either or both of these two results,

according as convenience may suggest. An ingenious plan is adopted for accommodating one or more intermediate offices, just as local stations are accommodated between the two termini of a railway. The cylinder or *carrier* travels from end to end of the tube, unless a block or check action is purposely put in force at an intermediate station; and the mode of effecting this is one of the most beautiful of Mr. Siemens's inventions relating to the subject. Two pieces of pipe, the *receiver* and the *transmitter*, are made exactly alike, and are so pivoted together that either may be adjusted into a cavity cut in the tube, and made temporarily to form part of it. The carrier, we will suppose, is intended to stop at the intermediate stations, to admit of the removal of some telegram papers and the introduction of others. A click is heard; the carrier strikes against an obstruction in the receiver; the cavity is opened; the exchange of papers is made; the carrier is re-introduced, but into the transmitter instead of the receiver; the cavity is closed again, and the carrier resumes its journey. All this is the work of a few seconds merely. If the intermediate station has nothing to send and nothing to receive, the transmitter alone is used, and the carrier travels on without stopping. The up-tube and the down-tube have each its apparatus of receiver and transmitter. The felt cylinder and its contents being very light, a slight rarefaction of the air in front of it, or condensation of the air behind it, is sufficient to produce a speed equal to twenty or thirty m. an hour. Practically, there is a *current* of air maintained, circulating through the two tubes and their terminal connections; wherever a carrier is placed in this current it is blown along, and there may be two or more carriers traveling at the same time.

PNEUMATICS (Gr. *pneuma*, spirit or breath, air) is the science which treats of the mechanical properties of aeriform fluids, such as their weight, pressure, elasticity, motion, etc. The great representative of the aeriform fluids is the atmosphere. The atmosphere is very frequently called "air," to distinguish it from the others, which are known as "gases." The fact of air having weight, and generally exercising pressure and resistance, was unsuspected by most of the ancients, though they were aware of the latter property in particular cases, from seeing and feeling the effects of the wind; but the idea that air in a state of rest exerts pressure on a body immersed in it, never seems to have occurred to them. Aristotle, however, asserted that air had weight, and so did several subsequent philosophers; but the truth of this opinion was not established till the time of Torricelli (q.v.), who not only showed that it had weight and exerted pressure, but also found the amount of this weight or pressure. See ATMOSPHERE. Pascal (q.v.) completed the investigation, and invented the barometer (q.v.). The experiments of these philosophers proved that what is called "suction" is nothing more than an effect of the pressure of the air on one side of a body, unbalanced by an equal pressure of air on the opposite side of it. To this property of air we owe the working of the various kinds of pumps (q.v.), the barometer (q.v.), the siphon, cupping-glass, etc. But the great distinguishing feature of aeriform bodies is the repulsive force which their molecules exercise over each other, and the constant expansion of these bodies when pressure is removed, or compression when pressure is increased. The investigation of the expansibility and compressibility of air was carried on by means of the air-pump (q.v.), an invention of Guericke (q.v.), and soon resulted in the discovery of a law by Boyle (about 1650), and Mariotte (1676), called *Mariotte's law*, (q.v.), which affirms, that "at a given temperature the volume of a gas is inversely as the pressure." See GASES. The second great law of tension and pressure is that of Dalton and Gay-Lussac (1801), which states, that "when the tension remains the same, the density of a gas varies inversely as the temperature"—that is to say, when the temperature is increased by equal increments, the bulk is increased by equal increments. The motion of gases is subject to the same laws with that of liquids, the laws which regulate the motion of liquids depending for their efficacy not on the liquidity, but on the fluidity (see FLUID) of these bodies. The flow of gases in tubes seems to be retarded by friction against the sides, in the same way as that of water is, and the diminished efflux at an orifice shows that the *vena contracta* exists for gases as well as for liquids. Abundance of examples and further explanations of the properties of air will be found under such heads as ATMOSPHERE, BALLOON, BAROMETER, DIVING-BELL, MAGDEBURG HEMISPHERES, etc.

PNEUMATIC TROUGH is a piece of chemical apparatus originally devised by Priestley, and now in daily requisition in every laboratory. By its means gases can be collected in vessels for experiments or examination, and can be decanted from one jar to another with as much ease as if we were dealing with liquids. The pneumatic trough consists of a vessel of water, provided with a ledge or shelf at the depth of 2 or 3 in. from the top. The jars in which the gas is to be collected are filled with water and placed with their mouths downward upon the shelf, which is kept a little under water, so as to prevent the entrance of air into the jars. When the edge of the jar is brought over the extremity of the tube carrying the gas, the bubbles of gas rise through the water, collect in the upper part of the jar, and displace the liquid. As soon as a jar is filled, it may be removed by sliding under its open mouth while still under water, a plate or tray containing enough of water to cover the edge of the jar; and oxygen and many other gases may be thus preserved for hours. Another jar full of water is substituted for the removed jar. The trough is best constructed of japanned copper, and may be made of any size corresponding to that of the jars; and in the shelf a groove should be

made about half an inch in width, and the same in depth, to admit the extremity of the gas-delivering tube beneath the jar.

PNEUMOGASTRIC NERVE, or *Par Vagum*, derives the first of its names from its supplying the lungs and stomach with nervous filaments, and the second from the wandering course which it pursues. It emerges from the medulla oblongata by eight or ten filaments, which unite and form a flat cord that escapes from the cavity of the cranium (in association with the glossopharyngeal and spinal accessory nerve) by the jugular foramen. In this foramen it forms a well-marked ganglionic swelling, while another is observed immediately after its exit from the skull. The nerve runs straight down the neck between and in the same sheath as the internal jugular vein and the carotid artery. Below the root of the neck its course is different on the two sides; the right nerve running along the back of the œsophagus is distributed to the posterior surface of the stomach, and finally merges into the solar plexus; while the left nerve runs along the front of the œsophagus to the stomach, sending branches chiefly over its anterior surface.

From anatomical considerations, based on the distribution of this nerve, and from the results of experiments on animals, it may be concluded that this is a mixed nerve, containing filaments both of sensation and motion. The pulmonary branches exercise a most important influence upon the respiratory acts, for when the pneumogastrics on both sides have been divided above the giving off of the pulmonary branches, the most severe dyspnoea comes on, the number of respirations is much diminished, and the animal breathes as if it were asthmatic; after a short time the lungs become congested and dropsical, and the bronchial tubes filled with a frothy serous fluid: and if the cut ends of the nerves are kept apart, the animal never survives above three days. The gastric branches influence the movements of the stomach, while their destruction does not materially affect the secretion of the gastric juice or the process of chylification. Loss of voice and difficulty of breathing have been frequently traced to the pressure of an aneurism or other tumor on the recurrent or inferior laryngeal. Whooping-cough is ascribed by many high authorities to an affection of the pneumogastric nerve; and the violent spasmodic cough which accompanies enlarged bronchial glands is probably due to the irritation of its pulmonary branches. The sympathy which exists between the digestive and the respiratory and circulating organs is explained by the anatomical relations of this nerve. For example, both asthma and palpitation of the heart are often to be traced to some deranged state of digestion. Vomiting may be excited by irritation of the central or the distal extremities of the nerve. In disease of the brain the vomiting, which is often an early symptom, is caused by irritation of the central extremity; and in sea-sickness it is that extremity also which is irritated by the disturbed state of the circulation in the cranium; while by introducing emetic substances into the stomach the vomiting is produced by the irritation of the peripheral (or distal) filaments.

PNEUMONIA, or inflammation of the substance of the lungs, is a disease which is divided by pathologists into three distinct stages, corresponding to different degrees or periods of inflammatory action. The first stage is that of *engorgement*, in which the lung or a portion of it is gorged with blood, is of a darker color externally, and crepitates (or crackles) less under pressure than healthy lung does; the air that ought to exist in the pulmonary cells being in a great measure replaced by fluid. On cutting the engorged portion the section is seen to be redder than natural, and to yield a great quantity of reddish and frothy serum. The most engorged portions will generally float in water, although they are heavier than healthy lung. If the inflammation continues, new characters appear. The affected portion of the lung ceases to crepitate under pressure, and sinks when placed in water, in consequence of its now containing no air. The spongy character of the lung is gone. It is now solid, and the cut surface so closely resembles that of liver that the term *hepatization*, first suggested by Laennec, is generally applied to this stage. On examining with the microscope a torn fragment of the hepatized lung, it will be seen to be composed of small red granulations pressing upon one another, which are doubtless the air-cells clogged up, thickened, and made red by the inflammation. In the third and most advanced stage the pulmonary tissue remains, as in the last stage, dense, solid, and impervious to air; but its section, in place of being red, is now of a reddish-yellow, or straw, or drab, or stone color, or is of a grayish tint, and the little granulations which were red in the second stage are now whitish or gray, from the presence of pus or matter which permeates through the pulmonary tissue, rendering it very soft and friable. To this stage, which is in reality one of *diffused suppuration*, Laennec applied the terms *gray hepatization*, or *purulent infiltration*. Besides revealing to us the above information regarding the changes which the pulmonary textures undergo in the three stages of this disease, morbid anatomy teaches us that inflammation does not attack all parts of the lung on both sides indiscriminately. It is much more common on the right side of the body than the left. Of 210 cases collected by Andral, 121 were on the right lung alone, and 58 on the left side alone; while in 25 it was double (i.e., occurred in both lungs), and in six the seat was uncertain; so that pneumonia is more than twice as common on the right side as on the left, and only occurs on both sides together as often as once in eight times. According to Grisolles, however, whose *Traité Pratique de la Pneumonie* is the standard work on this disease, the relative fre-

quency with which the right lung is affected is rather less than two to one (11 : 6). Moreover, pneumonia is considerably more common in the lower than in the upper lobes of the lung—a point of great importance in diagnosis. Of 88 cases observed by Andral, the inflammation was found to affect the lower lobe 47 times; the upper lobe, 30; and the whole lung at once, 11. Inflammation of the bronchial tubes so constantly accompanies inflammation of the tissues of the lung, that although bronchitis often exists without pneumonia, pneumonia never occurs without bronchitis. Moreover, a certain amount of pleurisy or inflammation of the investing membrane accompanies pneumonia in a very large majority of cases.

The alterations which take place in the tissue of the lung give rise to important modifications of the ordinary sounds yielded by auscultation and percussion, the discrimination of which, however, belong to the physician.

The following are the general symptoms, as distinguished from the physical signs, of pneumonia: The disease generally commences with inflammatory fever; and pain in the side, due to pleurisy in most cases, soon supervenes. The breathing is always more or less affected, especially when the upper lobe is inflamed. According to prof. Gairdner, the dyspnoea of *pure* pneumonia is a mere *acceleration* of the respiration, without any of the heaving or straining respiration observed in bronchitis, or in cases where the two diseases are combined. Delirium is a very frequent and always a dangerous symptom, indicating that the due arterialization of the blood is much interfered with, and that the impure circulating fluid is affecting the brain. The cough is usually dry at first, but in a few hours it is accompanied by the expectoration of sputa of so characteristic a nature as to afford almost certain evidence of the presence of the disease. On the second or third day the expectoration, which previously consisted merely of a little bronchial mucus, consists of transparent and tawny or rust-colored sputa, which unite in the vessel containing them into one gelatinous mass. The color is owing to the complete blending of the blood and mucus, and in proportion to the quantity of the former the sputa is more or less deeply tinged. So long as the expectorated matter flows readily along the side of the vessel when it is tilted, there is reason to believe, unless physical signs tell us otherwise, that the inflammation is still in the first stage; but when the sputa are so viscid that the vessel may be inverted and strongly shaken without their being detached, there is reason to fear that the pneumonia has reached the second stage. If improvement now commences, the sputa becomes less tenacious, less rust-colored, and gradually like the expectoration of common catarrh. But if the disease advances, the rust-colored sputa, although in less quantity, may go on to the end; or there may be no expectoration, either on account of its own tenacity or of the patient's want of power to eject it, in which case the air-passages get gradually filled and death from suffocation occurs; or there may be the expectoration of a fluid of the consistence of gum-water, and of a brownish-red color (resembling prune-juice), which, according to Andral, affords strong evidence that the disease is in its third stage; or, lastly, pure pus may be excreted during the third stage.

In its first and second stages this disease is tolerably amenable to treatment. Whether when the lung has reached the third stage it is still susceptible of repair we cannot tell, because we have no certain sign of the commencement or establishment of this third stage during life, although we may guess that it is established if the face has become very pale and corpse-like; if there is the prune-juice or purulent expectoration; and if the disease has lasted for a sufficient time to have advanced so far, although it would be very difficult to state, with any approach to accuracy, what the necessary time is. The average duration of pneumonia may be placed at ten days or a fortnight.

Of the causes of this disease very little need be said. Sometimes no cause can be traced. Very often it is the consequence of exposure to cold, especially when the body was previously heated by exercise; but why such exposure should in one person cause pneumonia, in a second pleurisy, in a third, pericarditis, and in a fourth, peritonitis, we cannot tell.

The following is a brief outline of the treatment to be adopted, provided the patient was previously strong and healthy: In the first stage, free venesection, tartarized antimony (one-third of a grain to half a wine-glassful of water every hour, and the dose to be increased to a grain or more hourly, if there is no purging or vomiting, which may often be prevented by the addition of a few drops of laudanum to each dose), and antiphlogistic regimen generally are of service. Under this system there are often signs of improvement in five or six hours, although sometimes there is no change for the better till 24 hours or more have elapsed. When the disease has reached the second stage, in preference to continuing the antimony we should as speedily as possible get the system gently under the influence of mercury, in the mode recommended in the articles PERICARDITIS and PERITONITIS. If there is great depression of the vital powers, as indicated by a feeble and irregular pulse, and the other ordinary signs of sinking, it will be requisite to administer stimulants, such as wine and carbonate of ammonia, and to feed the patient on beef-tea.

There are few diseases in which it is of greater importance to watch the patient during convalescence than in pneumonia. The convalescence is often rather apparent than real, and, as Dr. Watson truly observes, "a patient can never be pronounced perfectly secure so long as any trace of crepitation remains in the affected lung, and this

may often continue long; nay, it not unfrequently ceases only on the supervention of another more surely fatal though less rapid disorder, viz., tubercular consumption."

PO (anc. *Eridanus* and *Padus*), the largest river of Italy, rises in two springs on the n. and s. sides of Monte Viso, one of the Cottian Alps, close to the French frontier, and in lat. about 44° 40' north. It flows eastward for upward of 20 m., when, arriving before Saluzzo, it emerges from its rocky defiles and enters upon the plain. From Saluzzo it flows n.n.e. past Turin, and arriving at the town of Chivasso it changes its course toward the e., in which direction it flows to its embouchure in the Adriatic. Upward of 50 m. above its mouth it begins to form its delta, the principal branches being the *Po della Maestra* on the n., and the *Po di Primaro* on the south. The unhealthy marsh of the *Valli de Comacchio* extends immediately n. of the Primaro branch. The Po receives from the left the Dora Riparia, Dora Baltea, Sesia, Ticino, Adda, Oglio, and Mincio; from the right the Tanaro, Bormida, Trebbia, Taro, Parma, Enza, Secchia, and Panaro. At Turin the Po is about 750 ft. broad; at Pavia, 1050 ft.; at Cremona, 2,650 ft.; and below Polesella, after throwing off the Po di Primaro branch to the s., its breadth is about 850 feet. It has an entire length of 400 m., is navigable for small barges 60 m. from its source, and drains an area of nearly 40,000 sq. miles.

POA. See MEADOW GRASS.

POACHING, though not strictly a legal term, has so long been appropriated in popular parlance to describe a well-known legal offense, that it is now usually adopted in legal works. It means the unlawfully trespassing on another's lands for the purpose of catching or pursuing game; and it is likewise extended to the cognate offense of unlawfully catching or pursuing fish in another's waters.

1. *As to poaching game.*—The general law as to who is entitled to game, and in what circumstances, is stated under the head **GAME**. As a general rule, whoever is the proprietor of land is the only person exclusively entitled to catch and kill the game; and where the land is let to a tenant, then, in England and Ireland, if nothing is said or agreed on the subject, it is the tenant, and not the landlord, who is entitled exclusively to the game. In Scotland the rule is the reverse, for the landlord, and not the tenant, is there entitled to the game; but generally there is an express stipulation in leases, providing for this somewhat important right. As regards hares and rabbits, however, the law was altered for the whole United Kingdom by the ground game act of 1880, which gives to every occupier of land an inalienable right, jointly with the proprietor, to kill such ground game under certain restrictions, as to the method of killing and the number of persons entitled to kill. The right of the occupier under this act cannot be transferred. In England there is a day-poaching act and a night-poaching act, imposing penalties on poachers. By the day-poaching act (1 and 2 Will. IV. c. 32, s. 30), whoever unlawfully goes upon lands not his own to pursue or kill not only game (q.v.), but also rabbits, woodcocks, snipes, quails, and land-rails, is liable to a penalty of £2. It has been held that this offense is committed whenever a stranger has *de facto* gone upon the lands to shoot without having previously expressly obtained the permission of the party entitled to the game, even though he may have had good reason to believe that such permission, if asked, would have been granted as a matter of course, and though, after hearing of the trespass, the owner quite approved and ratified it. Moreover, any person whatever, whether interested in the lands or not, may institute the proceedings for the punishment of the poacher; and the informer is entitled to half the penalty, the other half going to the poor of the parish. When a poacher is found trespassing on lands in search of game, the person entitled to the game there, or the tenant, or a gamekeeper, or servant of either, may demand the poacher's name and place of abode, and if it is refused, may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is entitled to go at large. It is only the persons named (and not any one of the public, or even a constable) who can arrest the poacher, and it can only be done when he is caught in the act on the very lands; for if the poacher clear the fence, and go on to other lands, he cannot then be arrested at all. If game is found on the poachers at the time they are caught, and it appear to have been newly caught, the party who is entitled to arrest him is entitled to seize the game also. If the poacher when convicted do not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding two calendar months. The party may appeal against his conviction to the court of quarter sessions; but he must either remain in custody in the interval or give security for the costs. The offense of poaching is punished more severely when five or more go out together, showing thereby an attempt to intimidate gamekeepers and others, and in such case each is liable to a penalty of £5. Moreover, if any of these five or more persons, acting in concert, be armed with a gun, and use violence, each is liable to an additional penalty of £5. As to the night-poaching act (9 Geo. IV. c. 69) it is provided that any person by night—i.e., between the first hour after sunset and the first hour before sunrise—unlawfully trespassing in search of game, shall for a first offense be committed by the justices to the house of correction for three months, or in some cases for six months; for a second offense, shall be committed for six months, or in some cases for twelve months; and for a third offense shall be guilty of a misdemeanor, and be imprisoned for two years. In case such night-poachers are found on the lands and in the act, the owner

Poaching.

or occupier of the land or his servants may arrest the poachers and take them before justices. If the night-poacher, when arrested, use fire-arms, sticks, or offensive weapons he shall be guilty of a misdemeanor, and be punishable by two years' imprisonment in addition. In case of three or more night-poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanor, and is liable to imprisonment for three years. Poachers have no right to kill game on the highway any more than in fields or inclosures, for the owners of the adjoining land are entitled to the game on the highway. Under the former law it was, as already mentioned, incompetent for any person except the owner or occupier of the lands to apprehend the poacher, and even this could only be done when the poacher was caught in the act on the lands themselves; and hence, even constables had no power to seize the poacher, though seen to be coming from such lands. But by the recent poaching prevention act (25 and 26 Vict. c. 114), which applies to the United Kingdom, if a constable now meet a suspected poacher on the highway, whom he has reason to suspect of coming from land where he has been poaching, such constable may stop and search the poacher; and if game, or implements for taking game, are found on him, may seize and detain them, and summon him before the justices. When before the justices, if it be proved by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may have so used. The person convicted may appeal if he chooses to the next quarter sessions, or, in certain cases, to the court of queen's bench. With regard to the poacher's property in the game he kills, it is only in those cases where he is caught in the act, and on the spot, that the game can be taken from him; and this, for obvious reasons, seldom happens. In all other cases the general rule applies that whoever first catches (whether legally or illegally) a wild animal, is entitled to the property in it; and as game is in the category of wild animals, the poacher is entitled to keep the game, except where it was both started and caught on one and the same person's lands. The law of Scotland does not materially differ from that of England as to poachers; and the night-poaching act applies to it equally as to England. The Scotch day-trespass act (2 and 3 Will. IV. c. 68) closely agrees with the English act. But it is singular, that, in the case of night-poachers, the game cannot be taken from the poacher, even when caught in the act and on the lands; though it can be so in England.—Oke's *Game Laws*, by Bond, seventh edition, 1877, p. 360. The act conferring power on constables to stop and search poachers on the highway also extends to Scotland. In England the poaching of hares or rabbits by night in preserves is a misdemeanor; whereas it is only an offense punishable summarily in Scotland. In Ireland the law as to poaching is not identical with the law of England, there being distinct statutes, but substantially the law is the same.—*Paterson's Game-laws*, 182. The law of the United Kingdom has often been described as too severe against poachers, inasmuch as most of the penalties are cumulative, and the justices who administer the laws are generally game-preservers, and so inclined to convict on the smallest scintilla of evidence. But, on the other hand, it is answered that poaching is in reality only stealing under a milder name, and that the classes who poach are divided by a thin partition from thieves, game being, in every point of view, as much the fruit of the soil as apples or turnips, and the transition from habitual poaching to stealing being not only easy but inevitable. The objections above alluded to have been removed in Scotland by the Game Laws Amendment Act, 1877, 40 and 41, Vict. c. 28.

2. *Poaching fish* is the unlawfully entering on another's fishery in order to catch fish. The law of fisheries is not uniform in the United Kingdom. In England the general rule is that any one of the public may fish freely in the sea and in all navigable rivers; and where he can fish he can catch salmon as well as every other kind of fish. But there is an exception to this generality, which consists in this, that as the crown could before Magna Charta (which took away such right) legally grant a several or exclusive fishery in the sea or a navigable river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove that he has exercised this exclusive right as far back as one or two centuries, it will be inferred that his right dates from before Magna Charta, and therefore will be legal. When such is the case the public have no right to fish even in a navigable river or the sea at the specified places, the sole fishery being vested in this individual owner. In streams not navigable the rule is that each riparian owner—i. e., the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle line of the stream. If he is owner on both sides of the stream, then he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of the soil is the owner of a several fishery there, unless he has let it to another. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands abutting thereon; but much will depend on the title to the lands and the subsequent user. As a general rule, there is no such thing as a right in the public to fish anywhere, except in a tidal river or the sea, and that is subject to the exception of an individual claiming a several fishery, as before mentioned. It is often supposed that, at all events, if a highway adjoins a private stream, any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the collateral purpose of either fishing or poaching, the use of the highway, so far as the

public are concerned, being confined to the purposes of traveling or transport. The general rule as to all several—i.e., exclusive—fisheries is that whoever goes and poaches the fish commits an offense, for which he may be summoned before justices and fined £5, over and above the value of the fish taken; and if the fishery where he poaches is adjoining the dwelling-house of the owner of the fishery, it is a still higher offense, for it is then an indictable misdemeanor. It is immaterial what kind of fish is caught by poachers, whether salmon, or trout, or minnows; and it is immaterial how the fish are caught. But a milder punishment is awarded to the poaching angler, for even though he poach in a fishery adjoining the owner's dwelling-house, he incurs only a penalty of £5; and where the fishery does not adjoin a dwelling-house, he incurs a penalty of only £2. Whenever a fish-poacher is caught in the act of poaching, he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this can only be done while he is on the spot or near it, for if he escape to the highway or to other lands before being arrested, he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect a privilege is given to anglers, for in no case can these be arrested if angling during the day-time; they can only be summoned for the offense. The poacher, when arrested, must be taken within a reasonable time before a justice of the peace, and charged with the offense. Though anybody may arrest the fish-poacher, still it does not follow that the fish poached can be taken from the poacher; on the contrary, the rule is the same as with reference to game, that whoever first catches the fish, whether legally or illegally, is entitled to keep it; and though game can on certain occasions be taken from the poacher, this is by reason of an express provision in the game act; but there is no similar provision as to poached fish, so that the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is provided by an express section of the larceny act (24 and 25 Vict. c. 96, s. 25), that the owner of the fishery or land where the poacher is caught, or his servant, may demand, and if refused may seize, the net, rod, line, hook, or other implement used for taking the fish, but no other person can seize these. It may also be observed that the English salmon fishery act (24 and 25 Vict. c. 109), though singling out salmon from all other fish for peculiar protection, does not deal specially with poachers. Its chief object is to restrain the owners of salmon-fisheries themselves from fishing at certain times and by certain means, for which purpose a close season is declared, during which no person, whether otherwise entitled or not, can legally catch salmon. Of course, poachers are prohibited from catching salmon at the times and by the means forbidden to the owner, and in this sense come within the salmon acts. Thus, all persons are prohibited from poisoning salmon-rivers, from fishing salmon with lights, spears, gaffs, stroke, halls, or snatches; using fish-roe as a bait; selling or buying salmon-roe; using nets having meshes larger than 2 in.; from using fixed engines, fishing without a license, etc. See 24 and 25 Vict. c. 109, 28 and 29 Vict. c. 121, 36 and 37 Vict. c. 71. Bailiffs have power to arrest under Act 1878, 40 and 41 Vict. c. 39.

The law of Scotland, as to poachers of fish, differs considerably from that of England. In Scotland the fundamental rule is that salmon stands on a different footing from all other fish, and *prima facie* belongs to the crown; so that no person in Scotland is entitled to fish salmon (even by angling) unless he can produce a grant or charter from the crown, conferring upon him such right. But, in point of fact, nearly all the great landed proprietors are in possession of such rights as pertinent to their lands. And the theory of the crown's original right to the salmon applies not merely to rivers, but to the sea-coasts all round Scotland. Hence the public have no right to fish with nets even in the sea, except by leave of the crown, or of the grantee of the crown at the spot in question. Where a salmon-river belongs to several proprietors, the rule is that none can fish by using fixed engines; but the only legal mode is the mode of fishing by net and *colle* (or boat). As regards poachers of salmon, the law is contained in the act 7 and 8 Vict. c. 95. By that law, whoever poaches salmon in a river, lake, or within a mile of the sea-shore, incurs a penalty of £5, besides forfeiting the boat, net, or other engine used to catch the fish. While the law is as above stated with respect to fishing salmon with nets, even a grant from the crown is required to enable a riparian owner to angle for salmon. Hence the right of angling for salmon is not a pertinent of the property in the banks, and each owner is not entitled to angle up to the middle of the stream. Anglers, although riparian owners, or who have a permission from such, are therefore all poachers, and incur a penalty. The Scotch salmon acts (25 and 26 Vict. c. 97, 27 and 28 Vict. c. 118, 31 and 32 Vict. c. 123) also forbid owners of fisheries and others fishing salmon by fixed engines, during close-time, etc. As regards other fish than salmon, the general rule is that the riparian owner is entitled to catch all the fish he can, provided he do not interfere with the superior right of some crown grantee of the salmon-fishery. A person who poaches trout or other fresh-water fish with a net, or by double-rod fishing, or cross-line fishing, or set-lines, etc., incurs a penalty of £5, besides forfeiture of the fish caught. And he may be arrested if he is net-fishing, but not if he is fishing in another way. Moreover, a mere angler of trout, though a poacher, cannot be arrested, nor yet punished by any penalty; though he is liable to an action at law, which, however, is virtually no remedy at all. So, in the case of all poachers of trout (except angling poachers, who can neither be arrested, nor yet have their fish or fishing-rod taken from them by force), the owner of the fishery, or any person authorized by him, may seize the nets, boats, and fishing

implements, if the poachers are found on the spot. Though angling for trout is thus privileged in Scotland (above what it is in England) in this respect, that the poaching angler cannot be arrested or fined by justices of the peace, but is only liable to an action, yet the poaching angler of salmon may be fined. The public have no right to angle from a highway adjoining a stream. Where a stream runs through a farm, the farmer has no right to angle for trout, unless the lease expressly allow it; but he cannot fish for salmon with a net, or even by angling, for it interferes with the crown grantee, if there is one. It has also been held that he cannot fish for trout with a net, but this decision is supposed to be doubtful, and would probably be qualified if the point were raised. There are special salmon statutes for the river Tweed and for the Solway, and the Scotch rivers running into these, and for some other rivers; but these statutes do not substantially differ from the general law. In Ireland the law of poachers of fish is the same as in England in all the main points, for the same statute applies. See Paterson's *Fishery Laws of the United Kingdom*, by Bund, second edition, 1878.

POCAHONTAS, the legendary "princess Pocahontas," b. about 1595, was the daughter of an Indian chief of Virginia. It is due to the vanity of capt. John Smith, a bustling early settler, that this red Indian woman has been embalmed in his figmentary story as a heroine of romance, in that she died of love for the said John Smith years after she had prevented her father's braves from beating out his brains at the imminent risk of a similar visitation on her own; a fond imagination perpetuated in sculpture by Capellano, as may be seen any day over one of the doors of the capitol at Washington. But Mr. E. D. Neill, United States consul at Dublin, has recently dispelled the halo from the brow of this "blessed Pocahontas and great king's daughter of Virginia." According to evidence adduced by this gentleman, Pocahontas first appears in history tumbling wheels in the market-place of the English fort—a prototype of our city Arabs. Next she is living with a volunteer capt. called Cookham. Subsequently separate from him, she is betrayed by her uncle Patowomek (Potomak?) to capt. Argall, the unscrupulous deputy-governor of Virginia, and held by him as a hostage for the purpose of extorting from her father such terms as he required. In pursuance of this plan John Rolfe, a married Englishman, marries her. Sir Thomas Dale, the governor, afterward brings the "Virginian princess" to England, as a means of extracting money from the government of James I. for the plantation. She created a sensation of curiosity in London and at court, and died at Gravesend in 1616, aged 21. The son she bore to John Rolfe returned to Virginia. Richard Randolph, son of an "esteemed and industrious mechanic," is said to have married Jane Bolling, the great-grand-daughter of Pocahontas, who is accordingly proudly referred to as an ancestress of the Randolphs and other distinguished families of Virginia. See *English Colonization of America*, by E. D. Neill (1871).

POCAHONTAS, a co. in n.w. central Iowa, drained by the west fork of the Des Moines and the Lizard river; traversed by the Dubuque and Sioux City railroad, 575 sq.m.; pop. '80, 3,713—2,695 of American birth. The surface is rolling. The soil is fertile. The principal productions are corn, wheat, oats, barley, and hay. Co. seat, Pocahontas Center.

POCAHONTAS, a co. in e. West Virginia, drained by the Gauley and Greenbrier rivers, intersected by the Alleghany mountains; about 740 sq.m.; pop. '80, 5,591—334 colored. The surface is uneven and heavily wooded, and the soil fertile. The principal productions are corn, wheat, and oats. Co. seat, Huntersville.

POCHARD, *Fuligula*, a genus of ducks, of the oceanic section (see DUCK), having the bill as long or nearly as long as the head, broad and very flat, a little dilated toward the tip, the lamellæ of the upper mandible not projecting beyond the margin, the wings and tail short, the tail rounded. The windpipe of the male, in all the pochards, terminates in a labyrinth composed partly of bone and partly of membrane. There are numerous species, some of them natives of the arctic regions; some found, at least in winter, on the coasts of most parts of Europe, Asia, and North America; and some in the southern hemisphere.—The COMMON POUCHARD (*F.*—or *nyroca*—*ferina*), also known as the DUN BIRD, and as the *red-headed poker* and *red-eyed poker*, is a frequent winter visitant of Britain. It breeds in very northern regions, and is abundant in all of them, but in winter migrates southward, in America as far as Carolina and Louisiana, whilst in Asia it has been found even in Bengal. It is smaller than the mallard, but rather larger than the widgeon. The head and neck are bright chestnut, the eyes red, characters which at once distinguish it from every other British duck. It is highly esteemed for the table. Great numbers are sold every winter in the London market.—Several other species are reckoned among British birds.—The TUFTED DUCK (*F. cristata*) is a frequent winter visitant of the bays, estuaries, and lakes of Britain. It is a plump and short bird; black, with a white bar on the wing; the breast, belly, and sides white. The occipital feathers are elongated.—The CANVAS-BACK DUCK (*F. valisneria*) of North America is a species of pochard. It is very like the common pochard, but is much larger, and has the bill higher at the base, and less dilated toward the tip. The upper parts are also whiter. The canvas-back duck breeds in the northern parts of America, and migrates southward in flocks in autumn. In winter, it abounds particularly on the Chesapeake and its tributaries, and is also common southward to New Orleans, often collecting in very large

flocks, particularly toward evening. It is very shy, but vast numbers are killed, it being in very high esteem for the excellence of its flesh.

POCO (Ital.), a little, a term much used in music, as *poco animato*, rather animated; *poco forte*, abbreviated *pf.*, rather loud; *poco a poco*, signifies by degrees, little by little; *poco a poco crescendo*, becoming loud by degrees; *poco a poco rallentando*, becoming slower by degrees.

POCOCK, EDWARD, D.D., 1604–91; b. Oxford, Eng., where he graduated, 1622, having devoted himself chiefly to the Hebrew, Arabic, Chaldee, and Syriac languages, prepared a Syriac version of the epistles of Jude, I. and II. Peter, and II. and III. John, in order to complete the New Testament in that language. These were printed at Leyden 1629. Having taken orders in the English church he was appointed chaplain to the factory at Aleppo 1630, where for six years he prosecuted the study of the oriental tongues, acquiring great proficiency in the Arabic, and increasing his knowledge of the Hebrew, Ethiopic, and Syriac; was chosen professor of Arabic at Oxford 1636, and, having entered on his duties there, was sent to Constantinople to continue the study of Arabic, and to collect manuscripts; in 1640 returned home, and edited and translated into Arabic for circulation among Mohammedans the work of Grotius on the truth of the Christian religion, published 1660. The Arabic professorship had been endowed by archbishop Laud, but at his death the revenues he had set apart for that purpose were seized. Poccock then devoted himself to study in private; was presented by his college with the living of Childrey 1643; by the exertions of his life-long friend, Selden, was reinstated in the Arabic chair 1647; was made professor, also, of Hebrew 1649; received from the king a rich canonry, which was confirmed to him by the parliament; but, as it was not the one originally annexed to his professorship, he refused to receive the revenue. From this canonry he was ejected 1650; but was allowed to retain his professorships through the unanimous interposition of all the heads of houses, masters, and scholars at Oxford. In 1655 a plan to deprive him of his living was defeated through the influence of Dr. John Owen and other enlightened men, who strongly urged "the infinite contempt and reproach which would result from such treatment of a man whom all the learned, not of England only, but of all Europe, admired for his vast learning and accomplishments." All his attainments were devoted supremely to the work of biblical illustration. He contributed greatly to the completion of Walton's Polyglot; collated the Arabic Pentateuch; drew up an account of Arabic versions; contributed to the English Polyglot which appeared 1657; at the restoration he was restored, 1660, to the canonry of Christ church as originally annexed to the Hebrew professorship. In 1663 he published his translation of Abul-Faraj's compendium of the general history of the world from the creation to the end of the 13th c.; 1674, his Arabic translation of the church catechism and the English liturgy; 1677, his commentary on Micah and Malachi; 1685, on Hosea; 1691, on Joel. Of his learning, Hallam says that it was probably equal to that of any scholar whom Europe had produced. In person he was of middle height and slender; in conversation, free, affable, and facetious; in temper, modest, humble, and sincere; in beneficence, equaled by few.

POCOCKE, RICHARD, LL.D., 1704–65; b. Southampton, Eng.; graduated at Corpus Christi college, Oxford, 1731; traveled in the east in 1737–42; accompanied lord Chesterfield to Ireland as chaplain; was made archbishop of Dublin in 1745, bishop of Ossory in 1756, and transferred to the see of Meath in 1765. He published, in 1743–45, *A Description of the East and some other Countries*, with 179 drawings and maps, in 3 vols., and two years later the second volume of his travels, under the title of *Observations in Palestine, Syria, Mesopotamia, Cyprus, and Candia*. He was distinguished as a traveler for research, learning, and accuracy. He visited other parts besides the east, and described some remarkable objects in Scotland and Ireland. A French translation of his *Travels* appeared in Paris in 7 volumes. He contributed some papers to the philosophical *Transactions* and *Archæologia*.

POD. See LEGUME.

PODAGRA. See GOUT.

PODARGUS, a genus of birds of the family *caprimulgidæ*, nearly allied to the true goat-suckers (q.v.), but having no connecting membrane at the base of the toes, and the middle toe not pectinated. Some interesting species are natives of Australia, strictly nocturnal in their habits, and remarkable for the difficulty with which they are roused from their sleep by day. *P. humeralis* may be pushed off a branch, and seems scarcely to waken so as to save itself from falling to the ground; and if two are sitting together as is usually the case, one may be shot without its mate being much disturbed. But by night this bird is all activity.—Another species, *P. Cuvieri*, disturbs the night by a hoarse cry, resembling the syllables *more pork*, by which name it is therefore known in New South Wales.

PODESTA (Lat. *potestas*, power), an Italian municipal magistrate. The name was first applied to foreign magistrates with supreme authority, whom the emperor Frederick Barbarossa placed over the Italian towns on subjugating them. In the 13th and 14th centuries an officer bearing the same designation appears, at first occasionally, like the Roman dictator, afterward in most Italian cities as a permanent magistrate, appointed

either by the constituent parliament, or by the great council; he superseded all the ordinary magistrates, the military officers, and occasionally the judges. The cause of appointing such an officer was the jealousy that subsisted between the richer citizens and the nobles; the podestà was a stranger, generally belonging to the nobility, and prohibited, during his term of office, from forming any intimate connections in the city which he governed. His chief duty was the execution of summary justice on the lawless barons; and in the great Lombard towns he generally obtained a predominance for the citizens. Occasionally, however, the podesta became too strong for both parties, securing his re-election during a succession of years, and becoming the despotic ruler of the city.

Podestà is the name now given in many Italian towns to an inferior municipal judge.

PODGORITZA, a t. of Montenegro, in the district ceded to Montenegro by Turkey in terms of the treaty of Berlin. It is a fortified town, and has a population of about 7,500. Podgoritza is about 35 m. n. of Scutari.

PODICEPS. See GREBE.

PODIEBRAD AND KUNSTAT; **GEORGE BOCZKO OF**, son of Herant of Kunstat and Podiebrad, a powerful and influential Bohemian noble, of the Hussite party, was born in 1420. While still a youth he threw himself, with all the ardor and resolute force of his nature, into the Hussite struggles. Like the rest of his family, however, he adhered to the moderate party of the Hussites during the government of king Sigismund; but when, on the death of that monarch, the Catholic barons (1438) carried the election of Albrecht V. of Austria (II. of Germany), Podiebrad allied himself with the Utraquist orders in Tabor, and offered the sovereignty of Bohemia to Casimir, king of Poland. Albrecht immediately declared war against him, and invested Tabor, but was forced by Podiebrad to raise the siege and retire to Prague. From this time Podiebrad's influence was firmly established among the Utraquists; after Lipa, he was the first man of the party. When Albrecht died in 1439, Lipa was appointed regent during the minority of the new king Ladislas; but five years later Lipa himself died, and Podiebrad obtained the government of the country. He, however, was not satisfied. His ambition was to acquire the royal dignity. In 1449 he one night seized the capital, drove away all the Catholic barons, and even imprisoned his colleague in the regency, Meinhardt von Neuhaus. This outrage led to a year or so's fighting—the final result of which was that Podiebrad was acknowledged governor or regent by the whole of Bohemia. On the death of Ladislas in 1457, Podiebrad managed to get himself chosen his successor, and was crowned May 7, 1458. From this period he began to display the full power and strength of his administrative genius. He reorganized the forms of education and religion, and strove to bring about a peaceful settlement of the religious dissensions that had desolated the land. He even went the length of respectfully soliciting the papal co-operation in his humane endeavors; but his holiness would have no dealing with this Samaritan ruler, and in Dec., 1463, publicly proclaimed him a heretic. All the neighboring princes sent letters to Rome, exhorting or imploring the pope to moderation; but the only answer which Pius II. gave them was placing Podiebrad under the ban of the Vatican. Shortly after, Rudolf, the papal legate, excited the Catholics of Bohemia to insurrection. Podiebrad tried every means of conciliation, but in vain. In Sept., 1466, a German Catholic army burst into Bohemia, but this host of pseudo-crusaders was annihilated at Riesenberg. Once more Pius excommunicated Podiebrad; and in addition, he induced Mathias (q.v.) of Hungary to invade Moravia. The Bohemian king appealed to a universal council, but he also prepared to meet force with force. Summoning back from abroad the banished Taborite warriors, he crushed the insurrection, and compelled his enemies to grant him an advantageous armistice. In 1467 his son Victorin, on the renewal of hostilities, invaded and devastated Austria, while the Hungarians who had invaded Bohemia were surrounded at Vilemov, and forced to cease from hostilities. In spite of the magnanimity shown by Podiebrad on this occasion, Mathias acted falsely toward him, and in the following year had himself crowned king of Bohemia and markgraf of Moravia. Podiebrad instantly summoned the Bohemian diet, and proposed to the assembled orders that they should take the king of Poland as his successor, while his own sons should merely retain the family possessions. By this means he obtained the Poles for allies; the emperor Friedrich also declared in his favor, while his Catholic subjects were reconciled to him, so that the Hungarians found it advisable to conclude a peace. Podiebrad died March 22, 1471. His sons, Victorin and Henry of Münsterberg, fell back into the ranks of the Bohemian aristocracy; but in the stormy days that followed they rendered good service to their native land.

PO'DIUM, a pedestal continued horizontally, so as to form a low wall on which columns may be set. Like the pedestal, it has a base, die, and corona, all continued. When the podium breaks forward so as to form a pedestal for a column, it is called the stylobate.

PODOCARPUS, a genus of trees of the natural order *coniferae*, suborder *taxineae*, the order *taxaceae* of some botanists. The leaves, like those of the allied Ginkgo tree, have a remarkable resemblance to the fronds of ferns. The species are natives of New Zealand, the South Sea islands, and the Indian Archipelago. Some of them are valuable

timber trees. *Podocarpus cupressina* is one of the best timber trees of Java. It is found also throughout the neighboring islands and the South Sea islands. It is a beautiful tree, 50 to 80 ft. high, with spreading pendulous branches; the wood is yellowish, and takes a very fine polish. *P. totarra*, the TOTARRA or TOTARRA PINE, is the most valuable timber tree of New Zealand. It grows in the southern parts of New Zealand; and its trunk has been known to attain a diameter of fully 12 ft. Its wood is equal to the best Baltic pine in durability and for ship-building. The wood of *P. elatus*, the GAGALI of the Fijians, is peculiarly elastic.

PODO'LIA, or KAMINETZ, a government of West or "White" Russia, north of Bessarabia, and bordering on the Austrian frontier. Area, 16,170 sq.m.; pop. '80, 2,169,500. The surface is a table-land, strewn with hills, and containing many beautiful districts. Nearly three-fourths of Podolia is either arable or available for pasturage. Great quantities of corn and fruits, especially melons, are produced, and the fine climate is also favorable to the growth of the vine and mulberry. Hemp, flax, and tobacco are cultivated with success, and the rearing of bees is an important branch of industry. So rich and strong is the grass in the pastures or prairies, that the cattle, of which there are immense herds, can hide themselves from view in it. The population is composed of various races, who live together unmixed. The Russniaks (formerly "serfs"), make up the majority, and number over a million; next come the Cossacks; and then the Jews, who are almost all traders. The aristocracy are Poles; the officials and soldiery, Russians.

PODOPHTHAL'MA (Gr. stalk-eyed), a name often applied to a section or sub-class of crustaceans, part of the *malacostraca* of Cuvier, including the orders *decapoda* (crabs, lobsters, etc.) and *stomapoda* (shrimps, etc.). A distinguishing character, from which they derive their name, is their stalked and movable eyes. The stalks of the eyes are short in many, but very long in some, of which a beautiful example is presented by the sentinel crab of the Indian ocean.

PODOPHYL'LIN is the name commonly given to the resin obtained by means of rectified spirit from the root of *podophyllum peltatum*, or *May-apple*, a plant common throughout the United States. This resin, which occurs as a pale greenish amorphous powder, has (as well as the root from which it is derived) been introduced into the new British pharmacopœia, in consequence of the general favor which it has experienced during the last three or four years from the medical profession in this country. It is an active purgative, and seems to have the power of relieving the liver by exciting copious bilious discharges. As its activity seems to vary in different patients, it is better to begin with a small dose of half a grain, which may be combined with extract of henbane, with the view of preventing its griping. It is likely to prove one of the most valuable additions to our pharmacopœia.

PODOPHYL'LUM, a genus of plants variously ranked by botanists in the natural order *ranunculaceæ*, or made the type of a small distinct order, *podophylleæ*, or *podophyllaceæ*, differing from *ranunculaceæ* chiefly in having a solitary carpel. The genus *podophyllum* has 3 sepals, 6 to 9 petals, 12 to 18 stamens, a broad round stigma, seated almost on the top of the germen, and a many-seeded berry. *P. peltatum* is a perennial plant, with a solitary white flower in the axil of the two leaves; the fruit oval, an inch and a half long, smooth, yellowish, succulent, having a mawkish sweet and subacid taste. It is common in North America, growing in moist woods and on the shady banks of streams, and is known as *MAY-APPLE*, because it flowers and ripens its fruit very early in summer, also as *hog-apple* and *wild-lemon*. The fruit may be eaten, but is not agreeable. All the other parts are actively cathartic. See **PODOPHYLLIN**.

PODURA, a genus of small wingless insects of the order *thysanoura* (q.v.), having a linear or cylindrical body, a distinctly articulated thorax, rather long antennæ, and a long abdomen, terminating in a tail, which divides at its extremity into two branches. They bend the tail beneath the abdomen, and by suddenly extending it, make prodigious leaps. Hence their popular name, *SPRING-TAIL*. The species of this and allied genera are numerous, and some are found on plants, some under stones and in other damp places, some on the surface of stagnant waters. Their bodies are covered with scales, which are extremely interesting objects, and are among the favorite test-objects for the powers of microscopes.

POE, EDGAR ALLAN, perhaps the finest and most original poetical genius as yet produced by America, was b. at Boston, Feb. 19, 1809. His father, the son of gen. Poe, a distinguished officer in the revolutionary army, was educated for the law, but, falling in love with a beautiful English actress, he married her and went himself upon the stage. In a few years the youthful couple died within a very short time of each other of consumption, leaving three children entirely unprovided for. Edgar, the second child, was adopted by Mr. John Allan, a rich merchant, who had no children of his own. In 1816 the boy came to England with Mr. and Mrs. Allan, and was sent to a school at Stoke Newington. In 1821 he returned to America, and attended an academy at Richmond, Va. In 1826 he entered the university of Charlottesville, where he was a very successful student, but quitted it at the end of a year, deeply involved in debt, chiefly incurred through his strong passion for gaming. For a year or two he now remained quietly at

home; the story of his having gone to assist the Greeks in their heroic efforts to throw off the yoke of their Turkish oppressors has no other foundation than the fact that his elder brother, who had gone to sea, got into some trouble with the police at St. Petersburg, from which he was rescued by the American minister. In 1829 Poe published a volume of poems, his first known essay in literature, under the title of *Al Aaraaf, Tamerlane*, and other poems. He now expressed a wish to enter the army, and Mr. Allan exercised his influence to secure him a cadetship in the military academy at West Point. Here he grossly neglected his duties, drank to excess, and was finally cashiered on Mar. 6, 1831. In the same year he published an enlarged collection of his poems, dedicated to the U. S. corps of cadets. Upon leaving West Point, Poe returned to Richmond, and was kindly received by Mr. Allan, who had become a widower and married a second wife. It is related that Poe's conduct to this lady was such that Mr. Allan had to eject him from his house, but there is some reason to hope that this is mere calumny. It is certain, however, that Mr. Allan had some strong reason for displeasure with Poe, and at his death in 1834 he left him unmentioned in his will. Thus thrown upon his own resources, Poe devoted himself to literature as a profession. In 1833 the publisher of a Baltimore magazine having offered prizes for the best prose story and the best poem, Poe competed, and won both prizes. This led to his friendship with Mr. John P. Kennedy, one of the prize committee, who procured him literary employment in connection with the *Southern Literary Messenger* at Richmond. While here Poe married his cousin, Virginia Clemm, a beautiful and saintly creature, as destitute as himself, who died in 1848. In 1837 he removed to New York, where he lived by contributing to the *New York Quarterly Review* and other periodicals, and where in 1838 he published *The Narrative of Arthur Gordon Pym*. In 1839 he became editor of *The Gentleman's Magazine* at Philadelphia; and published a collection of his best stories with the title, *Tales of the Arabesque and Grotesque*. The next few years were spent in similar literary employment, chiefly at New York; the year 1845 being marked by the appearance of his famous poem *The Raven*, and 1848, by the publication of *Eureka, a Prose Poem*, in which he endeavored to elaborate a system of cosmogony.

In 1849 he went to Richmond, and it is said became engaged to a lady of considerable fortune. On Oct. 4 he left Richmond by train, which he quitted at Baltimore. Some hours later he was discovered insensible in the streets, and taken to the hospital, where he died on Oct. 7. The general belief that his death was caused by intoxication is emphatically denied by his physician, Dr. John J. Moran.

Scarcely any such dark and disastrous career as that of Poe has a place in all the sad records of genius. From the sins and aberrations of a creature so obviously abnormal, we need not seek to "point a moral." There is no doubt that Griswold in his life of Poe has been guilty of imputing to him a most exaggerated state of moral depravity. The assurance is given by those who best knew him, that the habits of at least his later life were temperate. There was about Poe a strange fascination; his friends loved him—those best who best knew him, and knew him in his wretchedest aberrations. By his wife and her mother he was regarded through all with an obstinacy of tender affection, not for an instant to be shaken.

Whatever may be thought of his morals, of his genius there will be little question. Slight in substance as for the most part it is, small in quantity, and in range limited, there is that in his poetry which ranks it above everything of this kind which his country has hitherto produced. Save for some traces of imitation in its earlier specimens, his verse is eminently a peculiar and individual product. In keen, clear, lyrical quality the music of Poe at his best is scarcely surpassed by that of any other poet. Many of his short prose tales are wildly and weirdly impressive, though too frequently indulging by morbid preference in ghastly and painful effects. Over very much that Poe has written, alike in prose and in verse, there broods a significant shadow of misery and hopeless portentous gloom. A much more favorable view than usual of Poe's character is taken by Mr. Ingram in the memoir accompanying his edition of Poe's works (4 vols., Edin., 1874); and Mr. Stoddard, in a memoir prefixed to a collection of his poems (New York and London, 1875), though not so favorable to his character as Ingram, shows him in a far better light than Griswold.

POE, ORLANDO M., b. Ohio, 1832; graduated at West Point with high honors in 1856, and entered the corps of topographical engineers. In 1861 he served for a time as chief engineer of the department of Ohio, and later was made col. of a Michigan regiment, and took part in the Potomac campaign. In 1862 he was made brig. gen. of vols., and had charge of the engineer department in Sherman's army, remaining with him until Johnston's surrender. He was made brevet brig.-gen. for gallant conduct. He was for a number of years secretary and member of the U. S. board of light-house commissioners, and had charge of the construction of the light-house at Spectacle Reef, lake Huron.

POË BIRD. See HONEY-EATER, *ante*.

POERIO, CARLO, a noble Italian patriot, was b. Dec. 10, 1803. His father, Giuseppe P., baron Belcastro, was also highly distinguished for his love of liberty and for his sufferings in her cause. Born at Belcastro, in Calabria, in 1775, he took part in the Neapolitan revolution of 1799, and suffered imprisonment on its suppression, but was released in 1802. He also took part in the revolution of 1820, for which Ferdinand handed him

over to the Austrians, who assigned him as a place of abode, first Grätz, in Styria, and afterward Florence. On the recall of the exiles by Ferdinand, in 1833, Poerio returned to Naples, where he spent the rest of his life, and died Aug. 15, 1843. He left two sons, the elder, Alessandro [born in 1802, celebrated as a poet and patriot, and died (of amputation of a limb) after the battle of Mestre, Oct. 27, 1848], and Carlo, the subject of our notice. Carlo was educated with great care under the parental roof, and trained even from infancy, by the example of his father and brother, to place the love of his country above every other affection. In 1828 he joined the liberals of Naples, and took part in the conspiracy of Avellino, for which he was imprisoned until Mar., 1838. He was concerned in the attempt made in 1847 to extort liberty, but was discovered, and after the movement at Reggio was sent back to prison with D' Ayala, Bozzelli, De Augustinis, Assanti, and others. The revolution in Sicily, which broke out at Palermo on Jan. 12, 1848, set him at liberty, and he immediately gave himself to the organization of the famous demonstration of Jan. 27, 1848, which was destined to produce the constitution of Feb. 10. Carlo was successively nominated director of police, and minister of public instruction; but he soon resigned, and also refused the rank of privy councilor, offered to him by Ferdinand. He was appointed deputy to the parliament.

On July 18, 1849, an unknown hand left in Poerio's house a note to the following effect: "Flee without a moment's delay. You are betrayed. Your correspondence with the marquis Dragonetti is in the hands of the government." As there had been no such correspondence, and as it was Poerio's wish to maintain the combat to the last on the ground of legality, he did not flee. On the following day he was arrested, and his house was ransacked. Six days after a letter of Dragonetti's was given him to read, in which he spoke of an invasion by Garibaldi, instigated by Mazzini and Palmerston. The letter was a forgery of the police! Poerio compared it with other authentic letters of Dragonetti, and proved it to have been forged. As the government could not bring him to trial on that pretext, it had recourse to a spy, Jervolino, who accused Poerio of being at the head of a sect—which never existed—called the Italian unity, which aimed at proclaiming a republic, and murdering the king and the ministers. Poerio demanded to be confronted with Jervolino, but this was refused. When this accusation also fell to the ground, Peccheneda, who was at the head of the police, tried to induce the others who were indicted for political reasons to denounce Poerio as a revolutionist, promising them liberty as the reward. His design partly succeeded. He extorted from Romeo the printer, and from Margherita some false accusations, which the fear of death caused those unfortunate persons to make. But they were of no avail, and recourse was again had to the accusation made against Poerio by Jervolino; and although Poerio brought forward many clear proofs that the informer was paid by the police to do him harm, the court paid no attention to that, nor to any other of his objections, and concluded by inflicting on him the penalty of passing 24 years in irons, and of a heavy fine.

Thus Carlo Poerio, a minister, and a member of parliament, a man of rare genius and of exemplary life, was cast into the hulks at Nisida, dressed as a felon, and dragging 15 pounds of chains; and thence, through the suspicions of the government, who dreaded his escape, he was conveyed from hulks to hulks, from Nisida to Procida, from Ischia to Montefusco, and finally to Montesarchio. Assassins and thieves were given him as companions in order to humble him, as if the virtue of the truly great man could be sullied by the presence of miscreants and cut-throats. He indignantly spurned the proposal to petition for his liberty.

The protests of the English and French diplomatists against the iniquitous state trials, which had been instituted in Naples with the sole object of condemning persons obnoxious to the king; the letters of Mr. Gladstone; the constant dread of a popular rising on behalf of the condemned political offenders, and especially of Poerio, disturbed the mind of Ferdinand II. to such a degree that he sought some means of ridding himself of the prisoners of Montesarchio. Having failed in every attempt to force them to ask pardon, he resolved to send them to America. On Jan. 19, 1859, Poerio and 66 other prisoners, among whom were Settembrini, Spaventa, Pica, the duke of Castromediano, Braico, Schiavoni, Argentino, Pace, Damis (all of whom became members of the Italian parliament), were conveyed to Pozzuoli, and put on board of the *Stromboli*, which immediately set sail for New York. When they reached Cadiz, Poerio and his companions were put on board an American vessel, the captain of which, however, was induced to land them at Cork, whence they returned, by London, to Turin. In the following year Poerio was elected deputy by two colleges in Tuscany, and took his seat in parliament.

When Garibaldi (q.v.) had driven out the Bourbon dynasty, Poerio returned to Naples. He declined the ministerial office offered to him by Cavour, and also the governorship of the southern provinces proposed to him by Constantino Nigra, but accepted the office of privy councilor. The privy council elected him its vice-president; then, being re-elected deputy, he was proclaimed vice-president of the parliament. He died in April, 1867.

POET-LAUREATE. See LAUREATE.

POETRY (from the Greek *poieo*, to make, or to create), according to the mere etymology of the word, signifies a creation or production of any kind; but its classical equivalent, *poiësis*, was applied by the Greeks almost exclusively to designate the artistic

productions of the imagination, expressed in language. Poetry is thus not necessarily associated—as many people seem to think—with verse or rhyme. It may find expression in prose, and in point of fact has often done so, both in ancient and modern times. The book of Ruth, for example, is decidedly poetical in substance, yet in form it is strictly prosaic. The same may be said in a still more remarkable degree of the book of Job and the prophetic writings, as they appear in our English version. Jeremy Taylor, Hooker, Rousseau, Burke, Carlyle, Ruskin, Hawthorne, Emerson, and other modern prose writers, are often as richly or profoundly imaginative as poets by profession; but although the essence of poetry lies rather in the nature and adornment of the thoughts expressed than in the form of the composition, yet in general it has subjected itself to certain rules of *meter* or measure, and often also to rules of *rhyme*. The reason of this practice lies in the fact that the music so produced by the mere words is found to heighten the emotions which their meaning is calculated to produce, and thus furthers the end that the poet has in view. It is from this circumstance that the term poetry has become almost synonymous with metrical composition. Poetical compositions are of several kinds or classes, to which particular terms are applicable; the principal are the epic (q.v.), the lyric (q.v.), and the drama (q.v.). To the first of these belongs the ballad (q.v.); to the second belong the song (q.v.) in all its varieties, serious and comic, the hymn (q.v.), ode (q.v.), anthem (q.v.), elegy (q.v.), sonnet (q.v.), etc.; the third embraces tragedy and comedy. Besides these three principal kinds others of less consequence may be mentioned, such as didactic poetry (q.v.), satirical poetry (see SATIRE), in which, however, imaginative and ideal elements in general mingle so sparingly that the stricter kind of critics exclude them from the circle of poetry altogether. The theory of poetry, or poetics (a branch of esthetics, q.v.), has been largely discussed in every cultivated language. Histories of the poetry of the several nations are numerous: Rosenkranz and Zimmermann have given us universal histories of poetry.

POEY, FELIPE, b. Havana, 1802; educated at Madrid, which he was compelled to leave on account of his connection with a political conspiracy. In 1837 he became a director of a natural history museum, which he had assisted in organizing, and soon afterward he was called to the chair of natural history in the university of Havana. He has published, among other works, *La Centurie des Lépidopteres*; *Geografía Universal*; and *Memorias sobre la Historia Fisico-natural de la Isla de Cuba*. His son ANDRES, b. Havana, 1827, is a meteorologist, and has been director of the Havana physico-meteorological observatory. He is also known as an advocate of the positive philosophy of Comte. Among his works are *Electrical Storms*, 1855, *Catalogue of Earthquakes in the West Indies*, 1858; and *Chronological Table of 400 Cyclones, etc.*, 1862. In the *Report of the Smithsonian Institution* for 1870 he proposed a new classification of clouds.

POGGE, *Aspidophorus Europæus*, a fish of the family *sclerogenidæ*, or *mailed cheeks*, and nearly allied to the bullhead (q.v.), but having the body cuirassed with large bony scales from the head to the tail fin, so that it is in form nearly a pyramid with eight faces. The head is thicker than the body, with points and depressions, the snout furnished with short recurved spines. The pogge is also known on the coast of England as the *armed bullhead*; and on the coasts of Scotland by the names *lyrie*, *pluck*, and *noble*. It is pretty common on the British coasts. It is seldom more than six inches long. Notwithstanding its uncouth appearance, its flesh is good.

POGGENDORF, JOHANN-CHRISTIAN, a German physicist, was born at Hamburg, Dec. 29, 1796. He studied pharmacy, chemistry, and physics; and was professor of physics at Berlin from 1834 till his death. In 1838 he became a member of the academy of sciences. His chief discoveries were in connection with electricity and galvanism, and these are reckoned of great value; he also invented a multiplying galvanometer for measuring the calorific action of currents. From 1824 onward he edited the *Annalen der Physik und Chemie*, contributing to this collection many important memoirs. He was one of the triad (Liebig and Wöhler being the other two) who prepared the *Dictionnaire de Chimie* (Brunswick, 1837-51). The two works published by himself are the *Linien zu einer Geschichte der exacten Wissenschaften* (Berlin, 1853), and *Biographisch-litterarisches Wörterbuch zur Geschichte der exacten Wissenschaften* (Leip. 1858-63, 2 vols.). Poggendorf died in Jan., 1877.

POGODIN, MIKHAIL PETROVITCH, b. Russia, 1800; professor at the Moscow university in 1833, but resigned in 1844 to pursue the study of archæology. His collection of Russian antiquities was bought by the government in 1852. He has written novels, histories, and a tragedy. He founded in 1867 a literary and political periodical called the *Russki*. He is an advocate of Pan-Slavism.

POGO'NIAS, a genus of acanthopterous fishes, of the family *sciænidæ*, having two dorsal fins, one of them deeply notched, and many small barbels under the mouth. The fishes of this genus are found on the coasts of warm countries; and are remarkable for sounds which they emit, which somewhat resemble those of a drum, and have obtained for them the name of DRUMFISH. It is not known how these sounds are produced; but sailors in vessels anchored near the shore, where species of this genus abound, are often prevented from sleeping, until they have become habituated to them. Some of the species attain a large size, one hundred pounds or more, and are excellent for the table.

POICTIERS, or **POITIERS**, a corruption of the Latin *Pictavium*, so called by the Gallic tribe, the *Pictavi*, who inhabited the district in Cæsar's time, is one of the oldest towns in France; it is the capital of the department of Vienne, and formerly of the province of Poitou. It occupies the summit and slopes of a little eminence, round the base of which flow the Clain and the Boivre, is encircled by walls and towers, and has a very dull appearance. Pop. 76, 31,692. It is connected by railway with Tours, from which it is 63 m. distant, and Bordeaux. Before the revolution, Poitiers had an immense number of churches, chapels, monasteries, and nunneries; even yet these are sufficiently numerous. The principal are the church of St. Jean (now converted into a *musée*), one of the oldest Christian monuments in France; and the cathedral of St. Pierre, one of the finest in France, belonging (in part) to the 12th c., and in which, or in the older edifice that occupied its site, 23 councils were held—the first in the 4th, and the last in the 15th century. It also contains the ashes of Richard cœur-de-leon. Its university, founded by Charles VII. in 1431, was also abolished after 1789, but its place has been supplied by a university-academy with two faculties. Poitiers possesses, besides, a very celebrated lyceum, and a variety of other educational institutions, a public library of 25,000 vols. and MSS., a museum, and several learned societies, of which the most distinguished is that for the cultivation of the antiquities of western France. In and around Poitiers are numerous Celtic and Roman remains. In the vicinity, Alaric II., the Visigoth, was defeated and slain by Clovis in 507. Somewhere between Poitiers and Tours a great battle took place in 732, between the Franks under Charles Martel (q.v.) and the Moors under Abd-ur-Rahmân. The Moors were routed with enormous slaughter—375,000 of them (according to one old exaggerating chronicler) being left dead on the field; later still (in 1356), at Maupertuis-le-Beauvois, about 5 n. of Poitiers, Edward the black prince, with some 12,000 or 14,000 Englishmen and Gascons, beat 60,000 of the troops of king Jean of France, and took the monarch himself and one of his sons prisoners.

POIN'DEXTER, **GEORGE**, 1779–1853; b. Va.; of Huguenot ancestry, and left an orphan in early childhood. Having studied law at Richmond and practiced successfully in Virginia, he removed to Mississippi 1802; was appointed attorney-general of the territory 1803; was its delegate to congress 1807–13; U. S. district judge 1813–17; a representative of the state in congress 1817–19; governor of the state 1819–21; practiced law exclusively 1821–31; U. S. senator 1831–35. He was involved in many personal and political quarrels, one of which led to a duel, in which he killed his adversary, Abijah Hunt, a leading merchant of the southwest. In this affair he was accused of unfairness, and was consequently forced into bitter and protracted disputes. While in the house of representatives, 1819, he made a speech in defense of gen. Jackson, which contributed greatly to the triumphant acquittal that followed. He did not vote with his party on the U. S. bank question, and brought on himself Jackson's bitter hostility by voting for the Clay resolution censuring the president. In 1835 he removed to Louisville, Ky., but returned soon after to Mississippi. He published a revised code of the laws of the state 1824.

POINDING (same root as Eng. *pound*), in the law of Scotland, means the seizing and selling of a debtor's goods under process of law, or under the warrant of a *debitum fundi*, in order to pay the debt. It is either real or personal. Real poinding is the attaching of goods or movables on the land over which some real or heritable security exists. It is one mode in which heritable security is made effectual. Thus the superior of lands can poind the ground to obtain payment of his feu duties; and the holder of a heritable bond can do the same in order to recover his debt. Personal poinding is the mode in which a decree of the court is made effectual by the messenger or bailiff seizing the movables of the debtor. They are then appraised or valued, and the messenger reports his execution to the sheriff, or other judge ordinary, who grants warrant to sell the goods by public roup after advertisements. The net amount of the sale is paid over to the creditor, or if no purchaser bid for them, they are delivered to the creditor at the appraised value. There is also another kind of poinding, called a poinding of stray cattle, which takes place whenever the cattle of a stranger trespass on lands, in which case the owner or occupier of the lands can seize them *brevi manu*, and keep them as a security until the damage done by the cattle is paid to the owner of the land. By an old Scotch statute the owner of the cattle is bound to pay, besides the damage, half a merk for each head of cattle; and for the damage, penalty, and expense of keeping the cattle, the owner of the land can detain the cattle until payment. The poinder must, however, take care to keep the cattle in a proper place, and feed them. In England the word poinding is not used, the corresponding term being distraining, or distress (q.v.).

POINSETT, a co. in n.e. Arkansas, bounded on the e. by the St. Francis river, and lake St. Francis, drained also by L'Anguille and other rivers; about 500 sq. m; pop. '80, 2,192—290 colored. The surface is level, with much wood-land. The soil is fertile. The principal productions are cotton and corn. Co. seat, Harrisburg.

POINSETT, **JOEL ROBERTS**, LL.D., 1779–1851; b. Charleston, S. C.; educated in Connecticut under president Dwight. He made a tour through Europe and Asia, studied medicine and military science, and on his return in 1809 was sent by president

Madison on a mission to South America to inquire into the condition of the Spanish provinces, then in revolt. He established commercial relations between this country and Buenos Ayres, and went across the continent to Chili. There with the assistance of a band of Chilians he re-captured from the Spanish authorities of Peru 10 American whale-ships which they had seized during an invasion of Chili. Returning to South Carolina he entered the state legislature, and was a member of congress 1821-25. He went on a mission to Mexico in 1822, and was minister to that country 1825-59. On his return he opposed nullification, and became the leader of the union party in South Carolina. He was secretary of war in Van Buren's cabinet. He afterward opposed the Mexican war. He founded an academy of fine arts at Charleston, and gave a museum to the Smithsonian institution.

POINT, in heraldry, a triangular figure issuing from the dexter and sinister base of the shield. It is common in French and German heraldry, and occurs in the shield of Hanover, which was a part of the royal arms of Great Britain from the accession of George I. till that of our present sovereign. A shield charged with a point is in heraldic drawing hardly distinguishable from one parted per chevron.

POINT-A-PITRE, a t. of the French West India island Gaudeloupe, capital of the division of Grande-Terre, on the Little Cul-de-Sac, 20 m. n.e. of Basse-Terre. The town is well built, and has a safe and spacious harbor. It is the center of the commerce of the colony. Pop. 14,000.

POINT-BLANK. See GUNNERY. The point-blank range of a cannon varies from 200 to 300 yards.

POINT DE GALLE, a fortified t. and sea-port on the s.w. extremity of the island of Ceylon, stands on a low rocky promontory of the same name, in lat. $6^{\circ} 1'$ n., long. $80^{\circ} 12'$ east. The harbor, formed by a small bay, the entrance to which is about a mile in width, is good, although there are numerous rocks, and a pilot is required to conduct vessels to the anchorage. Among the principal edifices are the fort—a mile in circumference—the old Dutch church, a Roman Catholic chapel, an excellent orphan asylum, barracks, and light-house, 103 ft. above sea level. This town has become important within recent years, and specially since the organization of the Peninsular and Oriental steam-navigation company. Vessels plying between Suez and Bombay and Calcutta, Australia, China, Penang, and Singapore, call here to coal and to tranship passengers. It is the seat of government of the southern province of the colony of Ceylon. Gold and silver ornaments, workboxes, etc., are made with great taste and nicety by the native workmen. Pop. '71, 47,954.

POINTE COUPÉE, a parish in central Louisiana, bounded on the e. by the Mississippi, on the w. by Atchafalaya bayou; about 600 sq.m.; pop. '80, 17,799—13,017 colored. The surface is even and low, frequently inundated, and well wooded. The soil is fertile. Corn, sugar, and cotton are the principal productions. Co. seat, Point Coupée.

POINTED ARCHITECTURE. See GOTHIC ARCHITECTURE.

POINTER, a kind of dog nearly allied to the true hounds (q. v.), but not reckoned one of them. It is remarkable for its habit of *pointing* at game; its whole body, and particularly its head, indicating the position of the game to the sportsman; and a well-trained pointer will remain long immovable in the attitude of pointing, not going forward to disturb the game which its exquisite power of scent has enabled it to discover. It is recorded of two pointers that they stood an hour and a quarter without moving, whilst Mr. Gilpin painted them in the act. The pointer, when he scents game, stops so suddenly and completely, that even the fore-foot, already lifted, remains suspended in the air. Without the pointer, the sportsman would have comparatively little success in the pursuit of grouse; but the dog performs for him the laborious task of "beating" the wide moors. Well-trained pointers will scarcely point at anything except "game;" but inferior dogs often point at almost any living creature the odor of which affects their nostrils. The habit of pointing, once acquired, appears to become hereditary, so that very young pointers often exhibit it in great perfection. It has been explained, with the crouching of the setter, as "the natural start of surprise or interest which all dogs give when coming suddenly upon the scent or sight of their natural prey; modified by cultivation, and by transmission through many generations, each, by education, improving upon the capabilities of the former."—See Bell's *British Quadrupeds*.

The breed of pointers now most common in Britain is believed to be crossed with the fox-hound, to which there is considerable resemblance in colors as well as in form. The figure is very muscular, the hair short, the ears pendulous, the upper lips moderately large, the tail pointed and destitute of brush. Dogs of this breed are very active, and capable of long-sustained exertion. The original breed, the *Spanish pointer*, probably brought to Spain from the e., is of more bulky form, less active habit, and less capability of continued exertion. The pointer is very forward and familiar in its manners, but is both affectionate and intelligent, although it has a reputation of inferiority in these respects to many other kinds of dogs.

POINT LEVI. See LÉVIS.

POINT PLEASANT, BATTLE OF, Oct. 10, 1774, between colonial troops of Virginia under gen. Andrew Lewis, and the Shuwanees, Delawares, and other Indians of the northern confederacy, led by Cornstalk as sachem of the Shuwanee tribe. Its field was on the e. bank of the Ohio river, just above its junction with the Great Kanawha. The village of Point Pleasant has since grown up on the spot where this battle was fought; and in the region the battle has always been spoken of as the first in the revolution. Lord Dunmore, governor of Virginia, had been busy in the interests of England, in stirring up a hostile feeling between the white settlers and the various tribes of Indians, the object of which had become apparent. At last a crisis was reached. The legislature took action, under which gen. Andrew Lewis gathered together 1200 men at Lewis Spring, now Lewisburg, W. Va., and proceeded to Point Pleasant, acting, as was understood, in concert with the colonial governor, who, in person, led about 1000 men through the wilderness, striking the Ohio at Wheeling, from which point he was to meet gen. Lewis. All this time, unknown to gen. Lewis, the agents of lord Dunmore had been busy concentrating the Indians in the neighborhood of Point Pleasant, and subsequent events indicate that he never intended to join his force with the troops under Lewis.

In this bloody battle about one-fifth of the entire army of gen. Lewis were either killed or wounded, and of the Indians the number must have been even greater. It was fought, on both sides, from behind trees, in a dense forest of primeval growth on one of the richest bottoms of the Ohio. It was wholly unexpected—the object being, on the part of gen. Lewis, in fulfillment of the purposes of the legislature, to proceed with an overpowering force in conjunction with governor Dunmore from Point Pleasant, to the Indian settlements on the Scioto beyond the Ohio. In vain did the brave Lewis look for the troops from Wheeling. During the night of the 9th and 10th, a body of Indians was reported by a scouting party as having encamped near the site of an old Shuwanee village about 6 m. above. At the same time advices were received that lord Dunmore would cross the country direct to the Scioto. Before sunrise on the morning of the 10th a hunting party returned and brought the startling report of a large body of Indians about a mile above the camp of gen. Lewis. The party had been fired upon. At once, on receipt of this news, the main body of the troops under col. Charles Lewis and col. Fleming, were mustered into line. The battle, which soon began, raged with varied fortune through nearly the entire day. The brave col. Lewis fell mortally wounded. Col. Fleming was soon after disabled, when col. Field, who had come up with a re-enforcement, took command. This officer had learned a lesson under the unfortunate Braddock; but he, too, soon fell. At times the battle raged like a tempest. The roar of musketry was continuous. The clarion voice of Cornstalk was nevertheless everywhere heard bidding his warriors “be strong!” “be strong!” Seeing a warrior shrink he sunk his tomahawk into his skull. Late in the afternoon three companies under capt. John Stewart, Isaac Shelby, and George Matthews, that had been detained in camp, perhaps on account of Indians in large numbers on the opposite shore of the Ohio, reached the rear of Cornstalk by a well-planned movement, and decided the fortunes of the day.

POINTS OF THE ESCUTCHEON, in heraldry. In order to facilitate the description of a coat-of-arms, it is the practice to suppose the shield to be divided into nine points, which are known by the following names: A, the dexter chief point; B, the middle chief; C, the sinister chief; D, the collar or honor point; E, the fess point; F, the nombril, or navel point; G, the dexter base point; H, the middle base point; and I, the sinister base point. The dexter and sinister sides of the shield are so called, not in relation to the eye of the spectator, but from the right and left sides of the supposed bearer of the shield.

Points of the
Escutcheon.

POISONING, SECRET, a mode of taking away life by poisons so slow in their operation that the gradual sinking of the victims under their influence closely resembled the effects of disease or the ordinary decay of nature. It has been practiced in all ages, and several undoubted and numerous supposed instances of it are mentioned by Greek and Roman writers. It was not, however, till the 17th c. that this atrocious practice became of frequent occurrence; but from this time it rapidly increased, spread over western Europe like an epidemic, and became gradually a regular branch of education among those who professed a knowledge of chemistry, magic, or astrology. These persons regarded the knowledge of the mode of preparing secret poisons as of the highest importance, and many of them realized large sums by the sale of their preparations, and occasionally of the secret of their composition. It was in Italy and France that this art was chiefly practiced and brought to the highest perfection; but it seems also to have prevailed in England to a considerable extent, for we find that in the 21st year of Henry VIII.'s reign an act was passed declaring the employment of secret poisons to be high treason, and sentencing those who were found guilty of it to be boiled to death. The only undoubted instance of this crime which appears prominently in English history is the murder of sir Thomas Overbury (q. v.) by viscount Rochester (the favorite minion of James VI.) and his wife, the divorced countess of Essex; though many suppose, and with some show of proba-

bility, that James VI. himself was a victim to similar nefarious practices on the part of Villiers, duke of Buckingham; and undoubtedly such was the popular impression at the time, for Dr. Lamb, a conjurer and quack, who was believed to have furnished Buckingham with the poisons, was seized by the angry populace in Wood street, Cheapside, London, and beaten and stoned to death. But it was in Italy where this mode of poisoning was most prevalent. There, judging from the writings of various authors, it seems to have been looked upon as a not unjustifiable proceeding to get rid of a rival or enemy by poison; and from the time of the Lombard invasion down to the 17th c. Italian history teems with instances which sufficiently show that poison was both the favorite weapon of the oppressor, and the protection or revenge of the oppressed. The Borgias are generally singled out and held up to the horror and detestation of mankind; but as far as their poisonings are concerned, they merely employed this method of destroying their adversaries a little more frequently than their neighbors. To show the popular feeling on this subject, we may instance the case mentioned in the memoirs of Henry II., fifth duke of Guise, of a soldier who was requested to rid the duke of Genaro Annese, one of his opponents in Naples. *Assassination* was the mode proposed to the soldier, but he shrank with horror from the suggestion, stating at the same time that he was quite willing to *poison* Annese. It was shortly after the date of this story (1648) that secret poisoning became so frequent; and the Catholic clergy, despite the rules of the confessional, felt themselves bound to acquaint pope Alexander VII. with the extent of the practice. On investigation it was found that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages were speedily dissolved by the sickness and death of the husband; and further inquiries resulted in the discovery of a secret society of young matrons, which met at the house of an old hag, by name Hieronyma Spara, a reputed witch and fortune teller, who supplied those of them who wished to resent the infidelities of their husbands, with a slow poison, clear, tasteless, and limpid, and of strength sufficient to destroy life in the course of a day, week, month, or number of months, as the purchaser preferred. The ladies of Rome had been long acquainted with the "wonderful elixir" compounded by La Spara; but they kept the secret so well, and made such effectual use of their knowledge, that it was only after several years, during which a large number of unsuspected victims had perished, and even then through a cunning artifice of the police, that the whole proceedings were brought to light. La Spara and thirteen of her companions were hanged, a large number of the culprits were whipped half-naked through the streets of Rome, and some of the highest rank suffered fines and banishment. About half a century afterward the discovery was made of a similar organization at Naples, headed by an old woman of three-score and ten, named Toffania, who manufactured a poison similar to that of La Spara, and sold it extensively in Naples under the name of *acquetta*, and even sent it to all parts of Italy under the name of "mauna of St. Nicola of Bari," giving it the same name as the renowned miraculous oil of St. Nicola, to elude discovery. This poison, now best known as the "acqua Tofana" or "acqua di Perugia," is said by Hahnemann to have been compounded of arsenical neutral salts; while Garelli states that it was crystallized arsenic dissolved in a large quantity of water; but both agree that it produced its effect almost imperceptibly, by gradually weakening the appetite and respiratory organs. After having directly or indirectly caused the death of more than 600 persons, Toffania was at length seized, tried, and strangled in 1719. From this time the mania for secret poisoning gradually died away in Italy.

About the middle of the 17 c, this horrible practice seems to have first become prevalent in France, and under similar circumstances, the agents being married women, and their husbands the victims; and as in Italy, the extent to which the practice was carried was first made known by the clergy. The government, acting on the information thus obtained, seized and imprisoned in the Bastille two Italians named Exili and Glaser, who were suspected of having been the manufacturers and venders of the poisons. Glaser died in prison: but Exili, becoming acquainted with another prisoner named St. Croix, communicated to him his secret, which the latter made considerable use of after his release, compounding in particular the poison known as "succession powder," which subsequently became so celebrated. It was the same St. Croix who played such a prominent part in the tragical history of the marquise de Brinvilliers (q.v.). Penautier, the treasurer of the province of Languedoc, and the cardinal de Bonzy, were both pupils of St. Croix, and managed, the one to pave the way for his own advancement, and the other to rid himself of his numerous creditors, by the administration of poison; but the great influence of these men, and the want of direct evidence, barred all proceedings against them. Secret poisoning now became fashionable; the passions of jealousy, revenge, avarice, and even petty spite, were all satisfied in the same way, and as a necessary consequence, other offenses decreased in proportion. The prisons teemed with suspected criminals, and the "chambre ardente" was instituted for the special purpose of trying these offenders. In Paris, this trade was chiefly in the hands of two women named Lavoisin and Lavigoreux, who combined with the ostensible occupation of midwife that of fortune-teller, and foretold to wives the decease of their husbands, to needy heirs that of their rich relatives, taking care at the same time to be instrumental in fulfilling their own predictions. Their houses were frequented by numbers of all classes, both from Paris and the provinces, among whom were the celebrated marshal de Lux-

embourg (q. v.), the duchess de Bouillon, and the countess de Soissons; the two former of these, however, went merely from curiosity. Lavoisin and her confederate were at last discovered, tried, condemned, and burned alive in the Place de Grève, Feb. 22, 1680; and from 30 to 50 of their accomplices were hanged in various cities of France. So common had this atrocious practice been, that madame de Sévigné, in one of her letters, expresses a fear lest the terms "Frenchman" and "poisoner" should become synonymous. For two years after the execution of the two Parisian poisoners, the crime continued to be largely committed, being fostered by the impunity with which offenders of high rank were allowed to escape; and it was not till more than 100 persons had died at the stake or on the gallows, that the government succeeded in suppressing it. The mania for secret poisoning has not since been revived to the same extent, though isolated instances of its practice have occasionally been discovered, particularly in England, where, within the last 40 years, very extraordinary disclosures have at different times been made of the prevalence of this frightful crime among the laboring classes in several of the rural districts. For further information consult Beekmann's *History of Inventions*, the historians of the period of James I.'s reign, the French *Causes Celebres*, and Mackay's *Popular Delusions*.

POISONS. A poison is commonly defined to be a substance which, when administered in small quantity, is capable of acting deleteriously on the body; but this definition is obviously too restricted, for it would exclude numerous substances which are only poisonous when administered in large doses, as niter, and the salts of lead, antimony, etc. A person may be as effectually poisoned by an ounce of niter as by five grains of arsenic, and hence the quantity required to kill must not enter into the definition. Dr. Taylor suggests the following as the most comprehensive definition that can be given: "A poison is a substance which, when taken internally, is capable of destroying life without acting medicinally on the system;" but this definition is not perfect, for it does not include poisons that act by absorption when applied to a thin and delicate membrane, as glanders, syphilitic poison, etc., or those which must be introduced directly into the circulation by a puncture or abraded surface, as the poison of insects, scorpions, and serpents, the wourali poison, and that of animals suffering from hydrophobia. Omitting, for the present, the consideration of the cases not included in Dr. Taylor's proposed definition, we may consider poisons as divisible into three classes, according to their mode of action on the system—viz., *irritants*, *narcotics* and *narcotico-irritants*.

The *irritants*, when taken in ordinary doses, speedily occasion intense vomiting and purging, and severe abdominal pain. They act chiefly on the stomach and intestines, which they irritate, inflame, and frequently corrode, and may thus occasion ulceration, perforation, or gangrene. Among those which possess corrosive properties, are the strong mineral acids, caustic alkalies, corrosive sublimate, etc.; while among the pure irritants which exert no destructive chemical action on the tissues with which they come in contact, may be mentioned arsenic, cantharides, carbonate of lead, etc. The *narcotics* act specially on the brain and spinal cord. Among their most common symptoms are giddiness, headache, obscurity of sight or double vision, stupor, loss of power of the voluntary muscles, convulsions, and, finally, complete coma. Moreover, many of the narcotic poisons present special symptoms, in some cases strongly resembling pure special diseases. Thus there is an almost exact similarity in the symptoms of poisoning by opium and of apoplexy, while prussic acid and some other poisons give rise to symptoms closely resembling those of epilepsy. These poisons have no acrid, burning taste, nor do they usually give rise to vomiting or diarrhea, and, excepting a slight fullness of the cerebral vessels, they leave no well-marked *post mortem* appearance. They are few in number, and none of them belong to the mineral kingdom. The *narcotico-irritants* have, as their name implies, a mixed action. "At variable periods," says Dr. Taylor, "after they have been swallowed, they give rise to vomiting and purging, like irritants, and soon or later produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. They possess the property, like irritants, of irritating and inflaming the alimentary canal. As familiar examples, we may point to nux vomica, monkshood, and poisonous mushrooms. . . . The fact of the symptoms occurring after a meal at which some suspicious vegetables may have been eaten, coupled with the nature of the symptoms themselves, will commonly indicate the class to which the poison belongs. Some narcotico-irritants have a hot, acrid taste, such as the aconite or monkshood; others an intensely bitter taste, as nux vomica and its alkaloid strychnia."

For a notice of the most important rules to be observed by the physician in all cases of suspected poisoning, both with respect to the symptoms and to the inspection of the body, we must refer to any of the standard works on poisoning, or on medical jurisprudence.

Under the head of *irritant poisons* may be included, (1) mineral acids, as sulphuric, nitric, and hydrochloric acids; vegetable acids, and other salts, as oxalic acid, bin-oxalate of potash, and tartaric acid (in doses of half an ounce or more); the alkalies, as pearl-ash (carbonate of potash), soap lyes (carbonate of soda), ammonia and its sesquicarbonate; and metallic compounds, as white arsenic (arsenious acid); yellow arsenic (orpiment), corrosive sublimate, bichloride of mercury, pernitrate and other salts of this metal, acetate of lead (sugar of lead) in doses of an ounce and upward, carbonate of

Poisons.

lead (white lead), sulphate of copper (blue vitriol) subacetate of copper (verdigris), arsenite of copper (commonly known as *Scheele's green* or *emerald green*, and much employed under the name of *extract of spinach* for coloring confectionary), tartarized antimony, chloride of antimony (butter of antimony), chloride of zinc (sir W. Burnett's fluid), nitrate of silver (lunar caustic), sulphate of iron (copperas and green vitriol), and bichromate of potash. (2.) Vegetable substances, viz., colocynth and gamboge in large doses, savin, croton oil, the leaves and flowers of the common elder (*Sambucus nigra*), etc. (3.) Animal substances, such as cantharides, to which must be added the occasional cases in which sausages, and certain fish and mollusks, usually quite innocuous, act as irritant poisons.

The *narcotic poisons* include opium, hydrocyanic (or prussic) acid, oil of bitter almonds, cyanide of potassium, henbane, especially the seeds, alcohol, ether, chloral, and chloroform; while *narcotico-irritant poisons* are nux vomica, meadow saffron (*colchicum*), white hellebore, foxglove, common hemlock, water hemlock, (*cicuta virosa*), hemlock water-dropwort (*anranthe crocata*), fool's parsley, thorn-apple, monkshood or wolf's bane, deadly nightshade, tobacco, Indian tobacco (*lobelia inflata*), the bark and seeds of the common laburnum, the berries and leaves of the yew-tree, and certain kinds of fungi.

The cases in which there are antidotes qualified to neutralize chemically the action of the poison are few in number. For the *mineral acids* we must prescribe chalk or magnesia in water, with the view of neutralizing them, after which milk should be given freely. The *alkalies and their carbonates* must be neutralized by vinegar and water, or lemon-juice mixed with water, after which milk should be given. For *oxalic acid* the antidote is chalk or magnesia in water, by which an insoluble oxalate of lime or magnesia is formed. For *arsenic*, the hydrated peroxide of iron has been regarded as an antidote, but its efficacy is doubtful. Vomiting should be excited by the administration of a scruple of sulphate of zinc in warm water, and after the stomach has been well cleared out, demulcent fluids, such as flour and water or milk should be given. *Corrosive sublimate* combines with albumen (white of egg), and forms an insoluble inert mass; *nitrate of silver* is neutralized by chloride of sodium (common salt) dissolved in water; *tartarized antimony* is to a great degree rendered inert by the administration of decoction of bark or gall-nuts; and *acetate of lead* is rendered inert by the administration of sulphate of magnesia, which converts it into an insoluble sulphate of lead. In all cases of suspected poisoning, in which the nature of the poison is not known, the safest course is at once to produce vomiting by sulphate of zinc, or in its absence by a dessert-spoonful of flour of mustard suspended in tepid water, and to continue the vomiting till all the contents of the stomach are discharged, after which milk should be given freely.

Most of the known gases—except hydrogen, nitrogen, and oxygen—have a poisonous action when inhaled into the lungs; but in these cases death, if it ensues, is popularly said to be due to *suffocation*, although strictly speaking a person who dies from the effect of carbonic acid, or sulphureted hydrogen, or of any other noxious gas, is in reality just as much poisoned as if he had taken oxalic acid or arsenic. *Carbonic acid* (q.v.), although seldom employed as an instrument of murder, is a frequent cause of accidental death, and in France is a common means of self-destruction. It is established by numerous experiments that air containing more than *one-tenth* of its volume of carbonic acid, will, if inhaled, destroy life in man and the higher animals. In its pure state it cannot be inhaled, because its contact with the larynx causes spasmodic contraction of the glottis; but when diluted with two or more volumes of air, it can be breathed, and produces symptoms of vertigo and somnolency; and so great a loss of muscular power, that the individual, if in an erect or sitting position, falls as if struck to the ground. The respiration, which at first is difficult and stertorous, becomes suspended. The action of the heart is at first violent, but soon ceases, sensibility is lost, and the person now falls into a comatose or death-like state. Those who have been resuscitated usually feel pain in the head and general soreness of the body for some days and in a few severe cases, paralysis of the muscles of the face has remained. As a winter seldom passes without several deaths being recorded from coal or charcoal being employed as fuel in ill-ventilated rooms (often without any kind of chimney), it is expedient that every one should know what is to be done in such an emergency. The patient must, of course, be at once removed from the poisonous atmosphere, after which artificial respiration should be had recourse to. If the skin is warm, cold water may be poured on the head and spine; while if the surface be cold, a warm bath should be employed. When respiration is re-established, venesection will often relieve the congestion of the vessels of the brain. The inhalation of oxygen gas is said to have been of service in these cases. *Carbonic oxide*, which exists largely in coal gas, is at least as active a poison as carbonic acid, and is doubtless the principal cause of the effects produced by the inhalation of diluted gas. Both carbonic acid and carbonic oxide act as powerful narcotic poisons. *Sulphureted hydrogen*, which occurs abundantly in foul drains, sewers, cess-pools, etc., is a gaseous poison whose effects are often noticed. Nothing certain is known of the smallest proportion of this gas required to destroy human life; but air containing only one eight-hundredth of its volume of this gas will destroy a dog; and when the gas exists in the proportion of one two-hundred-and-fiftieth, it will kill a horse. Dr. Taylor states that the men who were engaged in the construction of the Thames

tunnel suffered severely from the presence of this gas, which was probably derived from the action of the water on the iron pyrites in clay, and which issued in sudden bursts from the walls. By respiring this atmosphere, the strongest and most robust men were in the course of a few months reduced to an extreme state of exhaustion, and several died. The symptoms with which they were first effected were giddiness, sickness, and general debility; they became emaciated, and fell into a state of low fever accompanied by delirium. In this case the dilution was extreme; when the gas is breathed in a more concentrated form, the person speedily falls, apparently lifeless. It appears to act as a narcotic poison when concentrated; but like a narcotico-irritant when much diluted with air.

The action of the vapor of *hydrosulphate of ammonia*, which is also commonly present in cesspools, etc., is probably much the same as that of sulphureted hydrogen. The experiments of Dr. Herbert Barker show, however, that these matters do not produce similar symptoms on dogs (*On Malaria and Miasmata*, p. 212).

Many of the gases, which are only found as products of the laboratory, are in the highest degree poisonous, as arseniureted hydrogen, cacodyl, etc.; but as few persons run the risk of inspiring them, it is unnecessary to enter into any details regarding them.

We now turn to the consideration of the poisons not included in the definition, which, for want of a better, we have adopted. The poisons that may affect the body by direct introduction into the circulation, through a puncture or abrasion, may be derived from the mineral, the vegetable, or the animal kingdom; but, with a few exceptions (as, for example, wourali poison, q.v.), the poisons derived from the mineral and vegetable kingdoms would act as efficiently if introduced into the stomach as if injected into the circulating blood; while the animal poisons act only by direct introduction into the blood, and are inert when introduced into the stomach. Poisoned wounds derived from the dissection of recently dead bodies, commonly known as *dissecting wounds*, are occasionally attended with most alarming symptoms, and often terminate fatally. In the case of Dr. Pett, quoted by Travers in his work *On Constitutional Irritation*, the symptoms on the third day were "a haggard and depressed countenance; violent shiverings, followed by some degree of heat; extreme alteration in appearance; countenance suffused with redness; the eyes hollow and ferrety; some difficulty of breathing, which was sudden, irregular, and amounting almost to sighing; excessive torpor, and the whole aspect resembling one who had taken an overdose of opium: on the following day there was extreme exhaustion and feebleness, and death ensued on the fifth day." The symptoms produced by the bites and stings of insects, arachnidans, and serpents, and the treatment that should be adopted, are described in the article VENOMOUS ANIMALS, BITES AND STINGS OF. The poisoned wounds derived from diseased animals are sufficiently discussed in the articles GLANDERS and HYDROPHOBIA.

In point of law, the use of poison to kill or injure a human being or certain animals, renders the poisoner amenable to the criminal courts. With regard to the sale of poisons, the legislature found it necessary to put some restrictions on one description—viz., arsenic—in order to prevent persons obtaining it with facility, and in such a manner as to avoid detection. The 14 and 15 Vic. c. 13, requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, and later acts apply this rule to other poisons. It is not to be sold to one who is unknown to the vender unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of $\frac{1}{2}$ oz. of soot or indigo to the pound. All the boxes, bottles, etc., must be labeled "poison." Those who offend as to arsenic incur a penalty of £20; but, in ordinary prescriptions, poisons may be used in the ordinary way by duly qualified medical practitioners. As to the restriction on the sale of other poisons, see CHEMIST. The offenses committed by those who administer poisons to mankind are as follows: Whoever causes death by poison commits murder, for the means are immaterial if the death was caused by such means with a felonious intent. Where death is not caused, nevertheless whoever administers poison, or causes it to be administered to any person, with intent to commit murder is guilty of felony, and is liable to penal servitude for life, or for not less than 3 years. Moreover, whoever attempts to administer poison, or other destructive thing, to any person with intent to commit murder, is guilty of felony, and is punishable in the same way. These offenses are committed whether the poison administered, or attempted to be administered, does injury or not; and it is a sufficient committing of the offense if the poison is put in such a place that a party was likely, and was intended to take it. Moreover, even though murder was not intended, but merely an intent to endanger life or inflict grievous bodily harm, still the offense is felony, and is punishable by penal servitude varying from 3 to 10 years. There is also a similar punishment for the attempt to administer any stupefying drug. Not only is it a crime to administer, or attempt to administer poison to human beings, but if cattle are maliciously killed by poison, the offense is felony, punishable by penal servitude of from 3 to 14 years. So to kill by poison any dog, bird, beast, or other animal, ordinarily kept in a state of confinement, is an offense punishable by justices of the peace with imprisonment for 6 months, or a fine of £20 over and above the injury done. If any person lay poison on lands to kill game, he incurs a penalty of £10. And though tenants of farms, when entitled to kill the

game on the estate, may kill hares without having taken out any game certificate, yet they are prohibited from killing such hares by poison. Moreover, by a recent act, 26 and 27 Vic. c. 113, extending to the United Kingdom, whoever sells, or offers to sell poisoned grain, seed, or meal, incurs a penalty of £10. Whoever sows, lays, or puts on ground such poisoned grain incurs a like penalty. The use of poisoned flesh is also prohibited. But the sale or use of any solution, material, or ingredient for dressing, protecting, or preparing any grain or seed for agricultural use only, if used *bonâ fide*, is not interfered with. See PTOMAINES.

POISON UDER, **POISON IVY**, **POISON OAKS**, **POISON SUMACH**, and **POISON VINE**. See **SUMACH**.

POISSON, SIMEON-DENIS, a celebrated French geometer, was b. at Pithiviers, in the dep. of Loiret, June 21, 1781; and displaying an aptitude for mathematics, he was received into the école polytechnique in 1798. The striking talent he thus early exhibited attracted the notice of Lagrange and Laplace, both of whom anticipated for him a brilliant future. In 1802 he became a professor in the polytechnique; in 1808 a member of the bureau des longitudes; in 1809 professor of mechanics to the faculty of sciences; member of the institute in 1812, etc.; and this list of distinctions was crowned in 1837 by his elevation to the dignity of a peer of France. He died in 1840. Poisson's whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 memoirs, inserted in the publications of the école polytechnique, of the academy of sciences, and other scientific journals. A complete summary of these labors by Poisson himself is published by Arago (*Notices Biographiques*, vol. ii.). Of the separate treatises published by Poisson, the following are the chief: *Traité de Mécanique* (2 vols., 1833); *Nouvelle Théorie de l'Action Capillaire*; *Théorie Mathématique de la Chaleur* (1835); *Mémoire sur le Mouvement des Projectiles dans l'Air, en ayant égard à la Rotation de la Terre* (1839); and lastly, the celebrated work, *Sur l'Invariabilité des Moyens Mouvements des grands Axes Planétaires*. Poisson is fairly considered one of the chief founders of the science of mathematical physics, which was brought by him to great perfection, especially in what concerns statical electricity and magnetism. Many other ingenious discoveries and speculations are dispersed throughout his writings.

POITEVIN, AUGUSTE, 1819-73; b. France; studied sculpture at Paris. His first work of value was "The Devotion of Viola," exhibited in 1846. Among his other works are two statues called "The Renaissance" and "Greek Art," executed for the Amiens museum. A number of symbolical groups in the Louvre, some fine busts, and the group called "Judith."

POITIERS. See **POICTIERS**, *ante*.

POITOU, a former province of w. France, is now mainly comprised in the departments of Deux Sèvres, Vendée, and Vienne. It was divided into Upper and Lower Poitou, and had for its capital Poitiers (q.v.). Poitou first became a possession of the English crown when Eleanor, countess of Poitou and duchess of Aquitaine, after her divorce from Louis VII. of France in Sept. 1151, married, on Whitsunday following, Henry of Anjou, afterward Henry I. of England. Philippe-Auguste reconquered the province in 1204, and in 1295 it was formally ceded to France. By the peace of Bretigny, in 1360, it again reverted to England, but was soon after retaken by Charles V., who gave it to his brother, the duke of Berri. It was subsequently incorporated with the French crown.

POITRINAL, or **PECTORAL**, in ancient armor, was the horse's breastplate, formed of metal plates riveted together as a covering for the breast and shoulders.

POKANOKETS. See **MASSACHUSETTS INDIANS**.

POKE, the common name for *Phytolacca decandra*, called also gayet, pigeon berry, and scoke, the only representative in America of a small apetalous family, *Phytolaccaceæ*. It is found also in n. Africa, the Azores, China, and the Sandwich islands, and has been naturalized in southern Europe and the West Indies. *Phytolacca decandra* grows on roadsides, farmyards, and uncultivated fields. It has a stem from four to nine ft. high, bearing alternate, ovate-oblong acute leaves, with large petioles; calyx of five rounded and petal-like sepals, stamens 10, styles 10. The flowers, with white calyx and green ovary, grow on terminal racemes, which become lateral and opposite the leaves. It commences blossoming in June. The green ovary develops into a depressed globose five to ten-celled berry, with a single vertical seed in each cell. The berry ripens in Aug. and Sept., becoming a very dark purple, filled with crimson juice. The young shoots are often collected in the spring, and eaten as a substitute for asparagus, or cabbage sprouts. The root is large, fleshy, conical, and branched, being at the largest part often more than four in. in diameter. When dried, as seen in commerce, it is longitudinally wrinkled, brownish, yellowish gray-externally, breaking with a fibrous fracture. Internally it is of a dingy white color, possessing little odor. The taste is at first somewhat sweet, afterward acrid. It contains tannin, starch, resin, malate of lime, and other common constituents of plants, but no active principle has yet been separated. The powdered root is emetic and purgative in doses of one or two drams, and two teaspoonfuls of the juice of the fresh root has produced similar effects. It requires an hour or two for an ordinary dose to have its effect. An overdose, besides the effects

above named, causes great prostration of the nervous system, coldness and blueness of the skin, feebleness of the pulse, drowsiness, dimness of vision, coma, and sometimes convulsions. It has produced tetanic symptoms in a child, which, however, recovered. These effects are not produced unless more than thirty grains of the powdered root are given. It has been used in rheumatism, diseases of the skin, such as *scabies*, *tinea capitis*, *sycosis favus*, and *mange* in dogs, both internally and in the form of an ointment made of the powder, in the proportions of one part of the powder to eight of lard.

POKER, a game introduced into the United States about 40 years ago. The form of the game most popular at the present time is termed *draw poker*, to distinguish it from *twenty-deck poker*. It was formerly played with 20 cards, excluding *all below* the tens, the number of players being two, three, or four, who were confined to the cards first dealt. The entire pack is now used, cards being drawn from it to improve the game originally dealt to the players. The relative value of hands in their order, beginning with the best, is as follows: 1. A sequence flush of five cards, all of the same color; 2. Fours, which is four of the same denomination; 3. A full, consisting of three cards of the same denomination and two of likewise equal denomination; 4. A flush, containing all five cards of the same suit; 5. A sequence, containing all five cards in sequence, but not of the same suit; 6. Threes, with three cards of the same denomination, and two of different denomination from each other; 7. Two pairs; 8. One pair; 9. When a hand does not contain any of the above, the count is by the cards of highest value. In estimating the value of a sequence, an ace counts either as the highest or lowest card, that is, above a king or below a deuce. When two persons hold each a pair, or two pairs, of the same value, the next highest card or cards in each hand must be compared to determine who wins. An excellent pamphlet on the rules of draw poker was published in London by R. C. Schenck. in 1874. The game is unfortunate in its facilities for gambling.

POKHURN, a t. of India, in the Rajpoot state of Jodhpoor, 340 m. s.w. of Delhi. It is situated close to a deserted town of the same name, the site of which is marked by a very conspicuous temple in an elevated situation. Pokhurn has a considerable trade and a pop. of about 15,000.

PO'LA, the most important naval station of Austria, and one of the most beautiful havens in Europe, belongs to the markgrafate of Istria. The town occupies an eminence overlooking the Adriatic sea, 75 m. by sea south of Trieste. The bay is thoroughly sheltered, and is spacious enough to accommodate the largest fleet. The town is surrounded by bastioned walls, is protected by numerous batteries, and is overlooked by the citadel by which it and the bay are commanded. Pop. '69, 16,473.

Pola, a very ancient town, is said to have been founded by the Colchians, who were sent in pursuit of Jason. It was destroyed by Julius Cæsar, but rebuilt by Augustus at the request of his daughter Julia, on which account it was named *Pietas Julia*. In ancient times it had 30,000 inhabitants, and was a station of the Roman fleet. It contains numerous and interesting Roman remains, among which are a beautiful and well-preserved amphitheater, 436 ft. long and 346 broad. A temple and several ancient gates are also extant. See Allason's *Antiquities of Pola* (Lond. 1819).

POLACCA, or **POLACRE**, a species of vessel in use in the Mediterranean, with three masts and a jib-boom; the fore and main masts being of one piece ("pole-masts"), and the mizzen-mast with a top and top-mast. They generally carry square sails, though a few are rigged with a peculiar form of sail to which the term *polacre* is also applied. The fore and main masts have, of course, neither tops, caps, nor cross-trees.

POLAC'CA, or **POLONAISE'**, a Polish national dance of slow movement in $\frac{3}{4}$ time. It always begins and terminates with a full bar, and a peculiar effect is produced by the position of its cadence, the dominant seventh in the second crotchet of the bar preceding

the triad on the third crotchet:  The characteristic features

of the polacca are sometimes adopted in a rondo, or other lively and brilliant composition, which is then said to be written *alla polacca*.

PO'LAND, called by the natives *polska* (a plain), a former kingdom of Europe—renowned, in mediæval history, as the sole champion of Christendom against the Turks; and, till recently, an object of general and profound sympathy throughout western Europe, from its unprecedented misfortunes—was, immediately previous to its dismemberment, bounded on the n. by the Baltic sea from Dantzic to Riga, and by the Russian provinces of Riga and Pskov; on the e. by the Russian provinces of Smolensk, Tchernigov, Poltava, and Kherson; on the s. by Bessarabia, Moldavia, and the Carpathian mountains; and on the w. by the Prussian provinces of Silesia, Brandenburg, and Pomerania. Its greatest length from n. to s. was 713 English miles; and from e. to w., 693 miles, embracing an area of about 282,000 English sq.m.; an area which, in 1859, had a population of 24,000,000. This extensive tract forms part of the great central European plain, and is crossed by only one range of hills, which springs from the n. side of the

Carpathians, and runs n.e. through the country, forming the water-shed between the Baltic and Black sea rivers. The soil is mostly a light fertile loam, well adapted for the cereal crops, though here and there occur extensive barren tracts of sand, heath, and swamp, especially in the eastern districts. Much of the fertile land is permanent pasture, which is of the richest quality; and much is occupied with extensive forests of pine, birch, oak, etc. Rye, wheat, barley, and other cereals, hemp, wood and its products, honey and wax, cattle, sheep, and horses, inexhaustible mines of salt, and a little silver, iron, copper, and lead, constitute the chief natural riches of the country; and for the export of the surplusage of these products, the Vistula, Dnieper, Duna, and their tributaries afford extraordinary facilities.

The kingdom of Poland, during the period of its greatest extent, after the accession of the grand-duchy of Lithuania in the beginning of the 15th c., was subdivided for purposes of government into about 40 palatinates or voivodies, which were mostly governed by hereditary chiefs. The people were divided into two great classes—nobles and serfs. The noble class, which was the governing and privileged class, included the higher nobles, the inferior nobles (a numerous class, corresponding to the knights, gentry, etc., of other countries), and the clergy, and numbered in all more than 200,000; the serfs were the merchants, tradesmen, and agriculturists, and were attached, not, as in other countries, to masters, but to the soil. The serfs were thus much less liable to ill-usage, and retained more of human energy and dignity than the generality of slaves. The nobles were the proprietors of the soil, and appropriated the larger portion of its products, the serfs in many cases receiving only as much as was necessary for the support of themselves and their families. The nobles were chivalrous, high-spirited, hospitable, and patriotic; the serfs, who had also a stake, though a small one, in the independence of the country, were patriotic and good-natured, but sluggish. The present population of the provinces included in the Poland of former days consists of Poles, Lithuanians, Germans, Jews, Russians, Roumanians, gipsies, etc. The Poles, who number 15,600,000, form the bulk of the population; the Lithuanians, 2,100,000 in number, inhabit the n.e. of the country; the Germans, of whom there are 2,000,000, live mostly in towns and in villages apart by themselves, and bear the usual character for economy, industry, and that excessive love and admiration for the "Fatherland," which guided their politics during the last days of Polish independence; the Jews are very numerous, being reckoned at 2,200,000, but here they are poorer and less enterprising than in other countries; the remainder is composed of Russians (who are few in number, excepting in some of the eastern districts), Russian soldiery, Roumans, gipsies, Magyars, etc. Of Roman Catholics, there are about 9,400,000; Greeks, united and non-united, 7,900,000; Protestants (mostly Lutherans and German), 2,360,000; the rest are Jews, Armenians, Moslems, etc.

History.—The Poles are ethnologically a branch of the Slaves (q.v.). The name appears first in history as the designation of a tribe, the Polani, who dwelt between the Oder and Vistula, surrounded by the kindred tribes of the Masovii, Kujavii, Chrobates, Silesians, Obotrites, and others. In course of time, the Polani acquired an ascendancy over the other tribes, most of whom became amalgamated with the ruling race, whose name thus became the general designation. Polish historians profess to go as far back as the 4th c.; but the list of rulers which they give are probably those of separate tribes, and not of the combined race now known as Poles. At any rate, the history of Poland, previous to the middle of the 9th c., is so largely adulterated with fables, as to be little trustworthy. Ziemowicz, said to be the second monarch of the Piast dynasty, is considered to be the first ruler whose history is to any extent to be relied upon; and it was not till a century after, when his descendant, Micislas I. (962–92), occupied the throne, and became a convert to Christianity, that Poland took rank as one of the political powers of Europe. Micislas (as was the general custom among the Polish rulers), divided his dominions among his sons; but one of them, Boleslas I. (992–1025), surnamed "the great," soon reunited the separate portions, and extended his kingdom beyond the Oder, the Carpathians, and the Dniester, and sustained a successful war with the emperor Henry II. of Germany, conquering Cracovia, Moravia, Lusatia, and Misnia. He also took part in the dissensions among the petty Russian princes. Under him, Poland began to assume unity and consistency; commerce, the impartial administration of justice, and Christianity were encouraged and promoted; and about the same time, the distinction between the nobles or warrior class (those who were able to equip a horse) and the agriculturists was distinctly drawn. Boleslas was recognized as "king" by the German emperors. After a period of anarchy, he was succeeded by his son, Casimir (1040–58), whose reign, and that of his warlike son, Boleslas II. (1058–81), though brilliant, were of little real profit to the country. The latter monarch having with his own hands murdered the bishop of Cracow (1079), Poland was laid under the papal interdict, and the people absolved from their allegiance; Boleslas accordingly fled to Hungary, but being, by order of the pope, refused shelter, he is said to have committed suicide (1081). Boleslas III. (1102–39), an energetic monarch, annexed Pomerania, defeated the pagan Prussians, and defended Silesia against the German emperors. A division of the kingdom among his sons was productive of much internal dissension, under cover of which, Silesia was severed from Poland, though still nominally subject to it. Ultimately, Casimir II. (1177–94) reunited the severed portions, with the excep-

tion of Silesia, and established on a firm footing the constitution of the country. A senate was formed from the bishops, palatines, and castellans, and the rights of the clergy and of the peasantry were accurately defined. His death was the signal for a contest among the various claimants for the throne, which was speedily followed, as usual, by a division of the country, and during this disturbance Pomerania emancipated itself from Polish rule. About the same time, the Teutonic knights were summoned by the duke of Masovia to aid him against the pagan Prussians; but they soon became as formidable enemies to Poland as the Prussians, and conquered great part of Podlachia and Lithuania. The Mongols swept over the country in 1241, reducing it to the verge of ruin, and defeating the Poles in a great battle near Wahlstatt. From this time, Poland began to decline; various districts were ceded to the markgrafs of Brandenburg, while many districts began to be colonized by Germans. Numbers of Jews, persecuted in western Europe about this time, took refuge in Poland. Wladislas (1305-33), surnamed *lokietek* (the short), again restored unity to the country, judicial abuses and all illegally acquired privileges were abolished, and the first diet (1331) assembled for legislative purposes. In conjunction with Gedymin, grand duke of Lithuania, a vigorous war was carried on against the Teutonic knights, on returning from which the aged monarch (he was now 70 years old) experienced a triumphant reception from his subjects, who hailed him as the "father of his country. His son, Casimir III. the great (1333-70), greatly increased the power and prosperity of Poland by cultivating with zeal the arts of peace, amending the laws, and consolidating his territories by profitable exchanges with the neighboring powers. In the latter part of his reign, he was compelled to defend sundry new acquisitions against the Tartars, Lithuanians, and Wallachians, which he did successfully. With Casimir, the Piast dynasty became extinct, after a sway of 510 years, according to the old Polish chroniclers. His nephew, Lewis the great, king of Hungary, succeeded him, by the will of the deceased monarch and the election of the diet; but during his reign, Poland was treated merely as an appanage of Hungary. On his death without male heirs, the crown fell to Jagello (Wladislas II.), grand duke of Lithuania, the son-in-law of Lewis, who founded the dynasty of the *Jagellons* (q.v.) (1386-1572), and for the first time united Lithuania and Poland, thus doubling the extent, though not the population of the kingdom. However, his successor, Wladislas III., was acknowledged only in Poland proper, the Lithuanians preferring the rule of the younger son, Casimir. Wladislas was also chosen king of Hungary, and fell at the battle of Varna, being succeeded in Poland by Casimir IV. (1444-92), who again united it to Lithuania. Casimir recovered west Prussia from the Teutonic knights, and compelled them to do homage for east Prussia, rewarding the inferior nobles, or warrior class, with more extensive privileges, putting them on an equality of rank with the great chiefs of the realm, and at the same time necessarily oppressing the peasantry. Manufactures and commerce revived to a wonderful extent during his reign in the western provinces. The brief reigns of his three sons were marked only by the increased power of the two houses of the diet, which had by this time absorbed all but the symbols of supreme authority, and had converted Poland from a monarchy to an oligarchy (the king possessing little power beyond what his personal influence gave him). Sigismund I. (1506-48) surnamed the great, the fourth son of Casimir, raised the country to the utmost pitch of prosperity. Generous and enlightened, he was beloved by the masses, whom he endeavored to benefit physically and mentally, while his firmness and justness commanded the respect of the turbulent nobles. He wisely kept aloof from the religious quarrels which distracted western Europe, by allowing his subjects perfect freedom of choice in matters of religion; he was, however, forced into a war with Russia, in which he lost Smolensk; but he was partly compensated by obtaining lordship over Moldavia. His son, Sigismund II., Augustus, was a successor worthy of him. During his reign many abuses were rectified, and the extraordinary privileges of the higher nobles were curtailed or abolished; Lithuania was finally joined indissolubly to Poland, and from this time there was to be but one diet for the united realm; each retained, however, its own army, titles, treasury, and laws. Lithuania was at the same time reduced by the annexation of Podlachia, Volhynia, and the Ukraine, to Poland. Livonia was conquered from the knights sword-bearers (a community similar to, though much less distinguished than the Teutonic knights); and the power, prosperity, and opulence of the state seemed to guarantee its position as the most powerful state in eastern Europe for a long time to come. The population almost doubled itself under the two Sigismunds; but this dynasty, whose sway was so happy for Poland, ceased with them; and the warrior class having tasted the sweets of freedom, determined to preserve it by rendering the monarchy elective. The election was made by the two chambers of the diet—viz., the senate or chamber of the chief nobles, and the chamber of nuncios, or representatives of the inferior nobles. He who was chosen king possessed the right of assembling the diet, but had to give a list of the subjects to be discussed; and the representatives, before setting out, were instructed as to the side they were to support. The diet only lasted six weeks, and its decisions were required to be unanimous; so that if the *liberum veto* (the right of forbidding the passing of any measure) were freely exercised even by a single member, all legislation was at a standstill. The evil effects of these regulations were not so much felt at first, as the members

were characterized by honesty and zeal for the general good; but latterly, when venality and subservience to the neighboring powers began to show themselves, all the measures necessary for protecting Poland from dependence on her neighbors were, by a few corrupt and treacherous representatives, rendered of no avail. The first elective monarch was Henry of Valois (III. of France, q.v.), who, however, soon abandoned the throne for that of France, and was succeeded by Stephen Batory (1575-86), voivode of Transylvania, a man of energy and talent, who carried on war successfully against the Russians, who had attempted to seize Livonia, pursued them into the very heart of their own country, and compelled the czar to sue for peace; he also subdued the semi-independent Cossacks of the Ukraine, and to some degree introduced civilization among them. His successor, Sigismund III. (1586-1632), who was succeeded by his sons, Wladislas IV. (1632-48) and John Casimir (1648-72), was of the Vasa family, and was the crown-prince of Sweden; but his election, far from cementing a bond of union between the two countries, only embittered former dissensions. These three Swedish monarchs were most unworthy successors to Poland's ablest king, as they had neither talents for governing, nor characters and sentiments congenial to a warlike nation; on the contrary, their policy was weak, tortuous, and vacillating. Yet they were always quarreling with their neighbors, declaring war with Russia, Sweden, or Turkey, in the most imprudent and reckless manner, and often without valid pretext. But the Polish armies, though as little fostered and cared for as the other portions of the nation, were everywhere victorious; the Swedish and Muscovite armies were successively annihilated; Moscow was taken, and the Russians reduced to such an abject condition, that they offered to make Sigismund's son, Wladislas, their czar. Sweden made a similar offer to another son of the Polish monarch; but the latter's absurd behavior lost for Poland this rich result of her great victories; and the foolish policy of the whole three not only rendered fruitless all the lavish expenditure of Polish blood and treasure, but lost to the country many of her richest provinces, and left her without a single ally; while their religious bigotry commenced that reign of intolerance and mutual persecution between the various sects which was the immediate cause of Poland's downfall. To show the power of the Poles at this period, it will be sufficient to notice that Great Poland, Little Poland (Galicia, Podolia, Ukraine, etc.), Livonia, Lithuania, (including Samogitia and Black and White Russia, Polesia, and Tchernigov), Pomerelia and Ermeland, Courland, Moldavia, Bukovina, Wallachia, Bessarabia, and Prussia, were either integral parts of the Polish monarchy, or were subject to it. The imprudent attempts of the Swedish sovereigns to amend the constitution only excited the suspicion of the nobles, and led to a further curtailment of royal authority. During the reign of this dynasty, Wallachia and Moldavia were snatched by the Turks from under the Polish protectorate; Livonia with Riga was conquered (1605-21), along with part of Prussia (1629), by Sweden; and Brandenburg established itself in complete independence. The Cossacks, who had been goaded almost to madness by the most atrocious oppression and religious persecution, rose in rebellion to a man, put themselves under the protection of Russia, and ever afterward proved themselves the most inveterate enemies of the Poles. In the reign of John Casimir, Poland was attacked simultaneously by Russia, Sweden, Brandenburg (the germ of the present kingdom of Prussia), the Transylvanians, and the Cossacks; the country was entirely overrun; Warsaw, Wilna, and Lemberg taken; and the king compelled to flee to Silesia. But the celebrated staff of Polish generals was not yet extinct; Czarniecki's sword was as the breath of the destroying angel to Poland's enemies; and after being defeated in detail, they were ignominiously expelled from the country. But in the subsequent treaties, Ducal or east Prussia was wholly given up to Brandenburg; almost all Livonia to Sweden; and Smolensk, Severia or Tchernigov, and the Ukraine beyond the Dnieper, were given to Russia. Michael Wisniowiecki (1668-74), the son of one of the group of famous generals above alluded to, but himself an imbecile, was (contrary to his own wish—for he was well aware of his own deficiencies) elected as their next monarch; a war with Turkey, concluded by an ignominious peace, was the chief event of his reign. But the senate rejected the shameful treaty, the Polish army was again re-enforced, the Polish monarch resigned the command to John Sobieski the Hetman (q.v.), and the Turks were routed with great slaughter at Choezim (1673). After some dissensions concerning the election of a successor, John (III., q.v.) Sobieski (1674-96) was chosen; but his reign, though it crowned the Poles with abundance of the laurel wreaths of victory, was productive of no good to the internal administration. As Sobieski's successor, the prince of Conti was legally elected, and proclaimed king; but the cabinet of Versailles allowed this splendid opportunity of becoming supreme in Europe to escape; and Augustus II. of Saxony, a protégé of the house of Austria, entered Poland at the head of a Saxon army, and succeeded in obtaining the throne. Augustus, unlike all his predecessors, never seemed to identify his interests with those of his Polish subjects; and though he gained their hearts by promising to reconquer for Poland her lost provinces, yet this promise was chiefly made as an excuse for keeping his Saxon army in the country, in violation of the *pacta conventa* (the "magna charta" of Poland). His war with the Turks restored to Poland part of the Ukraine and the fortress of Kaminiec; but that with Charles XII. brought nothing but misfortune. The war with Sweden was unpopular in Poland; in fact, the Poles of the eastern provinces received Charles with open arms; but his attempt to force upon them Stanislas Les-

zynski: as their king severely wounded their national pride. Augustus returned after the battle of Poltava (q.v.); his rival retired without a contest; a close alliance was formed with Russia, and the Russian troops which had campaigned in Poland against the Swedes were, along with his Saxon army, retained. The Poles demanded their extradition, but in vain; and the Russian cabinet interfered (1717) between the king and his subjects, compelling both parties to sign a treaty of peace. This was the commencement of Poland's dependence on Russia, and her consequent decline. By the instigation of Peter the great, the Polish army was reduced from 80,000 to 18,000; and the country was further weakened by the diffusion of effeminacy, immorality, and prodigality, through the evil example and influence of the court. Religious fanaticism also more fully developed its most odious features during his reign, and the massacre of the Protestants at Thorn (1724) and the legalized exclusion of them from all public offices was the result. The succeeding reign of Augustus III. (1733-63) was of the same character; the government fell more and more under Russian influence, and its political relations with other countries gradually ceased. Toward the end of his reign, the more enlightened of the Poles, seeing the radical defects of the constitution, the want of a strong central government, and the dangers of the *liberum veto*, entered into a league to promote the establishment of a well-organized hereditary monarchy. But the conservative or republican party was equally strong, and relied on Russian influence; and the conflict between these parties became more embittered from the fact that the monarchists supported the Jesuits in disqualifying all dissenters from holding public offices, while the republican party supported the dissidents. The dissidents dated their grievances from 1717, but the great conflict between them and their opponents did not break out till 1763. The cabinets of St. Petersburg and Berlin now (1764) presented to the Poles Stanislas Poniatowski as their king. This gross insult, intensified by the incapacity of Stanislas for such an office, could not be borne in quiet; the king and the Russian ambassador were compelled in the diet to listen to the most spirited protests against Russian interference; but the intense national spirit of the Poles only recoiled upon themselves, for the Russian ambassador craftily incited them to insurrection, and kept alive their mutual dissensions. The monarchic, or Czartoryski party (so called because it was headed by a Lithuanian prince of this name), had succeeded in abolishing the *liberum veto*, and effecting many other improvements; but they at the same time more severely oppressed the dissidents; and Russia, finding that the political policy of this party was speedily releasing Poland from her grasp, joined the party of the dissidents as the champion of religious toleration! Her ambassador caused the chief leaders of the Catholic party to be secretly kidnapped, and sent to Siberia, and compelled the republicans to accept the protectorate of Russia. The "confederation of Bar" (so called from Bar in Podolia) was now formed by a few zealous patriots, an army was assembled, and war declared against Russia. The confederates were supported by Turkey, which also declared war against the czarina; and Russia, alarmed at the appearance of affairs, proposed to the king and diet an alliance, which both firmly refused. Frederic the great of Prussia, who had formerly gained the consent of Austria to a partition of Poland, now, in 1770, made the same proposal to Russia, and in 1772 the *first partition* was effected; Stanislas and his diet claiming the mediation and assistance of the other powers of Europe without effect. He was forced in the following year to convoke a diet for the purpose of recognizing the claims of the three partitioning powers to the territories they had seized, but few members appeared, and these preserved perfect silence. The territories seized by the three powers were as follows:

	Eng. sq. Miles.	Pop.
Russia.....	42,000	1,800,000
Prussia.....	13,000	416,000
Austria.....	27,000	2,700,000

The whole country was now aroused to a full sense of its danger; and the diet of the diminished kingdom labored to amend the constitution and strengthen the administration by a liberal code of laws and regulations, which gave political rights to the cities, civil rights to the peasantry, and rendered the kingly authority hereditary. In this they were encouraged by Prussia, whose king, Frederic William, swore to defend them against Russia; but in 1791, Catharine II., after great labor, obtained, by means of intrigues and bribery, the services of *five* (out of 200,000) of the Polish nobility, who protested against the new constitution which had just (May 3, 1791) been established, and drew up a document at Targowitz (q.v.), which they forwarded to the Russian court. Catharine, thus armed with a pretext for interference, advanced her army, and Prussia proving traitorous, a second fruitless resistance to the united Prussians and Russians, headed by Joseph Poniatowski (q.v.) and Kosciusko (q.v.), was followed by a *second partition* (1793) between Russia and Prussia, as follows:

	Eng. sq. Miles.	Pop.
Russia..	96,000	3,000,000
Prussia.....	22,000	1,100,000

which the diet were forced to sanction at the point of the bayonet. The Poles now

Poland.

became desperate; a general rising took place (1794); the Prussians were compelled to retreat to their own country, and the Russians several times routed; but then a new enemy appeared on the scene. Austria was chagrined at having taken no part in the second partition, and was determined not to be behindhand on this occasion; her army accordingly advanced, compelling the Poles to retreat; and fresh hordes of Russians arriving, Kosciusko, at the head of the last patriot army, was defeated; and the sack of Praga, followed by the capture of Warsaw, finally annihilated the Polish monarchy. The *third and last partition* (1795) distributed the remainder of the country as follows:

	Eng. sq. Miles.	Pop.
Russia.....	43,000	1,200,000
Prussia.....	21,000	1,000,000
Austria.....	18,000	1,000,000

King Stanislas resigned his crown, and died broken-hearted at St. Petersburg in 1798. The subsequent success of the French against the Russians, and the tempting promises of the emperor Napoleon to reconstitute Poland, rallied round him a faithful army of patriots, who distinguished themselves in the campaigns of the French against Russia and Austria; but all that Napoleon accomplished in fulfillment of his promise was the establishment, by the treaty of Tilsit (1807), of the *Duchy of Warsaw*, chiefly out of the Prussian share of Poland, with a liberal constitution, and the elector of Saxony at its head. The duchy was an energetic little state, and under the guidance of prince Joseph Poniatowski, wrested western Galicia from Austria (1809), at the same time furnishing a numerous and much-valued contingent to the French armies; but the advance of the grand allied army in 1813 put an end to its existence. After the cessions by Austria in 1809, the duchy contained 58,290 English sq. m., with a population of about 4,000,000. Dantzie was also declared a republic, but returned to Prussia (Feb. 3, 1814). The division of Poland was rearranged by the congress of Vienna in 1815, the original shares of Prussia and Austria were diminished, and that part of the duchy of Warsaw which was not restored to Prussia and Austria was united as the *kingdom of Poland* (see next article) to the Russian empire, but merely by the bond of a personal union (the same monarch being the sovereign of each), the two states being wholly independent of and unconnected with each other; and the other parts of Poland were completely incorporated with the kingdoms which had seized them. The partition of Poland, as thus finally arranged, was as follows:

	Extent in Eng. sq. m.	Pop. (in 1859.)	Present Political Divisions.
Russia.....	220,500	16,000,000	Provinces of Courland, Witebsk, Kovno, Vilna, Grodno, Minsk, Mohilev, Volhynia, Kiev, Podolia; and the <i>kingdom of Poland</i> (q.v.). Posen, most of W. Prussia, and several districts in E. Prussia. Galicia, Bukovina, Zips, etc.
Prussia.....	26,000	3,000,000	
Austria.....	35,500	5,000,000	

while, as if in mockery of its spirit of independence, the town of Cracow, with a small surrounding territory, was declared free and independent, under the guardianship of Austria. The czar at first gave a liberal constitution, including biennial diets, a responsible ministry, an independent judiciary, a separate standing army, and liberty of the press; and he seemed to take pride in his title of king of Poland; but his brother Constantine, having been appointed military governor, speedily put an end to the harmony between the czar and the Poles, and drove the latter into insurrection. Their discontent at first found vent in secret societies; but on Nov. 30, 1830, Constantine and his Russians were driven out of Warsaw, and a general insurrection of the people, headed by the aristocracy, took place. Prince Czartoryski was appointed president of the provisional government, and military leaders, as Radzivil, Dembinski, Bem, etc., were soon found; but a general want of energy in the administration, dilatoriness on the part of the military leaders, and the checking of the spread of the insurrection till fruitless negotiations had been entered into with Nicholas, were errors fatal to the success of the Poles. From Jan., 1831, till Sept. 8 of the same year, a series of bloody conflicts were fought, in which the Prussians and Austrians, with pitiable subservience, aided the czar. At first the Poles were successful; but the taking of the capital by Paskevitch (q.v.) soon ended the war, which was followed, as a matter of course, by imprisonment, banishment, confiscation, and enforced service in the Russian army. From this time the independence of Poland was suppressed, and in 1832 it was declared to be an integral part of the Russian empire, with a separate administration headed by a viceroy of the czar's choosing; the constitution and laws were abrogated; strict censorship of the press and the Russian spy-police system established in all its vigor; the country was robbed of its rich literary collections and works of art; and the most severe and arbitrary measures taken to Russianize the people. The outbreaks of 1833 and 1846 were punished by the gallows. Simultaneous disturbances (1846) in the Prussian and Austrian portions of Poland were summarily suppressed; their leaders in Prussia were imprisoned, and only saved from death by the revolution of Mar., 1848, at Berlin; and those in Austria were butchered by the peasantry, who preferred the Austrian to a national government. On Nov. 6, 1846, the republic of Cracow was incorporated with Austria. After the acces-

sion of the czar Alexander II., in 1855, the condition of the Poles was considerably ameliorated; an act of amnesty brought back many of the expatriated Poles, and various other reforms were hoped for, when, in 1861, another insurrection broke out. Its origin is curious, and gives a thorough insight into the relations between the Poles and their Russian rulers. A large multitude (30,000) had assembled in the neighborhood of the battle-field of Grochow (where two battles had been fought in the spring of 1831) to pray for the souls of those who had fallen; they were engaged in prayer and in singing religious chants, when they were charged by the Russian cavalry and gens d'armes, several of them killed, and numerous arrests made. This event excited intense national feeling throughout the country; and other national demonstrations, attended with similar massacres on the part of the Russians, produced such an intense dislike to the latter that most of the Poles in the Russian service either resigned or deserted. The Russians immediately had recourse to the most severely repressive measures, forbidding all assemblages even in the churches, punishing those who appeared to mourn the death of relatives killed in the previous massacres, or who wore garments of certain shapes or colors. The application of the Polish nation to the czar (Feb. 28) for the re-establishment of the Polish nationality, was rejected, but certain necessary reforms were promised. These reforms were on the whole very liberal, and tended greatly to allay the general excitement; but the Russian government was very naturally not trusted by the Poles, and new disturbances broke out in October of the same year. Poland was then declared to be in a state of siege, and gen. Luders appointed military commandant under the grand duke Constantine, the nephew of the grand duke Constantine above mentioned. The country continued in a state of commotion without any very decided outbreak; attempts were made to assassinate the grand duke and the other Russian officials; and on Jan. 13, 1863, Lithuania and Volhynia were also put in a state of siege. The committee of the national insurrection issued its first proclamation in Feb., 1863; and a week afterward Mieroslavski raised the standard of insurrection in the n.w., on the Posen frontier. The insurrection committee continued to guide the revolt by issuing proclamations from time to time; and many districts of Augustovo, Radom, Lublin, Volhynia, and Lithuania were speedily in insurrection. It was a mere guerilla war, and no great or decisive conflicts took place; but the sympathy of Europe was largely enlisted on behalf of the Poles. Remonstrances from Spain, Sweden, Austria, France, and Britain conjointly and repeatedly, Italy, the Low Countries, Denmark, and Portugal, were wholly disregarded by the czar's ministers, and mutual reprisals continued; incendiarism and murder reigned rampant; the wealthier Poles were ruined by fines and confiscations; and the whole populations of villages were put to the sword by the Russians; while murders and assassinations marked the reign of terror of the national committee. At last, with the officious assistance of Prussia, and the secret sympathy and support of Austria, the czar's troops succeeded in trampling out (1864) the last embers of insurrection. Great numbers of men, women, and even children, concerned in, or supposed to have favored the revolt, were executed; crowds were transported to Siberia; and these vigorous measures seem to have restored "tranquillity, but it is the tranquillity of the desert." Contemporary with this last outbreak, symptoms of similar disaffection were distinctly noticeable in Prussian Poland, but a strong force of soldiery in the border districts toward Russia prevented any outbreak. It deserves to be noticed that, with the exception of the single revolt of 1846 (which perished almost of itself), no rebellion has ever taken place in the portion of Poland belonging to Austria.

POLAND, KINGDOM OF, a province of European Russia, which was united to that empire in 1815—though the title of kingdom was left, and a peculiar form of government long continued to distinguish it from the other provinces—is surrounded by Prussia, Austria, and western Russia or Russian Poland, and contains 48,863 English sq. m., with a pop. (1881) of 7,104,760. In 1867 there were 4,326,473 Roman Catholics, 783,079 Jews, 331,233 Protestants (Lutherans and reformed), and 259,192 Greek church (mostly united). The surface of the country is in general very level, with now and then a hill, or rather undulation, which relieves the uniformity of the scene. In Radom, however, there is a range of hills, some peaks of which attain a height of 2,000 ft. above sea-level. The chief river of Poland is the Vistula, which enters the country by its southern boundary, and flows first n. and then n.w., making its exit near Thorn; two of its tributaries, the Wieprs and the Pilica, belong wholly, and third, the Bug, partially to Poland. The Warta, one of the tributaries of the Oder, drains the w., and the Niemen, the n.e. districts. The Vistula and the Niemen are wholly navigable in Poland; and the Bug, Narew, and Warta are so for a considerable portion of their course. By these means of communication the exports of the country are collected at Dantzic, Stettin, Memel, and Tilsit, on the Baltic, and the imports introduced into the country. The climate is severe, the summers being very hot, and the winters excessively cold. The soil very much resembles that of the other parts of the former kingdom of Poland, producing magnificent crops of wheat, rye, barley, oats, and buckwheat, the usual leguminous plants, hemp, tobacco, flax, and orchard-fruits. Upward of 13,000 sq. m. are covered with forests, and fully 8,000 sq. m. are waste. Since 1867 Poland is divided for administrative purposes into 10 governments—viz.

Governments.	Eng. Sq. Miles.	Pop.
Kalish.....	4,400	774,759
Keletz.....	2,890	622,842
Lomja.....	4,677	538,588
Lublin.....	6,506	860,382
Petrokoff.....	4,720	837,928
Plotsk.....	4,209	538,141
Radom.....	4,762	644,827
Sedletz.....	5,527	622,465
Suwalki.....	4,847	603,174
Warsaw.....	5,613	1,314,269
Total.....	48,151	7,357,375

The population is about 128 to the sq. m., being more than three times as dense as that of the rest of European Russia. A large proportion of the country population employ themselves in the rearing and breeding of horses, cattle, and pigs; sheep are not so common; but swarms of bees abound, and there is a large export trade in honey. The population of the towns is largely employed in wool-spinning and the manufacture of woolen cloth, cotton and linen spinning and weaving, the production of liqueurs, oil, vinegar, glass and earthenware, paper, beer and porter, etc. The most of the commerce is in the hands of the Jews. Poland, which had a separate government till 1864, was in that year deprived of the last remnant of its administrative independence. After the suppression of the revolt (see preceding article), the country was placed under eight military governors; in 1867 the administration was committed to a commission sitting at St. Petersburg; and by an ukase, dated Feb. 23, 1868, the government of Poland was absolutely incorporated with that of Russia. The total value of Polish industries in 1870-80 was £12,000,000 a year, a large sum, considering that the population is chiefly agricultural. In this period the commerce of Poland reached £26,000,000. The Warsaw daily press has an issue of 24,000 copies. Between 1877 and 1881 there were published 296 works in belles-lettres in the Polish tongue. About 13,000,000 persons, in all, speak Polish.

POLAND, LUKE P., LL.D., b. Vt., 1815; studied law and was admitted to the bar in 1836; he rose rapidly in the profession, was probate register in 1839, prosecuting attorney in 1843, and in 1848 became a member of the state supreme court. He remained on the bench 16 years, for the last five of which he was chief-justice. In 1865 he was elected U. S. senator to fill a two years' vacancy. From 1867 to 1875 he was a member of congress from Vermont, and was prominent among the republican leaders.

POLAR CIRCLE, or ARCTIC CIRCLE. See ARCTIC.

POLAR CLOCK, an instrument invented by sir Charles Wheatstone for telling the time of day by means of light which has been polarized by passing through the atmosphere. The reader of the article POLARIZATION will understand the manner in which the light of the sky is polarized in a direction at right angles to the sun's rays. If the Nicol's prism, which is described in that article, is used as an analyzer and placed with its axis parallel to that of the earth and turned around so as to change its position toward the plane of polarization, there will be a change of intensity of light and color. The same changes will be produced if the axis of the prism is not revolved with respect to the earth, because the earth's axial rotation will change the relative plane of polarization of the sun's rays. These remarks, taken in connection with the article POLARIZATION, explain the principle of the polar clock, whose description by the inventor may be condensed as follows: At the extremity of a vertical pillar a hollow conical tube is mounted upon a hinge so that its axis may be brought, at any part of the earth's surface, parallel with its axis. The plane of the base of the cone consists of a ring in which there is fitted a glass disk, whose plane is, of course, perpendicular to the earth's axis. On the lower half of this disk there is a graduated semicircle divided into 12 parts, indicating the hours from VI. to VI. This ring and glass disk are fixed upon an arm, and cannot be rotated. The other part of the cone, however, whose base fits within the ring, may be revolved on its axis, and in this base there is also fitted another glass disk, in whose center there is a small star, formed of thin scales of selenite, which, when examined by polarized light, exhibits strong contrasts of colors. An index upon the plate is placed in such a position as to be a prolongation of one of the principal sections of the selenite scales or plates. At the smaller end of the conical tube there is a Nicol's prism which has either of its diagonals 45° from the principal section of the selenite plates. Placing the eye behind the Nicol's prism the observer will find that the star will in general be richly colored; but as the tube is turned on its axis the colors will vary in intensity, and in two positions will entirely disappear. In one of these positions a smaller circular disk in the center of the star will be of a certain color, while in the other position it will have the complementary color. This effect is obtained by placing the principal section of the small central disk 22½° from that of the other sections of selenite forming the star. The time is ascertained as follows: the tube is turned on its axis until the color of the star entirely disappears, while the central disk remains red, when the index will point at the hour within a very few minutes. Unlike the sun-dial, the polar clock need not be

placed in the sun's rays; it may stand in the shade of a tree or a building, or at a n. window, and it may be used when the sky is overcast if the obscurity is not great, particularly in the direction of the n. star.

POLAR EXPEDITIONS. Under this head are classed all those voyages of discovery which have been made toward the n. and s. poles, and to the regions within the Arctic and Antarctic circles. The n. polar regions present a much greater land-surface than those round the s. pole, and on this account possess a higher temperature, and offer a more valuable field for discovery, for which reasons, as well as by reason of their greater proximity, polar expeditions have been far more frequently directed to the n. than to the south.

Arctic Expeditions.—Polar expeditions were commenced with a view to discover a shorter route to the golden realms of the east; but the first attempts were made by coasting along the n. of Europe and America. See NORTH-EAST AND NORTH-WEST PASSAGES. It was not till 1603 that the first arctic exploring expedition, consisting of one vessel, the *Godspeed*, commanded by Stephen Bennett, started for a voyage of northern discovery; and this, as well as the succeeding expeditions of Bennett, were devoted to morse-hunting rather than to geographical investigation. In 1607 Henry Hudson (q.v.) was sent out by the Muscovy company to penetrate to the n. pole, but he was stopped about the n. of Spitzbergen (in lat. $81^{\circ} 30'$) by the ice. The succeeding voyages of Jonas Pole in 1610, 1611, and 1612, and of Baffin in 1613, were not primarily voyages of discovery, and they added nothing to the previous knowledge of the polar regions; but in the expedition of Fotherby and Baffin up Davis's strait, in the following year, the latter discovered a northern outlet to the bay called by his own name, which was denominated Smith's sound. Fotherby was sent out again in 1615, and attempted to pass through the sea which lies between Greenland and Spitzbergen, but was again baffled, and compelled to return, after correcting some erroneous observations of Hudson. These seven expeditions were all sent out by the Muscovy company; and the cargoes of seal-skins, oil, teeth, etc., which they brought back helped to defray the expense of their outfit. For the next century and a half the attempts to reach the n. pole were not resumed; but the extraordinary zeal in the cause of naval discovery which sprung up in the beginning of George III.'s reign, produced two renewed efforts. The first of these was made in the spring of 1773 by an expedition consisting of two vessels, under capt. John Phipps (afterward lord Mulgrave), and fitted out by the admiralty purely for scientific purposes. Phipps sailed along the shore of Spitzbergen till he was stopped by the ice at Cloven Cliff; he then coasted backward and forward along the ice-field for nearly a month, trying the various narrow openings, some of which were two leagues in depth, till he found one which took him into open water. By a sudden change in the climate he was frozen in, and only extricated his ships after severe labor. The highest point to which he reached was lat. $80^{\circ} 48'$ n., less by 49 m. than the most northerly latitude attained by Hudson; and though he had a more than usual amount of difficulties to encounter, yet his failure, along with that of capt. Cook, who attempted to reach the pole by Behring's strait, but only penetrated to lat. $70^{\circ} 45'$ n., greatly disheartened other explorers. The offer of £5,000 by the British parliament to the crew that should penetrate to within 1° of the pole, awaked no competition; but in 1806 Mr. Scoresby, then mate of a Greenland whaler from Hull, reached a point directly n. of Spitzbergen, in lat. $81^{\circ} 30'$ n., and therefore only about 510 geographical m. from the pole. In following expeditions the same enterprising navigator made many geographical explorations of Jan Mayen's land and the e. coast of Greenland, largely adding to our knowledge of the character and products of the arctic regions. The subsequent expeditions of Buchan and Franklin in 1818, of Clavering in 1823, of Graab (Danish) in 1828, of De Blosseville (French) in 1833, may be considered as failures, as far as geographical discovery is concerned; for, omitting the French expedition, the fate of which is still involved in mystery, none of them reached so high latitudes as the previous English expeditions. After the failure of Buchan and Franklin's expedition, the impossibility of ever reaching the pole was generally accepted in this country as fact; but Mr. Scoresby, in a memoir which he communicated to the Wernerian society, endeavored to prove that this supposed impossibility was by no means such; in fact, that a journey to the pole could be made without any enormous amount either of difficulty or danger. The principal obstacle to be encountered being the alternation of ice-fields and water, which prevented all advance either by ships or sledges, Mr. Scoresby proposed the use of a vehicle which could be used either as a sledge or boat, and recommended a team of dogs to draw it, they being lighter (for conveyance by water, and for traveling over thin ice) and more tractable than reindeer. After some time this suggestion began to receive a considerable share of attention, and capt. Parry (celebrated for his discoveries in the polar seas n. of America) was put in command of an expedition fitted out in accordance with Scoresby's plans. He sailed from England in the *Hecla*, on Mar. 27, 1827; but it was June 22 before the exploring party quitted the ship, which was left on the n. shore of Spitzbergen, in charge of a small crew, and betook themselves to the boats; and in spite of the advanced season of the year they in the first two days advanced to $81^{\circ} 13'$. Here they began to encounter many difficulties; the ice-fields were small, and near each other, necessitating a constant conversion of the vehicle from a sledge to a boat, which could not be effected without

unloading it, an operation which consumed much time. This hardship, however, was endurable; but, to Parry's intense chagrin, he discovered, about July 22, that the ice over which they were traveling was moving southward as rapidly as they were advancing n., so that on the 24th, after having traveled apparently 22 m. in the three previous days, they found themselves in the same latitude as on the 21st. Under these circumstances Parry resolved to return, which he accordingly did, reaching his ship on Aug. 21. The highest point reached by him was $82^{\circ} 40'$. A new land, about 200 m. n. of Nova Zembla, to which the name Franz Joseph land has been assigned, was discovered by the Austro-Hungarian polar expedition of 1872-74, under lieuts. Weyprecht and Payer. Its s. coast lies about the 80th parallel, and it was explored, by means of sledges, up to $82^{\circ} 5'$ n., while land was seen extending as far as 83° north. In 1854 two American explorers passed through Smith's sound, and reached cape Constitution in $82^{\circ} 27'$ n. lat., and saw, as they thought, a boundless open polar sea. The *Polaris* sailed in July, 1871, from New London, Conn., and reached $82^{\circ} 16'$ north. The supposed polar sea being a sound entering Kennedy channel, gave hopes of reaching the pole through Smith's sound. An English arctic expedition under capt. Nares sailed in 1875, and, through Smith's sound, reached the highest latitude ever attained, $83^{\circ} 20'$. Unable to penetrate further, it returned in 1876. See NORTH-EAST AND NORTH-WEST PASSAGES.

Antarctic Expeditions.—The attempts to penetrate to the s. pole are of very recent date, mainly because a knowledge of the southern polar regions is only valuable to Europeans from a scientific point of view. Cook and Furneaux are the first navigators who are known to have crossed the antarctic circle, but the former penetrated only to lat. $71^{\circ} 10'$ s., and neither made any discoveries of importance. Bellinghausen, a Russian navigator, reached lat. $70'$ s. in 1819, and two years after discovered Alexander's land and Peter's land, then the most southerly islands known. In 1823 capt. Weddell reached lat. $74^{\circ} 15'$ s., long. $34^{\circ} 16'$ w., and saw beyond him an open sea to the s., but made no important additions to our geographical knowledge. In 1831 capt. John Biscoe discovered Enderby land; and in 1839 the sealing-schooner *Eliza Scott*, from New Zealand, discovered Sabrina land (q.v.); and in the same year the U. S. expedition, under capt. Wilkes, set out on a career of exploration, which resulted in the discovery (Jan., 1840) of what he with reason supposed to be a continuous coast-line, though an ice-line of from 8 to 12 m. in width prevented him from establishing its continuity beyond dispute. The (supposed continental) coast stretched from Ringold's knoll on the e. to Enderby land on the w., and was distinguished by the absence of currents to disturb the ice-barrier, and by a much less precipitous character than belongs to islands. In 1840 a French expedition, under D'Urville, discovered a line of coast lying directly s. from Victoria (Australia) on the antarctic circle. But the most important discoveries of all were achieved by capt. (afterward sir James) Clarke Ross, who made three several voyages in 1841-43, discovering Victoria land (q.v.), and tracing its coast from lat. 71° to lat. $78^{\circ} 10'$ (the highest southern latitude ever attained). In his third voyage Ross proved that the lands discovered by D'Urville were islands of inconsiderable magnitude; and his antarctic expedition has besides supplied much important information to the students of natural history, geology, and, above all, of magnetism (q.v.). Ross's geographical discoveries have since been confirmed; but a large extent of surface within the antarctic circle still remains unexplored.

*POLAR EXPEDITIONS (*ante*). In 1860 Dr. Isaac I. Hayes made an expedition to Smith sound; and, by sledge, to a point as far n. as 82.45 ; and in 1869 visited Greenland, and explored a considerable portion of its southern coast. See HAYES, ISAAC I. *ante*. Unsuccessful efforts were made to reach the n. pole by way of Barentz sea, from 1857 to 1867, by the Swedes, Germans, and Austrians; the German geographer, Petermann having given the weight of his authority to the opinion that this was the most feasible route. Capt. Hall made his first expedition in 1860; and his last, on the *Polaris*, in 1870. See HALL, CHARLES FRANCIS. He added materially to the existing geographical knowledge concerning the arctic regions, and gained valuable information regarding the fate of the Franklin expedition. Lieutenants Weyprecht and Payer, of the German expedition of 1870, discovered the farthest northern land yet found, reaching to lat. 83° . In 1875 capt. Nares made an unsuccessful attempt to reach the n. pole by Smith sound. In 1875, '76, and '78, prof. Nordenskjöld explored from the Norwegian coast by way of the Kara sea, and past the mouth of the Lena river, skirting the whole of Siberia to Behring's straits, demonstrating the practicability of making the voyage by this route from Norway to Japan. On July 8, 1879, the *Jeannette*, a bark-rigged steam-yacht of 420 tons burden, sailed from San Francisco for a voyage of exploration to the arctic regions, via Behring's straits; the first to attempt it by this route. This expedition was fitted out by James Gordon Bennett, proprietor of the New York *Herald*, who, in 1877 had bought the *Pandora* (which had made one arctic voyage under capt. Young), and after having her thoroughly refitted, had christened her the *Jeannette*. She was convoyed as far as St. Paul's, by the U. S. steamer *Alaska*, and after taking in coal, and a supply of trained Esquimaux dogs, set sail for the discovery of the n. pole: at the present writing (April, 1881) the success or failure of this expedition is not known, and the subject of fitting out a vessel to go in search of it is under consideration by congress. The *Jeannette* was commanded by lieut. George W. De Long, U. S. N. In 1877 capt.

H. W. Howgate, U. S. N., proposed a plan for future exploration within the 81st parallel, which met with general approval. This was to establish a colony at some point of the region named, to be made up of hardy and experienced arctic explorers, with a view of making this the base of constant future exploring northward. A bill appropriating \$50,000 for this purpose was introduced into congress; but the design, though not abandoned, has not been as yet accomplished.

Antarctic exploration has not been pursued to near the extent of that which has been directed toward the n. pole. Sir James Ross reached lat. $78^{\circ} 11'$ s. in 1839-43, and this is the most southern point made by any navigator. The climate of the antarctic region is much more severe than that of the arctic; and while there are more and different varieties of birds, there are apparently no quadrupeds. Vegetation, which is prolific within the arctic circle, ceases in the antarctic at a certain point, which for trees is about 56° s. lat. See Supp., page 897

POLARISCOPE, an instrument used for testing the amount of polarization in a beam of light. See **POLARIZATION OF LIGHT**. As polarization of light consists in reducing the luminous vibrations to one plane, that part of a polarizing apparatus—of which there are several kinds—which is called the analyzer performs the office of a polariscope; but to make an efficient instrument, several additions are required. There are different forms. In Arago's polariscope a plate of quartz cut across its axis is placed in one end of a tube, which carries at the other end a double refracting prism, by means of which two images are seen, which in common light are colorless, but in polarized light exhibit complementary colors. In the saccharimeter of Soleil there is a disk of rock crystal made of two semicircular plates respectively cut from crystals of right and left-handed rotatory power. This disk produces the best effect when of a thickness of 0.148 of an inch. When common light passes through this disk, and then through an analyzer, it does not become colored; but if it has been polarized, that is, reduced to vibrations in one plane, the two semicircles of which the disk is composed will exhibit complementary colors, except in one position, when the tint will be the same in both. Any alteration in the power of the medium through which a polarized ray passes to turn the plane of polarization to the right or to the left will cause a reappearance of color, and therefore this instrument is useful in examining sugars. See **SACCHARIMETER** and **SACCHAROMETER**.

POLARITY. The n. and s. poles of the earth's axis are terms familiar to all, and so are the derived terms of the n. and s. poles of a magnet (q. v.). A right-handed and a left-handed corkscrew, or helix, are also perfectly well known. The distinction between the members of any of these pairs leads us to the consideration of polarity, which it is difficult to define except by illustrations. In the case of the helix, it is the difference between right-handed and left-handed; not as in a magnet, the difference between the two ends. If we look closely into the question, we find that it is impossible to define the term "right-handed rotation" in the abstract. We may define it as being the same as that of the hands of a watch, or that of the apparent motion of the celestial bodies about us *in this northern hemisphere*; but to a person at the equator, or to one who had never seen a watch, such comparisons would be without meaning. In fact, it is impossible to give a definition of even such a simple term as *right, down, east, etc.*, independent of reference to the motion or position of some external object. But there is, in many cases, an important scientific reality underlying, and perhaps causing these difficulties. To a spectator looking down upon the n. pole of the earth, the axial rotation would appear to be left-handed, or opposite to that of the hands of a watch; while at the s. pole the appearance is the reverse. In fact, as motion in a horizontal straight line appears to be from right to left, or from left to right, according to the side on which the spectator stands; so motion in a curve appears to be right-handed or left-handed, according to the side of its plane from which it is looked at. And this is now known to be the cause of the difference of poles in a magnet; the hypothesis of two magnetic fluids is dismissed, and Ampère's explanation, that in a magnet currents of electricity revolve round each particle in planes perpendicular to the direction of magnetization, at once accounts for the dissimilarity of the poles. Such a figure as this gives a clear idea of the subject. A little electric current, such as that in the figure, in which positive electricity passes in the direction indicated by the arrow-head, acts upon external bodies exactly as a small magnet would whose axis is, as in the cut, perpendicular to its plane, the arrow-head representing the *north* pole; that is, the pole which turns toward the *south*. Again, an electric current passing in a straight wire would at first sight appear to be altogether independent of polarity; yet it is found that such a current moving in the *straight* line in the cut, in the direction of the arrow-head, tends to make the *north* pole of a magnet rotate round it in the direction indicated by the arrow-head in the circle. Again, there are certain crystals, which, when heated, become electric. One end of a prism of tourmaline, for instance, takes positive, the other negative electricity. Also certain crystals of quartz cause a ray of polarized light, which passes along their axis, to rotate right-handedly; others left-handedly. The difference in these cases is due to molecular arrangement, other effects of which are easily seen in the tourmaline, in the dissymmetry of the two terminals of the prism, and, in quartz, in

the position of certain small faces of the crystal, so that a preliminary inspection enables us to predict the direction of the effect to be obtained from any particular specimen. The term has various other applications, amongst the least defensible of which is that to light. See POLARIZATION OF LIGHT.

POLARIZATION OF LIGHT. A ray of light from the sun or a lamp, which has not been reflected or refracted in its course to the eye, possesses no properties by which one *side* of it can be distinguished from another; if, for instance, it be divided into two by a colorless doubly-refracting crystal, such as Iceland spar, these two rays will be of apparently equal intensity in whatever position the crystal be placed (REFRACTION, DOUBLE). But if the ray has been reflected from a surface of glass or water, it is found that in general the intensities of the two rays into which it is divided by the doubly-refracting crystal are not only unequal, but dependent upon the position of the crystal with reference to the plane in which the light was previously refracted or reflected. This is a conclusive proof that the light has undergone some change by reflection or refraction, so that it is no longer the same all round, but possesses *sides* (in the language of Newton), or (in modern phraseology) is *polarized*. Perhaps the most complete illustration of this very important fact is to be found by using two doubly-refracting bodies—two small crystals of Iceland spar, for instance—and pasting on a side of one of them a slip of paper with a pin-hole in it. On looking through this crystal, the covered side being turned toward a bright body, we see two images of the pin-hole, *equally* bright. Look at these through the second crystal, each is in general doubled; we see four images of the pin-hole, but these are generally *unequal* in brightness; and by turning either of the crystals round the line of sight as an axis, we find that there are positions, at right angles to each other, in which only *two* images are visible. If we turn further, the lost images appear faint at first, and gradually becoming brighter, while the others become fainter in proportion; till, when we have completed a quarter of a revolution, the new images alone remain, the others having disappeared. From this it follows that each of the rays into which a single beam of light is decomposed by double refraction possesses *sides*, or is polarized; and to such an extent as to be incapable of being again doubly refracted in certain positions of the second crystal. By taking advantage of the difference of the refractive indices (REFRACTION) of the two rays produced by Iceland spar, and the close agreement of one of them with that of Canada balsam, Nicol constructed his “prism,” which is one of the most useful pieces of polarizing apparatus. It consists of two pieces of Iceland spar cemented with Canada balsam, and *allows only one of the two rays produced by double refraction to pass through*. When we look at a flame through two Nicol’s prisms in succession, we find that the amount of light transmitted depends on their relative position. If they are *similarly* placed, we have the maximum amount—viz., half the incident light; if they are *crossed*, that is, if one be made to rotate through a right angle from the position last mentioned, *no* light, not even the most powerful sunlight, can pass through the transparent combination. There are certain doubly-refracting bodies, such as tourmaline, iodosulphate of quinine, etc., which by absorption stifle one of the two rays into which they divide a beam of light, and which act therefore precisely as Nicol’s prism does. But they have the great disadvantage of *coloring* the transmitted light very strongly; and this renders them unfit for the study of the gorgeous phenomena of color (perhaps the grandest displays in optics) which are produced by polarized light. But for the verification of the facts to which we now proceed, a tourmaline or a Nicol’s prism will do equally well, and will be called the analyzer. And first as to the reflection of light, a cause of polarization first detected by Malus. If we examine by the analyzer light reflected from water, unsilvered glass, polished or varnished wood, jet, etc., we find that it is more or less completely polarized; but that there is a particular angle for each substance, at which if light be reflected (see REFLECTION) from its surface it is completely polarized; that is, can be completely stopped by the analyzer in certain positions, just as a ray which has passed through a Nicol’s prism. It was discovered by Brewster that this angle, called the *polarizing angle*, has its tangent equal to the index of refraction of the reflecting body: or, in another form, the reflected light from a surface of glass, water, etc., is completely polarized when its direction is perpendicular to that of the corresponding refracted ray. The light reflected from the second surface of a glass plate is also completely polarized at the same angle; and one of the most useful polarizers which can be made is a pile of thin glass plates, from the surfaces of which light is reflected at the proper angle, which is for ordinary window-glass about 54° . The light which passes through the glass plates is partially polarized, and its polarization is more nearly complete the greater the number of plates employed. And it appears that these rays are polarized in planes perpendicular to each other—i.e., that the analyzer which extinguishes the reflected ray has to be turned through 90° to extinguish the refracted ray.

In order that we may arrive at some ideas as to the nature of polarization, we must consider on the basis of the undulatory theory of light (q.v.) *how* a ray of light can have sides. If we take, for a comparison, waves of sound, as we know that in them (SOUND) the particles of air move back and forward in the line in which the sound travels, we see that a beam of sound cannot possibly have sides, since the motions of the particles of air in it are precisely the same from whatever side we consider them. Next take waves

in water, where we see the water rising and falling as the undulation (*not* the water) travels uniformly onward in a horizontal direction; and this at once gives the required analogy. So far as phenomena of interference (q.v.; see also DIFFRACTION) are concerned, waves, whether in air or in water, present them, so that they merely show us that light depends on undulations, but not the kind of undulation. But when, from the facts of polarization, we find that a ray of light can have sides, we see that the vibrations of the luminiferous medium must be *transverse to the direction of the ray*. Common light, then, consists of vibrations which take place indifferently and in succession in all directions transverse to that of the ray; while light which is completely polarized has its vibrations limited to a *particular* transverse direction. A Nicol's prism allows no light to pass through it except that which vibrates in a particular transverse direction, depending upon the position of the axes of the pieces of Iceland spar of which it is made. Light which has passed through one Nicol's prism is sifted so as to contain none but such transverse vibrations, and will of course pass freely through a second prism, or be completely or partially stopped by it; according as the two prisms are similarly situated, or turned so that the directions of the vibrations they can transmit are inclined at right angles, or at any other angle.

It is not yet settled what the direction of these vibrations is in any particular case; whether they take place *in*, or *perpendicular to*, the plane of polarization; and the point is extremely important in the theory of the subject, though not to the explanation of the ordinary experimental results. To explain the nature of this difficulty, we merely mention the simple case of polarization by reflection at a glass plate. Do the vibrations of the reflected ray take place *perpendicular to* the plane of reflection (i.e., parallel to the reflecting surface), or do they take place *in* the plane of reflection? Some high authorities are in favor of the latter hypothesis, but the general opinion of scientific men at present unquestionably leans to the former. Many delicate experiments have been made to decide the question, but their results have been irreconcilable with each other. From the results which we have just arrived at, it is evident that the oscillations, or vibrations of the luminiferous medium, of which light consists, are similar to those of the bob of a pendulum (q.v.), the ray in this case being supposed to proceed vertically downwards. Polarized light consists of vibrations analogous to those of the ordinary pendulum, backward and forward in a line. But we have seen that any motion of the pendulum may be compounded of two such motions in planes perpendicular to each other. This is analogous to the decomposition of common light by a doubly-refracting crystal into two rays polarized at right angles. But we find in nature, and can produce artificially, motions of the luminiferous medium resembling exactly the elliptic, and circular motions of the (conical) pendulum. They occur in nature in all cases of reflection from metallic surfaces, and also from the surfaces of highly refractive bodies, such as diamond, etc. The easiest artificial method of procuring them is to allow polarized light to pass through a thin plate of a doubly refracting crystal, such as a film of mica. Thus if OA be the direction of vibration of the polarized light, the ray moving perpendicularly to the paper Oa , Ob , the directions (at right angles to each other) of vibration of the two rays into which it is divided by the mica, we have only to let fall from A perpendiculars on Oa and Ob to determine the extent of the resolved vibrations in these directions. Now if the two rays moved equally rapidly through the mica, they would simply recombine on leaving it into a single plane polarized ray, whose vibrations would be represented by OA as before. But, in general, one of the rays is retarded more than the other, and the combination of two such oscillations is seen by geometrical considerations to give an ellipse whose center is at O , and which touches each side of the rectangle of which Aa and Ab are half sides. The limiting forms of these ellipses are, of course, the diagonals of the rectangle; so that there are two cases for the light remaining plane polarized after passing through the mica, for an infinite number in which it will be elliptically polarized. Also the difference of retardation of the two rays may be such as to correspond to a description of these ellipses either right-handedly or the opposite. In particular cases the ellipse may be a circle; then it is obvious that the rectangle must become a square, that the directions of vibration of the two rays in the mica must be equally inclined to that of the original polarized ray, and that one ray must be retarded an odd number of quarter oscillations more than the other. If it be 1, 5, 9, etc., quarter oscillations, the rotation is in one direction; if 3, 7, 11, etc., it is in the opposite. Circularly polarized light cannot be distinguished by the eye, even with the help of a Nicol's prism, from common light; but by the interposition of a thin plate of a doubly refracting crystal, phenomena are produced which common light cannot give. Before we leave this part of the subject, it may be remarked that the composition of two equal and opposite circular vibrations produces a plane vibration, whose plane depends upon the simultaneous positions of the revolving bodies in their circular orbits. Hence a plane polarized ray may always be considered as made up of two circularly polarized rays, and if these pass through a medium which retards one more than the other, the plane of polarization of their resultant, when they leave the medium, will in general not be the same as that of the incident ray. In other words, the plane of polar-

FIG. 1.

ization will have been caused to rotate through a certain angle, which will be proportional to the difference of retardation of its circular components. This is the explanation of what Biot called *rotatory polarization* in quartz, turpentine, sugar, etc., and of the rotation of the plane of polarization discovered by Faraday when a polarized ray passes through a transparent body under the action of a magnet.

In the first of these cases, the retardation is due to molecular heterogeneity; in the second, it depends upon molecular motions produced by the magnet. The effect is greater in each case the more refrangible the rays; and therefore, when the light which has passed through the medium is examined with an analyzer, the successive colors of the spectrum are cut off each at a different angle, and the observed tint is that compounded of those which remain. The saccharometer (q.v.), for the determination of sugar in a liquid, is an application of the first case; the second has not as yet been applied to any practical purpose, but it has given most valuable information as to the ultimate nature of magnetism.

When polarized light passes through a slice of any uniaxial double-refracting crystal, nearly in the direction of its axis, it is obvious that the difference of retardation of the two rays into which it is divided will depend only upon (1) their refrangibility and (2) their inclination to the axis of the crystal. Hence, if we suppose the light to be homogeneous, the effects of interference, and subsequent application of the analyzer, must be to produce appearances of bright and dark spaces, symmetrically disposed round the axis; that is, a series of concentric circular rings. The superposition of the separate sets of rings, for each color of the spectrum, produces the appearance actually observed; a series of colored rings, like those known as Newton's rings, due to interference (q.v.). Besides these, however, there is a dark or bright cross, consisting of two black or white

• Fig. 2.—Uniaxial Crystal; Black Cross.

bands, intersecting each other in the common center of the rings. The dark bands are due to the absolute stoppage by polarizer or analyzer, when placed in positions 90° from symmetry, of all light whose vibrations are executed in the principal planes of the polarizer and analyzer. A similar explanation applies to any other case. The system of colored rings thus produced is one of the most splendid results of the optical combinations yet produced; and may be seen by any one by the help of such simple apparatus as two fragments of window-glass and a piece of clear ice from the surface of a pond. In undisturbed freezing, the axis of the ice crystal is perpendicular to the surface of the water, and the cake of ice is therefore, as it were, cut for our purpose. If light be reflected at an angle of about 54° from the first piece of glass, pass perpendicularly through the ice, and be again reflected (at 54°) from the second piece of glass, the phenomena above described will be at once seen, the appearances varying with the relative position of the planes in which the reflections take place from the pieces of glass. If these planes be at right angles to each other, we have the black cross as in figure 2; if parallel, a white cross.

If, instead of a uniaxial crystal, a biaxial crystal, such as riter or arragonite, be employed, the system of colored rings and dark brushes is more complex; symmetry now requiring their arrangement about the *two* optic axes. The general appearance of the rings and brushes depends now, not only on the relative position of the polarizer and analyzer, but also on the position of the crystal (which is no longer symmetrical about an axis) with reference to these planes.

By employing circularly or elliptically polarized light, the appearances may be still further varied, but we cannot enter into details.

Every doubly refracting body produces a change upon polarized light which passes through it. Hence the application of the polarizer and analyzer (usually glass mirrors, or Nicol's prisms) to the microscope is often of very great use in detecting crystalline, and other structural peculiarities. Solid bodies, such as glass, which are singly refractive, become doubly refractive when strained either by external forces or by unequal heating. A permanent state of strain is produced in glass when it is cooled quickly. All these phenomena are beautifully exhibited by polarized light. Again, the application of polarized light is sometimes of great importance in qualitative analysis, where only an exceedingly small quantity of a substance is procurable for examination, by enabling the chemist to determine whether a minute crystal is doubly refractive or not.

A practical application of a polarizing prism may be mentioned. In salmon spearing it is often exceedingly difficult to see the fish at the bottom of the stream, on account of the glare of light reflected from the surface. But as this light is always partially, sometimes wholly polarized, a great part of it may be arrested by the analyzer held in a proper azimuth; while the light escaping from the water will suffer little loss.

The light of the sky, being mainly reflected light, is of course partially polarized. The investigation of this subject has been most ably conducted by Brewster (*Trans. R. S. E.*, 1862-63).

POLDER, a word used in the topography of the Netherlands, is the name given to land below the level of the sea or nearest river, which, originally a morass or lake, has been drained and brought under cultivation. An embankment, forming a canal of sufficient height to command a run toward the sea or river, is made, and when carried quite round, as in the case of the Haarlem lake, it is called the *ringvaart*. At one or more points on the embankment apparatus for lifting water is placed, and worked by wind or steam power. If the lake deepens toward the center, several embankments and canals are necessary, the one within the other, formed at different levels as the water-surface becomes lessened, a connection being maintained with the outer canal, which secures a run for the drainage water. In the Schermer polder, north Holland, are four canal levels, the land between forming long parallelograms. The water from the inner space is lifted into the first canal; that again, with the drainage of the second section, is thrown into the second, and so on until the outer canal is reached, and a fail obtained. The Netherlands polders are very numerous. The Beemster, a rich district of north Holland, till 1612 water, is crossed at right angles by fine avenues, and dotted with farm-houses and orchards. In 1865, pop. 3,938. The Zype, Schermer, and Purmer are fertile polders, but the most important is the drained Haarlem lake (q.v.). The land reclaimed amounted to nearly 50,000 acres, and, in 1875, had a pop. of 12,570, with 2,867 horses, 5,897 head of horned cattle, 7,923 sheep, etc. There were in cultivation—colza, 633 acres; madder, 318; flax, 2,572; beans, 2,353; potatoes, 737; wheat, 4,562; rye, 2,302; barley, 2,145; oats, 12,734; beet, 400; peas, 737; mustard, 95; canary seed, 42; and other crops, 270. In 1874 in the Haarlemmeer were 644 births, 334 deaths, and 95 marriages. In connection with the new canal from the North sea to Amsterdam, several extensive tracts of land have been reclaimed from the Ij, and formed into valuable polders, some of which are now bearing heavy crops.

POLE, Cardinal REGINALD, b. in Staffordshire in the year 1500, was the son of sir Richard Pole, lord Montacute, by Margaret, countess of Salisbury, daughter of the duke of Clarence, the brother of Edward IV. His early education was received from the Carthusians at Sheen, whence, being liberally provided for by the king his relative, he passed to Magdalen college, Oxford, and having received deacon's orders, was advanced to several valuable preferments, through the favor of the king, Henry VIII. For the future prosecution of his studies, he went to the university of Paris, and thence to Padua, where he formed the friendship of a distinguished group of scholars and friends, all of whom subsequently took a leading part in public affairs—Contareni, Bembo, Sadoleto, and others. In 1525 he returned to England, where the highest ecclesiastical dignities awaited his acceptance. But it was about this time that Henry had resolved upon the divorce from his queen Catharine, and Pole not only withheld his assistance in carrying out the project, but provoked the undying resentment of the king by his well-known treatise, *De Unitate Ecclesiasticâ*. His preferments and pension were withdrawn, and preparations were made for his impeachment. This, and probably still more extreme measures, he evaded by withdrawing from England. The king's resentment fell instead upon his elder brother, and upon his aged mother, the countess of Salisbury. During the rest of Henry's reign, Pole remained in exile. The pope, for the maintenance of whose authority, in the cause of the injured Catharine, Pole was regarded as a martyr, treated him with distinguished favor, and elevated him to the cardinalate. He was employed in many affairs of the highest importance, being sent as legate, in 1537, to France and the Low Countries, from both which states Henry VIII. in vain demanded his extradition. He also took an active part in the discussion on the interim, and when the council of Trent was opened, he was appointed one of the three legate-presidents who acted in the name of the pope, Paul III. (q.v.). On this pontiff's death in 1549, Pole was all but elected to succeed. For some time after Paul's death, he resided chiefly in a monastery near Verona, in comparative retirement, until the accession of Mary called him back to active life, as the main instrument of the reconciliation of England with the papacy. On Nov. 24, 1554, Pole solemnly entered London as legate and plenipotentiary of the Roman see, possessing in an equal degree the confidence of the queen. In the arduous charge thus intrusted to him, he acquitted himself with much prudence, and, considering the circumstances of the time, with singular moderation. In the religious or politico-religious severities which marked the later history of Mary's reign, it is all but certain that Pole had no share. He was created archbishop of Canterbury, and chancellor of the universities of Oxford and Cambridge. On the difficult and critical question of the disposal of the church property confiscated in the former reign, Pole, who saw the necessity of moderation, was for a time at issue with the pope; but his representations were successful in producing a more moderate policy, and the work of reunion appeared to proceed with every prospect of a complete permanent issue, when it was interrupted by the death of the queen in 1558. Pole died within less than twenty-four hours afterward. Besides the treatise *De Unitate*, already mentioned, he is also the author of a book *De Concilio*, and of other treatises on the authority of the Roman pontiff and the reformation of England, and of very many most important letters, full of interest for the history of the time.

POLEAXE, a weapon consisting of an axe-head mounted on a long pole. There were many varieties of this arm, passing from a great hand-axe to an axe-headed spear or

halbert, several of the longer sorts bearing but little resemblance to an axe. In the navy, a poleaxe or boarding-hatchet is a hatchet with a handle about fifteen inches long, and a sharp point bending downward at the back opposite the blade. It is used for boarding or resisting boarders.

POLECAT, or **FITCHET**, *Mustela putorius*, or *Putorius fœtidus*, a quadruped of the weasel family (*mustelidæ*), and commonly referred to the same genus with the weasel, stoat, or ermine, etc. It is the largest British species of that genus, the length of the head and body being about a foot and a half, the length of the tail more than five inches, the form stouter than that of the weasel or of the ermine. Its color is a deep blackish brown; the head, tail, and feet almost black, the under parts yellowish, the ears edged with white, and a whitish space round the muzzle. The hair is of two kinds—a short woolly fur, which is pale yellow, or somewhat tawny; and long shining hairs of a rich black or brownish-black color, which are most numerous on the darkest parts. The nose is sharp, the ears short and round, the tail pretty equally covered with longish hair. There is a pouch or follicle under the tail, which exudes a yellowish, creamy substance of a very fetid odor; and this odor is particularly strong when the animal is irritated or alarmed. Hence, apparently, its name *foumart* (*foul marten*), which, with various provincial modifications, as *fulimart*, *thoumart*, etc., is prevalent in most parts of Britain. The origin of the names polecat and fitchet is much more uncertain.

The polecat was much more common in Britain in former times than now, and is almost extirpated from some districts, through the constant war waged against it by gamekeepers and others. It eats everything that the gamekeeper wishes to preserve. It is extremely destructive in the poultry-yard, the abundance present there inviting it to drink blood and eat brains, which seem to be its favorite luxuries. The rabbit is followed by the polecat into its burrow, and its ravages among poultry are partly compensated by its destruction of rats.—The taming of the polecat does not seem to have been attempted. The smell prevents it.—The skin is imported from the n. of Europe under the name of *fitch*, and is used as a kind of fur, similar but inferior to that of the marten (q.v.). It is imported to some extent from the n. of Europe. To artists, the hair of the *fitch* or *fitchet* is well known as that of which their best brushes are made; the hairs used for this purpose being the long hairs already noticed, which grow through the lighter-colored fur of the animal.—The ferret (q.v.) is supposed by some to be a mere variety of the polecat.—A dark-colored kind of ferret is commonly regarded as a cross between the polecat and the ferret, and is sometimes called the *polecat-ferret*. The polecat breeds in May or June, making its nest in an old rabbit burrow or similar hole, and producing four, five, or six young.—In North America the skunk (q.v.) is called polecat.

POLEMONIA'CEÆ, a natural order of exogenous plants, allied to *convolvulaceæ*, and containing more than 100 known species, natives of temperate countries, and particularly abundant in the north-western parts of America. They are mostly herbaceous plants, with alternate and often pinnated leaves; regular hermaphrodite flowers; 5-cleft calyx; 5-lobed corolla; 5 stamens, springing from the tube of the corolla; the ovary free, surrounded with a fleshy disk; the style surmounted by a 3-cleft stigma; the fruit a capsule with 3 cells and 3 valves; the seeds often enveloped in mucus, which contains spiral threads. Some of the species are favorite garden flowers, as *polemonium cœruleum*, *codea scandens*, and species of *phlox*, *ipomopsis*, *gilia*, etc. None are of value otherwise. *Polemonium cœruleum*, the only British species, and a rare plant in Britain, is well known in gardens by the curious name of *Jacob's ladder*. It is also called *Greek valerian*. It is not supposed to be really the *polemonium* of the ancients, to which great medical virtues were ascribed by them. It has a stem from one to two feet high, pinnate leaves, and a panicle of blue (or white) flowers.

POLEN'TA, a preparation of semolina (q.v.) or of Indian corn or maize meal, which is used as food by all classes in Italy. By the poorer classes, maize is universally used. The material is mixed with milk or water, and boiled until it is just thick enough to pour out into a dish, in which it becomes as firm as a thick jelly. Cheese is grated over it, and other condiments are added according to taste, and it is cut out in slices, and either eaten at once, or sometimes the slices are lightly fried in oil or butter. Semolina being much more expensive, is only used by the wealthier people, and many ingredients are added to suit their taste.

POLES (Gr. *polos*, a turning-point), in *geography*, are the two extremities of the axis round which the earth revolves; they are therefore situated the one on the n. and the other on the s. side of the equator, and equidistant from all parts of it, or in lat. 90° n. and lat. 90° south. They are called the north and south poles of the earth.—In *astronomy*, the poles, which, for distinction's sake, are frequently denominated “celestial poles,” are those points in the heavens to which the earth's axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astronomers and geographers, so that the determination of their position in the heavens is a matter of the utmost importance. Unfortunately no stars mark their exact situation (see **POLE-STAR**) though there is a minute telescopic star only a few seconds from the north pole, which may be employed instead of it in rough observations—and therefore it is necessary to adopt some means for discovering its precise position. This is effected in the following manner: A bright star (generally the pole-star) is selected, and its position

in its upper and its lower *culminations* (q.v.) is accurately noted; the point midway between these two positions of the star is the pole of the heavens. The observation of the star's two positions must be corrected for refraction, and it is for this reason that the pole-star is selected, since the effect of refraction is much the same in both positions of the star. The term "poles" has, however, a wider application, as denoting the extremities of a line passing through the center of a great circle perpendicular to its plane; thus, we have the poles of the horizon (viz., the zenith and nadir), the poles of the ecliptic, the poles of a meridian; and in the same sense, the terrestrial and celestial poles are spoken of as the poles of the equator and equinoctial respectively.—Pole, in *geometry*, is used in a very indefinite sense; and in *physics*, it denotes those points of a body at which its attractive or repulsive energy is concentrated. See POLARITY and TERRESTRIAL MAGNETISM.

POLE-STAR, or POLARIS, the nearest conspicuous star to the north pole of the celestial equator. The star which at the present time goes under the name of the "pole-star" is the star α in the constellation of Ursa Minor. By examining attentively the general movement of the stars throughout a clear winter's night, we observe that they describe circles which are largest at the equator, and become smaller and smaller as we approach a certain point (the north pole of the celestial equator), close to which is the star above mentioned. This "pole-star" is, however, a little less than $1\frac{1}{2}^\circ$ from the pole, and has a small but sensible motion round it. See POLES. Owing to the motion of the pole of the celestial equator round that of the ecliptic (see PRECESSION OF THE EQUINOXES), this star will in course of time (about 2100 A.D.) approach to within 28' from the north pole, and will then recede from it. At the time of Hipparchus (156 B.C.), it was 12° , and in 1785, $2^\circ 2'$ from the north pole. Its place can easily be found in the heavens, for a line drawn between the stars α and β (called the two *pointers*, from this peculiarity) of the constellation Ursa Major, or the Great Bear, and produced northwards for about $4\frac{1}{2}$ times its own length, will almost touch the pole-star. Two thousand years ago, the star β of Ursa Major was the pole-star; and about 2,300 years before the Christian era, the star α in the constellation of the dragon was not more than 10' from the north-pole; while 12,000 years after the present time, the bright star Vega in Lyra will be within 5° of it.

The south pole of the celestial equator is not similarly marked by the near neighborhood of a bright star, the only star deserving the name of the south pole-star being of the sixth or least visible magnitude.

POLIAN'THES. See TUEEROSE.

***POLICE'** (Lat. *politia*, Gr. *politeia*, civil government; from *polis*, a city) are constables or peace-officers appointed in all parts of town and country for the purpose of watching property and detecting crime, and arresting offenders and maintaining public order. Though the word policeman is now, especially in towns, a household word, the legal denomination is that of constable; but he is a paid constable, to distinguish him from unpaid constables and special constables. In each parish in England the justices of the peace have power to appoint constables to act gratuitously and compulsorily; but the vestry has power to resolve that one or more paid constables shall be appointed, in which case the justices are to make the appointment, and these paid constables supersede the unpaid constables. The salary of these parish constables is paid out of the poor rates of the parish by the overseers. The justices also appoint a superintendent constable for each petty sessional division, to settle the fees and allowances which are to be paid to the constables for the service of summonses, and for the execution of warrants incidental to the office of justices of the peace. In all boroughs in England, the corporation is empowered, by the municipal corporation acts, to appoint a watch committee, who appoint a sufficient number of men to act as constables. The treasurer of the borough pays their salaries, wages, and allowances, as well as extraordinary expenses incurred by them. By an act of parliament applicable to counties, the justices are empowered to establish a sufficient police force for each county, and a chief constable is appointed to govern the whole.

The duties of constables or police-officers are exceedingly multifarious, and they receive printed regulations to guide them in the proper discharge of such duties. They have important duties in reference to the apprehension of offenders, and their powers are necessarily larger than those of private individuals. Wherever a person is seen in the act of committing a felony, it is the duty of every one, not merely of constables, to apprehend him or her without any warrant, for no warrant is needed. Persons found offending in many misdemeanors may also be apprehended by anybody without a warrant; but in other cases, a constable only can make an arrest. In case of a riot, anybody may arrest the rioter. Constables are bound to arrest hawkers trading without a license; and vagrants who are offending against the vagrant acts, such as telling fortunes, loitering about premises, etc. The powers of constables are much greater than those of individuals with reference to crimes after they are committed. Thus, where the constable has not seen the offense committed, but is merely told of the fact, and he has reason to believe it, he is entitled to arrest the party charged without any warrant; he must, however, in such cases act only on reasonable suspicion. He is not justified, for example, in apprehending a person as a receiver of stolen goods on the mere assertion of the principal felon; nor is a constable justified in taking a person into custody for a mere assault without a warrant, unless he himself was present at the time the assault

was committed, or reasonably apprehends a renewal of it. If a constable have a reasonable suspicion that a man has committed a felony, he may apprehend him; and so a private individual may do so. The difference between the authority of the constable and the private person in this respect is, that the latter is justified only in case it turn out that a felony was in fact committed; but the constable may justify the arrest and detention whether a felony was committed or not. It is the duty of a constable to raise a hue and cry in search of a felon, and all private individuals are bound to join in it, otherwise they may be indicted and fined. An arrest by a constable is usually made by laying hands on the party, and detaining him; but it is enough for the constable to touch him and say: "I arrest you, in the queen's name." If the party arrested be in a house in hiding, the constable may demand admittance, and if he is refused may then break open the doors; this is so in all cases where the party has committed treason or felony, or has dangerously wounded another. In cases where the constable is not authorized at common law or by some statute to arrest a party without a warrant, then he must produce a warrant signed by a justice of the peace, and show it to the party if it is demanded; and if the constable happens not to have the warrant in his pocket at the time, even though it is not asked for, it is an illegal arrest. When a party is arrested, it is the duty of the constable to take him without any unreasonable delay before a justice of the peace, and meanwhile lodge him in safe custody. The party arrested must not be treated with harshness beyond what is necessary for safe custody, and therefore it has been held that a constable has no right to handcuff a person whom he has apprehended on suspicion of felony, unless such person has attempted to escape, or it be necessary to prevent an escape. Nor has a constable in general a right to search a person apprehended, unless the latter conduct himself violently.

The conduct of constables in reference to public-houses is of some importance. It is an offense in publicans and beer-house keepers, and indeed the keepers of all places of public resort, to refuse to admit the constable into such house or place at any time. Thus, in the case of these places being open on Sundays at the times prohibited by statute, the constable, if he suspect that the act is being violated, may demand admittance, and thus satisfy himself as to the fact. It is owing also to this power of a constable to enter at all times, that he is enabled to detect other offenses in public-houses, such as harboring prostitutes and disorderly characters. Constables, when suspecting that a betting house is kept, must first get a warrant from a justice of the peace, which can be obtained without notice to the parties, and can then break into the house. So as to gaming-houses. While constables have summary power of entering public-houses, still this is not to be abused; and it is a distinct offense in the keepers of all public places where wine, spirits, beer, cider, or any fermented or distilled liquors are sold on the premises, to knowingly harbor, or entertain, or suffer to remain there such constables during the time they are on duty, except when quelling disturbances or restoring order. It is an offense punishable with more than usual severity to assault constables when in the execution of their duty. Though constables are paid in great part by each county and borough, and thus by the public at large, it is often requisite for individuals to require the services of extra constables, in which case such individuals must pay for them at their own expense, as is usual in theaters and large establishments. Of late years, considerable complaint had been made as to constables interfering in the protection of game-preserves and fisheries, it being considered that the owners of those properties ought to bear the extra charge, if required, of the constables' giving more than ordinary attention to poachers. But by the recent act, extended powers of detecting poachers of game were given to constables, who are now entitled, whenever they suspect people on the highway of being engaged in poaching, to stop and search them, and then summon the poachers, if necessary, before justices. See POACHING.

In 1880 the total police and constabulary in England and Wales amounted to 31,480 men. These are subdivided into chief constables of counties, 56; head constables of boroughs, 163; superintendents, 521; inspectors, 1,311; sergeants, 3,008; constables, 25,511; additional constables, 390. The proportion of policemen to the population is about 1 to 800. In 1880 the total police expenses amounted to £3,113,725, of which less than £500,000 was paid by her majesty's treasury and out of the superannuation fund. In the estimates for 1878-79, the total expenditure on the police force of the United Kingdom was entered at £2,543,235. It is noticeable that in the same year in which the clothing and accoutrements of the police cost £177,678, the station-house charges, printing, and stationery amounted to £187,372. The public revenue pays nothing toward the city of London police; it pays all the cost of the dock-yard police; it pays nearly one-fifth of the other branches of the police.

In Ireland, the first regular police force was established in 1814, which was improved in 1836 and 1839. Originally, the expense was defrayed partly out of the consolidated fund; but in 1846 the whole expense was borne by the consolidated fund, with trifling exceptions. In 1880 the total cost of the constabulary of Ireland amounted to £1,095,121, which included items of expenditure, such as pensions, gratuities, rent of barracks, horses, forage, arms, ammunition, pay, and clothing. The number of constables in 1880 was 11,121, besides 1,111 Dublin metropolitan police.

In Scotland, during the year ending Mar., 1880, the police force for the counties was 1,331, and that for the burghs was 2,371; total, 3,702. In addition to this number, the

Tweed commissioners paid for 30 constables; 12 more are paid by other fishery commissioners, 20 employed by companies or private persons, and 161 by harbor boards. See Supp., page 897.

POLICE, MILITARY, has two significations—1st, the organized body employed within an army to preserve civil order, as distinct from military discipline; and 2d, a civil police with a military organization. The police of an army commonly consists of steady intelligent soldiers, who act under the orders of the provost-marshal, and arrest all persons out of bounds, civilians not authorized to pass the lines, disorderly soldiers, etc.; they also attend to sanitary arrangements. As in all military matters, the police of an army possess summary powers, and a sentence of the provost-marshal is carried out immediately after it is pronounced.

Of civil police with military organization may be instanced, as specimens, the gendarmerie (q. v.) of France, the Sbirri of Italy, and, in an eminent degree, the Irish constabulary.

POLICY (a corruption of the Lat. *polyptycha*, [analogous to *diptycha*, i. e., two-fold, or a pair of tablets] applied in the middle ages to memoranda or registers written on a set of several tablets), as a legal term, denotes the contract of insurance (Ital. *polizza d'assicurazione*). The usual contracts are for the insurance of life, or rather against the risk of death, against fire, against loss of a ship; but the same name is given to a similar instrument adapted to meet any other risk. See INSURANCE.

POLIGNAC, an ancient French family, which takes its name from a castle said to have been built in the 5th c., on a rock of the Cevennes, near Puy-en-Velay, in the department of Haute-Loire, on the site of a Roman temple dedicated to Apollo, whence—according to certain rather credulous genealogists—the castle was originally called *Apollianique*, of which Polignac is affirmed to be only a later corruption. The first of the Polignacs who acquired celebrity was MELCHIOR DE POLIGNAC, younger son of ARMAND, 16th MARQUIS DE POLIGNAC, and born at Puy-en-Velay, Oct. 11, 1661. Destined by his parents for an ecclesiastical career, he received an excellent education at Paris in the colleges of Clermont and Harcourt. In the negotiations of cardinal de Bouillon with pope Alexander VIII. at Rome in 1689, the young but astute and insinuating abbé took a principal part. In 1695 he was sent to Poland as French ambassador, when John Sobieski was dying, and diplomatized and intrigued so cunningly in favor of prince de Conti, that the latter was actually elected his successor. Events, however, frustrated this policy, and both Conti and Polignac had to leave Poland rather precipitately, in consequence of which the latter lost the royal favor. He now retired to his abbey at Bonport, where he spent the next four years, partly occupied in the composition of a Latin poem entitled *Anti-Lucrétius*, which was intended as a refutation of the skepticism of Bayle. It appears to be a very respectable and even able performance. In 1702—after a stroke of his usual neat flattery—he was recalled to Versailles, and rose higher into favor than ever. Named *auditeur de rote* in 1706, he was sent to Rome, where he devoted himself to the study of canon and civil law, was associated in the negotiations of cardinal de la Trémouille, and honored with the friendship of pope Clement XI. In 1712 he was appointed French plenipotentiary at the congress of Utrecht; and after his return, obtained the abbeys of Corbie and Anchin. When Louis XIV. died, Polignac was at the top of his reputation and influence. During the regency of the duke of Orleans, he took part in the conspiracy of Cellamare, and was banished to his abbey of Anchin. In 1720 he was sent to Rome, charged with the conduct of French affairs, and remained here for about ten years, and signalized his mission by healing the quarrel that was dividing the Gallican church on the subject of the famous bull *Unigenitus*. In 1726 he was raised, in his absence, to the archbishopric of Auch; and on his return to France, spent the remainder of his days in literary repose, and in the high esteem of courtiers, scholars, and the like. He died April 3, 1742. Polignac succeeded Bossuet at the académie Française in 1704, and became an honorary member of the *académie les sciences* (1715) and of the *académie des belles-lettres* (1717). See C. Faucher's *Histoire du Cardinal de Polignac* (2 vols., Paris, 1772), St. Simon's *Memoires*, and D'Argenson's *Memoires*.

The other members of the Polignac family who have an historical name at all are more notorious than noteworthy. In the reign of Louis XVI., TOLANDE-MARTINE, GABRIELLE DE POLASTDRON, DUCHESSE DE POLIGNAC (born 1749; died at Vienna, Dec. 9, 1793), and her husband, JULES, DUC DE POLIGNAC (died at St. Petersburg, 1817), were among the worst, but unhappily most favored advisers of Marie Antoinette. They obtained vast sums of the public money from their royal master and mistress, and were largely, if not mainly responsible for the frightful pecuniary extravagance of the court. The discovery of the famous *libre rouge* occasioned the exulting cry of Mirabeau: *Mille Écus à la famille d'Assas pour avoir sauvé l'état; un million à la famille Polignac pour l'avoir perdu!* The Polignacs—knowing the deep hatred felt toward them by the French people—were the first of the *noblesse* to emigrate (July 16, 1789). From the empress Catharine of Russia the duke received an estate in the Ukraine, and did not return to France at the restoration. He left three sons and a daughter, of whom only one has become historical—AUGUSTE JULES ARMAND MARIE, PRINCE DE POLIGNAC (born at Versailles, May 14, 1780). On the restoration, he returned to France; became intimate with the comte d'Artois, afterward Charles X.; showed an ardent attachment

to the church of Rome—or at least to its policy—and, in consequence, received from his holiness, in 1820, the title of prince; was appointed ambassador at the English court in 1823; and finally, in 1829, became head of the last Bourbon ministry, in which capacity he promulgated the fatal ordonnances that called France to arms, and drove Charles X. from the throne. He then attempted to flee from the country, but was captured at Granville on Aug. 15; was tried, and condemned to imprisonment for life in the castle of Ham, but was set at liberty by the amnesty of Nov. 29, 1836. He took up his residence in England, but died at Paris, Mar. 2, 1847.

POLISH LANGUAGE AND LITERATURE. The Polish language is one of the most widely-spread branches of the Slavic, forming (according to Dobrowsky), along with the Bohemian, the western branch. It surpasses almost all the other Slavonic tongues in euphony and flexibility, and is scarcely excelled by any language in point of brevity. It does not make use of the article, but has a most elaborate declensional system, comprising seven cases. The conjugation of the verb is equally elaborate, and enables a Pole to express transitions and delicate niceties in the conditions of time and gender quite unknown to the French, or German, or English verb. The Polish vocabulary is also uncommonly rich. The number of harsh consonants in the language, it must be admitted, is large, and this fact is a marked distinction between it and its eastern sister, the Russian; but in pronunciation, these are so much softened that its euphony is preserved. It alone of all the Slavic dialects, with exception of the old Slavic church language, has two nasal sounds: one like the French *on*, the other like the French *in*. The letter *l* has also a peculiarly broad snarling sound. After the introduction of Christianity, Latin, the language of the church, exercised a powerful influence on its structure and development, and subsequent to the 14th c. it adopted into its vocabulary numerous German words. In the 16th c., Polish, as a written language, rapidly attained so high a degree of perfection that it supplanted even Latin itself, until then the language of the state and of the learned. The best Polish grammars are those of Mrongovius (3d ed., Danz. 1837), Bandtke (Breslau, 1824), Muczowski (Crac. 1845), and Booch-Arkossy (1866); the most comprehensive dictionary is that of Linde, after which rank those of Bandtke (2 vols., Breslau, 1806), Mrongovius (Königsb. 1835), Trojanski (4 vols., Posen, 1835-46), and Liebkind (1855).

The history of Polish literature is divisible into five clearly-marked periods. The *first* extends from a date antecedent to the introduction of Christianity down to the close of the 15th century. Of pre-Christian Polish literature, nothing has survived but some popular songs and proverbs. Among the very oldest literary monuments is a hymn to the virgin Mary, ascribed to St. Adalbert. The introduction of Christianity paved the way for a Latin literature more or less ecclesiastico-historical. Casimir III. (q.v.), surnamed the Great, did more than any other early Polish monarch for the encouragement of literature, and, among other things, founded the university of Cracow, which, from the beginning of the 15th c., long continued to be the center of intellectual life and culture in Poland. To the 15th c. belong Jan Długosz (Lat. *Longinus*) author of a most interesting and valuable *Historia Poloniæ*, in 13 books, and otherwise worthy of remembrance as an able diplomatist and philanthropist; also Jan Łaski, archbishop of Gnesen (b. 1457, d. 1531), whose collection of the oldest Polish laws, *Commune Incltyi Poloniæ Regni Privilegium*, is of great historical importance. In 1490 the first printing-press in Poland was established at Cracow.

The *second* period of Polish literature embraces the 16th and first quarter of the 17th c., and is marked by the use of the Polish as a written language. The reigns of Sigismund I. and Sigismund II. Augustus are regarded as the golden era of Polish literature, properly so called. The series of poets begins with Nikol. Rej (b. 1515, d. 1568), commonly called the *father of Polish poetry*, a native of Zoravno, in "Little Russia," and educated at Lemberg and Cracow. He spent his life at the court of the Sigismunds. His principal works, *Wizerunek Żywota Człowieka Poczciwego* (Crac. 1560) and *Apophthegmata* (Crac. 1568), are full of sharp wit and strong satire, and though the language is rough and unpolished, it is genuinely poetical. After Rej, the brothers Jan and Piotr Kochanowski hold the highest rank. Szymonowicz or Simonides (d. 1629) acquired by his Latin odes the name of the "Latin Pindar;" and his *Sielanki* ("Idyls," new ed., Leip. 1837), modeled on those of Theocritus, exhibit a charming simplicity of style. Still more original, if scarcely so graceful, are the *Sielanki* (new ed., Leip. 1836) of his friend Zimorowicz (d. 1629). Sebastian Klonowicz, called *Acernus* (d. 1608), is celebrated as a satirist and descriptive poet. The reformation, which rapidly made way in Poland, being tacitly approved of by the rulers and magnates, gave a powerful stimulus to the intellectual and spiritual activity of the nation—visible in translations of the Bible, hymn-books, and an important pulpit or sermon literature. Among the historians of this period, the most celebrated are the brothers Bielski; Lukasz Górnicki (d. 1591), author of a history of the Polish crown (*Dzieje w Koronie Polskiej*, Crac. 1637, Wars. 1804); Strzickowski (d. 1582), whose *Chronicle of Lithuania* (Königsb. 1582) is an admirable work; and Paprocki (d. 1614).

The *third* period of Polish literature, extending from 1620 to 1750, is coincident with the rule of the Jesuits, who first obtained a footing in Poland about 1566, through the influence of cardinal Hosius, soon possessed themselves of the schools, and, on the whole.

seriously checked the literary and religious growth of the nation. The most conspicuous poet of this retrogressive period is the Jesuit Kazimierz Sarbievski (1595-1640), who wrote only in Latin; others more or less noteworthy are Kochowski (d. about 1700); Twardowski (d. about 1660); Opalinski (d. 1655); Chros'cinski, the translator of Lucan; Morsztyn, the translator of Corneille; and Elz'sbieta Druz'backa (d. 1760). Among the historians of this period, it may suffice to mention Starovolski (d. 1656), author of *Polonia, sive Status Regni Poloniæ Descriptio* (Wölfenbuttel, 1656), and other works; Kojalowicz, a Jesuit (d. 1677), and Kaspar Niesiecki, a Jesuit (d. 1745), whose *Korona Polska* (4 vols., Lemb. 1728-43) is the most important work on Polish heraldry.

The *fourth* period, commencing with the middle of the 18th c., and extending into the first quarter of the 19th, owes its characteristics partly to the influence of the French literature of Louis XIV.'s time; partly also to the liberal patronage of literature and science by king Stanislas Augustus, the princes Czartoryski, Jablonovski, and other magnates, and the educational reforms of Stanislas Konarski (b. 1700, d. 1773). The good work begun by Konarski was carried on by Kopczyn'ski (1735-1817), who was the first to thoroughly establish on a scientific basis the grammar of the Polish language in his *Grammatyka Norodowa*; by Piramowicz (d. 1801); by Bohomolec, the Jesuit, who translated a multitude of stage-pieces from the French; but above all, by Adam Stanislas Naruszewicz, the accomplished translator of Tacitus; and Ignacy Krasicki (1735-1801), called the "Polish Voltaire," the center of the whole Polish literature of his age, whose satires and fables are reckoned the first in his native language. As poets of this renaissance period, occur the names of Trembecki, Cajetan Wegierski, Godebski, and Wezik. The most noted dramatist is Boguslavski (d. 1829), who wrote about 80 plays—the majority of which, under the title of *Dziela Dramatyczne*, were published at Warsaw (9 vols., 1820).

The political storms that swept over Europe at the close of the 18th and the first years of the 19th c., did not quite destroy the new literary life that had burst into blossom under Stanislas Augustus. In 1801 the historian Tadeusz Czacki, Franciszek Dmochowski, and bishop Jan Albertrandy founded at Warsaw the "society of the friends of knowledge," which, especially under the auspices of the state-councilor Staszyc, bore good fruit till it was dissolved in 1832, when its library of 50,000 vols. was carried off to St. Petersburg. At the same time, Jozel Maximilian Ossolinski, Hugo Kolontaj, and Stanislas Potocki, by word and writing exercised a mighty influence on the renovation of the national spirit. The transition to this *newest* or *fifth* period was made by Karpinski (1745-1825), whose songs and idyls (4 vols., Warsaw, 1804; new ed., Leip. 1836) live on the lips of the Polish people; by chancellor Voroniecz (1757-1829), a richly imaginative poet, and a great orator; by Niemcewicz (1757-1841), a statesman, soldier, and author of celebrity in his own land; and by the poet Kasimierz Brodzinski (1791-1835). At Wilna, which, after 1815, became the center of Polish literary activity, and a rallying-point for all the enthusiastic spirits of the land, several young men united, with Adam Mickiewicz (b. 1798) at their head, in a crusade against the still dominant French style of literature. We can only name some of his numerous and brilliant associates, as Malczewski (1792-1826), whose best production is his epic-lyric narrative of Ukraine life, entitled *Marja*; Goszczynski (b. 1806; poems, 3d ed., Breslau, 1852); Bohdan Zaleski (b. 1802); *Poezye*, Pos. 1841, and later); Tomasz Padura (*Pienia*, Lemb. 1842); Odyniec (*Poezye*, Pos. 1833); Korsak (*Poezye*, Pos. 1833); Chodzko (*Poezye*, Petersb. 1829); Groza (*Poezye*, Wilna, 1836); Lucyan Siemienski (b. 1809), an excellent novelist and translator; Bielovski (b. 1806), a lyric poet and translator; Gorecki, renowned for his pungently sarcastic fables (*Bajki i Poezj nowe*, appeared at Paris in 1833); Garczynski (*Poezye*, Paris, 1833); and Slowacki, the most fertile of all the recent Polish poets. Most of these writers became either "banished men," or men who, while living, were forced to expatriate themselves. They belonged to the "Polish emigration," whose headquarters was Paris. The most many-sided and prolific of all the modern Polish novelists is Jozef Ignacy Kraszewski, who was born at Warsaw in 1812. The new national tendency of Polish literature, which naturally first showed itself in poetry, soon became visible in other departments also. Thus, Joachim Lelewel (b. 1786) rose to the first rank as a writer of Polish history, and a study of his works is absolutely indispensable to a knowledge of that subject; next to him (and later) in the same department stand Bandtke, Maciejovski, count Raczynski, and count Plater. Narbutt of Wilna wrote a very solid and comprehensive work on Lithuanian history (Wilna, 1837 *et seq.*), and Lukaszewicz of Posen has furnished numerous important contributions to the history of the reformation in Poland. A multitude of works more or less weighty have been devoted to a record of the revolution of 1830, chiefly, of course, by Polish emigrants. In philosophy, theology, and physical sciences Poland has nothing of consequence to show.—The principal works on Polish literature are those of Muczkovski, Bentkovski, Ossolinski, Chodyncki, Lukaszewicz (Posen, 1860) and the comprehensive history by Viszniewski. See also Nitschmann, and works by Morfill.

POLISHING MATERIALS. See DIAMOND-GRINDING, EMERY, PASTES, and PUTTY POWDER.

POLISHING OF METALS. This is effected by first removing any tarnish or oxidation by means of some material which will chemically act upon it; for this purpose sulphuric,

hydrochloric, oxalic, and acetic acids are used to different metals, and in various states of dilution. Usually, it is necessary to remove the acid with clean water, and dry rapidly, to prevent re-oxidation; and then either friction with various polishing materials, or rubbing with a smooth hard surface or burnisher, brings out the luster of the metal.

POLISHING SLATE, a mineral composed chiefly of silica, with a little alumina, lime, oxide of iron, and water; white, yellowish-white, or yellow; and of specific gravity about half that of water. It is found in Bohemia, Saxony, and Auvergne, and is supposed to be a volcanic product. It is used for polishing glass, marble, and metals.

POLISHING OF STONE. See **STONE-CUTTING**.

POLISTENA, a t. of s. Italy, province of Reggio, Calabria. The village which occupied the site of the present town was totally destroyed by an earthquake in 1783. Pop. '71, 7,559.

POLITIANUS, ANGELUS. See **POLIZIANO**, *ante*.

POLITICAL ECONOMY. The word economy is derived from the Greek for house-law or house-regulation. It refers to the material portion of domestic regulations, and does not, for instance, embrace the observance of religion or the communication of instruction. The most important part of it is the adjustment of the expenditure of the household to the income at their command. Hence the word economy is sometimes applied, both in a public and a private sense, to the saving of money. The term "political" came to be used along with it as a convenient method of expressing the application to a state of a sound system of management in relation to its affairs. In later times, however, the word, as applied to a community, came to be something totally different from its application to a household. It was thought that one could regulate a people just as a house is regulated, by adjusting the spending and the getting of the national wealth. Hence arose several doctrines now discarded—such, for instance, as "the balance of trade," which taught that the trade with any nation is only profitable when you sell more to that nation than you buy from it; the system of bounties upon special trades, as being more profitable to others; and lastly, the system of protection to native industry—the last relic of what may be called the positive school of economists. Political economy now means, not the art of regulating communities in this respect, but the science of those laws which Providence has established for their regulation. Hence the analogy with domestic economy ceases. Domestic economy is the positive regulation of a household—not the leaving of it to follow its own dictates; and, indeed, that there is a disposition, more or less in the head of every house, to limit its expenditure to its income, is one of the phenomena by which things right themselves, as it were, and make up those laws of nature which constitute political economy. A man knows that if he buys too much, he will become bankrupt; but we do not now order the wholesale merchant not to buy too much from this or that country, so as to place the balance of trade against us—we know that this naturally rights itself, because we must expect our own produce to pay for what we bring in. Even if we should have to pay for it in gold, *that* is a commodity produced by our people. The income and expenditure of the government, as apart from that of the people of the community, are of course under regulation like those of a household; but these form a separate field of operation, called finance (q.v.). There are a few people who still hold that there is no natural system sufficient in itself to regulate the material affairs of mankind, and that these should be committed to the hands of special managers. Finding the approved doctrines of political economy going further and further from their direction, such persons, though few in number, have been very absolute in their views, and zealous in pushing them. One class of these are called socialists; and another, who go further lengths, are called communists. It has not been considered necessary here to go beyond the mere description or definition of the nature of political economy, because the various parts of which it consists are given each under its own head, as **BOUNTY, CAPITAL, COLONY, COMMUNISM, COMPETITION, CORN LAWS, DEMAND AND SUPPLY, EXCHANGE, FREE TRADE, LABOR, MONOPOLY, NAVIGATION LAWS, RENT, VALUE**, etc. Also: **MACHINERY, POLITICAL ECONOMY OF: GEORGE, HENRY.**

POLITICAL OFFENSES, crimes considered injurious to the safety of the state, or such crimes as involve a violation of the allegiance due by a subject to the supreme authority of the state.

By the Roman law, in the early times of the republic, every act injurious to the state was comprehended under the name *perduellio*, and visited with death. That term included conspiracy against the government, aiming at kingly power, aiding the enemies of Rome, and losing an army. The word *perduellio* afterward fell into gradual disuse, and the chief state offenses were known by the term *majestas* or *crimen læsæ majestatis*, somewhat akin to the treason of modern times. In the republican period, the crimes to which the epithet *læsæ majestatis* was most frequently applied, were the betrayal or surrender of an army to the enemy, the excitement of sedition, and such a course of administration as impaired the dignity of the state. In imperial times, acts and words disrespectful to the reigning emperor were included, and an indignity to his statue was visited nearly as severely as an offense against his person. *Læsæ majestatis* was generally punished with death, confiscation, and infamy. The criminal might even be tried after his death, to the effect of confiscating his property, and rendering his memory infamous

—a practice which has been resorted to both in France and Scotland as late as the beginning of the 16th century.

In modern times, the acts brought under the category of political offenses have varied much at different periods and in different countries. They have in general been more leniently dealt with under constitutional than under despotic governments. It is, however, a principle which has been generally recognized by the most constitutional of governments, that when the legislature thinks itself endangered by a secret conspiracy against the state, or an understanding with the enemies of the country, it permits the executive, for a limited time, to arrest suspected citizens, without the formalities which are required in ordinary circumstances.

In England, a large number of the graver political crimes are included under the denomination of treason, and the treason law has sometimes been stretched so as to include offenses which, by a fair construction, could hardly come within it, such as the use of violence to reform religion or the laws, or to remove the councilors of the sovereign. Even riotous assemblies with the object of destroying all property of a particular class have been held treason. Political offenses also include a number of crimes against government falling short of treason, and passing under the name of sedition, which, though they have for their ultimate object the violation of the public peace, do not aim at direct and open violence against the laws or the sovereign, but rather the dissemination of a turbulent spirit tending to produce such violence. The British government does not permit the political offenders of other countries to be included in extradition treaties; and in modern times, generally speaking, extradition does not apply to political offenders; contrary to the doctrine laid down by Grotius. In some countries, conspiracy against the sovereign of any country in league with the state is a special offense; in Great Britain, however, this seems not to be the case. A bill introduced in 1858 to make it felony to conspire to commit a murder without as well as within her majesty's dominions, was rejected by the house of commons on the second reading, from the idea that it was dictated by France.

POLITICAL PARTIES, FRENCH. The states-general, that is to say, a convocation made up of deputies from all classes in France, convened by royal order in 1789, opened its sessions May 5, in Paris. It was called the constituent assembly, but by its own act, June 17, 1789, named itself the national assembly. At its opening, which was in a temporary hall erected for the purpose at Versailles named the "hall of the three orders," there was no such distinction as "left" or "right" to characterize political opinion. The deputies of the *tiers-état*, or common people, as distinguished from the nobility and clergy, were in that building seated in the lowest and back seats; while the nobles occupied elevated seats prepared for them on the left side of the hall, and the clergy the corresponding seats on the right side. The nobles numbered 285, the clergy 308, and the commons 661. Mirabeau, though of the nobility, had been deprived of its privileges for misdemeanors, and entered the assembly as one of the deputies of the *tiers-état*, and was seated with them on the floor of the great hall. Among the deputies on the floor were also Bailly, Robespierre, Danton, Barnave, Siéyes, Camille Desmoulins, and a host of others, who little dreamed then of the conspicuous figure they were soon to make in history. For a time the nobles and the clergy endeavored to have separate sittings from the commons; but the latter resolutely refused to go on with business except as one body. A universal desire for the abrogation of all feudal privileges seized all classes, and even those who were about to lose them resolved to offer voluntarily as a sacrifice what they foresaw would soon be demanded. On the motion of the marquis de Noailles, Aug. 4, 1789, all feudal privileges except royalty were abolished, including those of the religious orders. All deputies were thenceforward at liberty to range themselves according to their individual opinions and affiliations. The revolution was in full ferment in Paris, and demanded that the king, the court, and the assembly should come thither. The great riding hall connected with the Tuileries was prepared for the assembly. There the seats seem to have been ranged as in an amphitheater. The historians of the revolution here for the first time allude to *la droite* and *la gauche*, the right, and the left, as representing the extremes of political opinion. At that time the representatives of the old nobility and clergy and their friends grouped themselves on the right side of the hall, those with less decided opinion occupied the center, and deputies of more boldly progressive opinions took the left side. The most violent democrats seem to have taken the highest seats on the extreme left, probably to be in more direct communication with the populace outside. "Danton took his seat on the high and remote benches which gave the name of 'the mountain,' to the thorough-going revolutionists who sat there." Mirabeau, though the leader in all the great reforms of that convention, was not in the classification of "the mountain." It was his pride to consider himself alone a party. It was not, however, until the flight of Louis XVI. in 1791, that parties in the assembly became sharply defined so that the left signified republicans alone. Previous to that time the assembly, though legislating to root out all other feudal institutions, had been singularly moderate as to royalty; and had shaped the new constitution for France so as to keep the king as the nominal executive, completely subject to constitutional control, yet still an integral part of the new system. But after his flight, capture, and return to Paris, the subject of royalty became the puppet of the demagogues

Political.

Pétion and Robespierre charged "the center" with weakness for not declaring the throne vacant, and proceeding to judge the king. In the center were then Mirabeau, Barnave, and a group of strong men with whom the more radical mountain was beginning to measure swords. The club of the Jacobins thenceforward directed the policy of "the left."

The assembly after its two years' work on the new constitution interdicted its members from becoming members of the new legislative assembly. It resulted that the experienced statesmen of the old center were not in the new legislative assembly. Most of the old members of "the left" were members of the Jacobin club, and the old members of the center were not. The club had every element of forensic and political power, and all the turbulent population of the city in affiliation. The left and the mountain in the assembly became little more than its mouth-piece, voicing the aggressive and destructive force of the revolution. It was not republican, it was ultra-democratic. Its appetites for absolute equality were only equalled by the individual appetites of its leaders for absolute power. Inspired by Robespierre and Danton from without, Chabot and Bazire were the club speakers from the mountain. Below that group, but still on the left, or left center, and known as ardent republicans, were the party of the Gironde—all new members—men of education, young, gifted, and ambitious. They prided themselves on their superiority in character and qualifications to the leaders of the Parisian club, and actuated by pure and noble motives, would not associate with them or submit to their leadership. Its principal members were Vergniaud, Gaudet, Gensonne, Barbaroux. The house of Mme. Roland was their place of meeting, and the genius of that noble woman was one of their inspirations. Eloquence and fine philosophy was their *forte*. Too proud to use the means employed by the Jacobins to secure popular support in the city, and too advanced in their radical republicanism to have the support of the classes who regretted the downfall of the old order of things, though outnumbering the mountain, they were not able to make head against the club which governed Paris and laid out the work of the assembly.

A new assembly called the national convention was elected and convened in Sept., 1792. This body by the law of its existence had uncontrolled power. The guarantees of individual liberty secured by the constitution established by the national assembly, were abrogated by it for "the defense of France." The Girondists who had been with *the left* in overthrowing the monarchy and establishing the republic, now became the center and *the right*. They had a majority in the new convention. The mountain, now led by its real leaders restored to their seats who were still leaders of the Jacobin club, and that under the control of Robespierre, was practically a unit for all combats, knew what it wanted, and knew how to make the people seem to impel them to do it. Driven by this power of Robespierre, not alone the leading Girondists, but Danton and Camille Desmoulins as well, went to the guillotine during the life of that convention. The mountain has always suffered much of the reproach for the horrors of that time; yet it suffered almost as much from the infernal policy of Robespierre as the right or the center. Danton and his friends of the left would gladly have joined with the Girondists in political legislation to check the tyranny of the clubs; but the leaders of that party rejected help which did not subordinate itself to them. It was lack of appreciation of the good motives and practical sagacity of such members of the mountain that dissipated the power of the majority and enabled a few leaders of the clubs to commit France to the reign in which accusation, trial, and judgment, all emanated from the same individual, Robespierre. He at last, and not the left or the mountain, reigned in the convention, in the clubs, in the committee of public safety, and in the Paris commune. It was the mountain that first dared his power. Its leaders made the overtures to the moderate of the center and the left center, which resulted in his complete overthrow. On Nov. 11, 1794, soon after the death of Robespierre, the reactionists of the right and the republicans of the center and left center had become strong enough to suppress the Jacobin club, and the high left or mountain complained that the reaction was against the republic. A crowd of Girondins proscribed from the convention when their leaders were guillotined, returned to it. They demanded and procured the accusation of the remaining leaders of the commune and the Jacobin club; even those who had been conspicuous in aiding the downfall of Robespierre. The remains of the Girondist party became the extreme right, vindictive in retaliation. The guillotine, which had laid low the heads of all the great leaders of both parties, left the followers to beat against each other in aimless conflict. The mountain was stigmatized as the top-knot. It kept up its habit of trying to secure its influence over the convention by organizing outside mobs to make a show of pressure of public opinion upon it. That old trick was now met by the other side, by the organization of similar mobs to meet them on the way. The center and right, with a majority of the convention, had the advantage of the law, that made the defense of the convention the defense of the representatives of the republic. On April 1, 1795, the leaders of the clubs, with the sympathy of a small knot of the mountain, made a last attempt by a mob to overawe the convention. Again the convention found its salvation in summoning a counter-crowd of its friends from the streets of Paris, and sent 17 members of the high left to prison. On May 20 the mob of Paris succeeded in getting possession of the hall of the convention; beheaded one of its orators who expostulated with them; scattered the deputies of the right, and dictated to the rest of the convention a series of measures to

restore themselves and their proscribed friends to power. Curiously enough it was the same butcher Legendre whose brutal violence at the top of the mountain in the beginning of the revolution made him one of the most notorious leaders, who now came to the relief of the besieged convention at the head of a resolute body of Parisians better organized than the other, and drove out the intruders. The victory of the moderates was complete. But no sooner were men secure from the tyrannies of the Jacobin club and the revenges of the Girondists than the royalists raised their heads, and the extreme right and right center used the laws to shed the blood of the Jacobins, which flowed at their instigation all over France. The reaction was called the "white terror." In legislative parlance it was a reaction of the right against the left. Toward the close of the session of the convention in Aug., 1795, it had matured a new constitution, called the constitution of the year, 3 which gave the future power of government to three distinct and co-operative bodies, called the council of the five hundred, the council of the ancients (senate), and an executive directory of five members. Naturally when the discussion of public questions was divided between two deliberative bodies, and executive authority lodged in a third, the divisions among members were less sharply defined, both in real opinions and in leadership, than when all the powers of the state were wielded by one body. There was still the old division of left, right, and center to mark three shades of opinion, but there was far more freedom for all opinions. Old Jacobin leaders had secured a majority in the directory, but the right and center controlled the new councils. Honest royalists were not strangled for their opinions, and the center or belly of the council, as the Parisians called it, was swayed to the right or to the left as the reaction, or the Jacobin side, seemed to be the stronger. The conflict between the mountain and the conservative part of the council was changed to one between this conservative majority and the majority of the directory. Not long before this time the last well-organized insurrection against the convention had been crushed by the skill of the young lieutenant Bonaparte, and the actions of the new councils were therefore more free from popular intimidation than any of their predecessors. The glamour of Bonaparte's military triumphs, and his assumption of all powers in France, soon made its legislative assemblies only the echoes of his will. On the accession of Louis XVIII. it was the same, but from a different cause; the people were tired of war both in the field and in the forum. In 1817, however, the weak attempts to re-establish the feudal system awakened the republicans, who elected 25 members to the chamber of deputies. Among them were Lafayette, Benj. Constant, Dupont, Lafitte, and Manuel. They were the nucleus of a new left. Their ability and integrity gave them an influence disproportioned to their numbers. In 1819 their number had increased to 86. In 1820-21 the left and the extreme right joined votes against the ministers, though with different objects in view. In 1822 the right became the governing power, and under Villèle, the chief minister of Louis XVIII., went forward boldly to restore France to the feudal condition preceding the revolution. The press of Paris was the chief weapon of the left. Its opposition and that of the republican leaders in the chamber of deputies was met by suppression and arrest. Charles X., on coming to the throne, pursued the same policy. But while that Bourbon policy was apparently suffocating all republican aspirations in France, the pamphleteers, the caricaturists, the encyclopædists, were filling the nation with the yeast of a great rising. The left, crowded out of the halls of legislation, found expression as it best could through the press. The revolution of 1830 which chased Charles X. out of France and installed Louis Philippe was the work of the journalists. Thiers and Guizot appear among its leaders. For a time the new chambers were composed principally of men so anxious to avoid the confusion and anarchy to be dreaded in a change of government that no other thought seemed to be dominant than that of crystallizing the constitutionality of the last kingly experiment. The nucleus of a distinct left hardly showed itself in the chamber of deputies until the election of Armand Carrel and Garnier-Pagès in 1832. They took seats as avowed republicans. The great mass of the deputies of the center, however, who supported the government of Louis Philippe, were at heart republicans; but they were so fearful of revolutionary uncertainties that they desired to test in peace the value of the change already made before attempting another. The right, while dreading the power that could so quickly banish one branch of the Bourbons and plant another in its place, were mostly wealthy members of the old aristocracy, who decidedly preferred to save their estates at the sacrifice of their titles, rather than make war against the new monarchy. On April 1, 1833, an occasion offered for the left to show itself. The *Tribune* newspaper had charged the government of Louis Philippe with constructing the fortification around Paris for the purpose of buckling it in—to menace rather than to defend. The editor was summoned to appear at the bar of the house. The left opposed it as unbecoming to the house and unjust to the editor, against whom the laws alone should be used if he had violated them. Rochefoucauld, Gautier de Rumilly, generals Bertrand and Lafayette, Thouvenel, and Garnier-Pagès, were its speakers. The vote was 205 to 92, the latter being the full strength of the left. But, after hearing the bold and able speeches of Cavaignac and Marrast, the two arrested editors, their censure was confirmed by a vote of 304 to 204 against. Notwithstanding the terrible exposures of the selfishness and corruptions of Louis Philippe's government, the king managed to keep the chamber of deputies at his service till near 1848. In the beginning, Thiers, Guizot, Lamartine, and many who subsequently became thoroughly

republican, were his supporters; but Odillon Barrot, Garnier-Pagès, Beranger, Portalis, Lafayette, and others, divorced themselves from his government, and opposed his measures almost from the beginning. The defense of the liberty of the press against the laws for its suppression was the main subject of difference between the left and the center. In Feb., 1848, the left and the center were gradually uniting against the then pronounced tendency to despotism of Louis Philippe. Guizot was endeavoring to sustain his policy; Odillon Barrot and Thiers were joined in the opposition. The government could command but 33 majority against them. Paris rose in revolution, and on the 24th the king abdicated in favor of his son. Thiers and Odillon Barrot—the one leader of the center, the other of the left—were called to form a new cabinet. But the nation then demanded a provisional government, and not a new king's cabinet. Lamartine, Dupont de l'Eure, Arago, Garnier-Pagès, Marie, Ledru-Rollin, Crémieux, all radical republicans of the left in the assembly, were made the provisional government, with Lamartine the leading spirit of the committee. A singular incident in the flight of the old king was that Crémieux, one of the extreme left in the assembly, helped him into the carriage hired for the occasion, and when the king expressed his obligation for the kindness, he replied—"Not at all; it is 17 years I have been waiting for this day." Until the election of a new assembly under the provisional government, there was of course no right or left. That body, composed of 900 members, convened May 4. Lamartine, to the astonishment of those who supposed that his thoroughly aristocratic culture would entrain his opinions against a democratic republic, became frankly the leader of the left in the assembly, and, while wielding all the power of his eloquence to prevent excesses by Paris mobs, defended the progressive republic. In fact, the left-center became suspicious that he was abandoning the conservatives to throw himself into the current of the democrats. At this time he acted frankly with Ledru-Rollin. The assembly reappointed five of the old members of the provisional government as their executive committee, leaving out Crémieux and Dupont de l'Eure; the former a radical of the left, and the latter the superannuated leader of the center. On May 15 the hall of the assembly was invaded and taken possession of by the communists of Paris under the lead of Barbé, Blanqui, and others, using the name of Ledru-Rollin as one of their party. The latter tried to expostulate with them in the assembly, but was obliged to desist. Lamartine could not be heard, and retired to wait an opportunity to make head against the movement outside the assembly room. When the mob left he joined Ledru-Rollin, put the troops of the government in motion, and soon afterward arrested the leaders of the mob. Speaking of the commission appointed by the assembly to draft a new constitution for France, lord Normanby, then English ambassador in Paris, and a watchful eye-witness to the daily legislation of the assembly, writes: "The composition of the committee is good. There are hardly any of the very violent party upon it, and almost all the leading men of the *gauche*."

This shows how well the patriotic republican movement of that time was divorced from the violent leaders of the Paris commune. By the month of June, Lamartine's popularity was on the wane. The government was in disrepute. It was too republican to suit the provinces, too conservative to suit the Paris commune. The election to fill some vacancies showed a large vote of republicans and royalists accidentally united on the same persons. Thiers, Victor Hugo, Louis Napoleon, were among the members returned. In general the election showed a desire to strengthen the center rather than the left. Louis Napoleon's name caused uneasiness at once; and the more, that the hangers-on around the assembly were raising a hurra for Napoleon that indicated the dangerous popularity of the name. *Vive l'Empereur* was heard on the streets, and so promptly was the danger of that name felt, that Lamartine at once moved for the exclusion and exile of Louis Napoleon by virtue of an old law. It was adopted by the executive committee, though Napoleon had been regularly elected from three different districts. The next day an order was issued by the executive committee for the arrest of Napoleon wherever he might be found. The left was nervously afraid of the name. The mountain recognized instinctively the divergence between republicanism and Bonapartism. On this occasion M. Jules Favre, though of the left, reflected severely upon the committee for its unwarranted subversion of the rights of Napoleon as a deputy. In the assembly the vote for his admission was carried by a large majority against the executive committee. M. Thiers, Louis Blanc, and the extreme right or legitimists, found themselves voting together with the left in the minority; the center and scattering votes from both the extremes being apparently spontaneously united to support Napoleon's right to sit as deputy in the assembly. The army soon afterward began to cry, "Down with liberty! *Vive l'Empereur!*" A letter from Louis Napoleon to the executive committee, dated London, June 14, 1848, was read in the assembly on the 15th, and created great excitement. It was a shrewdly modest missive. It expressed regret that his election should be the occasion of unfortunate wrangles and suspicions of his ambition; but that if the people imposed upon him a duty he would fulfill it: that his name was a symbol of order, of nationality, of glory; and he announced his willingness to remain in exile rather than to add to the present misfortunes of France. He caused to be distributed at the same time a letter of thanks to the constituencies who had voted for him. The letter produced a tumult in the mountain. There had not been a word of mention by Napoleon of the existence of the republic. The republicans felt, rather than knew, its import. Even those who the day before had voted for his admission, now perceived the imperial shadow.

Favre openly expressed regret for his vote of the day before. The next day, however, another letter, dated London the 15th, directed to the president of the assembly, contained his resignation as deputy in cunning phrases, well adapted to increase his popularity, and alluded to the republic in these words; "I desire order, and the maintenance of a wise, grand, and intelligent republic," etc. The assembly had no ground then for any action concerning him. Legitimists now hardly raised their voices, and there was therefore no extreme right. The center continued to be more and more Napoleonic in its desires. The commune, red republicans, and ultra radicals of the laboring classes, fought their battles outside the halls of the assembly, in clubs, emeutes, and barricades. On Jan. 23, 24, Paris was declared in a state of siege, and the executive powers were placed in gen. Cavaignac alone; the five members of the executive committee resigning. Three days of bloody fighting in the streets of Paris resulted in the defeat of the insurrection on the 26th, after some of the most horrible incidents of such warfare; among which was the death of the archbishop of Paris when seeking to prevent the further effusion of blood. On the 28th, the insurrection having been repressed, a law for the transportation of the prisoners was opposed by a group in the mountain, but passed by an immense majority. The other part of the left, among whom were Thiers and Berryer, busied themselves to secure an executive council in conjunction with Cavaignac. It resulted in making Cavaignac president of the assembly, with power to nominate heads of bureaus; in short, president of the republic. Measures, vigorous, despotic, and essential for the moment, were sanctioned by the assembly. Liberty of the press and the clubs was required to conform to laws of surveillance akin to suppression. The center, by some again called the Gironde, was becoming anti-republican. Louis Napoleon sent in another letter of resignation of another election, with characteristic words of devotion to the republic, "devoid of personal ambition," etc. The law against the clubs passed by a majority of about 6 to 1. A proposition of Proudhon for the confiscation of property, under the guise of a new system of taxation, was voted down by a majority of 691 to 2; Ledru-Rollin, Louis Blanc, and others of the mountain, being of the majority. M. Emile Girardin had been imprisoned, and his journal, *La Presse*, had been suppressed by Cavaignac. This grievous stretch of dictatorial powers against a fellow-republican called up a discussion, in which Victor Hugo took part and asked Cavaignac whether the duration of the suppression was a mere matter of personal will on his part, or to be regulated by law: to which the president made no reply, and the assembly acquiesced in that assumption of power. A week afterward he relieved eleven journals, including *La Presse*, of the disabilities imposed on them. In August the left were searching for means to delay elections for vacated seats in the assembly, evidently afraid of the conservative turn in public sentiment. The legitimists, or right, were gaining strength. The country in general endured the existing government, called a republic, not because it liked it, but because it dreaded a worse. The legitimists were stronger than the Orleans party in the country. Both, however, voted for candidates who endured the republic rather than for those who desired a republic. The legitimists of these days were a very different class of men from the dissolute courtiers of Louis XVI. in the first revolution. They had profited in the school of misfortune. They had become country gentlemen in the true sense of the word; and while a part of their old family possessions had been restored to them, they had been forced to attend to their management in order to secure incomes, and had become citizens identified with the interests around them. They, therefore, took part in politics with a strong common sense and courage in doing the best thing possible under the circumstances that was wanting among the ancient *emigrés*. They now voted for the best candidates put up, and used their influence for them without much reference to the class from which they came; thus exercising a sort of balance of power in the provinces. Their candidates were usually elected. In this assembly they numbered from 120 to 130. M. Berryer was their leader, as M. Thiers was of the center. These two great men usually worked together for the consolidation of the republic as the intermediary by which the legitimists might come to the monarchy without plunging France into a worse revolution; and the republicans hoped that they might arrive at a better form of republic through the present experiment. But after Napoleon had been elected a deputy, the left, the right, and the right-center had to make common cause against a sentiment in "the belly of the assembly," which sprang into existence with unexpected force. His skillful letters of resignation brought him into a prominence that surprised everybody. His strength in the provinces spread like fire in a dead forest that has waited for the torch. The dissatisfaction of all parties with the miserable failures and blunders of the last three Bourbon kings, and with the equally bad record of half a dozen ephemeral constitutional republics, made the advent of Napoleon seem like a godsend to the dissatisfied of every shade. Memories were awakened of all that was glorious about the first empire in a generation that had not felt, or had forgotten, its meannesses and the horrors of its glory. With such a mingling of all shades of opinion, the strong men of the assembly were able to form another republican constitution, with a president to be elected. But when the election came on, to the surprise of the left, Louis Napoleon had an enormous majority of all the votes of France. He took the oath of office Dec. 20, 1848. From that time the left had to make a strange battle to try to defeat his foreseen perfidy to the republic by efforts to abridge the universal suffrage which they had always before insisted on. Napoleon had the logic of the situation all in his favor, and, had he

been content to keep his oath as president, it is difficult to see what remedy the democratic republicans would have had against his domination without stultifying their own democratic principles. But they did seek to revise the constitution so as to get rid of the preponderating peasant vote by which Napoleon was made president. The latter finally cut short the struggle by his *coup d'état* of Dec. 2, 1851, by which he accepted perjury as the price of the imperial crown, and stifled the voice both of the left and the right for a period of eighteen years of his remarkable reign.

POLITICS (Gr. *pōlis*, city or state), that branch of ethics which has for its subject the proper mode of governing a state, so as to secure its prosperity, peace, and safety, and to attain, as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which government is founded, the hands in which the supreme power may be most advantageously placed, the duties and obligation of the governing and governed portions of society, the development and increase of the resources of the state, the protection of the rights and liberties of the citizens, the preservation of their morals, and the defense of the independence of the state against foreign control or conquest. While the philosophy of governing constitutes the *sciencē* of politics, the *art* of politics consists in the application of that science to the individual circumstances of particular states. The ancient Greek writers treated politics with reference to an ideal perfect state, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The politics of a country, in common parlance, implies the course of its government, more especially in its relations with foreign powers.

POLIZIANO, ANGELO, whose name is perhaps better known under the Latin form of **POLITIANUS**, was the son of a doctor of civil law, and was b. at Montepulciano in Tuscany, July 14, 1454. The family name was Ambroginis, but Poliziano took his from his native town—in Latin, *Mons Politianus*. He studied Latin at Florence under Cristoforo Landia, Greek under Andronicus of Thessalonica, the Platonic philosophy under Marsilio Ficino, and the Aristotelian under Argyropulos. He also devoted some attention to Hebrew. Poliziano's talent for poetry was early developed. When scarcely 15 years of age he took the Florentines with surprise by the publication of his famous *Stanze* (a poem of 1400 lines) in honor of Giulio de Medici, who had carried off the palm at a tournament. Lorenzo de Medici took notice of the brilliant lad, and at once placed him in a condition to continue his studies without any pecuniary harassments, by appointing him tutor to his two sons, and subsequently gave him a residence in his charming villa near Fiesole, where Poliziano, who was passionately fond of country life, resumed his studies with fresh ardor. In 1484 he accompanied the Florentine ambassadors to Rome, and was received in a flattering manner by the pope, at whose request he translated (into Latin) the Greek historian Herodianus, for which he received 200 golden crowns. He also made Latin versions of the *Enchiridion* of Epictetus, the *Charmides* of Plato, and other works, with such elegance, that Erasmus pronounced him a master in translation. After having filled for some years a chair of Latin literature, he commenced the teaching of Greek. His popularity as a professor was great. Pupils came to study under him from all the great cities of Italy, and even from distant parts of Europe; the principal were Francesco Pucci, Fortiguerra, Maffei de Volaterra, P. Crinitus Guillaume Grocyn, Thomas Linacre, and Michael Angelo. His copies of Ovid, Statius, Pliny the younger, Quintilian, etc., and other authors, are still preserved in the different libraries of Italy, and are covered with marginal notes. His copy of the famous *Digest* of Roman law, with an elaborate philological and grammatical commentary, is still preserved in the Laurentian library at Florence. In 1489 appeared his *Miscellanea*, a collection of critical and other observations on the ancient authors. Toward the close of his life he entered into orders, and was made canon of the cathedral of Florence. He died Sept. 24, 1494. Among the brilliant scholars of the classical renaissance, Poliziano occupies a foremost place in virtue of his vigor and originality. His intellect was indeed penetrated by an admiration of the chaste and noble literature of antiquity; but there was nothing servile in his imitations; he reproduced without difficulty—because he was a himself a kindred genius—the strength of Tacitus, the elegance of Livy, and the conciseness of Sallust; his Latin poems, especially his elegies, display the beauty and ardor of his imagination. Among his vernacular pieces may be mentioned his *Canti Carnascialeschi* (Carnival or Merry Ballads), remarkable for their felicity of style, sweetness of pathos, and abundance of imagery. Another proof of his varied poetical power was his *Orfeo*, one of the earliest dramatic compositions produced in Italy. The editions of Poliziano's separate writings have been numberless. See Seraszi's *Vita di A. Politiano*; N. A. Bonafous's *De A. Politiani Vita et Operibus* (Paris, 1845), Tiraboschi's *Storia della Letterat. Italiana*; Greswell's *Memoirs of Politiano*, and Roscoe's *Lives of Lorenzo de Medici and of Leo X.*

POLK, a co. in w. Arkansas, watered by Cossatot river, the Brushy fork of Ouachita river, and Saline bayou; about 950 sq.m.; pop. '80, 5,857—64 colored. The surface is irregular and hilly. The soil is fertile in some parts. Cotton and corn are grown. There are deposits of iron, lead, and slate. Co. seat. Dallas.

POLK, a co. in central Florida, bounded on the e. by Kissimmee lake and river; about 1900 sq.m.; pop. '80, 3,153—120 colored. The surface is level, heavily wooded, and

contains a number of lakes. The soil is fertile in parts. Corn, potatoes, and live stock are the principal productions. Co. seat, Bartow.

POLK, a co. in n.w. Georgia, adjoining Alabama, drained by Coosa river and Euharlee creek; 400 sq.m.; pop. '80, 11,952—4,147 colored. The surface is hilly, and heavily timbered. The soil is fertile in parts. The principal productions are corn, cotton, and wheat. Slate is quarried. Co. seat, Cedar Town.

POLK, a co. in s. central Iowa, drained by the Des Moines, Raccoon, and South Skunk rivers and Beaver creek, traversed by the Chicago, Rock Island and Pacific, the Des Moines and Minnesota, and the Keokuk and Des Moines railroads; 575 sq.m.; pop. '80, 42,395—36,162 of American birth. The surface is prairie or woodland. The soil is fertile. The principal productions are wheat, corn, oats, hay, and live stock. Bituminous coal is mined. Co. seat, Des Moines.

POLK, a co. in n.w. Minnesota, adjoining Dakota, bounded on the w. by the Red River of the North, drained by Red lake and Wild Rice rivers, intersected by the St. Paul and Pacific railroad; about 4,500 sq.m.; pop. '80, 11,433. The surface is level, mostly prairie. The soil is fertile. The principal productions are corn and wheat. Co. seat, Crookston.

POLK, a co. in s.w. central Missouri, drained by the Pomme de Terre and Little Sac rivers; about 650 sq.m.; pop. '80, 15,745—15,649 of American birth. The surface is rolling or hilly, much of it covered with forests. The soil is fertile. The principal productions are wheat, corn, oats, and live stock. Lead and limestone are found. Co. seat, Bolivar.

POLK, a co. in e. central Nebraska, bounded on the n.w. by the Platte river, drained also by the north fork of the Big Blue river; about 450 sq.m.; pop. '80, 6,846—4,963 of American birth. The surface is rolling or level, with few trees. The soil is fertile. The principal productions are corn, wheat, oats, and hay. Co. seat, Osceola.

POLK, a co. in s. North Carolina, adjoining South Carolina; drained by Green river; about 200 sq.m.; pop. '80, 5,062—1,144 colored. The surface is hilly, and heavily timbered. The soil is fertile. The principal productions are corn, oats, hay, and pork. Co. seat, Columbus.

POLK, a co. in n.w. Oregon, bounded on the e. by Willamette river; drained by the Rickreal and the s. fork of the Yam Hill rivers; about 750 sq.m.; pop. '80, 6,601—6,129 of American birth. The surface is irregular, intersected by the Coast range in the w., and heavily timbered. The soil in the Willamette valley is fertile. The principal productions are corn, wheat, oats, hay, and live stock. Lumber is exported. Co. seat, Dallas.

POLK, a co. in e. Tennessee, adjoining Georgia, drained by the Ocoee and Hiwassee rivers; about 450 sq.m.; pop. '80, 7,269—7,208 of American birth. The surface is uneven and mountainous, and heavily timbered. The soil is partly fertile. The principal productions are corn, grass, and wheat. There are valuable copper mines. Co. seat, Benton.

POLK, a co. in e. Texas, bounded on the s.w. by Trinity river; watered by Sandy and other creeks; about 800 sq.m.; pop. '80, 7,191—7,123 of American birth—2,848 colored. The surface is mostly level, and heavily timbered. The soil is fertile. Corn, cotton, and live stock are the principal productions. Co. seat, Livingston.

POLK, a co. in n.w. Wisconsin, adjoining Minnesota; bounded on the w. by St. Croix river; drained also by Apple river; about 950 sq.m.; pop. '80, 10,018—6,212 of American birth. The surface is irregular, contains many small lakes, and is heavily timbered. The soil is partly fertile. The principal productions are corn, wheat, and oats. Co. seat, Osceola Mills.

POLK, JAMES KNOX, eleventh president of the United States of America, was born in Mecklenburg co., N. C., Nov. 2, 1795. His ancestors, who bore the name of Pollock, emigrated from the n. of Ireland early in the 18th century. Though his father was a farmer in moderate circumstances, he was educated in the university of North Carolina, and studied law with Felix Grundy of Tennessee, an eminent lawyer and statesman. Admitted to the bar in 1820, he was three years after elected a member of the legislature of Tennessee, and soon after to the federal congress by the democratic party. In 1826 he was chosen speaker of the house of representatives, a position he filled during five sessions with firmness and ability. After serving fourteen years in congress he was, in 1839, elected governor of Tennessee; and in 1844 unexpectedly nominated, as a compromise candidate, for the presidency, against Henry Clay, and elected. During his term the Oregon boundary was settled by a compromise offered by England, though the party cry which helped to elect him was a claim for the entire territory to 54° 40' n. lat. The annexation of Texas caused, in 1846, a war with Mexico; 50,000 volunteers, added to the small regular force, sufficed to take the capital (Sept. 14, 1847), and enabled the government to dictate terms of peace, by which it acquired California and New Mexico. Having pledged himself to a single term of office, Mr. Polk refused a renomination, and retired to his home in Nashville, Tenn., where he died three months afterward, June 15, 1849. Mr. Polk was a man of respectable abilities, and of a solid, firm, honest, and religious character. He was devoted to the principles of the democratic party of Jeffer-

son and Jackson—state rights, a revenue tariff, independent treasury, and strict construction of the constitution.

POLK, LEONIDAS, D.D., 1806–64; b. N. C.; graduated at West Point in 1827; was appointed brevet second lieut. of artillery, with leave of absence. Resigning, he studied theology, and was ordained in the Protestant Episcopal church in 1831; missionary bishop of Arkansas and Indian Territory, with the provisional charge of the diocese of Alabama and Mississippi, in 1838–41; bishop of Louisiana in 1841–61. In 1861 he took up arms against the union, was appointed maj. gen. of the rebel army; occupied Columbus, Ky., Sept., 1861, and evacuated it Mar., 1862; commanded a division at the battle of Shiloh in April, 1862, also at Murfreesboro, Chattanooga, and Chickamauga; served as lieut. gen. at the battle of Stone river in 1863. He was killed near Kenesaw mountain, Ga., in June, 1864.

POLK, THOMAS; b. N. C. about 1732; was the owner of a large estate near Charlotte; took part in the war of the revolution; led an expedition against the tories of North Carolina; was commissary-general for the state. The time of his death is not known.

POLK, WILLIAM, 1759–1835; b. N. C.; present at the Mecklenburg declaration of independence, 1775; joined the army of the revolution 1777; was in the battles of Brandywine and Germantown; with generals Gates and Greene in the southern states, and was wounded at Eutaw Springs; after the war, was in the legislature of North Carolina, 1787; removed to Raleigh and was an active politician; declined a nomination as brig. gen., 1812, because of his opposition to the war with England; was himself a witness and collected the testimony of others to establish the genuineness of the Mecklenburg declaration. He lived to be the last surviving field officer of the North Carolina line.

POLKA, a species of dance, of Polish or Hungarian origin, the music to which is in $\frac{2}{4}$ time, and has the rhythmical peculiarity of being accented on the third quaver of the measure. It was introduced as a fashionable dance into western Europe about 1841.

POLLACK, *Merlangus pollachius*, a fish of the family *gadidae*, of the same genus with the whiting and coal-fish. It is common on the coasts of all parts of Britain; and in Scotland and some parts of Ireland it is called *lythe*. It is a very playful fish, often gambolling on the surface of the water. It attains about the same size as the coal-fish. It has three dorsal fins; the body is of a longish shape; the lower jaw is much longer than the upper; the tail is slightly forked. The flesh is reckoned superior to that of the coal-fish. Young pollacks are sometimes sold as whittings, to which, however, they are not nearly equal. No fish more readily rises to the artificial fly, and in this way great numbers are caught on the British coasts. The fly is merely a bit of white feather tied to a common bait-hook. Worsted is sometimes used instead of the feather; and flies of different colors are sometimes used together, with great success. No reel is employed, and any stick is good enough for a rod; a few yards of string make a sufficient line.

POLLAN, *Coregonus pollan* (see **COREGONUS**), a fresh-water fish of the family *salmonidae*, a native of lakes in Ireland. It is particularly abundant in lough Neagh, where it is often seen in large shoals, which issue from the deep waters, and haunt the shore from spring to autumn, when great numbers are taken by nets, and sold in the neighboring country. The pollan is from 10 to 12 in. in length; it resembles the gwyniad, but has not the snout produced like that fish; and there are differences in the size and position of the fins. It is very like *coregonus sikus*, a species found in the most northern parts of Norway. The spawn of the pollan is deposited in November and December on the rocky or stony parts of the bottom of the lake which it inhabits. It is a well-flavored fish. The cry of "fresh pollan" is even more common in Belfast during summer than that of "fresh herring."

POLL-ACT, a sanguinary act, passed at Trim, in Ireland, by the junto of the Pale, in 1465, under the earl of Desmond, deputy. It ordained "that it shall be lawful to all manner of men that find any theeves robbing by day or night, or going or coming to rob or steal, or any persons going or coming, having no faithful man of good name and fame in their company in English apparell, that it shall be lawful to take and to kill those, and to cut off their heads, without any impeachment of our sovereign lord the king. And of any head so cut off in the county of Meath, that the cutter and his ayders there to him cause the saed head so cut off to be brought to the portreffe to put it upon a stake or spear, upon the castle of Trim, and that the saed portreffe shall testify the bringing of the same to him. And that it shall be lawful for the saed bringer of the saed head to distrain and levy by his hand (as his reward) of every man having one ploughland in the barony, two pence, and of every man having half a ploughland, one penny; and of every man having an house and goods, value forty shillings, one penny; and of every cottier, having one house and smoak, one half-penny." Much slaughter is said to have been committed under this remarkable act.

POLLANARRUA, an ancient city of Ceylon now in ruins, in the province of Tamankadme, about 60 m. n.e. of Candy. It was the capital, 769–1319. It was a large and splendid city in the reign of Prakrama Bahoo I., who surrounded it with a rampart. The streets were from 15 to 26 m. long. It contained a palace of 7 stories, two edifices of 5 stories for priests and devotees, and a coronation hall, all built by Prakrama Bahoo, also the Rankot Dagoba, built by his queen, several hospitals, a college for medical stu-

dents built by king Dappola I.; also a superb structure of several stories containing a golden image of Buddha. The city was repeatedly taken by the Malabars, and recovered by the Singhalese, but the last time the Malabars took it, about 1204, they demolished and reduced it to its present condition. The most remarkable building is the Jaitawanarama temple. Opposite the entrance is an image of Gautama Buddha 50 ft. high. The Satmaha Prasada is a handsome pyramidal building. The palace of Prakrama Bahoo I. is on the borders of the Toopawewa, an artificial lake, the waters of which were carried through the buildings and poured by an ornamented spout into the king's bath, which is a large circular space built of hewn stone. There are two stones covered with inscriptions, one of which, neatly ornamented, is 25 ft. long and 4 broad. The characters are small and beautifully cut, and for the most part Singhalese.

POLLARDING (*to poll*, to cut off, or shave the head) is the cutting off of the whole crown of a tree, leaving it to send out new branches from the top of the stem. Trees thus treated are called *pollards*. The new branches are never equal in magnitude to the original branches of the tree, although often more numerous, and when pollarding is often repeated, the scars and stumps form a thick ring at the top of the stem, from which many small branches spring. Pollards are not beautiful; but pollarding is practiced with advantage in districts where fuel is scarce, the branches being cut off in order to be used for fuel, and the operation repeated every third or fourth year. It is much more prevalent in many parts of Europe than in any part of Britain, and in Britain is almost confined to those districts of England which are furthest from coal. Willows, poplars, alders, elms, oaks, and limes are the trees most frequently pollarded, and in some parts of Europe the white mulberry. The trees of most rapid growth are preferred where fuel is the object; and willows, poplars, and alders are planted along water-courses, and in rows in moist meadows and bogs. Oaks are sometimes pollarded chiefly for the sake of the bark of their branches, and the whole treatment very much resembles that of copsewood. In some parts of Germany, landscapes may be seen of open country with many scattered oak and elm pollards, presenting a very peculiar appearance.

POLLEN. See STAMEN and FECUNDATION.

POLLEN'ZA, a well-built t. in the northern part of the island of Majorca, about 2 m. w. of the bay of Pollénza, and 28 n.w. of Palma. It has a Jesuits' college and some manufactures of black woolen cloth. Pop. about 7,500.

POLLIO, C. ASINIUS, a politician, soldier, and author of considerable merit, and still more considerable reputation, was b. in Rome 76 B.C., but belonged to a family of Mar-ruccinian descent. His first ambition was to be an orator, and in his youth he seized every opportunity of hearing such men as Hortensius and Cicero. When civil war broke out between Cæsar and Pompey, Pollio sided with the former, was present at the crossing of the Rubicon, and accompanied the great general in his rapid triumphal march through Italy. He joined Cæsar in his expedition to Greece against Pompey, and took part in the decisive battle of Pharsalia, 48 B.C. At the time of Cæsar's assassination (Mar. 15, 44 B.C.), Pollio was governor of Hispania Ulterior (further Spain), and carrying on the war against Sextus Pompey. In the subsequent struggles, he sided with the triumvirate (Antony, Lepidus, and Octavian) against the oligarchic senate; and on the triumph of the former, was appointed administrator of transpadane Gaul, in which capacity he saved the property of the poet Virgil at Mantua from confiscation. After Antony and Octavian had quarreled, it was Pollio who effected their temporary reconciliation at Brundisium, 40 B.C.; next year he conducted a successful campaign against the Parthini, a people of Illyria, and in consequence, obtained a triumph. After this event, however, he withdrew altogether from political life. He lived 18 years after the emperor Augustus, dying at his Tusculan villa, 4 A.D., in the 80th year of his age. Besides having a reputation for oratory, Pollio was celebrated as a historian, poet, and critic; and there seems little reason to doubt that he was an author the loss of whose writings is to be regretted. His literary and political criticism of his contemporaries, in particular, appears to have been valuable. He also claims remembrance as a distinguished patron of men of letters, such as Catullus, Horace, Virgil, and as the founder of the first public library at Rome.

POLLNITZ, KARL LUDWIG VON, noted as a writer of memoirs of his time, was b. near Cologne in 1692. He was equally remarkable for his talents and want of principle; and while his father's position as minister of state to the elector of Brandenburg gave him access to court-circles, his extravagance and eccentricity, coupled with his vagabond habits, often reduced him to the greatest poverty. But after wandering all over Europe, taking service in the church in Austria, and in the army in Spain, he finally attracted the favorable notice of Frederick the great, who appointed him his reader, and made him director of the theater at Berlin. After having twice changed from Catholicism to Calvinism, he proclaimed himself a member of the church of Rome shortly before his death, which occurred in 1775. Among the numerous memoirs, either written by or ascribed to him, the following were the most popular in their day, and the most applauded for the powers of observation and the wit which they exhibit: *Lettres et Mém.*, et la Relation de ses premiers Voyages (Amst. 1735); *Etat abrégé de Saxe sous Auguste III.* (Frankf. 1734); *Hist. secrète de la Duchesse d'Hanovre, épouse de George I.* (Lond. 1732). After his death, Brunn brought out Pollnitz's *Mémoires pour servir à l'Histoire des quatre derniers Souverains de la Maison de Brandenbourg* (2 tomes, Berl. 1792).

POLLOCK. See **POLLACK**, *ante*.

POLLOCK, Sir **FREDERICK**, 1783–1870; b. England; brother of sir George; graduated at Cambridge in 1806, and a year later became a fellow of Trinity college, and was admitted to the bar, of which he became a distinguished member. In 1827 he was king's counsel, and was knighted in 1834. He was the representative from Huntingdon in parliament 1831–44, and served as atty.gen. under sir Robert Peel in 1834–35, also 1841–44. He was lord chief-baron of the court of exchequer and privy counselor 1844–66, after which he retired with a baronetcy.

POLLOCK, Sir **GEORGE**, 1786–1872; b. England; received his education at Woolwich academy. In 1802 entered the army as lieut. of the Bengal artillery, in service of the East India company, and in 1805 became capt. He took part in the sieges of Dieg and Bhurtpore in 1809, and was promoted to the rank of col.; became maj.gen. in 1841, and a year later took command of the British troops in the war against the Afghans, forced the Khyber pass, and a few months later, reduced Cabul to submission. For these valuable services, on his return to London, he received a pension of £1000 from the East India company, of which he was a director for 2 years. Many marks of distinction were conferred upon him, among which were the freedom of the city of London, and the order of grand commander of the star of India. He was brevetted field-marshal, and became constable of the tower of London in 1871, and baronet in 1872.

POLLOCKSHAW'S, a municipal borough in the co. of Renfrew, Scotland, is situated on the banks of the White Cart, about 2½ m. s.w. of Glasgow. The name is derived from the estate of Nether-Pollock, on which the town stands, and from the Scotch word "shaw," which means a "grove" or "plantation." Pollockshaws is entirely a manufacturing town; cotton-spinning, calico-printing, silk-weaving, bleaching, iron-founding, and fancy dyeing are extensively carried on. Pop. '81, 9,333.

POLLOK, **ROBERT**, a Scottish poet, was b. in 1799 at Muirhouse, in the parish of Eaglesham, in the co. of Renfrew. After receiving the ordinary course of instruction in country schools, he was sent to the university of Glasgow, and on the completion of his curriculum in arts, he entered the divinity hall of the secession church, where he studied 5 years. In 1827 he was licensed to preach. By this time he had written the *Course of Time*, and its composition, together with the ardor with which he pursued his studies, brought on consumption. The poem was published by Mr. Blackwood in the same year in which the author received license. It was highly praised, but the voice of praise fell on a dying ear. In his critical state, his medical attendants recommended residence for a time in Italy, and in compliance with their advice, he set out, accompanied by his sister. On his arrival in London, his symptoms became suddenly worse, and unable to prosecute his journey, he went to reside at Shirley common, near Southampton, where he died on Sept. 17, 1827. He was interred in the churchyard at Millbrook, and over his grave an obelisk has been erected.

The *Course of Time* has run through more than 20 editions, and is extremely popular in Scotland. It is a work of genius, but curiously unequal in merit. It contains eloquent and spirited passages, but considerable portions of it read like a dull sermon turned into blank verse. The writer drew his inspiration from nature, from Milton, and the shorter catechism—from the last, perhaps, most of all. His memoir, written by a brother, was published in 1843. Pollok also wrote *Tales of the Covenanters*, which were published anonymously.

POLL-TAX. See **CAPITATION**.

POLLUX. See **CASTOR AND POLLUX**.

POLLUX, **JULIUS**, b. at Naucrates, Egypt, and flourished in the reign of the emperor Commodus in 183 A.D. After a preparatory training under his father, he studied under the Sophists, and became a learned grammatical critic. He opened a school of rhetoric at Athens, and became so famous that he was made preceptor of the emperor Commodus. He prepared for the use of the emperor an *Onomasticon*, a Greek vocabulary divided into 10 books, designed to facilitate the learning of the Greek language by the young prince. It contains a variety of synonymous words and phrases, is useful in the study of Greek literature and art, and is valuable also because in the first part it treats of the gods and their worship. An edition was published by Dindorf at Leipsic in 5 volumes, and followed by that of Bekker of Berlin. Pollux was the author of several works, of which Suidas has preserved the titles.

PO'LO may be described as hockey on horseback. It is a game of Asiatic origin, and was introduced into England in 1872 by cavalry officers who had learned it in India. Two goals, as for football, are set up about 350 yds. apart, and the object is to drive a ball about the size of a cricket-ball through the goal by striking it with long sticks having bent or crooked ends. The players are mounted on ponies, and much depends on the skill with which these are managed. Four or five a side are the usual numbers, and those scoring the greater number of goals win the game. Polo has become very popular among English cavalry officers, and a few clubs have also been formed.

POLO, **MARCO**, the celebrated traveler, was born of a noble family of Dalmatian origin, at Venice, about 1250. His father, Nicolo Polo, and his uncle, Matteo Polo, both emi-

nent merchants, had, previous to his birth, set out on a mercantile expedition, visiting Constantinople, Soldaya or Sondach (on the Euxine), and Bulgar (on the Volga), the capital of Barkäi, the khan of Keptchak. Thence they traveled round the north side of the Caspian sea to Bokhara, where they remained three years, studying the Mongol language and trading; but in 1261, some ambassadors from the Perso-Mogul khan to Kûblai (q. v.), the grand khan of the Mongols, happening to pass through Bokhara, the brothers Polo resolved to accompany them to Kementfu, the summer residence of the khagan. They were well received by Kûblai, who was very inquisitive concerning the peoples and mode of government in Europe, and commissioned them to act as his envoys to the pope, bearing a written request for 100 Europeans, well learned in the sciences and arts, to act as instructors to the Mongols. They reached Venice in 1269; but finding it impossible to discharge the mission with which they had been intrusted, they set out on their return in 1271, taking with them young Marco, and arrived again at the court of Kûblai khan in 1275. Their second reception was still more honorable than the first, and the khagan took special notice of Marco, from the rapidity with which he learned the customs and language of the Mongols. His wisdom and the nobility of his demeanor also recommended him as a fit envoy to the various neighboring rulers; and during his residence at their several courts, Polo was in the habit of closely observing the manners and customs of the country, and delivering on his return a detailed report to the khagan. These reports were the groundwork of the book which informs us regarding the state of central and eastern Asia in the end of the 13th century. Polo's first mission was to the court of Annam or Tonquin (1277), and during his residence there, he acquired much information, both from his own observation and from report, concerning Thibet, Yunnan, Bengal, Mien (or Pegu), and the south of China; he was next employed to aid in making an inventory of the archives belonging to the court of the Song dynasty; and soon afterward was appointed governor of the town of Yang-tchow, in the province of Kiang-si, in eastern China, a post he held for three years. He also accompanied a Mongol army to the attack of the kingdom of Pegu; and closed the list of services rendered to Kûblai by accepting the embassy to Tsiampa, the south part of Cochin-China. Having thus passed 17 years in the service of the Mongol khan, and visited the chief countries and cities in eastern Asia, traveling through kingdoms (as China) which no European had ever seen before, and acquiring much knowledge of other kingdoms (as Japan, called by Polo *Zipangu*), the existence of which was not even suspected, he succeeded in obtaining permission to join the escort of a Mongol princess, who was traveling to the court of Persia. The three Polos accordingly set out in 1291, traveling through China, and thence, by sailing through the Chinese sea and Indian ocean, finally arrived at Teheran, where they stayed for some time; but learning that Kûblai khan was now dead, they continued their journey, and arrived at Venice in 1295, bringing with them much wealth and many precious objects, the fruits of their trading. Marco, in the following year, fought his own galley in the great battle off Curzola, in which the Venetians, under Dandolo, were defeated by the Genoese under Doria, and was taken prisoner and immured in a dungeon at Genoa. Here he dictated, with the aid of the memoranda he had made during his travels, an account of his journey through the east, which was subsequently revised with care. After his liberation he returned to Venice, where he was appointed member of the grand council, and died in 1323, eleven years after his father. His work is variously entitled, but the best edition is *Il Milione di Messer Marco Polo Veneziano*, edited by count Baldelli (Florence, 4 vols. 4to, 1827), and accompanied with a map, notes, and illustrations. Polo's narrative created an immense sensation among the learned public, and many did not hesitate to affirm that it was a pure fiction; but the Catholic missionaries and subsequent Venetian travelers into these remote regions, verified many of Polo's statements, and then came a reaction of public opinion; Polo's wonderful minuteness, extensive research, and accuracy being the theme of universal admiration. His work was of inestimable value as a stimulant and guide in geographical research; it encouraged the Portuguese to find the way to Hindustan round the cape of Good Hope; and it roused the passion for discovery in the breast of Columbus, thus leading to the two greatest of modern geographical discoveries. The first edition of Polo's "Voyages" was published by Ramusio in his *Raccolta di Navigazioni e Viaggi* (Venice, 1550-59). English translations have been published in Edinburgh (1844), and in London (1854 and 1871-75). There is also a German one by Burck, with notes by Neumann (1846).

POLOTSK', a t. of west Russia, in the government of Vitebsk, on the banks of the Düna, where that river is joined by the Polota. It was founded in the 9th c., is the seat of a bishop of the Greek United church, and has several churches, besides a convent and a school for the nobility. Here, in 1812, the Russian general, Wittgenstein, defeated the French under Oudinot and Sire. Pop. '80, 12,200.

POLTAVA, a government of Little Russia, between the governments of Kiev on the w. and Kharkov on the east. Area, 19,071 sq. m.; pop. '80, 2,400,000. The surface is flat, with a gradual slope s. w. to the banks of the Dnieper, which forms the southern boundary, and into which the chief rivers—the Sula, Psiol, and Worskla—flow. The government does not abound in wood, but possesses rich and extensive pastures. The soil is for the most part clay and fertile vegetable mold, and the climate is healthy.

Agriculture and cattle-breeding are the staple occupations. Many of the peasantry are employed with their oxen in bringing salt from the lakes of the Crimea, and fish from the Don. The manufactures are not numerous nor important. Commerce is chiefly in the hands of Jews, and is mostly transacted at the fairs, the most important of which are those of Poltava and Romny.

POLTAVA, chief t. of the government of the same time, is situated on the right bank of the Worskla, a tributary of the Dnieper, about 934 m. s.s.e. of St. Petersburg. Pop. '80, 34,000. Poltava has few manufactures, and its trade displays activity only during the annual fairs, of which there are four. The most important is called the Illinsky, which lasts about a month. At these fairs merchandise is exposed for sale worth £4,000,000. The principal articles of traffic are cloths, woolen tissues, colonial productions, fur, wool, horses, and agricultural produce and implements. Poltava is famous as the scene of Charles XII.'s defeat by Peter the Great in 1709, and a monument commemorating the victory of the czar stands in the principal square; while three m. from the t. a mound surmounted by a cross still known as the "Swedish Tomb," marks the battle-field. Poltava has a cathedral, numerous churches, and a school for cadets.

POLYANDRY, or **POLYANDRIA**, that form of polygamy which permits a woman to have several husbands. See **MARRIAGE**. The hot-bed of polyandry is Thibet. There a wife commonly is the wife of a whole family of brothers—the elder brother being chief husband. In the Himalayan and sub-Himalayan regions adjoining and under the influence of Thibet it is of frequent occurrence in the same form; as in the valley of Cashmere, in Ladak, among the Koech, among the Telingese. Further s. in India, we find polyandry among the Tudas of the Nilgherry hills, the Coorgs of Mysore, and the Nayars of Malabar. We find it again off the Indian coast in Ceylon; and going eastward, strike on it as an ancient though now almost superseded custom in New Zealand, and in one or two of the Pacific islands. Going northward, we meet it again in the Aleutian islands; and taking the continent to the w. and n. of the Aleutians, it is found among the Koryaks, to the n. of the Okhotsk sea. Crossing the Russian empire to the w. side, we meet it among the Saporogian Cossacks; and thus have traced it at points half round the globe. This is not all, however. It is found in several parts of Africa, and it occurs again in many parts of America among the red men. We have the authority of Humboldt for its prevalence among the tribes of the Orinoco, and in the same form as in Thibet. "Among the Avaroes and the Maypures," he says, "brothers have often but one wife." Humboldt also vouches for its former prevalence in Lancerota, one of the Canary islands. Thus, polyandry is a phenomenon of human life, independent of race and country.—See Latham's *Descriptive Ethnology* (1859), vol. i. pp. 24, 28; vol. ii. pp. 398, 406, and 462; Humboldt's *Personal Narrative*, Williams's translation, 1819, vol. v. part 2, p. 549; and chap. i. vol. i. p. 84; Hamilton's *New Account of the East Indies* (Edin. 1727), vol. i. pp. 274 and 308; Reade's *Savage Africa*, p. 43; Erman's *Travels in Siberia*, vol. ii. p. 531; *Marriage Ceremonies*, by seignior Gaya (translation), 2d edition (Lond. 1698), pp. 70 and 96; Emerson Tennent's *Ceylon*, 3d edition (1859), vol. ii. p. 429; Grey's *Polynesian Mythology* (1855), p. 81; *A Summer Ramble in the Himalayas* (1860); Vigne's *Kashmir; Journal Asi. Soc. Bengal*, vol. ix.; *Asiat. Resch.*, vol. v.; also M'Lennan's *Primitive Marriage* (1865); and Herbert Spencer's *Principles of Sociology* (1876).

From ancient history we learn that the area over which polyandry at one time existed was even more extended; while in certain cantons of Media, according to Strabo (lib. ii. p. 798, and see Goguet, vol. iii. book vi. c. i.) polygynia was authorized by express law, which ordained every inhabitant to maintain at least seven wives; in other cantons, precisely the opposite rule prevailed: a woman was allowed to have many husbands, and they looked with contempt on those who had less than five. Cæsar informs us that in his time polyandry of the Thibetan type prevailed among the Britons (*De Bello Gallico*, lib. v. c. xiv.). We find direct evidence of its existence among the Picts in the Irish Nennius App. li., not to mention the traces of it remaining in the Pictish laws of succession. Indeed, to pass over communities in which something like promiscuity of intercourse between the sexes is said to have prevailed—such as the Massagetæ, Agathyrsi, and the ancient Spartans—we find several among which polyandry, or a modified promiscuity, must have been the rule. Assuming that the legal obligation laid on younger brothers in their turn to marry the wives of their deceased elder brother, is a relic of polyandry of the Thibetan type, then we must hold that polyandry prevailed at one time throughout India (*Institutes of Menu*, chap. iii. s. 173, and chap. ix. ss. 57, 58), among the ancient Hebrews (Deut. xxv. verses 5-11); in Siam, Burmah, in Syria among the Ostiaks, the But (Bodo), the Kasia, and the Puharies of Gurhwal. Traces of it indeed remained in the time of Tacitus among the Germans (*Tac., Germ.*, xx., Latham's edition, p. 67 et seq.). In short, polyandry may be regarded as one of the transitional forms in the advance from a state of promiscuity, on the assumption that pure promiscuity ever existed. Of the origin of this peculiar institution our space forbids us to write; but we believe it to be connected with the want of balance between the numbers of the sexes, due to the practice of female infanticide, which is its almost invariable accompaniment. Tribes of warriors, wholly devoted to a military life, find women an incumbrance rather than a solace; and from this cause, and probably from the difficul-

ties of subsistence, formed the practice of killing their female children, sparing them only when they were the first-born. The disparity of the sexes would lead to polyandry, and once instituted, the custom would in many cases continue to exist after the habits and necessities which produced it disappeared. In several places, as in Landak, where polyandry prevails, the sexes are now either equally balanced, or the female sex predominates. In these cases, polygynia and polyandry are commonly found existing side by side. The subject is one which demands, and as yet has not received full investigation.

POLYANTHUS (Gr. many-flowered), a kind of primrose (q.v.), much prized and cultivated by florists. It is generally believed to be a variety of the common primrose (*primula vulgaris*), produced by cultivation, in which an umbel of numerous flowers is supported on a common *scape* (leafless flower-stem), instead of each flower rising on its own stalk from the crown of the root; a modification to which a tendency often appears in the wild plant itself. Thus in its habit it somewhat resembles the cowslip and oxlip, whilst in the size of its flowers it is more like the common primrose; but instead of the pale uniformity of the wild plant, it exhibits great variety of delicate and beautiful colors. The subvarieties are innumerable, new ones being continually produced from seed, and of short duration. The seed is sown about midsummer, and flowers may be expected in abundance next year, if the young plants are properly planted out. A rich free soil is most suitable. The polyanthus loves shade and moisture more than its congener, the auricula. It is very hardy, and seldom suffers from the most severe winters. Fine kinds are preserved for a time by dividing the root. The cultivation of the polyanthus is prosecuted with particular assiduity and success in England.

POLYANTHUS NARCISSUS. See NARCISSUS.

POLYATOMIC ALCOHOLS. The term *alcohol*, originally limited to one substance—viz., spirit of wine, or hydrated oxide of ethyl, has begun to be applied to a considerable number of organic compounds, many of which, in their external characters, bear little resemblance to common alcohol. Most of them are fluid and volatile, some of them are combustible, and all of them are composed of carbon, hydrogen, and oxygen, behave in a precisely similar manner toward the same decomposing agents, and are perfectly neutral to test-paper.

Every alcohol, when acted on by oxidizing agents, loses two equivalents of hydrogen, and is converted into an *aldehyde*; and by the prolonged action of the oxidizing agent, the aldehyde takes up two equivalents of oxygen, and is converted into a *special acid*. Moreover, all alcohols, by the abstraction of the elements of water, yield ethers. Hence, every alcohol has its own ether, aldehyde, and special acid; the aldehydes of the alcohols termed polyatomic, have, however, not been formed.

According to the theory of organic radicals, the alcohols are hydrated oxides of an alcohol radical. Thus, common alcohol, or spirit of wine, is the hydrated oxide of the radical ethyl (C_4H_5), and is represented by the formula C_4H_5O, HO ; similarly, wood-spirit is the hydrated oxide of the radical methyl (C_2H_3), and is represented by the formula C_2H_3O, HO . According to the theory of chemical types (see TYPES, CHEMICAL), the alcohols are divided into *monatomic* and *polyatomic*. A molecule of water consists of two atoms of that substance, and is therefore represented by the formula H_2O_2 , which may be arranged in the form $\left. \begin{matrix} H \\ H \end{matrix} \right\} O_2$. If half the hydrogen in this typical formula be replaced by an organic radical, such, for example, as $C_nH_{n+1}, C_nH_{n-1}, C_nH_{n-3}, C_nH_{n-7}$ or C_nH_{n-9} (n being even in all these cases), we obtain what is termed a monatomic alcohol one equivalent of hydrogen being here replaced. Besides the primary water-type represented by one molecule of water, there are derived or secondary and tertiary types, represented by two and by three molecules of water, and expressed in the forms $\left. \begin{matrix} H_2 \\ H_2 \end{matrix} \right\} O_4$ and $\left. \begin{matrix} H_3 \\ H_3 \end{matrix} \right\} O_6$. If half the hydrogen in $\left. \begin{matrix} H_2 \\ H_2 \end{matrix} \right\} O_4$ be replaced by an organic radical, we obtain an alcohol said to be *diatomic*, in consequence of its being formed by the replacement of two equivalents of hydrogen. Similarly, if half the hydrogen in $\left. \begin{matrix} H_3 \\ H_3 \end{matrix} \right\} O_6$ be replaced by an organic radical, we obtain a triatomic alcohol. The term *polyatomic* is applied to all alcohols which are not monatomic.

POLYBASIC ACIDS. Most of the inorganic acids combine with bases in such a manner that one atom of the acid is united with one atom of a metallic oxide to form a neutral salt. Nitric acid may be taken as an illustration of the acids possessing this property, and which may therefore be called *monobasic*. In other cases, as, for example, that of pyrophosphoric acid (see PHOSPHORUS), one atom of acid possesses the property of combining with two atoms of base; such acids are termed *bibasic* or *dibasic*. There are strong grounds for believing that sulphuric acid is bibasic, in which case its formula would require to be doubled, and to be written $2HO, S_2O_6$. Common phosphoric and arsenic acids are examples of a third class of acids in which one atom combines with three atoms of base, and which are therefore termed *tribasic*. Whether any polybasic acids beyond tribasic acids exist, is uncertain, but it is probable that silicic acid is a *tetrabasic* acid.

Amongst the organic acids a similar relation takes place, acetic, succinic, and citric acids affording examples of the monobasic, dibasic, and tribasic class.

The following are the most important general differences shown by acids of different degrees of basicity:

1. Each *monobasic* acid can form but *one* ether, which is neutral. 2. A *monobasic* acid cannot form a stable, well-defined acid salt or a salt with two or more metallic bases.

1. Each *dibasic* acid can form *two* ethers, one neutral, and the other acid. 2. *Dibasic* acids can form with each metallic base a neutral salt and an acid salt. They can also form double salts containing two metallic bases.

1. Each *tribasic* acid can form *three* ethers, one neutral, and two acid. 2. *Tribasic* acids can form *three* salts with the same metallic base, two of them acid and one neutral.

Many attempts have been made to account for the polybasic or monobasic character of an acid, from its composition. According to Kekulé (*Lehrbuch der Organisch. Chemie*, vol. i. p. 210–219), the basicity depends not, as was formerly supposed, on the molecular constitution of the acid, but upon the amount of oxygen contained in its radical. For further details on this subject, the reader is referred to the article ACIDS in Watt's *Dictionary of Chemistry*, vol. i. 1863.

POLYBIUS, the Greek historian, was born about 204 B.C. in Megalopolis, a town of Arcadia. From Lycortas, his father, who was among the leading men of the Achæan league, he received valuable instruction in the science of politics and in the art of war. In 181 he would have visited Egypt in the capacity of ambassador, but the project of sending an embassy to that country was given up. His engaging in public affairs probably dates from this period, and he rapidly gained the confidence of his countrymen. He was one of the 1000 noble and influential Achæans who, after the conquest of Macedonia in 168, were sent to Rome on the summons of the commissioners from that city to answer the charge of having failed to assist the Romans against king Perseus. On their arrival in Italy in 167 they were not put upon their trial, but were distributed among the towns of Etruria. Owing, perhaps, to his having formed the friendship of Æmilius Paulus, or of his sons Fabius and Scipio, he was more fortunately allocated than others of his countrymen. His residence was fixed at Rome and in the house of Paulus. Scipio, then about 18 years of age, became strongly attached to Polybius, made him his companion in all his military expeditions, and profited greatly by his knowledge and experience. Polybius in his turn derived much advantage from the protection and friendship of Scipio, who gave him access to public documents, and aided him in the collection of materials for his great historical work. In 151 the surviving Achæan exiles were permitted by the Roman senate to return to Greece, and among them was Polybius, who arrived in Peloponnesus after a residence of 17 years in Italy. He soon, however, rejoined Scipio, followed him in his African campaign, and was present at the destruction of Carthage in 146. But the outbreak of war between the Achæans and Romans summoned him again to Greece, where he arrived soon after the taking of Corinth. All his influence was now exerted to procure from the conquerors favorable terms for the vanquished; and so grateful were his countrymen for his services in their behalf, that they erected statues in his honor at Megalopolis (his native town), Mantinea, Pallantium, Tegea, and other places. It must have been about this time that Polybius undertook the writing of his great historical work, the materials of which he had so long been collecting. We cannot now fix with accuracy at what period of his life he visited in foreign countries the places which he had to describe in his history. We know from himself that at one time, probably while accompanying Scipio, he undertook long and laborious journeys into Africa, Spain, Gaul, and even as far as the shores of the Atlantic, in order to add to the scanty knowledge previously existing with regard to these regions. In the latter period of his life he traveled in Egypt; and about 12 years before his death, he probably accompanied Scipio to Spain, where he witnessed the fall of Numantia. He died about 122 B.C., in his 82d year, in consequence of a fall from his horse.

As a historian Polybius occupies a high rank. His work, which began where that of Aratus broke off, includes the period between 220 and 146 B.C., the year when Corinth fell, and, with it, the independence of Greece. Of the two parts into which it was divided, the first embraced a period of 53 years, commencing with the second Punic war and the social war in Greece, and concluding with the subjugation of the kingdom of Macedonia in 168. This, the chief portion of his history, was designed to show how, in the short space of 53 years, the greater part of the world had been conquered by the Romans; and in order that his countrymen might have a better knowledge than they possessed of the rise of that people, he gives a sketch of the history of Rome from its capture by the Gauls to the outbreak of the second Punic war. This occupies the first two books, and may be regarded as an introduction to the work. The second part embraces the period from the fall of the Macedonian kingdom, in 168, to the taking of Corinth in 146. This part is to be viewed as supplementary to the first, and seems to have brought down the history of the conquest of Greece to its completion in the 39th book, while the 40th and last probably contained a chronological summary of the entire work. The style of Polybius is not his most striking feature, and he incurred the censure of later Greek critics for his negligence in the choice of words and in the structure of his sentences. His great merits are the care with which he collected his materials.

his strong love of truth, and his sound judgment, which was materially assisted by his familiarity with political and military life. His tone is too didactic in general, and although his readers are prepared for this by his calling his work not a *Historia*, but a *Pragmateia*, still the continuity of the narrative is too often interrupted by digressions, sometimes interesting and valuable in themselves, but fatal to artistic effect. Much the greater part of his work has perished. Of the 40 books, we possess only five entire; and of the rest, merely fragments or extracts. Some of these latter, however—such as the account of the Roman army—are of considerable length and value, and four separate collections of them have been added from time to time to the remains of the work. The first of these, discovered soon after the revival of learning, in a MS. of Corfu, gives us the greater part of the 6th book, and portions of the remaining 11. The second consists of extracts made in the 10th c., entitled *Excerpta de Legationibus*, and published at Antwerp by Ursinus in 1582. The third, entitled *Excerpta de Virtutibus et Vitiis*, was published in 1634 by Valesius. The fourth, entitled *Excerpta de Sententiis*, was discovered by cardinal Mai in the Vatican, and published by him at Rome in 1827. The history of Polybius was very closely followed by Livy after the period of the second Punic war, and by Cicero in his account of the Roman constitution in his treatise *De Republica*.—The best annotated edition of Polybius is Schweighäuser's (Leip. 1789). The best editions of the text, including that of the Vatican fragments, are those of Bekker (Ber. 1844) and L. Dindorf (1866).

POLYCARP, Bishop of Smyrna, and one of the most illustrious of the early Christian martyrs, was born in the latter part of the 1st c. A.D., but neither the date nor the place of his birth is known. He was, however (according to a legendary fragment ascribed to an unknown Pionius), brought up at Smyrna, where his pupil, Irenæus, states that Polycarp was taught the doctrines of Christianity by the apostles, particularly by John, with whom he had "familiar intercourse." The testimony of Irenæus on this point is of immense value, as it furnishes the chief historical link uniting the apostolic age—that age which is reflected in the later parts of the New Testament—with the rising church of the 2d century. The passage occurs in an exhortatory epistle to a Roman heretic, Florinus, and is preserved by Eusebius (*Hist. Eccl.* chap. xx.). "I can tell also the very place where the blessed Polycarp was accustomed to sit and discourse; and also his entrances, his walks, the complexion of his life, and the form of his body, and his conversations with the people, and his familiar intercourse with John, as he was accustomed to tell, and also his familiarity with those that had seen the Lord. Also concerning his miracles, his doctrines, all these were told by Polycarp, in consistency with the holy Scriptures, as he had received them from the eye-witnesses of the doctrine of salvation." The fragment of Pionius (to which reference has already been made) informs us that Polycarp, when only a little child, was adopted by a rich Christian lady named Callisto, who left him heir to all her wealth; in consequence of which he was enabled to gratify his love of works of beneficence and charity. We are, however, utterly without the means of determining what truth (if any) there is in the narrative of Pionius, and can only feel certain that in some way or other he had distinguished himself at a comparatively early period, for before the death of the apostle John (i.e., at the latest, before 104 A.D.), he was ordained bishop of Smyrna (according to Tertullian and Jerome) by John himself; according to Irenæus, by "the apostles;" and according to Pionius, by "the bishops of the neighboring churches"—statements which are quite reconcilable with each other. Polycarp was in the exercise of his episcopal functions when Ignatius of Antioch passed through Smyrna on his road to Rome (107–16 A.D.), and we are told that the two pupils of St. John, who had probably known one another in earlier years, had much delightful Christian converse. Almost half a century afterward Polycarp himself visited Rome, when Anicetus was bishop there (157–68 A.D.), and had a friendly conference with his brother on the subject of the proper time to hold Easter. They could not agree—but they agreed to differ. His martyrdom, which is related at great length and in a touching manner by Eusebius (*Hist. Eccl.* chap. xiv.), took place probably in 166 A.D., during the persecution under the emperors Marcus Aurelius and Lucius Verus. When asked, or rather entreated "to revile Christ" by the proconsul Statius Quadratus, who, being deeply impressed with the venerable appearance of the aged bishop, wished if possible to save his life, Polycarp replied, "Eighty-and-six years have I served Him, and He never did me wrong; and how can I now blaspheme my King that has saved me?" Polycarp was burned alive. In such profound reverence was he held by his fellow-Christians, for his almost perfect graces of character, that the Jews (who had been conspicuously zealous in collecting "wood and straw from the shops and baths" to burn him) instigated the proconsul not to give up the corpse of the martyr to his co-religionists, "lest, abandoning Him that was crucified, they should begin to worship this one." More convincing evidence of a saintly character has never been adduced.

Polycarp wrote several *Epistolæ*, of which only one has been preserved, the *Epistola ad Philippenses*, valuable for its numerous quotations from the New Testament—especially from the writings of Paul and Peter. It is, however, doubtful whether this epistle is really by Polycarp. In the most recent edition of the Apostolic Fathers (*Patrum Apostolicorum Opera*, Leipsic, 1877), prof. Zalm defends its genuineness. There are English versions by Cave, Clementson, and Wake.

POLYCHROME PRINTING, the art of printing in one or more colors at the same time. Although several attempts had been previously made to carry out this process, Congreve, in 1820, was the first to do it successfully with metal plates. Sir William Congreve had seen Applegath's polychromatic block-printing press, by which very rude colored pictures were produced, and he conceived the idea of improving upon it, and doing it with metal. His plan is extremely simple, though requiring great nicety in carrying it out. First, the picture is outlined upon a metal plate; and supposing it intended to have two colors, then the details of only the chief color are completed upon it, and all the parts for the other color are cut out, and into those parts other plates are fitted, like the portions of a child's puzzle-map, but with very great exactness; and upon these the engraving for the parts of the second color are completed. When these are done, a thickness of type-metal is attached to the back of these interior pieces, so that they can be held separately, and pushed forward or drawn backward at pleasure. Then they are so adjusted to the machinery of the press, that they are withdrawn when the first color-roller passes over the surface of the main plate, and are pushed forward beyond the face of the main plate, so as to receive the color of the second roller, which then passes over them without touching the first or main plate. Having received their colored ink, the secondary plates are again moved back to a perfect level with the other, so as to form an entire plate, carrying two colors, which are thus, in the ordinary way, imprinted on the paper. Since sir William Congreve's patent very many improvements have been made, the principle, however, remaining the same, and it has now a very wide application.

POLYCLÉTUS, a Greek sculptor and architect, supposed to have been b. at Sicyon about 430 B.C., and a citizen of Argos. He is said to have been the pupil of Argive Ageladas, who was also the instructor of Phidias and Myron. His greatest work is thought to be the statue of "Hera," in the temple, between Argos and Mycenæ, carved in ivory and gold. The goddess is represented on a golden throne, crowned with a garland on which are cut the graces and hours, and holding the scepter surmounted by a cuckoo in one hand, and a pomegranate in the other. The upper portion of the figure and the feet are of ivory, the robe of gold, falling from the waist. Polyclétus probably intended this statue to surpass the chryselephantine statues, "Athena" and "Zeus," the works of Phidias, and though it equaled them in beauty, it was exceeded by them in size. His celebrated statue, the "Spear-bearer," was considered the canon for students on account of its fine symmetry. He designed the theater at Epidaurus, thought to be the most beautiful of all theaters, whether Greek or Roman, and was considered the greatest architect of his time. Phidias, it is said, was unrivaled in his images of gods; Polyclétus in his images of men. He was the author of a treatise on the proportions of the human body. Nothing is known of his personal history.

POLYCOTYLED'ONOUS PLANTS, those plants of which the embryo has more than two seed-lobes or cotyledons. See **COTYLEDON** and **DICOTYLEDONOUS PLANTS**. In some of the *coniferae* in particular, there are numerous cotyledons; the genus *pinus* has from three to twelve. These cotyledons are placed in a whorl, and have the gemmule of the embryo in the midst of them. Polycotyledonous plants do not form a separate division of the vegetable kingdom, but are ranked with the dicotyledonous plants; for plants with two, and plants with more cotyledons are found not only in the same natural order, but in the same genus.

POLYCRATÉS, "tyrant" of Samos, is a well-known name in ancient Greek history. He was b. in the first part of the 6th c. B.C., but nothing is known of him until the time when, with the assistance of his brothers, Pantagnôtus and Sylosôn, he obtained possession of the island. The three brothers at first ruled conjointly, but after a short time, Polycratés put Pantagnôtus to death, banished Sylosôn, and made himself sole despot. His energetic, unscrupulous, and ambitious character now showed itself more conspicuously than ever. He conquered several islands of the Archipelago, and even some towns on the Asiatic mainland, waged war successfully against the inhabitants of Milétus, and defeated their allies, the Lesbians, in a great sea-fight. His fleet amounted to 100 ships, and was probably at that time the most powerful in all Greece. Polycratés seems to have aspired to the sovereignty of the Ægean, if not also of the cities of Ionia. His intimate alliance with Amasis, king of Egypt, proves the importance in which this daring island-prince was held even by great monarchs. According to Herodotus, Amasis drew off from his alliance through alarm at the uninterrupted good fortune of Polycratés. He dreaded, we are told, the misfortunes that the envious gods must be preparing for so lucky a mortal, and to which his friends would also be exposed. The particular incident that is said to have finally ruptured the alliance is doubtless mythical, but is so well known that we cannot afford to overlook it. Amasis is reported to have written a letter to Polycratés, earnestly advising him to throw away the possession that he deemed most valuable, and thereby avert the stroke of the spleenful gods. Polycratés, in compliance with this friendly advice, cast a signet-ring of marvelously beautiful workmanship into the sea; but next day a fisherman presented the "tyrant" with an unusually big fish that he had caught, and in its belly was found the identical ring. It was quite clear to Amasis now that Polycratés was a doomed man, and he immediately broke off the alliance. So, at least, Herodotus tells the story; but Grote (*History of Greece*, vol. iv.

p. 323) suggests—and the suggestion is far more probable—that Polycratés, with characteristic perfidy, abandoned the Egyptian for a Persian alliance when he found the latter likely to be of more value to him in his ambitious designs. When Cambyses invaded Egypt (525 B.C.), Polycratés sent him a contingent of forty ships, in which he placed all the Samians disaffected toward his “tyranny,” and told the Persian king privately not to let them come back! However, they escaped in some way or other the fate which Polycratés had designed for them, returned to Samos, and made war against the “tyrant,” but without success. Hereupon, they went to Sparta, and succeeded in enlisting the sympathies, or, at any rate, in securing the help of both the Spartans and Corinthians. A triple force of Samians, Spartans, and Corinthians embarked for Samos, and attacked the city. After vainly besieging it for forty days they sailed away, and Polycratés now became more powerful than ever; but Nemesis had her victim after all. A certain Orœtes, the Persian satrap of Sardis, had, for unknown reasons, conceived a deadly hatred against Polycratés, and having enticed the latter to visit him, by appealing to his cupidity, he seized and crucified him. Thus perished ignominiously, in the midst of his power and splendor, one of the most famous *thalassokrats*, or sea-kings, of Greek antiquity. He was a patron of literature and the fine arts, and had many poets and artists about his court. His intimacy with Anacreon, in particular, is quite a celebrated thing, and in his praise that joyous bard wrote many songs. To Polycratés also, in all probability, belongs the construction, or at least the enlargement, of those great buildings which Herodotus saw at Samos.

POLYDIPSIA (Gr. *great thirst*) is the term now commonly applied to the disease formerly known as *diabetes insipidus*. It is characterized, as its name implies, by extreme thirst, and by an enormous discharge of pale watery urine. The affection is one of rare occurrence, and the persons most liable to it are dyspeptics who have passed the period of middle life, and whose bodily powers are failing, although (as the case we shall immediately notice, and one recorded by Dr. Watson, show) it may begin in childhood. The two prominent features of this disease usually lead to the suspicion that true diabetes is present; but the low specific gravity of the urine, and the absence of sugar in it in polydipsia, and the reverse condition in diabetes, seem to make the distinction easy. Dr. Willis, in his work *On Urinary Diseases*, records the case of a man, aged 45, who was admitted for an accident into the Hôtel-Dieu at Paris, and who passed daily, on an average, thirty-four pounds of urine, and drank thirty-three pounds of water, the normal daily excretion of urine being a little less than two pounds. This person reported that he had been affected in a similar manner ever since his fifth year, and that, from the age of 16 upward, he had daily consumed not less two bucketfuls of water, and discharged a commensurate quantity of urine. Little good can be effected by treatment, further than stimulating the action of the skin by the use of Dover's powders, Turkish baths, etc., and by inducing the patient to take as little drink as may be at all consistent with his comfort.

POLYGALÆÆ, or **POLYGALACEÆ**, a natural order of exogenous plants, herbaceous or shrubby, sometimes twining; the leaves without stipules, and generally simple; the flowers resembling papilionaceous flowers, but the odd petal inferior, and the odd sepal superior; the flower-stalks with three bracts; the calyx of five very irregular sepals; of which the two interior are usually petal-like; the corolla of three, or sometimes five petals, the anterior petal the largest, and often crested; stamens eight, monadelphous or diadelphous, or four and distinct; the ovary superior, generally 2-celled, one ovule in each cell; style and stigma simple; fruit generally a capsule opening by valves, sometimes a drupe. There are about 500 species, diffused throughout all parts of the world.—The genus *polygala* has a persistent calyx, eight stamens, the lateral sepals large and petal-like, and hairy or wrinkled seeds. The species are very numerous, annual and perennial herbaceous plants, and small shrubs, natives chiefly of warm and temperate climates. One is found plentifully in Britain; the COMMON MILKWORT (*P. vulgaris*), a small perennial plant, growing in dry hilly pastures; with an ascending stem, linear-lanceolate leaves, and a terminal raceme of small but very beautiful flowers, having a finely-crested keel. It varies considerably in size, in the size and even shape of the leaves, and in the size and color of the flowers, which are sometimes of a most brilliant blue, sometimes purple, pink, or white.—Several species are natives of the south of Europe.—North America produces a greater number. The cape of Good Hope and other subtropical countries produce many beautiful species, some of which have become common ornaments of greenhouses.—*P. senega* is a North American species, with erect simple tufted stems, about 1 ft. high, and terminal racemes of small white flowers. The root, which is woody, branched, contorted, and about half an inch in diameter, is the SENECA ROOT, SENEKA ROOT, or SNAKE ROOT of the United States, famous as an imaginary cure for snake-bites, but really possessing important medicinal virtues—stimulating, diuretic, diaphoretic, emmenagogue, and in large doses emetic and purgative—employed in catarrhs, pulmonary affections, rheumatisms, low fevers, etc. Its chief active principle is *polygalic acid*, $C_{22}H_{18}O_{11}$. The root of *P. senega* has been employed as a cure for snake-bites by the American Indians from time immemorial, and it is a curious fact, that *P. crotalarioides* is employed in the same way in the Himalaya. *P. vulgaris* is tonic, stimulant, and diaphoretic; and *P. amara*, a very similar European species, possesses

the same properties in a higher degree, as does *P. rubella*, a small North American species. The root of *P. poaya*, a Brazilian species, with leathery leaves, is an active emetic, and in a fresh state, is employed in bilious fevers. Similar properties seem to pervade the whole genus. Another medicinal plant of the order is *rattany* (q.v.) root. Species of several genera are used as tonics. The bark of the roots of *monnina polystachia* and *M. salicifolia* is used in Peru as a substitute for soap. *Mundia spinosa*, a s. African shrub, produces an eatable fruit.

POLYGAMOUS (Gr. *polys*, many, *gamé*, marriage), in botany, a term employed to designate those plants which produce both unisexual and hermaphrodite flowers either on the same or different plants. In the Linnæan sexual system these plants formed a class, **POLYGAMIA**, the genera included in which were perhaps more completely disjoined from their natural allies than those of any other class of that system, forming by themselves a very heterogeneous assemblage.

POLYGAMY. See **MARRIAGE.**

POLYGASTRICA. See **INFUSORIA.**

POLYGLOT (Gr. *polys*, many; and *glōtta*, tongue) means, in general, an assemblage of versions in different languages of the same work, but is almost exclusively applied to manifold versions of the Bible. The Hexapla (q.v.) of Origen contained, besides the Hebrew text, several other versions. All these, however, were in the Greek language, and the Hexapla is not commonly reckoned among the polyglots. They are divided into two classes, the greater and the lesser polyglots. To the former belong four works, known as the Complutensian Polyglot; the Antwerp, or king of Spain's Polyglot; the Parisian Polyglot, and the London or Walton's Polyglot.—The Complutensian Polyglot derives its title from Complutum, the Latin name of Alcalá de Henares, where it was printed in 6 vols. folio, 1502–1517. It was published at the cost, and under the direction of the celebrated cardinal Ximenes, who spared no expense, whether in collecting the most ancient and authentic MSS., or in bringing together the most distinguished scholars of all countries for the carrying out of his design. The Complutensian Polyglot contains, besides the Hebrew text, the Septuagint Greek and the Chaldee (each with a literal Latin version), and the Latin Vulgate.—The Antwerp Polyglot, so called from its being there printed (1569–72), at the celebrated press of Plantin, was published at the cost of Philip II. of Spain, under the direction of the distinguished scholar, Benedict Arias Montanus. It is in 8 vols. folio, and contains, in the Old Testament, the Hebrew, the Greek, the Targum of Onkelos, and the other Chaldee paraphrases, and the Latin Vulgate. In the New Testament, besides the Greek and Latin, it contains a Syriac version, printed both in Syriac and in Hebrew characters. Arias Montanus was assisted by many scholars of eminence, chiefly of Spain and the Low Countries.—The Parisian Polyglot was printed at Paris in 1645, at the cost and under the editorship of Guy Michel le Jay. It is in 10 splendid volumes, and contains, in addition to the contents of the Antwerp Polyglot, another Syriac version, and an Arabic version, together with the Samaritan version and the Samaritan text of the Pentateuch, each of these being accompanied by a literal Latin translation.—The London Polyglot was edited by Brian Walton, afterward bishop of Chester, and it engaged for many years a number of the most eminent linguists of the period. The number of its languages is not the same in all parts of the Bible; but it may be said to contain the Bible, or portions of it, in nine languages: Hebrew, Samaritan, Chaldee, Syriac, Arabic, Ethiopic, Persic, Greek (each of these accompanied by a literal Latin version), and Latin. It is in 6 vols. folio, and was published in 1654–57; and was followed in 1669 by the *Lexicon Heptaglotton* of Edmund Castell, 2 vols. folio, containing dictionaries of all the languages of the polyglot, except the Greek and Latin. Of the minor polyglots the chief are (1) the Heidelberg Polyglot (1586), Hebrew, Greek, and Latin; (2) Wolder's Polyglot (Hamburg, 1596), Hebrew, Greek, Latin, and German; (3) Hutter's Polyglot (Nürnberg, 1599), Hebrew, Chaldee, Greek, Latin, German, and French; (4) Reineccius's Polyglot, in Syriac, Greek, Latin, and German (Leipsic, New Testament, 1712; Old Testament, 1750, 1751); (5) Bagster's Polyglot, a very valuable collection of modern versions, folio (London, 1831). It contains 8 versions in the Old Testament, viz., Hebrew, Greek, English, Latin, French, Italian, Spanish, and German; and 9 in the New, Syriac being added to those already named. (6) A useful "Hand Polyglot," containing in the Old Testament, Hebrew, Greek, Latin, Vulgate, and Luther's German version; and in the New, Greek, Latin, Luther's German, and in the fourth column, in which are presented the chief differences between this and other German versions.

Besides the Bible, many other works, or small pieces, have been published in polyglot. Of smaller pieces, the Lord's prayer has been the favorite, of which many collections, containing a greater or less number of languages, have been published from the 16th c. downward. Of these, the most comprehensive, and, for philological purposes, by far the most valuable, is the well-known *Mithridates* of Adelung, which contains the Lord's prayer in nearly 500 languages, with vocabularies and grammatical explanations of most of the specimens.

POLYGNOTUS, a distinguished Greek painter of antiquity, was b. toward the beginning of the 5th c. B.C. He was a native of the isle of Thasos, and belonged to a family

of painters, who came to Athens to practice their profession, probably after the subjugation of Thasos by Cimon. Polygnotus and his brother, Aristophon, were instructed in the principles of art by their father, Aglaophon. We know almost nothing of their lives, except that Polygnotus was a friend of the Athenian general above mentioned, and is said to have been attached to his sister, Elpinice. He died about 426 B.C. Polygnotus was a contemporary of the great sculptor Phidias (q.v.), and flourished during the supremacy both of Cimon and Pericles; but we hear little or nothing of him under the latter ruler; and although the first painter of his day, it does not appear that he was engaged in the decoration of any of those splendid buildings with which that statesman adorned Athens. It is not at all unlikely that Pericles was averse to patronizing a friend of Cimon, and, at all events, Polygnotus was absent from Athens for 14 years (449–435 B.C.) of Pericles's rule, painting at Delphi and elsewhere. His principal works (following a chronological arrangement as far as it can be ascertained) were: 1. Paintings in the temple of Theseus at Athens. 2. In the stoa poecile (or painted portico) at Athens, representing the Greek princes after the taking of Troy, assembled to judge of the violation of Cassandra by Ajax. 3. In the anakeion, or temple of the Dioscuri, a painting of the marriage of the daughters of Leucippos. 4. In the temple of Athena Areia at Plataea, a picture of Ulysses after having slain the suitors of Penelope. 5. In the leschê (or "conversazione saloon"), a famous quadrangular court, or peristyle, surrounded by colonnades, built at Delphi by the Cnidians. The walls of this edifice were covered by Polygnotus with a series of paintings representing the wars of Troy, and the return of the Greek chiefs, and considered Polygnotus's masterpiece. 6. In the chamber adjoining the propylæa of the acropolis. From the criticism of the ancients, it seems quite clear that Polygnotus was a great advance on any of his predecessors. He was the first who gave life, character, expression to painting. According to Pliny, he opened the mouth and showed the teeth of his figures; he was the first to paint women with transparent drapery, and with rich head-dresses. Lucian also speaks of his exquisite skill in painting eyebrows and the blush on the cheek; while Aristotle extols the ethical or ideal beauty of his conceptions, saying that Polygnotus "represented men as better than they were," and finding a parallel for his style in the epic poetry of Homer.

POL'YGON (Gr. *polys*, many; *gōnia*, a corner), a plane figure, bounded by a number of straight lines; the name is conventionally limited to those plane figures whose bounding straight lines are more than *four* in number. Polygons of 5, 6, 7, 8, etc., sides are denominated pentagons, hexagons, heptagons, octagons, etc.; and when the number of sides exceeds twelve, the figure is merely mentioned as a polygon of so many sides. The quindecagon, or figure of 15 sides, is the only common exception to this rule. Polygons have many general properties; such as that the sum of the angles of a polygon, when increased by four right angles, or 360° , is equal to twice as many right angles as there are sides in the polygon, and that (supposing the number of sides of the polygon to be expressed by n) the number of its diagonals is $\frac{n(n-3)}{2}$; also if a polygon of an even

number of sides be circumscribed about a circle, the sums of its even and odd sides are equal; and if a polygon of an even number of sides be inscribed in a circle, the sums of its even and odd angles are equal. A polygon which has all its sides and angles equal is called a *regular* polygon. All polygons of this class are capable of being inscribed in or circumscribed about a circle; but though the problem is merely to divide the circumference of a circle into a number of equal parts, corresponding to the number of sides in the polygon, geometry was till lately only able to perform it in those cases where the number of sides of the polygon belongs to one or other of the series 2, 4, 8, 16, etc.: 3, 6, 12, 24, etc.; or 5, 10, 20, 40, etc. Gauss (q.v.), however, in the beginning of the present century, showed how it could be done in the case of all polygons, the number of whose sides was of the form $2^n + 1$ (provided it be a prime number), or a multiple of this prime number by any power of 2. This discovery supplies us with innumerable series representative of the numbers of the sides of polygons which can be described around or inscribed in a circle, such as 17, 34, 68, etc.; 257, 514, 1028, etc.

POLYGO'NEÆ, or **POLYGONA'CEÆ**, a natural order of exogenous plants, mostly herbaceous plants, but including a few shrubs, and even trees. The leaves are alternate, sometimes without stipules, but more generally with stipules cohering around the stem. The flowers are not unfrequently unisexual. They have an inferior, often colored perianth, generally in four, five, or six segments; three to nine stamens inserted into the bottom of the perianth; a one-celled ovary, usually formed of three carpels, but containing only one ovule; styles and stigmas as many as the carpels of the ovary; the fruit generally a nut, often triangular, the seed with farinaceous albumen, which has an economic importance in buckwheat. A few species produce a succulent edible fruit. The order contains nearly 500 known species, natives of almost all parts of the world, but particularly abundant in the temperate regions of the northern hemisphere. Many of the species are common weeds in Britain, as different species of dock (q.v.) and *polygonum*. Bistort (q.v.), buckwheat (q.v.), and sorrel (q.v.) belong to this order.—The genus *polygonum* has a colored perianth of five segments, stamens in two rows, styles more or less united at the base, and two or more in number; the fruit invested by the

persistent perianth. The species are very numerous. A number are natives of Britain. KNOT-GRASS (*P. aviculare*), a very common British weed, is one of the plants remarkable for most extensive distribution over the world. It is an annual of very humble growth, but very variable, with much branched trailing stems, small lanceolate leaves, and very small flowers, two or three together, in the axils of the leaves. Thunberg says that in Japan a blue dye is prepared from the plant. *P. amphibium*, one of the species often called *persicaria*, is abundant about margins of ponds and ditches in Britain and throughout Europe, and is remarkable for the difference between the leaves which float on the water, as is often the case, and those on stems growing erect, those of the former being broad and smooth, those of the latter narrow and rough; the spikes of flowers being also of somewhat different form, and the stamens in the flowers of the floating stems shorter than the perianth, in the upright stems about as long as the perianth; differences which might be held to indicate different species, yet both may be found growing from one root. The stems have been used on the continent of Europe as a substitute for sarsaparilla. Some other species are occasionally used for medicinal purposes. *P. hydropiper*, often called WATER PEPPER, a plant common by sides of lakes and ditches in Britain, is acrid enough to be used as a vesicant. Several species are occasionally used for dyeing, as the SPOTTED PERSICARIA (*P. persicaria*), a very common weed on dunghills and in waste places in Britain; but the only species really important on this account is that called DYERS' BUCKWHEAT (*P. tinctorium*), a native of China, biennial, with ovate leaves and slender spikes of reddish flowers, the cultivation of which has been successfully introduced in France and Flanders. It yields a blue dye scarcely inferior to indigo.—*P. orientale* has long been occasionally cultivated in flower-gardens in Britain, and is quite hardy, although a native of the West Indies.—*Fagopyrum cymosum*, a species of buckwheat abundant on the mountains of the n. of India, affords an excellent substitute for spinach.—*Mühlenbeckia adpressa* is the Macquarrie Harbor vine of Tasmania, an evergreen climbing or trailing shrub of most rapid growth, sometimes 60 ft. in length. It produces racemes of fruit somewhat resembling grapes or currants, the nut being invested with the large and fleshy segments of the calyx. The fruit is sweetish and sub-acid, and is used for tarts. *Coccoloba uvifera* is the SEA-SIDE GRAPE (q. v.) of the West Indies. See also CALLIGONUM.

POLYHYMNIA, or **POLYMNIA** ("the many-hymned one"), one of the nine muses (q. v.). She was reputed by the ancients to be the inventress of the lyre, and to preside over lyric poetry and eloquence. In works of art she is usually represented in a pensive attitude, with the forefinger of the right hand upon the mouth.

POLYMERISM, a form of ISOMERISM (q. v.).

POLYNE'MUS and **POLYNEMIDÆ**. See MANGO FISH.

POLYNE'SIA, or the region of many islands (Gr. *polys*, much or many, and *nesos*, an island), is the name usually given, with more or less of limitation, to the numerous groups of islands, and some few single islands, scattered throughout the great Pacific ocean, between the eastern shores of Asia and the western shores of America. In its widest signification, the term Polynesia might be understood as embracing, besides the groups hereafter to be mentioned, the various islands, large and small, of the Indian archipelago, in one direction; and the vast island of New Holland or Australia, with its dependency of Van Diemen's land, in another. Including these, the whole region has sometimes been called Oceania, and sometimes Australasia—generally, however, in modern times, to the exclusion of the islands in the Indian archipelago, to which certain writers have given the name of Malaysia. In proportion, also, as the area of maritime discovery has become enlarged, it has been thought convenient by some geographers to narrow still further the limits of Polynesia to the exclusion of Australia and Van Diemen's land; while others, again, exclude Papua or New Guinea, New Ireland, Solomon's isles, the Louisiade group, the New Hebrides, New Caledonia, and certain other groups and single islands, together with New Zealand, from the area of Polynesia, and give to these, in union with Australia, the collective designation of Australasia. To all these, with the exception of New Zealand, French writers have given the name of *Melanesia* or the *Black Islands*; while a similar name, *Kelanonesia*, has been given to them by Prichard and Latham—purely, however, on ethnological grounds, as we shall presently notice.

Thus we have the three geographical divisions of Malaysia, Australasia, and Polynesia, the last mentioned of which embraces all the groups and single islands not included under the other two. Accepting this arrangement, still the limits between Australasia and Polynesia have not been very accurately defined; indeed, scarcely any two geographers appear to be quite agreed upon the subject; neither shall we pretend to decide in the matter. The following list, however, comprises all the principal groups and single island not previously named as coming under the division of Australasia: viz., 1. North of the equator—The Ladrone or Marian islands, the Pelew islands, the Caroline islands, the Radack and Ralick chains, the Sandwich islands, Gilbert's or Kingmill's archipelago, and the Galapagos. 2. South of the equator—The Ellice group, the Phoenix and Union groups, the Fiji islands, the Friendly islands, the Navigator's islands, Cook's or Harvey islands, the Society islands, the Dangerous archipelago, the Marquesas islands, Pitcairn island, and Easter island.

These islands, which extend from about 20° n. of the equator to about 30° s. of it, are some of them volcanic in their origin, and some of them coralline. The volcanic islands generally rise to a considerable height above the level of the ocean, and are therefore called the high islands, in contradistinction to the coralline or low islands. They consist of basalt and other igneous formations. Of these, the principal are the Friendly islands, one of which, Otaheite or Tahiti, has a mountain rising to the height of 10,000 ft.; the Marquesas islands, also very high; the Samoan or Navigator's islands; and the Sandwich islands, of which Owyhee or Hawaii possesses several both active and extinct craters, 13,000, 14,000, and even 16,000 ft. high. The Galapagos group, nearest of all to South America, are likewise of igneous origin, and have several still active craters. The remaining islands are for the most part of coralline formation.

The coral islands (q.v.) may be distinguished into three classes—namely, atolls or lagoon islands, barrier reefs, and fringing reefs. The atolls are rings of coral reefs, surrounding a basin of sea-water of considerable depth, which is inclosed within this area. Examples of these are found in the Caroline islands, the Dangerous archipelago, and several other groups. Barrier reefs differ from the atolls chiefly in the fact of their containing an island in their center, the island being separated from the reef by a body of deep water; while the reef is in some instances entirely converted into land, and in others the sea washes over it, except in certain portions which project above the level of the ocean. Barrier reefs occur among the Society islands, the Gambier islands, and many other groups. Fringing reefs are collections of coralline formation, which are found skirting the coasts of an island in the same manner as the barrier reefs, but without any interior deep water channel. They are found in almost all the groups. From the fact of some of these islands being undoubtedly volcanic, it has been argued that all were originally of the same character; those of coralline formation being based upon the crests of submarine volcanoes, over which the coral insects have for an indefinite series of years been engaged in rearing their limestone structures. In opposition to the volcanic theory, Dr. Darwin has propounded one of his own—namely, the *theory of subsidence*, which, after mature consideration, he believes to be the only one capable of explaining the various phenomena observable in the coral atolls, barrier reefs, and fringing reefs of the Pacific. All these he considers as being the production of saxigenous insects, working upward from the foundations of what were originally so many islands, erect above the surface of the ocean, but which during long ages have been in a state of gradual subsidence. With respect to the atolls, he states it as his belief, that the lagoon is precisely in the place which the top of a shoal, and, in other cases, the highest part of an island, once occupied. So soon as these have sunk to a depth of from 120 to 180 ft. below the surface, the coral insects (which it is agreed are never found at a lower depth) commence their operations, and these working on in countless myriads, the sunken island, or a portion of it, is in process of time again reared to the level of the surrounding sea. It would take too long to specify all the phenomena upon which Dr. Darwin has based this ingenious theory, especially those connected with what are called the fringing reefs. It must be mentioned, however, that paradoxical as such a theory may seem, it has received the hearty support of no less distinguished a geologist than sir Charles Lyell, who, in the early editions of his *Principles of Geology*, having held to the volcanic theory, has since abandoned it for that propounded by Dr. Darwin. Nor is this all; for, in the last edition of sir C Lyell's work, we find him mentioning with approval Dr. Darwin's "important generalization that the Pacific and Indian seas, and some of the lands which border them, might be divided into areas of elevation and areas of subsidence, which occur alternately.

Of the islands generally, we need only further observe that, although situated within the tropics, the heat of the atmosphere is delightfully tempered by a succession of land and sea breezes. The soil is exceedingly fertile; and besides the vegetable productions found growing when the islands were first discovered by Europeans, it has given a welcome home to the orange, lemon, sugar-cane, guava, cotton, potato, melon, and other fruits and plants introduced by foreign visitants. The only native quadrupeds on any of the islands when first visited were pigs, dogs, and rats; but the ox, the sheep, the goat, and even the horse, have since been successfully introduced into many of the groups. The feathered tribes are numerous, likewise the insects, and the coasts everywhere abound with a vast variety of fish and crustacea, highly important as a matter of food to the inhabitants of those islands in which quadrupeds, whether native or introduced, are found in only a small number.

For a more particular description of the several groups, we refer to the distinct articles of FIJIS, FRIENDLY ISLANDS, SANDWICH ISLANDS, etc.; and shall now proceed to speak of the inhabitants generally under the head

POLYNESIANS.—This race of people, supposed at one time by certain writers to be of American origin, is now almost universally admitted to have a close affinity with the Malays of the peninsula and Indian archipelago, and hence is classified with them by Dr. Latham under his subdivision of *Oceanic Mongolidæ*. In physical structure and appearance, the Polynesians in general more nearly resemble the Malays than they do any other race, although differing from them in some respects, as, indeed, the natives of several of the groups also do from each other. In stature, they are generally taller than the Malays, and have a greater tendency to corpulence. In color, also, they more nearly

approach that of the Europeans. The hair is often waved or curling, instead of long and straight, and the nose is frequently aquiline. These differences, however, which may all have been produced by lapse of time and different conditions of existence, offer no barrier to the strong presumption, that at some long antecedent period these islands were colonized by Malay adventurers. The Malays are known at the present time to be expert and daring sailors, and in the 16th c. were so powerful at sea, that they had frequent naval combats with European fleets in the Indian archipelago. In 1573 the king of Acheen, with a powerful armament, attacked and destroyed three Portuguese frigates; and in 1582 the same king attacked Malacca with a fleet of 150 sail. At a later period—namely, in 1615, one of his successors attacked the same settlement with a fleet of 500 vessels of various sizes and 60,000 men. If this was their strength and enterprise at a comparatively modern period, may they not have been as enterprising, if not quite so powerful, in far more remote times? The distance between the more western groups of Polynesia and the eastern islands of the Indian archipelago is not so great but that it could have been easily overcome by a hardy race of sailors, even although their vessels may have not been so well constructed as in modern times; and the same reasoning holds good with respect to the other groups extending still further e., or still more to the n. or south. Each island or group, as it was attained, would only form a convenient point of departure in process of time for some other island or group more remotely situated. It is true that the affinities of language are not great between the Malays and the Polynesians; still, some affinity has been recognized by philologists; while in their manners and customs a strong resemblance has been shown to exist, as in the institution of caste, the practice of circumcision, the chewing of the betel-nut, and other things. Many other facts might be mentioned in favor of the theory of a Malay settlement, not only of Polynesia, but of the islands called Melanesia or Kelænonesia as well; the last mentioned being inhabited by a race almost identical with the Negritos or Pelagian Negroes of the Eastern archipelago. Dr. Latham, in treating of the Polynesians, divides them into two branches—viz., 1. The Micronesian branch, and 2. The proper Polynesian branch. His theory as to the probable line of migration is as follows: “The reason for taking the Micronesian branch before the proper Polynesian, involves the following question: What was the line of population by which the innumerable islands of the Pacific, from the Pelews to Easter island, and from the Sandwich islands to New Zealand, became inhabited by tribes different from, but still allied to, the Protonesian Malays? That line, whichever it be, where the continuity of successive islands is the greatest, and whereon the fewest considerable interspaces of ocean are to be found. This is the general answer *à priori*, subject to modifications from the counterbalancing phenomena of winds or currents, unfavorable to the supposed migration. Now, this answer, when applied to the geographical details regarding the distribution of land and sea in the great oceanic area, indicates the following line: New Guinea, New Ireland, the New Hebrides, the Fijis, and the Tonga group, etc. From hence, the Navigator’s islands, the isles of the Dangerous archipelago, the Kingsmill and other groups, carry the frequently diverging streams of population over the Caroline islands, the Ladrones, the Pelews, Easter island, etc. This view, however, so natural an inference from a mere land and sea survey, is complicated by the ethnological position of the New Guinea, New Ireland, and New Hebrides population. These are *not* Protonesian, and they are not Polynesian. Lastly, they are not intermediate to the two. They *break*, rather than propagate the continuity of the human stream—a continuity which exists geographically, but fails ethnographically. The recognition of this conflict between the two probabilities has determined me to consider the Micronesian archipelago as that part of Polynesia which is most likely to have been first peopled, and hence a reason for taking it first in order.” The islands comprised in the Micronesian branch are the Pelew islands, the Caroline islands, the Marian islands, and the Tarawan or Kingsmill group. In physical appearance the inhabitants of these groups more nearly resemble the Malays than is the case with the Polynesians proper. In person they are not so tall as the latter. Their language has numerous dialects, most of which would perhaps be unintelligible to the groups further s. and east. In religion they are pagans; but their mythology and traditions differ from those of the Polynesians proper. Neither is the custom of the taboo and the use of kawa so prevalent as they are found to be among the latter. The proper Polynesians, so called, are found in the Fiji islands, but not to the same extent as in the following—viz., the Navigator’s or Samoan islands, the Society islands, and Friendly islands; also in the Sandwich islands, the Marquesas, the Dangerous archipelago, etc. In physical appearance, they are the handsomest and tallest of all the natives of the Pacific islands, with the exception, perhaps, of the New Zealanders or Maoris. The aquiline nose is commonly seen among them, and there are many varieties both of hair and complexion. Their face is generally oval, with largish ears and wide nostrils. In the islands nearest to the equator, the skin is said to be the fairest, and it is darker in the coral islands than in the volcanic. Their language is said to bear some affinity to the Tagala, and is split up into numerous dialects, all, however, to a great extent mutually intelligible among the several groups. Paganism, originally prevalent among all the groups, is becoming gradually extirpated through the efforts of the missionaries, principally English and American, as in the Samoan, Sandwich, and Society groups, where but few absolute pagans now remain. The superstition of the taboo, the

use of kawa as an intoxicating drink, cannibalism, infanticide, tattooing, and circumcision, which were also formerly prevalent in all the groups, are now fast disappearing, under the influence of Christianity. Unfortunately, however, the contact of these islanders with civilization has not been always productive of unmixed good; the introduction among them of the use of ardent spirits, and of the vices and diseases of Europeans, having thinned the population to a lamentable extent. Further particulars with respect to the natives of Polynesia will be found in some of our articles on the groups regarded as being the most important.

POLYNICES. See ETEOCLES.

POLYPHEMUS, a genus of *branchiopoda* (q.v.), of the order *cladocera*, remarkable for the extraordinary size of the solitary eye, which occupies almost the whole head. One species (*P. stagnorum*), is common in stagnant pools and ditches in some parts of Britain and of the continent of Europe. It is about the size of a flea, and moves rapidly in the water, executing all kinds of evolutions, employing both its legs and antennæ as organs of swimming. The shell, consisting of two pieces, is so transparent that all the viscera may be seen through it. The abdomen is terminated by a long tail suddenly folded back.

POLYPHEMUS, in the Homeric mythology, the son of Poseidôn and the nymph Thoosa, the most celebrated of the fabulous Cyclops (q.v.), who inhabited the island of Sicily. He was of immense size, and had only one eye. When Ulysses landed on that island, he entered the cave of Polyphemus with twelve companions, of which number this tremendous cannibal ate six. The others stood expecting the same fate, but their cunning leader made Polyphemus drunk, then burned out his single eye with a blazing torch, and so escaped, leaving the blinded monster to grope about in the darkness.

POLYPHON'IC (Gr. *polys*, many, and *phoné*, voice). When a musical composition consists of two or more parts, each of which has an independent melody of its own, it is said to be polyphonic, in opposition to a homophonic composition, consisting of a principal part with a leading idea, and accessory parts employed to strengthen it. Each part of a polyphonic composition aims at melodic perfection, and while supporting the other, has an equal share in the entire effect, as in the following example:

A fugue (q.v.) is the most perfect example of polyphonic composition. The difference between homophonic and polyphonic compositions is not always so marked as to leave it free of doubt whether a part is subordinate or independent; and many compositions consist of an alternation of homophonic and polyphonic passages. The construction of polyphonic phrases is called counterpoint.

POLYPI, or **POLYPS**, a class of animals which were, till the last few years, included in the **RADIATA** of Cuvier, but which, since the radiata have ceased to be regarded as a subkingdom, have found a place in the subkingdom **CŒLEENTERATA**. See **SUBKINGDOMS, ANIMAL**. The name *polypi*, or *polyps*, was given by Reaumur about the middle of the last century to these animals, on account of their external resemblance to the many-armed cuttle-fishes, which were so denominated by Aristotle; and our knowledge of these organisms, as members of the animal kingdom, hardly dates back much more than a century. All polyps are aquatic in their mode of life, and almost all of them are inhabitants of the sea, two genera only (*hydra* and *cordylophora*) of fresh-water polyps being as yet known. Most of them live in societies of considerable extent, supported on a common stock, to which the term *polypidom* (polyp-home) is usually given, and which is sometimes horny, and sometime calcareous. The polyps are either imbedded in cavities in the substance of the calcareous polypidom, or inclosed in minute cups or tubes, from which the body can be protruded, and into which it can be retracted at pleasure, in the horny polypidoms. The solitary species often attain a considerable size (as, for instance, many of the actinias); but the social polyps are always minute, although the combined power of some of the species in modifying the earth's crust is neither slight nor limited in extent. "They have built up a barrier reef along the shores of New Caledonia for a length of 400 m.; and another, which runs along the n.e. coast of Australia, 1000 m. in extent. To take a small example: a single atoll (or coral island) may be 50 m. in length by 20 in breadth; so that if the ledge of coral rock forming the ring were extended in one line, it would be 120 m. in length. Assuming it to be a quarter of a mile in breadth, and 150 ft. deep, here is a mound, compared with which the walls of Babylon, the great wall of China, and the pyramids of Egypt are but children's toys; and built, too, amid the waves of the ocean, and in defiance of the storms."—Owen, *Lectures on the Invertebrate Animals*, 2d edit., p. 143.

The bodies of these animals are generally soft, and cylindrical or oval in shape; and

the mouth, which is the only aperture of the digestive canal, and is quite destitute of any masticating apparatus, lies in the center of the anterior or free extremity of the body, and is surrounded by a fringe or circle of tentacles or arms. The skin in the social polyps is exceedingly soft and delicate; but in the solitary species it is often of a leathery consistence. It almost always contains peculiar urticating organs, or thread-like cells, which may be regarded as one of the distinctive characters of the cœlenterata. Various arrangements of the polyps have been proposed, but it is sufficient for all practical purposes if we admit two orders—namely, the *hydrozoa* and the *anthozoa* (or *actinozoa*), which differ essentially in the following points: in the *hydrozoa* the wall of the digestive sac is not separated from that of the somatic (or bodily) cavity, and the reproductive organs are external; while in the *anthozoa* the wall of the digestive sac is separated from that of the somatic cavity by an intervening space, subdivided into chambers by a series of vertical partitions, on the faces of which the reproductive organs are developed. The hydra (q. v.), or fresh-water polyp, is the type of the *hydrozoa*. A few of these polyps are simple animals, as, for example, *hydra*, *corymorpha*, *vorticifera*, and *myriothela*; but the greater number are compound or composite, exhibiting a numerous colony, connected with one another by a common trunk or *cœnosarc* (from the Gr. *koinos*, common, and *sarx*, flesh), which usually presents an erect tree-like form. A sufficient idea of the form and structure of the *simple* polyps of the class will be obtained by a reference to the article HYDRA, which attains a length of between 4 and 5 inches, and was discovered by Forbes and Goodsir when dredging in the n. of Scotland. They observe that when it was placed in a vessel of sea-water, it presented the appearance of a beautiful pink flower, its head gracefully nodding (whence the specific name given to it by Sars, who had previously discovered it on the Norwegian coast), and bending the upper part of the stem; it waved its long white tentacles to and fro at pleasure, but seemed to have no power of contracting them. The *compound* hydrozoa include, *inter alia*, the orders *sertulariæ* (embracing the various species of *sertularia*, *campanularia*, *laomedea*, etc.), and *tubulariæ* (embracing the various species of *tubularia*, *eudéndrium*, *bimeria*, etc.). A good idea of the nature of the compound hydrozoa may be formed from the consideration of the *campanularia dichotoma*, a common organism on our shores. The compound polyp-animal, or association of polyps, resembles a miniature tree. It consists essentially of a ramified tube of irritable matter, defended by an external flexible, and frequently jointed horny skeleton; and is fed by the activity of the tentacula, and by the digestive powers of the alimentary sacs of a hundred polypi, the common produce of which circulates through the tubular cavities for the benefit of the whole community. The soft integument of the nutrient polyps contains the thread-cells, to which allusion has previously been made. These are protruded when the skin is irritated, and give the tentacles the appearance of being beset by minute bristles. The digestive sac of each polyp is lined by a ciliated epithelium; but there is a perforation at the base communicating with the central tube. This outlet admits only of the passage of the fluid contents of the stomach, undigested matters being ejected by the mouth. There is reason to believe that sea-water enters the branches of the tube and circulates, by means of the ciliated epithelium, through the compound organism; and by this means contributes to the respiratory process. "At certain points of these ramified polyps," says prof. Owen, "which points are constant in and characteristic of each species, there are developed little elegant vase-shaped or pod-shaped sacs, which are called the ovigerous vesicles, or *ovicapsules*. These are sometimes appended to the branches, sometimes to the axillæ. They are at first soft, and have a still softer lining membrane, which is thicker and more condensed at the bottom of the vesicle. It is at this part that the ova or germs are developed, and for some time these are kept in connection with the vital tissue of the polyp by a kind of umbilical cord. In all the compound *hydrozoa*, the *ovicapsules* are deciduous; and having performed their functions in relation to the development of the new progeny, drop off like the seed-capsules of plants." On other individuals of the same species sperm-capsules are developed, which, in form, resemble the *ovicapsules*, but in place of ova, contain spermatozoa. The act of fertilization in most cases occurs by diffusion of the spermatozoa in the surrounding water. There is much that still requires elucidation in reference to the various modes of reproduction of this class. Many of the hydrozoa have been shown to be merely larval forms of medusæ. See GENERATIONS, ALTERNATION OF.

The leading anatomical distinction between the *anthozoa*, or *actinozoa*, and the *hydrozoa* has been already noticed. The common *actinia* (q. v.) may be regarded as the type of this class, all of which are marine, and principally inhabit the warmer or tropical seas. Many of the larger tropical polyps of this class combine with a structure similar to that of the *actinia* an internal calcareous axis or skeleton, which, penetrating into the interior of the organism, presents the lamellated and radiated structure recognizable in the *fungiæ*, and in the skeletons of *caryophyllæ*, *madreporæ*, etc. Such anthozoa are termed coralligenous; and every hard structure deposited in or by the tissues of this class, and forming a uniform framework, is recognized by zoologists as a coral. Like the members of the preceding class many of the anthozoa multiply freely by gemmation, complex or compound animals or colonies of animals being formed, in which individual polyps are united by a *cœnosarc* or polypidom. For a description of the mode in which communication takes place between the common body or mass and the individual polyps, we must refer to the article ALCYONIUM. Various arrangements of this class

have been proposed by zoologists. If we exclude the consideration of fossil genera, we may divide the anthozoa into two orders—the *alcyonaria* and the *zoantharia*.

The *alcyonaria* may be characterized as anthozoa in which each polyp is furnished with eight tentacles, not simple, as in actinia, but furnished with pinnate margins, with eight somatic chambers, and eight mesenteries. With the exception of one genus they are all composite in structure; their polyps being connected with one another by a cœnosarc, which is traversed by prolongations of the somatic cavity of each polyp, a system of canals being thus formed whose parts freely communicate and are readily distensible. Carus, in the *Handbuch der Zoologie*, 1863, vol. 2 (of which he is joint author with Peters and Gerstaecker), mainly adopting Milne-Edwards's arrangement, divides the alcyonaria into the three following families: 1, *alcyonidæ*; 2, *gorgonidæ*; 3, *pennatulidæ*. In the *alcyonidæ* he includes the beautiful organ-pipe corals, of which Green and others make a separate family. The polypidom constructed by *tubipora musica* consists of successive stages of cylindrical tubes of a rich crimson color, united at various heights by means of horizontal connecting plates. The tubes placed upon the upper stage are alone inhabited by living polyps, of a violet or green color, the occupants of those below having successively perished as fresh generations appeared above them. As an example of the *gorgonidæ* we may take *isis hippuris*, in which the skeleton is made up of alternate joints of calcareous and horny matter, with the view of giving the necessary flexibility. In the *pennatulidæ*, the polypidom is free, and no polyps are attached to its basal portion. The *sea-pens* (*pennatula*) of our own coast afford a good example of this family. See PENNATULA for description and figure.

The *zoantharia* may be characterized as anthozoa in which the tentacles are either simple or branched, in general numerous, and together with the mesenteries, disposed in multiples of five or six. They may be arranged in the three following suborders: 1. *Z. malacodermata*; 2. *Z. sclerobasica* or *antipatharia* (Milne-Edwards); and 3. *Z. sclerodermata* or *madrepores*. The first sub-order has been variously subdivided into families and subfamilies, which it is unnecessary to notice. It contains all the sea-anemones and animals allied to them, including the genera *actinia*, *anthea*, *corynactis*, *capnea*, *adamsia*, *ilyanthus*, *sagartia*, *bunodes*, *edwardsia*, *peachia*, etc., and the *zoanthidæ*, which are aggregated polyps arising from a common creeping root-like fleshy band, and of which at least one species, *zoanthus couchii*, is an inhabitant of the British seas. All the members of the second sub-order are composite structures. *Antipathes*, the type of the group, presents a stem-like, simple, or branching cœnosarc, which in one species tapers to a length of more than 9 ft., with a diameter at the base not exceeding three-tenths of an inch. The third sub-order (the *madrepores*) is a very extensive one. It is divided into the *madrepora aporosa* and *M. perforata*, according as the coral exhibits a solid or a porous structure. *M. aporosa* may be arranged in the following families: 1. *turbinolidæ* (including the sub-families *caryophyllinæ* and *turbinolinæ*); 2. *oculinidæ*; 3. *astræidæ*; 4. *echinoporinæ*; 5. *merulinaceæ*; 6. *fungidæ*, while the *M. perforata* are divided into (1) *madreporidæ* and (2) *poritidæ*. A few of the commoner forms of madrepora are described in the articles CORAL and MADREPORE. Among the most important works on this department of zoology may be mentioned Dana's *Structure and Classification of Zoophytes* (Philadelphia, 1846); and his *Report on Zoophytes*, and *Atlas of Zoophytes* (U. S. exploring expedition), 1849; Johnston's *British Zoophytes*, in 2 vols.; Hincks, *British Hydroid Zoophytes*—an excellent monograph; Milne-Edwards and Haime, *Histoire Naturelle des Coralliaires ou Polypes proprement dits* (3 vols., 1857–60); and Lacaze-Duthiers, *Histoire Naturelle du Corail, Organisation, Reproduction*, etc. (1864). See also works by Huxley, Haeckel, Claus, etc.

POLYPO'DIUM, a genus of ferns, with spore-cases on the back of the frond, distinct, ring-shaped, in roundish *sori*, destitute of *indusium*. Several species, differing very considerably in appearance, are natives of Britain, where no fern is more common than *P. vulgare*. It grows on rocks, trees, dry banks, etc., and has fronds 2 to 18 in. long, deeply pinnatifid, with large *sori*.—*P. dryopteris*, with delicate ternate bipinnate fronds, is a fine ornament of many dry stony places in Scotland.—*P. calaguala*, a native of Peru, is said to possess important medicinal properties—solvent, deobstruent, sudorific, etc.

POLYPO'ROUS. See AMADOU and DRY ROT.

POLYP'TERUS, a genus of fishes, ranked by Cuvier among malacopterous fishes and in the family *clupeidæ*, notwithstanding very important differences of structure; but now constituted by Müller and others into a family, *polypteridæ*, of the order of ganoid fishes. The shape is round and elongated; the head defended by large bony plates, the body covered with large and strong ganoid scales, which are very closely affixed to the skin. These curious fishes, existing remains of a type which was prevalent in former geologic periods, inhabit the rivers of Africa, and lodge in the soft mud. Their flesh is very pleasant. The polypterus of the Nile, called *bichir* by the Egyptians, is said to be one of the finest fishes of that river. It is about 18 in. long.

POL'YPUS, in surgery, is an antiquated term employed to signify any sort of pedunculated tumor attached to a surface to which it was supposed to adhere like a many-footed animal, as its name indicates. The most common seat of polypuses is the mucous membrane, especially that of the nostrils and uterus; but these tumors are also found in the rectum, the larynx, and the external auditory passage of the ear. The only satisfac-

tory mode of treatment consists in their removal, which must be effected in various ways, according to their position, as by the forceps, the cecraseur, the ligature, etc.

POLYSTYLE, a term applied to a building with a number of columns, but not the strict number of any of the classic arrangements.

POLYTECHNIQUE (ÉCOLE POLYTECHNIQUE), or POLYTECHNIC SCHOOL (Gr. *polys*, many; *technē*, art), was first established in Paris (1794) by the national convention, under the name of *école des travaux publics* (school of public works). No students were admitted but those who intended to enter the public service; and though the general object of the institution was the supplying of well-educated youths to all branches, it was more particularly devoted to the thorough instruction of recruits for the corps of civil and military engineers. The institution received the name of "école polytechnique" in 1795. The pupils were at first 349 in number, and each received, during his stay of two years in the institution, an annual stipend of 1200 francs (£48 nearly); the teachers were in most cases the most eminent savants of France. In 1799 some modifications were introduced into the working of the school; the number of pupils was at the same time limited to 200, and they were put into uniform. The advantages of an institution of this sort, when ably conducted, soon made themselves evident, and the polytechnique, in consequence, rose into high estimation, not only in France, but throughout Europe, so much so, that it became common for foreign nations, when entering into a treaty with France, to stipulate for the admission of a certain number of their subjects into the institution, after passing the prescribed entrance examination. In 1804 the emperor Napoleon introduced various modifications into its working, and gave it a military organization; it was also removed from the Palais Bourbon (where it had existed from its first establishment) to the old college of Navarre. The institution became more and more, as the end of the Napoleonic empire drew near, a training-school for young artilleryists and engineers; and such was the enthusiasm of the pupils in the emperor's cause, that, after the disasters of 1814, they demanded to be enrolled *en masse* in the ranks of the French army. However, Napoleon was (to use his own words) not inclined "to kill the hen for the golden eggs;" but he allowed them to form three out of the twelve companies of which the artillery corps of the national guard was composed. These three companies rendered important service in manning the walls of Paris, and behaved heroically in the battle of Mar. 30, 1814. After the first restoration, the polytechnique, being considered to be evil-disposed to the government, suffered considerable reductions; but was restored to its former importance for the brief period of the "hundred days." After the second restoration (July, 1815), the staff of professors was remodeled; Lacroix and some others were dismissed, and replaced by Poisson, Arago, Cauchy, etc. Notwithstanding these changes, the government still had its doubts as to the loyalty of the establishment, and took advantage of an outbreak, April 3, 1816, to break it up. It was reconstituted in September of the same year, under a revised code of regulations, and in 1822 the old severity of military discipline was restored. During the war of 1870-71, the government of national defense ordered the pupils to meet at Bordeaux, and classes were opened there under distinguished pupils of the school brought from all parts of France. However the attempt had to be abandoned, and the pupils having sought permission to take part in the war, were divided among the different sections of the army, in which their services were highly appreciated. The constitution of the school, which has so frequently suffered change, was in the end of 1873 regulated by *décret* of Nov. 30, 1863, and ministerial rules issued on Mar. 5, 1857. 1. No pupil can be admitted unless he has been successful in the public competitive examination which is held each year. 2. The conditions of admission to the competitive examination are, that the candidate shall be a Frenchman; that he shall be more than 16, and less than 20 years of age, on the 1st of January of that year; and that he shall be either a bachelor of letters or a bachelor of sciences of the university of France. If he holds both degrees he is allowed 50 marks in the examination for admission. 3. Regular soldiers are admitted up to the age of 25 years, provided they have been on real and effective service for two years. 4. The charge for board is 1000 francs (£40) per annum, and the cost of outfit (to be also paid by the pupil) about 600 francs. 5. The duration of the course of instruction is two years: the pupils, after finishing their course, must pass a final examination; the successful candidates, if found to be physically qualified, are arranged in order of merit, and choose in order what branch of the public service they wish to enter. 6. The branches of the public service which are recruited from the polytechnique are, the corps of land and naval artillery, military and naval engineers, the imperial marine, the corps of hydrographic engineers, that of engineers of roads, bridges, and mines, the corps of staff-officers, the superintendence of telegraphs and gunpowder and tobacco manufactories; and generally every department which, requiring special scientific knowledge, may be added by *décrets* to these.

The following branches of study were embraced in the curriculum in 1873: Mathematics, physics, chemistry and chemical manipulation, history and literature. German, written exercises, drawing, geodesy, mechanics, architecture, art militaire. Lessons in fencing, music, and dancing are given out as optional, and must be separately paid for. The number of pupils varies with the requirements of the public service. In 1794 there were 396 pupils; in 1820 only 66. During the first empire, the numbers increased from

110 in 1808, to 227 in 1813; under Louis Philippe the average number was 130. During the second empire, it had risen to 140 and 150. After the war with Germany in 1870-71 the number rose to 260. The numerous and admirably equipped technical schools of Germany (see TECHNICAL EDUCATION in SUPP., vol. x.), often called *polytechnica*, have received no military restriction, and are available for all interested in the industrial arts; they are in many cases scientific centers comparable to the universities.

POLYTHEISM. See God.

POLYTRICHUM (Gr. many-haired), a genus of mosses, having the capsule supported on a stalk (*seta*) which is terminal, and thus appears as an elongation of the stem; the peristome single, of 32 or 64 short equidistant teeth, which are curved inward, and their summits united by a horizontal membrane closing the mouth of the capsule. A number of species are found in Britain, of which the most abundant is *P. commune*, sometimes called *hair-moss*, *golden maidenhair*, and provincially *goldilocks*; growing in heaths and woods, particularly where the soil is sandy; the stems not at all branched, or only at the base, several inches long; the narrow slender leaves sometimes nearly half an inch long. This beautiful moss is very common in the most northern parts of Europe and Asia.

POLYZOA known also as BRYOZOA (from the Greek *bryon*, moss, and *zoon*, an animal; because many of these organisms incrust other animals or bodies like moss), and CILIOBRACHIATA (from the circumstance that their tentacles are ciliated), are so called from many individuals being united into a colony or polyzoary. Although Dr. Grant, in his *Observations on the Structure and Nature of Flustræ*, in 1827, and Milne-Edwards and Audouin, in their *Résumé des Recherches sur les Animaux sans Vertébres faites aux îles Chaussey*, in 1828, indubitably showed that these animals more closely resembled, in the details of their organization, the molluscos than the radiate subkingdom, with which they were formerly confounded, some of our most esteemed English writers (including prof. Owens) persist in retaining them among the polyps, instead of placing them in their true position amongst the *molluscoïd animals*.

Most of the polyzoa are microscopic; but as they occur in colonies, they often collectively form sufficiently conspicuous masses, and although there is little diversity in the form or structure of the animals themselves, there is much difference in the form, arrangement, and composition of the cells or chambers in which the individual animals reside. "In general," says Mr. Gosse, "the form of the cell is ovate or oblong; but the general shape is variously modified, being tubular, club-shaped, horn-shaped, cradle-shaped, square, etc." The arrangement is often shrub-like, or the cells may be arranged in close series, either adhering in irregular patches, as the *lepraliæ*, or rising into broad, flexible leaves, as the *flustræ*, or common sea-mats, or in solid strong walls, or coral-like masses, as the *escharæ*, or calcareous sea-mats. Each animal lives freely in its cell, with whose walls it is connected only by means of muscular bands and threads at certain points, and by the covering of the mouth of the cell. The animal may either expand itself to a considerable extent out of the mouth of the cell, or it may be altogether restricted within the latter; its movements being due partly to pressure upon the outer walls, and partly to the muscular bands, which act chiefly as retractors. On examining one of these organisms in the expanded state, the mouth is seen to be surrounded by a crown of tentacles, which are most commonly ten or twelve in number, and are clothed with vibratile cilia, which lash the water toward the mouth, and thus create numberless little whirlpools, by which nutritious matter is conducted into the oral aperture of the polyzoa. These ciliated tentacles constitute one of the essential points of difference between these animals and the hydraform polyps, with which they were formerly associated. The mouth leads to a funnel-shaped cavity or pharynx, which is succeeded by an œsophagus, and a true digestive stomach (between which a muscular gizzard intervenes in certain genera), after which the intestine turns back upon itself, and terminates in an anus near the mouth. In the separate intestine and anal orifice, we have another characteristic distinguishing these animals from the polyps. At the base of the tentacular circle, just above the anal orifice, is a nervous ganglion, which in all the polyzoa lies on the re-entering angle, between the two extremities of the intestinal canal. No heart has as yet been discovered, the matters, which result from digestion, percolating through the intestinal walls, and becoming mixed with the fluid in which the viscera floats. According to prof. Allman, three distinct modes of reproduction occur in the polyzoa, viz., by buds or gemmæ, by true ova, and by free locomotive embryos. This subject, however, requires further investigation.

Minute appendages, of a very remarkable character, are fixed to the cells of many of the genera. They are termed *avicularia*, or "bird-head processes," and *vibracula*, or whip-like spines. The *avicularia* were described by Ellis, who first noticed them (in his *Essay towards a Natural History of the Corallines*, 1758), as resembling "a bird's head with a crooked beak, opening very wide;" they consist of a fixed and a movable nipper, like a crab's claw, the latter being worked by special muscles. These moving beaks have been often observed to seize minute animals; but as these organs have no power of passing their prey to the mouth, the polyzoa cannot receive nourishment from this source. Mr. Gosse ingeniously suggests that "the seizure of a passing animal, and the holding of it in the tenacious grasp until it dies, may be a means of attracting the proper prey to

the vicinity of the mouth." The *vibracula* consists of a long, slender movable *seta* or bristle, which, according to Gosse, serves "to rid the animal of intruding vagrants, and to cleanse away accidental defilement, by sweeping across the orifice of the cell." Both these kinds of organs are of service in determining genera. Excellent magnified representations of the *avicularia* and *vibracula* may be seen on referring to Figs. 13 and 11, in Mr. Busk's excellent article, POLYZOA, in *The English Cyclopædia*, to which, as also to that gentleman's *Catalogue of Marine Polyzoa in the British Museum*, and to prof. Allman's "Report on the Fresh-water Polyzoa," published in the *Reports of the British Association* for 1850, the reader is referred for further information regarding this remarkable class of animals. See also the British Association report on *Fossil Polyzoa*, 1882.

POMACEÆ, or **POMEÆ**, according to some botanists, a natural order of plants, but more generally regarded as a suborder of rosaceæ (q.v.). The plants of this order are all trees or shrubs, abundant in Europe, and chiefly belong to the temperate and colder regions of the northern hemisphere; they are rare in very warm climates, and are not found at all in the southern hemisphere. They have the botanical characters described in the article rosaceæ (q.v.), and in addition are distinguished by having the tube of the calyx more or less globose, the ovary fleshy and juicy, lined with a thin disk, its carpels adhering more or less to the sides of the calyx and to each other; the fruit a *pome* (q.v.), 1 to 5 celled, in a few instances spuriously 10-celled; the ovules in pairs, collateral. Many of the species are prized for the beauty and fragrance of their flowers, some produce valuable timber; but the order is chiefly remarkable as producing a number of the very finest fruits of temperate climates. See APPLE, PEAR, QUINCE, MEDLAR, LOQUAT, HAWTHORN, CRATÆGUS, AMELANCHIER, ROWAN, SERVICE.—There are about 200 known species.

POMADE, or **POMATUM**, is a preparation used instead of liquid oil for the hair. It consists of a fine inodorous fat, such as lard or suet; but neither of these are quite free from smell, and the most careful perfumers render them so by a peculiar process. They melt them in a steam-bath, and to every $\frac{1}{4}$ of cwt. add 1 oz. of alum and 2 oz. of salt, continuing the action of the heat till any scum ceases to rise; the scum is carefully removed, and the fat allowed to cool, after which it is levigated with cold water with great care and patience until every particle has been acted upon, and the salt, alum, and albuminous matters are perfectly washed out, after which it is remelted in the steam-bath, and any remaining water falls to the bottom; when cold, it is fit for use. The perfumer then takes portions of this prepared fat, and remelting each separately, adds a little wax or spermaceti to give it consistency, and perfumes it with some essence. The varieties of pomades are as numerous as the perfumed essences. Anciently, they were made by boiling over-ripe apples in fat, by which the peculiar smell of the fruit was communicated, and this originated the name, which is derived from *pomum*, an apple.

POMARE IV., Queen of the Society Islands: 1813–77: succeeded her brother Pomare III., 1827, Jan. In 1843, in spite of her protests, the island of Tahiti was placed by native chiefs under the protection of the French, who subsequently gained possession of all the neighboring islands. Public attention in France was thus directed to the islands, which were painted as a sort of savage El Dorado, and became favorite subjects with chansonniers and vaudevillists. Heine makes frequent mention in his later poems of Queen Pomare and her court of dusky beauties. A celebrated dancer at the Mabilie, in Paris, Élise Sargent (1824–52) was dubbed Queen Pomare by the students, and to celebrate her coronation invented the cancan. Allusions to this woman may be found in Balzac, Eugene Sue, Gautier, and many other writers.

SUPPLEMENT TO VOLUME XI.

*An * indicates that the article to which it is prefixed is continued from the main work.*

OPHRYDEÆ : a tribe of orchidaceous plants, having the granular pollen united in two pollinia by an elastic tissue or axis, and attached to a gland or viscid disk ; anther terminal, usually erect, persistent, with two separate, perfect cells ; terrestrial plants, with tuberous or fleshy fibrous roots ; inhabitants of all temperate and sub-tropical regions (Central and Southern Europe and South Africa), but scarce in the tropics. There are some 17 cultivated genera, of which *Orchis* and *Habenaria* are represented in the U. S.

ORANGE, WILLIAM NICHOLAS ALEXANDER FREDERICK CHARLES HENRY, Prince of : 1840-79 ; eldest son of William III., King of Holland. He was a prospective son-in-law of Queen Victoria, but on his way from the Hague to London, it is said that some in high authority at court in Paris, in order to make the young prince unacceptable to the English royal family, handed him over to one of the most dissolute members of the court to initiate him into Parisian life. Whether this story be true or not, it is certain that the young prince became estranged from his family and former friends, making Paris his home and the Bouvelards the sphere of his ambition, and that his life was shortened by his excesses.

ORCHHÁ, or TEHRI : a native state in Bundelkhand, Central India, s. of the British dist. of Jhānsi, between 24° 26' and 25° 34' n. lat., and 78° 28' and 79° 23' e. lon. ; abt. 2,000 sq. m. ; pop. 1881, 311,514. The soil is poor, a great portion of the area being hill jungle. O. is the oldest and highest in rank of the Bundela principalities. The cap., Tehri, is an ill-built town.

O'REILLY, JOHN BOYLE : b. Ireland, 1841 : studied at a private school. From his youth he sympathized with the Irish revolutionary movement. In 1865 he enlisted in the British army for the purpose of winning over Irish soldiers to the revolutionary cause ; on detection, 1866, he was convicted and sentenced to 15 years' penal servitude. After four years in the penal colony of Australia he escaped to the U. S. on an American whaler ; settled in Boston, where he became editor and part owner of the *Pilot*. Two volumes of his poetry have been published, *Songs of the Southern Seas* and *Statues in the Block* ; also a story of penal life, *Moondyne*.

O'REILLY, PATRICK T., D.D. : b. Ireland, 1833 : emigrated to America when young, and studied at St. Charles' coll., Md., and at St. Mary's sem. ; was ordained a Rom. Cath. priest, 1857 ; labored as a missionary and pastor, and was consecrated bp. of Springfield, Mass., 1870.

ORMISTON, WILLIAM, D.D., LL.D. : b. Lanarkshire, Scotland, 1821 : educated at Victoria coll., Coburg, Canada ; was prof. of moral philosophy in this institution for one year ; was pastor of a Pres. church at Clarke, Durham co., Canada, 1853-57 ; master and lecturer in the normal school, Toronto ; examiner in the univ. of Toronto, and inspector of grammar schools and examiner in Knox coll. ; pastor of Central Pres. church, Hamilton, Canada, 1857-70 ; and in 1870 was installed as one of the pastors of the Collegiate Reformed (Dutch) church, New York. Dr. O. has assisted in preparing a series of school books, and edited, with notes, *Meyer on the Acts*, besides publishing sermons, pamphlets, etc. He has prepared for several years the International Sunday-school lessons.

ORTELIUS, or ORTEL, or OERTEL, ABRAHAM : 1527-98 ; b. and d. Antwerp : of almost equal rank with Mercator as a geographer. He was the author of the first modern atlas, *Theatrum Orbis Terrarum*, 1570, which, notwithstanding its many defects, is a noble and wonderful work. His other productions were : *Synonymia Geographica*, a critical estimate of ancient geography ; *Thesaurus Geographicus*, *Itinerarium per Nonnullas Gallix Belgicæ Partes*, and *Deorum Dearumque Capita*. Philip II. recognized his merits, and appointed him royal cosmographer, 1575.

ORTHONYX : a name invented by Teniminck in 1820 to denote a bird supposed by him to be distinct from all others. Three species are known : (1) *O. Spinicauda*, found in s. e. Australia ; (2) *O. Spaldingi*, from Queensland, less typical and larger than the

first; (3.) *O. Novæ-Guinææ* from the island of that name. The proper classification of the *O.* is a matter of dispute; its characteristics are a spiny tail and large feet. Some naturalists place it among the *Dendrocolaptidæ*; others among the *Menaura*; while a third class, led by Sundevall, consider it a relative, if not a member, of the *Timelia*. This latter view, from dissection, would seem correct; but examination shows the bird to belong to a family distinct from any hitherto known.

OSBORNE, RALPH BERNAL: 1814-82; b. Eng. He was the son of Ralph Bernal, the art collector; was educated at Trinity coll., Cambridge, and entered the army, 1830, but retired a few years later with the rank of capt. He married an heiress, Miss Catherine Osborne, 1844, and assumed her surname. He was sec. of the admiralty under Lord Aberdeen and Lord Palmerston, and was a Liberal M. P. during the years 1841-74, standing for Wycombe, Middlesex, Dover, Liskeard, and Waterford City.

OSMAN DIGNA: b. Suakin, Africa, abt. 1830; commonly reported as of French family, but, according to latest authorities, of Turkish descent on his father's side, and on his mother's a member of the non-Arab tribe of the Hadendowas. He succeeded to the business of his father, a prosperous slave merchant; and when this was ruined by the Anglo-Egyptian convention against slavery, he sought to stir up the sheikhs of Suakin to revolt. Failing in this, he allied himself with the chief of the anti-Egyptian movement in the Soodan, and when El Mahdi declared himself, he became one of his first followers, receiving the title of "Emir of the Dervish of God," with authority over the Soodanese sheikhs. He seems to have bravely held his own against the English, often vanquished, but regaining his positions, and always ready to be on the offensive, until 1885, June, when his camp at Tamai was reported to have been permanently broken up.

OSMUN, THOMAS EMBLEY, M.D., known by his pseudonym of ALFRED AYRES: b. Ohio, abt. 1825: a physician, resident in New York; has published *The Verbalist*, *The Orthoëpist*, and an edition of Cobbett's *English Grammar*.

OSTIAKS, or OSTYAKS: a tribe of Finnish origin, numbering abt. 27,000, chiefly inhabiting the basin of the Obi in w. Siberia, though a few hundreds are nomads in the basin of the lower Yenisei. They are held to be identical with the Yugra of the Russian annals. The Obi *O.* are to a great extent Russianized in their manners and costume, and live almost exclusively by fishing.

OSWALDTWISTLE: a tp. of Lancashire, Eng., on the Leeds and Liverpool canal, and the East Lancashire railway, 24 m. n. of Manchester. It contains printworks, bleaching factories, collieries, stone quarries, and other industries. Pop. '81, 12,206.

*OTTENDORFER, OSWALD: established, 1884, a branch of the New York Free circulating library, in a handsome building, thoroughly fitted, containing, 1885, July, abt. 9,600 carefully selected vols., nearly one half German. This comparatively small library has had a monthly circulation averaging 9,241 vols. It has also a well-supplied free public reading-room. The late Mrs. Oswald O., well known for her charities, having begun the erection of a handsome building for a free German dispensary, her husband finished it after her death; and it was presented, 1884, May, to the German Dispensary of New York.

OURAY: a co. in s. w. Colorado; formed, 1877, from part of San Juan; crossed by Rio San Miguel and Rio Dolores; surface mountainous, Mt. Wilson, a noted summit, having a height of 14,280 ft. Productions: gold, silver, copper, and galena. Forests of fir and pine abound. The valleys are fertile. Pop. '80, 2,669—6 colored, 3 Chinese, 1 Indian. Co. seat, Ouray.

OURAY, CHIEF: b. Colo., abt. 1820; d. at Los Pinos agency, Colo., 1880. He was the eloquent chief of the Uncompahgre Utes, and frequently visited Washington in the interests of his tribe. He was friendly to the government, and though a warrior in his youth, accepted in his old age the conditions of civilization.

OVERCOMERS: a sect of Christians which sprang up near Chicago, in 1881, basing its doctrines upon a new interpretation of certain passages in the New Testament, especially Rev. ii: 11, 17, 26, 27, which allude to "him that overcometh." Mr. M. H. G. Spofford, the founder, was formerly a ruling elder in the Pres. church, but his new views caused his dismissal for heresy, whereupon he joined, with other church-members who had embraced his teachings, in founding a new congregation. The fundamental doctrines of the *O.* are that only those who overcome—*i.e.*, wholly sanctified Christians—are immediately saved at death, while all others, including Christians partially renewed, must go through purifying purgatorial fires; but that future punishment is not eternal, and that the soul of even the worst sinner will eventually be restored through the atoning blood of Christ. There is a congregation at Lake View, Ill., and another at Valparaiso, Ind.

OVERTURE: in the Scottish ecclesiastical courts a proposal, legislative or administrative, sent up by one of the inferior courts of the various Pres. churches to the supreme court of that church, to be there examined, and, if approved, passed into an act.

OWENS COLLEGE, Manchester, Eng.: was founded, 1851, under the will of John Owens, merchant of that city, who left £100,000 for the instruction of young men "in such branches of science and learning as were then and might be thereafter usually

taught in English universities." Handsome new buildings have been erected, and the college has now a staff of about 50 professors and lecturers in the two departments of art, science, and law, and of medicine. There are abt. 30 scholarships and prizes and a valuable fellowship. O. C. has been constituted a college of Victoria univ., chartered 1880, which will ultimately be a federation of colleges, having its seat in Manchester, and which, unlike London univ., is at once a teaching and examining body, exacting from intending graduates attendance on a defined course of study.

OXFORD : a tp. in Warren co., N. J., including Oxford (or Oxford Furnace) vill., and Belvidere t. Pop. '80, 6,367.

*OYSTER : in America, found from Maine to Mexico on the Atlantic and gulf coast, and from Puget sound to Mexico on the Pacific. The *ostrea borealis* and *Virginica* are the varieties of the e., and the *ostrea conchifila* and *lurida* of the w. coast. The American O. does not hatch its eggs in its shell, but the spawn of the male and female mingles in the water, where fertilization takes place, and the young O. is produced. Long Island sound, the New Jersey coast, Delaware and Chesapeake bays, are the localities from which, mostly, oysters are obtained. The spawning season lasts from April to October. They begin to spawn when about a year old. Large numbers are taken from Chesapeake bay to northern waters to be replanted; they are also sent to the Pacific coast for the same purpose, the early spring being the best season. The star-fish, borer, and winkle destroy many of them; also ice and storms are injurious. Much attention is now paid to their cultivation on account of the growing scarcity. Many breeds, especially in Chesapeake bay, have been almost destroyed by dredging. The last U. S. census puts the capital employed at \$10,500,000, and the value of the shore property at \$5,500,000.

*OYSTERS, LAW AS TO. The rule as to the exclusive ownership of shell-fish above the water-line of the owner of the sea-shore is the same in the U. S. as in England. It has also been decided that the state legislatures have the power to pass laws restricting the taking of oysters below low-water mark along the shores of their respective states. And such a restriction, which discriminates against the inhabitants of other states, is not unconstitutional. So too in several states there are provisions of law by means of which any person may acquire an interest in a certain number of acres of land under water for the purpose of planting and maintaining there an oyster bed for the propagation of oysters. If the requirements of the statute relative to staking, giving notice, etc., are complied with, the planter has the exclusive use of that part of the land under water staked out by him. Any person who, in disregard of his right, takes oysters from such a bed is guilty of larceny.

PACHICO, ROMNALDO : b. Santa Barbara, Cal., 1831 : was a member of the state legislature, 1853; was county judge, 1853-57; was a state senator, 1851, and again in 1861; was state treasurer, 1863, and lieut.-gov., 1871, becoming gov., 1873, upon Gov. Booth's election to the U. S. senate. He ran for congress on the repub. ticket, 1877, and was declared elected by one vote, but the house awarded the seat to P. D. Wigginton, dem. Mr. P. was subsequently elected to the XLVIth and XLVIIth congresses.

PACKARD, STEPHEN B. : b. Auburn, Me, 1838 : served in the civil war in the 12th Me. reg.; has lived in New Orleans since the war. He was appointed U. S. marshal in La. by Pres. Grant, in which position he became the leader of the repub. party in that state, and wielded an immense political influence. He was chairman of the repub. state committee for several years, and in 1876 was nominated by his party for governor. The returns of the election showed that the opposing candidate (Nicholls) had the majority of votes cast; but the state was claimed by the republicans, and P. was declared elected by the returning board (at that time consisting altogether of republicans). Intense excitement followed, and charges of fraud and illegal violence were made by both parties. In 1877, Jan., the rival legislatures—for the contest was not confined to the governorship—met in separate buildings, and each declared its candidate to be the duly elected governor. P. was inaugurated Jan. 8, at the state house, and Nicholls at St. Patrick's hall on the same day. It became evident that the P. government could not stand, and Pres. Grant determined to remove the U. S. troops from New Orleans—a course which was carried out by Pres. Hayes. P. and his legislature finally withdrew from the state house, April 16, and Nicholls was acknowledged gov. by the federal authorities.

PACKER, ASA : 1805-79 : b. Groton, Conn.; d. Philadelphia : began as a poor boy, walking from Conn. to Penn. in search of employment; worked as a carpenter in Susquehanna co., Penn., and New York; lived for 10 years as a pioneer on the upper Susquehanna. He undertook the charge of one of the first boats of the Lehigh canal co., from Mauch Chunk to tide-water, and rapidly rose to the position of a contractor for the building of locks on the Lehigh river, and of boats for the transportation of coal from Pottsville to New York. He was the projector of the Lehigh valley railroad, built in 1852, and of the railroad from Mauch Chunk to Eric. He served in the Penn. legislature, 1845. He was twice elected as a dem. to congress, serving 1853-57, and was a prominent candidate for the presidency of the U. S. before the dem. convention of 1868. Having amassed great wealth, he made munificent use of it, his most notable charity being the founding and full endowment of Lehigh univ., at Bethlehem, Penn., with its many complete departments, for furnishing to young men a free collegiate education.

PACKER COLLEGIATE INSTITUTE, Brooklyn, N. Y.: founded, 1845, under the title of the Brooklyn Female Academy, and opened, 1846, May 4. In 1853 it was destroyed by fire, when Mrs. Harriet L. Packer, widow of William S. Packer, endowed it with \$65,000 out of her late husband's estate, with the desire of associating his name with some permanent public work. The restored building was opened, 1854, Nov. 9, under its present name. It contains 20 study and recitation rooms, a library with over 5,000 volumes, a chapel, studios, laboratory, and gymnasium, and is surrounded by handsome grounds. Its aim is to provide liberal education for young women through the several grades of primary, academic, and collegiate instruction. In 1885 it had 38 instructors and 661 students. Pres., Truman J. Backus.

PADDOCK, ALGERNON S.: b. Glenn's Falls, N. Y., 1830: was educated at the acad. in that place; studied law, and removed to Omaha, Neb., 1857; was a delegate to the first territorial repub. convention of Neb., 1859; was sec. of Neb., 1861, until its admission as a state, 1867, and acted as gov. for a large part of this period; was repub. candidate for congress, 1866; U. S. senator from Neb., 1875-81.

PADDOCK, JOHN ADAMS, D.D.: b. Norwich, Conn., 1825: graduated at Trinity coll., Hartford, Conn., 1845, and at the General theol. sem., 1849; was ordained priest in the Prot. Epis. church, 1850. He was for a number of years the highly efficient rector of St. Peter's church, Brooklyn; and was consecrated missionary bp. of Washington terr., 1880.

PAEZ, PEDRO: 1564-1622; b. Olmedo, Old Castile: a distinguished Jesuit missionary. He was sent to Goa, 1588, and on his way thence to Abyssinia, 1589, he was captured by pirates, and held for seven years as a galley-slave. He engaged in missionary enterprises on the w. coast of India; and having finally reached his original destination, in 1603, he prepared a catechism in the Abyssinian tongue, having in the mean time defeated the native priests in argument. The king, Za-Denghel, became a convert, and asked for additional missionaries; and in a resulting insurrection, the king was killed. P.'s influence increased, however, and the royal court was induced to accept the new faith, and to abandon idol worship. P. died of yellow fever, contracted in his missionary labors.

PAGET, VIOLET: b. England, abt. 1857. She has resided in Italy since 1871, and devotes herself to literature—writing generally under the name of Vernon Lee—and to the care of an invalid half-brother, Eugene Hamilton, somewhat known as a poet. She contributes to the leading English periodicals, and has published *Studies of the 18th Century in Italy*, 1880; *Belcaro*, a vol. of essays on æsthetical subjects, 1882; *The Prince of a Hundred Soups*, 1883; *Ottilie, an 18th Century Idyl*, *Euphorion*, a collection of essays, the *The Countess of Albany*, a biography, 1884, and *Miss Brown*, a novel, 1885. Though young, she is a writer of great force and originality, whose work reveals extensive and varied knowledge.

PAINT, ASBESTOS. Asbestos, on account of its incombustible qualities, has been applied in the composition of a fire-proof paint. The mineral is ground, and then mixed with coloring matters. After drying it forms upon the surface of the wood a mineral coat that will resist the action of heat at a high temperature.

PAINT, LUMINOUS: a highly phosphorescent substance obtained from lime and sulphur in certain proportions, and patented by the late Mr. Balmain. Exposure to the light renders articles painted with this substance capable of retaining a distinct glow for a long time. The violet rays of light produce the most noticeable effect upon the paint, while the red and yellow rays do not increase the glow. It is said to be weather-proof and capable of resisting the action of the sea. The substance is sold at about \$7 a pound.

PALAMPUR: a native state in Guzerat, Bombay, India: lies between 23° 57' and 24° 41' n. lat., and between 71° 51' and 72° 45' e. lon.; area, 3,510 sq.m. The country is wooded and mountainous in the n. and open in the e. and s.; principal rivers, Saraswati and Banás. Pop., 234,402. Cap., Palampur; pop., 17,547.

*PALMER, EDWARD HENRY: resigned his position at Cambridge, 1881, to devote himself to journalism and general literature. In 1882 the government—anticipating a general religious war in Egypt and the possible destruction of the Suez Canal, which could be averted only by preventing the Bedawin tribes to the e. of the Red Sea from allying themselves with Arabi Pasha—selected P. to accomplish this. The appointment was most fit, the work requiring rare skill in diplomacy, a thorough knowledge of languages, and uncommon courage. He visited the Bedawin in disguise, and was successful, up to the point of perfecting his plans, when he was treacherously murdered by some guides who wished to rob him. His *Life*, as written by his friend, Walter Besant (1883), exhibits him as a man of rare gifts and accomplishments. The ease with which he acquired languages, particularly those of the East, as Arabic, Persian, and Urdu was extraordinary. He was so well acquainted with the life and language of the gipsies as to be regarded by them as one of their own blood. In feats of legerdemain he could outwit professionals, and he possessed strong mesmeric power, which he never used. In the survey of w. Palestine he did most valuable work in deciphering inscriptions and getting the correct nomenclature of localities, as is shown by the vol. *The Survey of Western Palestine* (1878), which he edited with Besant. Among his works are an *Arabic Grammar* and a translation of

the Quran. He contributed to the *Encyclopædia Britannica*, papers on "Hafiz," "Legerde-main," etc.; helped translate the poems of Runeberg of Finland; and revised, with Dr. Bruce, Henry Martyn's Persian translation of the New Testament.

PALMER, SAMUEL: 1805-81; b. London; d. Reigate, Eng. He studied art at the British museum and under various masters. He was elected a member of the Etching club, 1853, and of the Soc. of painters in water-colors, 1854. His pictures are distinguished for coloring and poetic charm. Among his works are, "The Ballad," 1860; "The Fall of the Empire," 1871; illustrations to "L'Allegro" and "Il Penseroso," 1877; and etchings illustrating Virgil's *Eclogues*, pub. 1883.

PALMER, THOMAS WITHERELL: b. Detroit, Mich., 1830: was educated at Michigan univ., and became a farmer and manufacturer. He served upon the board of estimates of Detroit, and was a state senator, 1879-80; was elected to the U. S. senate as a repub., 1883.

PÁNCH MAHÁL: a district in the e. of Guzerat, India, between 22° 30' and 23° 10' n. lat., and between 73° 35' and 74° 10' e. lon.; 1,613 sq.m. The s. w. portion is for the most part a fertile plain; the n. portion is rugged and barren. Limestone, sandstone, granite, and other building stones are found. Pop. '81, 255,749, principally Hindoos.

PANTÆNUS: an early Christian teacher, head of the catechetical school at Alexandria, 180-202. His most noted pupil was Clement, who succeeded him. He seems to have been originally a Stoic, and on account of his zeal and learning was, after his conversion, sent as a missionary to Yemen. His works, which included commentaries on the Scripture, have been lost excepting a few fragments.

***PAPER**. The uses made of P. in manufactures are now almost unlimited; but in the larger part of the articles the material is not all P., the latter forming the matrix only that binds the whole together. The manufacture of P. car-wheels has now become a large industry. In the ordinary process the straw board is cut into round disks; these are then pasted together, and subjected to hydraulic pressure, afterward dried at a high temperature, and re-pressed. They are then as firm as the hardest wood, and are ready to be turned and fitted with steel tires, which are forced on under hydraulic pressure. Afterward the hub is fitted in, and iron bands placed on both sides, and held by bolts passing through the wheels. A P. wheel is practically indestructible; the tires only have to be replaced. It has also been found that axles last much longer with P. than with iron wheels. P. has also been used for making gas-pipes; it is passed through a bath of melted asphalt, and then rolled around a core till the desired thickness is attained; and after being pressed, makes a very strong and durable pipe. Household utensils, and even stoves, have been made of paper.

PAPER, IMPRESSION: is used for duplicating writing. It is manufactured by mixing lampblack and oil till it reaches the consistency of molasses. With a brush, this mixture is applied to tissue paper, which is then dried. One or both sides of the paper can be treated with the preparation. If colored impressions are desired, the lamp-black is replaced by colored chalks.

***PAPUA, or NEW GUINEA**. In 1883, Apr., the ministry of Queensland proclaimed the annexation to that colony of the e. half of New Guinea: Lord Derby, on behalf of the home government, promptly disavowed the act; but in 1884, May, the British government determined to establish a protectorate over the s. coast, and instructions were issued to Admiral Erskine, at the Australian station. Accordingly, he sailed in the *Nelson*, and from Port Moresby, Nov. 6, proclaimed the protectorate, and appointed the principal chief as the queen's deputy lieut. The protectorate extends from the 141st meridian eastward, as far as East Cape, and includes the adjacent islands. A short time after the British occupation of the s. coast the German government took possession of the n., together with the islands of New Britain, New Ireland, and several others. The Australians were so indignant that the home government should allow the Germans to annex territory deemed essential to their own prosperity, that the question of their separation from Great Britain was agitated.

***PARAPHERNALIA**. While it is true that in this country the husband has only a qualified property in the P. of his wife, yet, with the exception of N. Y., and possibly two or three other states, the husband must join with the wife in an action to recover damages for any injury to her P. There must be, however, express proof of gift to the wife to enable the wife to sue alone, even in these exceptional instances.

PARENZO: a city on the w. coast of Istria, Austro-Hungary, 30 m. s. of Trieste; on a peninsula nowhere more than 5 ft. above the sea-level. It contains the handsome cathedral of St. Maurus, dating from the first part of the 6th c., the remains of two Roman temples, etc., and is interesting in history as the ancient Parentium conquered by the Romans, B.C. 178. It subsequently grew to be a place of some note, with abt. 15,000 inhabitants in both city and suburb; was made an episcopal see, A.D. 524, and in the middle ages acknowledged the supremacy of Venice. It was several times attacked by the plague, which in 1630 reduced the inhabitants to barely 100. By 1800 they had increased to 2,000, and in 1879 were 2,825.

PARET, WILLIAM, D.D. : b. New York, 1828 : was educated at Hobart coll., Geneva, N. Y. ; held charges as a clergyman of the Prot. Epis. church at Moravia, N. Y., and Washington ; was consecrated bp. of Md., 1884.

*PARK, EDWARDS AMASA, D.D. : since the date of the main article has retired from active duty in his professorship at Andover theol. sem., and is now prof. emeritus. He is engaged in preparing his lectures on theology for publication—a work whose result is awaited with unusual interest.

PARKER, CORTLAND, LL.D. : b. Perth Amboy, N. J. ; graduated at Rutgers coll., 1836 ; was admitted to the bar, 1839, where he has since been prominent. He was one of the commissioners to settle the boundary line between N. J. and Del., and was one of the revisers of the N. J. laws, 1874-75. Without being active in politics, Mr. P. has been a firm repub., and was nominated by Pres. Hayes as minister to Russia, and by Pres. Arthur as minister to Austria both of which positions he declined. He is prominent also as a legislator in the general conventions of the Prot. Epis. church. He resides at Newark, N. J.

PARKER, JOHN HENRY : 1806-84 ; b. London : in 1821 became a bookseller, and in 1832 succeeded to his uncle's business in Oxford. The firm published the *Oxford Pocket Classics* and other successful works. But in the cares of business he found time to devote himself to the study of architecture. In 1836 he brought out his *Glossary of Architecture*, an important aid to the revival of Gothic art. His subsequent works were : *Introduction to the Study of Gothic Architecture*, 1849 ; *Mediæval Architecture of Chester*, 1858 ; *Architectural Antiquities of the City of Wells*, 1866 ; and *Archæology of Rome*, 3 vols., 1873-84. The latter work was based upon personal explorations conducted by authority of the pope and the king of Italy.

PARKER, LINUS, D.D. : b. Rome, N. Y., 1829 : entered the ministry of the Meth. Epis. church, 1849 ; was presiding elder of the La. conference, and editor of the *Christian Advocate* for a number of years ; was elected bp. of the Meth. Epis. church, South, 1882.

PARKHURST, CHARLES H., D.D. : b. Clinton, Mass., 1842 : graduated at Amherst coll., and studied theology at Leipsic and at Halle. He was pastor of the Cong. church, Lenox, Mass. ; and in 1880 became pastor of the Madison Square Presb. church, New York. He is master of a finished pulpit style.

PARLIAMENT, REDISTRIBUTION OF SEATS IN. In 1884 a new Franchise bill was passed in Great Britain through the instrumentality of Mr. Gladstone. By this act the franchise is conferred on all resident male-householders or rated occupants of dwelling-houses, on lodgers, and on certain persons not occupying separate tenements or apartments, but living in houses occupied by others, who are to vote under what is called the "service franchise." This is in effect little more than an extension of the privileges already enjoyed by the "boroughs" or towns to the "counties" or country districts ; and it adds over 1,300,000 voters to the register in England and Wales, over 200,000 in Scotland, and over 400,000 in Ireland. A redistribution of seats in Parliament, or reapportionment, as we would call it, became necessary. A commission was appointed to convert both the boroughs and the counties into electoral districts according to population. Boroughs having less than 12,000 pop. go out of existence as electoral districts ; boroughs with more than 12,000 and less than 50,000 return only one member ; boroughs with from 50,000 to 165,000 return two members ; and, roughly speaking, every additional 54,000 of pop. will entitle a borough or county to an additional member. All boroughs and counties returning more than one member are to be divided into as many separate districts as there are members to be returned. The total number of seats liberated under all schedules is 160 ; these are turned over to the counties and new boroughs, and the total number of the members of the house is increased from 652 to 670. All the above provisions are contained in the Redistribution of Seats bill, the immediate passage of which Mr. Gladstone made a condition of his granting forbearance on the part of the Liberals to the conservative cabinet on its assumption of office, 1885, June.

PARLOA, MARIA : appeared as a lecturer on cookery in Boston in 1877 ; she opened a cooking-school, which was fully attended by public and private classes ; was special instructor or lecturer, at various seminaries in Mass. and N. H., and gave courses of lessons in sick-room cookery to Harvard medical students ; instructed normal classes of teachers for cooking-schools ; gave free instruction at evening mission schools. In 1878 Miss P. visited Paris for study. In 1881 she lectured in western cities, and in 1882 she opened her still prosperous cooking-school at 222 East 17th st., New York. She has published : *The Appledore Cook-Book*, 1872 ; *Camp Cookery*, 1878 ; *First Principles of Household Management and Cookery*, 1879 ; and *Miss Parloa's New Cook Book and Marketing Guide*, 1882.

PARMER : a co. in the "Panhandle" of Texas, with New Mexico as its w. boundary : formed, 1876 ; unorganized, and attached to Wheeler co. for judicial purposes.

PARR : a name originally given to certain Salmonoids, once supposed to constitute a distinct species, but proved by Shaw to be merely typical of the early growth of the salmon. They have the characteristic marks of young Salmonoids—visible until the fish has returned from the sea. The graylings, as well as the migratory and river trout, pass through a similar growth, the latter two being distinguished from others by the possession

respectively of from 9 to 10, and from 7 to 9 bars. The P. of salmon, possessing usually over 11 bars, are remarkable for the development of their generative organs, which, notwithstanding their early age, are invariably found to be fully matured.

PARSONS: a city in Labette co., Kan., on the Missouri Kansas and Texas, and on the Memphis Kansas and Colorado railroad. It has a national bank, 5 churches, 2 school-houses, 2 newspaper offices, and several manufactures. Pop. '80, 4,199.

PARTÁBGARH, PRATABGARH, or PERTABGURH: a dist. of Oudh, India; between $25^{\circ} 34'$ and $26^{\circ} 10' 30''$ n. lat. and $81^{\circ} 22'$ and $82^{\circ} 29' 45''$ e. long.; 1,450 sq.m. It is bounded on the e. by the Gumti and on the s. w. by the Ganges. The mineral products are salt, *Kankar* (nodular limestone), and saltpetre; wild cattle, monkeys, hogs, and wolves abound. The Sai river is navigable after rainfalls. P. is fertile and well wooded; wheat, rice, and barley are the chief cereals; sugar-cane and poppy are grown. The district has become of the first importance to Great Britain as a grain-exporting depot; its gross revenue, 1882-83, was £175,735. About 3,500 pupils attend school. Pop. '81, 847,047, including 763,054 Hindoos, 83,944 Mohammedans, 48 Christians.

P. should not be confounded with the native state of the same name in Rájputána, India, which has an estimated area of 1450 sq. m., and an estimated pop. of 80,000.

PASSAIC: a city in Passaic co., N. J., on the Passaic river, the Erie railroad, and the Boonton Branch of the Delaware Lackawanna and Western railroad; 11 m. n. w. of Jersey City and 5 m. from Paterson. It is a growing place, with 9 churches, 2 large print works, a woolen-mill, whip-factory, and a manufactory of blankets. Pop. '80, 6,532.

*PASSENGERS. In the U. S., as in England, common carriers of P. are bound to use the greatest possible care in fulfilling their contracts for the transportation of their patrons; but there is a difference between the states as to the question of the effect of contributory negligence on the part of the P. In many states, as in England, the burden of proof is upon the carrier to show that the negligence of the P. contributed to the injury; but in others (as N. Y.) the P. must establish affirmatively that he was not guilty of negligence, or else he cannot recover. There has been much discussion as to the relative merits of these conflicting rules; and while it must be confessed that the English rule has a wholesome influence upon railroad companies and other carriers, it must also be admitted that it often opens the door to fraud, and causes the companies to be unjustly mulcted in damages. All states agree that where the P. is clearly negligent he cannot recover damages; but there are distinctions in some of the western states as to the degrees of negligence which are not generally recognized. Carriers are particularly liable for any acts of ill treatment which a P. may suffer at the hands of their employés. And the relation of carrier and P. can be created by a *bona fide* intention on the part of the P. In general the carrier must accept all who apply to be carried; but drunkenness, refusal to pay fare, the fact that there is no room in the conveyance, the fact that the person applying is afflicted with a contagious disease, or that the person is a fugitive from justice—all have been held sufficient to excuse a carrier from receiving the person for transportation. The carrier may, however, make reasonable regulations for the proper conduct of his business; and for this reason a regulation that colored persons should ride in a particular car may not be unlawful, if the accommodations so provided are equally agreeable with those allotted to the white P. Full provisions for the health and safety of P. at sea have been made by the U. S. law.

*PASTEUR, LOUIS: in molecular chemistry he has achieved important results; and in the province of fermentation and the germ theory (q.v.) his works are of special value. His studies on the diseased conditions of wine and beer have rendered possible the prevention of these conditions. His investigations into the silk-worm's disease, *pebrine*, and its cure have proved of signal service. His discovery of bacteria as the cause of anthrax (splenic fever) in cattle was an epoch in the science of disease. Similar results were obtained with regard to fowl cholera; and his experiments show success in preventing the various diseases caused by septic bacteria, by inoculating animals with a milder form of the disease by means of a weaker brood of bacteria, artificially cultured. In 1883 he studied cholera in Egypt. P. has found that by keeping a cultured crop of specific micro-organisms at a certain temperature with a full supply of oxygen, he can reduce the organisms to an incapacity for producing spores, therefore to sterility; but before this point is reached it is claimed that the cultured organism loses its virulence, although still germinating; and vaccination with it produces a mild disease, which effectually protects from the fatal scourge of splenic fever, of fowl's cholera, and other diseases. In the same manner he deals with splenic apoplexy (q.v.), which disease he has shown to be due to the presence in the blood of small organisms, specific bacteria. By artificially cultivating these bacteria he further succeeded in developing a weaker crop of germs. By inoculating healthy animals with the virus he produced a milder form of the disease, which is believed to afford protection from the more violent and dangerous malady. [From Chambers'.] See GERM THEORY: KOCH.

PASTON LETTERS, THE: a collection of letters written during the Wars of the Roses by or to the members of the family of Paston in Norfolk. They had been preserved in that family for several generations, then passed through a succession of hands till they reached Mr. John Fenn, who published them in 5 vols., 1787-94. The authenticity of

the series, at first assailed by many historical students, has now been settled beyond a doubt.

PATARNES, OR PATERNES: a name given in the 11th c. to the extreme opponents of clerical marriages. The party was led by Arialduus, a deacon of Milan, where its members used to meet in the Pataria, or ragman's quarter, *pates* being a provincial name for a rag. Early in the 13th c. the title, from an erroneous idea that it came from the word *patis*, to suffer, was appropriated by the Cathari, who condemned marriage altogether.

***PATRIA POTESTAS.** This term is still recognized in the modern civil law, though its meaning is very different from what it was under the Roman law. It is now practically vested in both parents alike, though generally, as a matter of fact, exercised by the father; and when there is a difference of opinion his will prevails. Parents are entitled to the use of the property of minor children, subject, of course, to the obligation of properly supporting and educating them. In all legal matters the father acts as the general guardian of the child. The father may also designate by will a proper person as guardian for his children after his death, and such a person will become a "testamentary guardian." The power over the child for purposes of correction and training must be exercised with care, and excessive corporal punishment will be looked upon as a misdemeanor.

PATTERSON, JOHN JAMES: b. Waterloo, Penn., 1830: graduated at Jefferson coll., Penn., 1848. He edited the *Juniata Sentinel* during the Scott campaign, 1852, and the *Harrisburg Telegraph*, 1853-63; was in the Penn. legislature, 1858-61; served in the Union army as aid to Gen. Williams. He removed to S. Car., 1869, and was elected from that state as a repub. to the U. S. senate, serving 1873-79.

PATTISON, MARK: 1813-84; b. Yorkshire, England: graduated, 1836, at Oriel coll., and was elected fellow of Lincoln coll., 1840. In 1861 he became director of the Crewe charities. During the latter part of his life he gave much of his time to writing upon literary and philosophical subjects. In 1860 he published *Tendencies of Religious Thought in England, 1688-1750*; *Life of Isaac Casaubon*, 1875; *Life of Milton*, 1880; *Milton's Sonnets, with Notes*, 1882.

PATTISON, ROBERT EMORY: b. near Snow Hill, Somerset co., Md., 1850; son of Robert H. Pattison, a popular Meth. minister. He was educated in the public schools of Philadelphia, and admitted to the bar of that city, 1872. In 1877 he was elected city controller of Philadelphia, and proved so efficient and courageous in his resistance of corrupt municipal combinations, that he easily secured a re-election in 1881. Next year he was elected gov. of Penn.

PATTON, WILLIAM, D.D.: 1796-1879; b. Philadelphia; d. New Haven, Conn. He graduated from Middlebury coll., Vt., and studied theology at Princeton sem. He was pastor of several churches in New York, and in 1862 removed to New Haven, Conn. He became well known as a temperance advocate and as the author of several theological works; and was vice-pres. of the National Temperance soc. from its organization, 1865. He repeatedly visited England, and delivered temperance addresses there. His most important published work upon temperance was *Bible Wines; or, the Laws of Fermentation and the Wines of the Ancients*. Among his theological works are: *The Judgment of Jerusalem*, *Jesus of Nazareth*, and *The Village Testament, with Notes*, etc.

PAULI, GEORG REINHOLD: 1823-82; b. Berlin: was educated at the universities of Berlin and Bonn. He served as private sec. to Chevalier Bunsen, ambassador at the court of St. James, 1849-52, and then conceived the plan of investigating the history of England in its original sources. His first book was *König Aelfred*, 1851, which he followed with numerous essays in old English history. He held several professorships in German and Prussian colleges, the last being the chair of history at Göttingen, 1869-82. His most important work is *History of England, 1814-52*, in 3 vols., pub. 1864-75, a continuation of Lappenberg's great work.

***PAWNBROKING.** Whatever may be the social or economical results of P., as far as the community is concerned, it cannot be doubted that it is an occupation much in disrepute, and serving often as a cloak for the receiving and disposing of stolen goods. The statutes of the states generally regulate this business very carefully. The usury laws do not apply to loans by pawnbrokers, and they charge a high rate of interest, fixed by statute. The laws on this point are, as a rule, modelled after the English statute, but vary from it in unimportant details. In N. Y., for example, the statute provides that no person shall act as a pawnbroker without a license as such; and such licenses can be granted only in cities whose charters of incorporation give them specially the right to issue such licenses. Pawnbrokers must return goods to the rightful owner, but can oblige him to give a bond to answer in damages, should the title prove to be in some other person.

PAXTON, JOHN R., D.D.: b. Canonsburg, Penn., 1843: was educated at Jefferson coll., Penn., and at Princeton and Alleghany theol. seminaries. At the outbreak of the civil war he enlisted as a private in a Penn. regiment, and was mustered out as second lieut., 1865. He was pastor of the Pres. church, Churchville, Md., 1870-74; of the Pine st. church, Harrisburg, Penn., 1874-78; of the New York ave. church, Washing-

ton, D.C., 1878-82, whence he was called to the West Pres. church, New York. The vigor of his thought and the originality of his style attract large audiences.

PAYN, JAMES : b. Cheltenham, Eng., 1830 : graduated at Cambridge, 1854, and adopted literature as a profession. He pub. two youthful vols. of poems ; contributed largely to periodicals ; and in 1858 became editor of *Chambers' Magazine*. His novel of *Lost Sir Massingberd*, which he contributed to that magazine, is said to have raised its circulation by nearly 20,000. Since then he has pub. numerous novels, the best known of which are *Cecil's Tryst*, *Fallen Fortunes*, *What He Cost Her*, *Less Black than We're Painted*, *By Proxy*, and *A Grape from a Thorn*. Since 1882 Mr. P. has been editor of the *Cornhill Magazine*.

PAYNE, HENRY B. : b. Hamilton co., N. Y., 1810 : studied at Hamilton coll., N. Y., and began to practise law at Cleveland, O., 1834 ; served in the O. senate, 1849-50 ; was the dem. candidate for U.S. senator, 1851, and for gov., 1857. He was elected to the XLIVth congress by a fusion of democrats and liberal repubs. He has been prosperous in his business ventures, and has a prominent place among the leaders of his party.

PEABODY EDUCATIONAL FUND. In 1867 the eminent philanthropist George Peabody (q.v.) addressed a letter to Gov. Wintthrop, of Mass., and other nominated trustees, intimating a gift of \$1,000,000, with \$1,100,000 Mississippi state bonds, to be dispensed by them for promotion of "intellectual, moral, or industrial education in the most destitute portions of the southern states." The trustees were created a corporate body, and large gifts of books (130,000 in all) were received from Messrs. Appleton and A. S. Barnes & Co. Dr. Barnas Sears was appointed general agent, who directed his attention to elementary education in the states which had suffered most from the war, the object being not so much to create new schools as to strengthen or resuscitate old ones, and stimulate local effort. In 1869 Mr. Peabody contributed another million dollars and \$384,000 Florida bonds. The trustees had authority to expend 40 per cent of the principal during the first two years, after which the amt. was to remain unchanged for 30 years, when they might close the fund, giving not less than $\frac{2}{3}$ for educational purposes and the remainder for literary. When the trustees entered on their office no southern state had a modern system of public schools ; now none is without one.

The rules guiding the action of the trustees may be summarized thus : 1. Schools aided must have at least 100 pupils with a teacher for every 50, be graded, and open 10 months yearly. 2. Trustees to act in unison with state authorities, and co-operate with school superintendents. 3. The largest sum allowed to a school of 100 pupils to be \$300 ; of 200, \$600 ; of 300, \$1,000. 4. Every grant to be made on condition of the district paying twice as much. 5. Limited aid to normal schools by grants and scholarships for training teachers.

PECK, J. ORAMEL, D.D. : b. Groton, Vt., 1836. At the age of 20 years he joined the Meth. Epis. church, and after studying at Newbury sem., and graduating at Amherst coll., 1862, he was ordained to the ministry, and filled several appointments under the New England conf. ; was transferred to the Rock River conf., occupying Centenary church, Chicago, Ill., whence he was transferred to the Baltimore conf., and became pastor of Mt. Vernon church. He was afterward transferred to the New York East conf. ; and was, 1885, July, pastor of Trinity Church, New Haven. He is a popular lecturer.

PEDLAR : a magisterial dist., Amherst co., Va., containing post-hamlet of Pedlar Mills. Pop. '80, 5,665.

PEEL, ARTHUR WELLESLEY : b. 1829 ; youngest son of Sir Robert : received his education at Balliol coll., Oxford, where he graduated, 1852, and subsequently read law. He ran for parliament, 1863, but failed of election ; in 1865 he stood, as a Liberal, for Warwick ; was elected, and has been in parliament ever since. In 1880 he was appointed under-sec. of state for the home dept., and in 1884 he became speaker of the house of commons.

PEEPLER : a tp. in Hampton co., S. Car., containing Brunson t., pop. '80, 167 ; and Hampton t., pop. '80, 169. Pop. of tp. '80, 4,735.

PELIAS : in classical mythology son of Poseidon and of Tyro, daughter of Salmones. With his twin brother he was abandoned by his mother, but was found and nurtured by a herdsman, who called him P. because his face was discolored by a kick from a mare, and called his brother Neleus, because a dog had nursed him. When the brothers grew up they found their mother, who had married Cretheus, king of Iolcus in Thesaly, and on the death of the latter P. seized the throne. He despatched Jason (q.v.) in search of the Golden Fleece, and on the return of that hero was ignorantly put to death by his own daughters, through the instrumentality of Medea.

PELLICANUS, CONRAD : 1478-1556 ; b. Ruffach, Alsace ; d. Zurich, Switz. His paternal name was Kürsner ; the name of Pellicanus was given him by his uncle, an ecclesiastic, who sent him to the univ. of Heidelberg, 1491-92. In his 16th year he determined to become a friar, and was sent to the Minorite convent at Tübingen, 1496, where he began the study of Hebrew. He was a useful helper to Reuchlin, and published the first Hebrew grammar in a European tongue, 1503. He was ordained priest, 1501, and served his order until 1526, when he threw aside his cowl, having gradually adopted

Protestant views, and became prof. of Hebrew at Zurich, whence he was called by Zwingli. He was twice married, and remained at Zurich until his death. His linguistic scholarship was rare for his time. His chief work was a biblical commentary in 7 vols., Zurich, 1532-39. His Latin autobiography is one of the most interesting documents of the Reformation period.

PELOUSE, LEON GERMAIN: b. Pierrelaye, France, 1839. He was early placed in a business house at Roubaix, but at 27 years of age he took up art as a profession. He settled at Cernay, and before long was recognized as one of the foremost landscape painters in France. Among his salon pictures are: "After the Rain," 1872; "Norman Farm," 1875; "Cornfields," 1881; "Banks of the Ellé," 1882; and "Grand Camp at Low Water," 1884.

PELTIER, JEAN CHARLES ATHANASE: 1785-1845; b. Ham, France; d. Paris. He was a watchmaker, but gave up his trade abt. 1815, to apply himself to experimental and observational science. He made a great discovery concerning the thermal effects at junctions in a voltaic circuit, 1834, finding that the junctions in a heterogenous circuit of metals could be heated or cooled according to the direction in which an electric current is made to pass round the circuit. He published numerous scientific papers.

PENARTH: a seaport of Glamorganshire, Wales, at the mouth of the Taff, opposite Cardiff. It was an unimportant village until 1856, when it was made a tidal harbor. Docks were built upon an extensive scale, and P. is now an important shipping port for the minerals of South Wales, especially coal, iron, and alabaster. In 1883, 1,130 steamers and 567 sailing-vessels entered the port, and 2,274,003 tons of coal and coke were shipped. The custom-house and dock offices are the principal buildings. Pop. '81, 6,228.

PENDER: a co. in e. part of N. Car.; formed, 1875, from part of Hanover co. traversed by North-east Cape Fear river, and crossed by the Wilmington and Weldon railroad. The surface is level, with few pine forests; soil sandy. Productions, Indian corn and cotton. Pop. '80, 12,466—colored, 6,957. Co. seat, South Washington.

PENJDEH, or PUNJ DEEN: an oasis in the n. w. part of Afghanistan, 130 m. n. of Herat; lat. 36° 4' n.; long. 62° 41' e. It is triangular in shape, formed by the Murghab river; comprises an area of 300 sq. m.; its greatest length is abt. 27 m., and its greatest breadth abt. 20 m. It was an integral part of the province of Herat, to which it paid tribute, and with which it is connected by a road. Its population consists of about 8,000 Sariks, who occupy themselves chiefly in raising flocks and weaving carpets and fine cloths. A conflict occurred, 1885, March, between a body of Afghan troops occupying P. and a Russian force under Gen. Komaroff stationed on the neighboring boundary. The Afghans were routed, and the Russians took possession of P. This event added a serious element to the boundary dispute between England and Russia, and became the subject of special investigations, reports, and negotiations in St. Petersburg and London, accompanied with extensive military preparations. The threatened war was averted, and P. remained in Russian possession.

PENNINGTON: a co. in s. w. Dakota; formed, 1875; organized, 1877: drained by South Fork of Cheyenne river and the North Fork or Belle Fourche; soil fertile; surface mountainous, being a portion of the Black Hills. Much gold has been discovered here. Pop. '80, 2,226.

PENNOCK, ALEXANDER M.: 1813-76; b. Portsmouth, N. H. He entered the navy, 1828, as a midshipman; was promoted to commander, 1855; to captain and commodore, 1863, and to rear-admiral, 1872. He was an officer in the Paraguay expedition, 1859-60, and was fleet-captain of the Mississippi squadron, 1862-64. He was in command of the European squadron flagship, the *Franklin*, 1868-69.

*PENSIONS and PENSIONERS. The policy of the U. S. up to the year 1869 had been to confine the bestowment of P. upon officers and privates who had served either in the army or navy during the earlier wars in which the country was engaged, or who had been wounded or otherwise disabled in active service during the more recent wars; or to the widows, children, and other dependent relatives of the slain. The only exception to this rule had been in the case of a few private acts granting P. to individuals for some public service or some act of signal heroism. But in that year a bill was passed which provided, among other things, that any judge of the U. S. courts who resigned his commission after 10 years' service, or longer, should continue during the remainder of his life to receive his full salary. Since that time P. have been conferred on ex-presidents' widows (Mrs. Lincoln, Mrs. Garfield, Mrs. Polk, and Mrs. Tyler), on members of the life-saving department, on employées in the quartermaster's and paymaster's departments, etc. Military P. may be said to date from the first year of the Revolution. In 1776 it was resolved that all officers who should continue in the service until the end of the war should receive half pay for 7 years after peace was established. In 1780 the provisions of this law were extended to the widows and orphans of those who died in the service. The half pay for 7 years was next extended to half pay for life, and subsequently commuted to full pay for 5 years. Between 1806 and 1818 the principle was established that all persons, whether officers or privates, who had been disabled in the course of either military or naval service should be provided for at the public expense.

In 1818 P. were granted to all the survivors of the Revolutionary war who for any reason stood in need of pecuniary assistance; and subsequent legislation extended the provisions of the pension laws to other wars than the Revolution, so that they included military service wherever rendered. Since the civil war numerous acts have been passed for the relief of those who suffered, either directly or indirectly, while fighting for the union, and of the dependent relatives of the fallen. The provisions of the laws which determine the various classes of these beneficiaries, the amounts of their respective P., and the manner of making applications for the same, are too minute and intricate to be entered into here. A pamphlet containing the laws, with forms and instructions, is furnished free of charge by the commissioners of P.; or the laws themselves may be found in the *U. S. Revised Statutes*, sections 4692-4791. There are 18 pension agencies in the U. S., and there is probably no county without its P. In 1884 the total number of Pensioners on the roll was 322,756, and the total disbursement on account of P. was \$57,273,536.74.

PEPPER, GEORGE W.: b. Ireland, 1832. He emigrated to the U. S., and was admitted as a traveling preacher of the Northern Ohio Meth. Epis. conference, 1855. He became an ardent abolitionist, and, later, a defender of Irish nationalist principles. He was a vigorous and acceptable platform speaker in the repub. presidential campaign of 1884. He is pastor of Trinity Meth. church, Wooster, O.

PERCHÉ, NAPOLEON JOSEPH: 1805-83; b. Angers, France; d. New Orleans. He was ordained priest, and labored in several parishes until 1836, when he emigrated to Kentucky. In 1842 he was called to New Orleans and made rector of the cathedral; in 1870 was consecrated bishop and assigned as coadjutor to Abp. Odin. The same year, on Odin's death, he became abp.

*PERIODICALS. Perhaps the most remarkable development in the periodical literature of America during the last decade has been in illustrations. *Harper's Monthly* and *The Century* (the name assumed by *Scribner's Magazine* in 1881, Nov.) have vied with each other in bringing the art of wood-engraving to a technical perfection never reached before. While this has largely increased the cost of publication, it has also swelled their subscription lists to unprecedented dimensions. Both magazines have a large circulation in Great Britain as well as in the U. S., the Harpers publishing an edition there which is expressly prepared for the market by an English editor. The only British periodical approaching in circulation these American monthlies is Macmillan's *English Illustrated Magazine*, founded in 1884, Feb.; but its subscription price is less than half that of its rivals, and consequently neither in the quantity nor in the quality of its illustrations does it attempt to compete with them. *Longman's Magazine*, founded 1882, Nov., is another recent transatlantic experiment in cheap periodical literature which maintains a high standard of literary merit. Unlike the *English Magazine*, it is not illustrated. Two short-lived American P., which started with great expectations that were apparently warranted by their intrinsic merits, were *The Continent* and *The Manhattan*. The latter was founded in New York, 1883, Jan., and expired in less than two years. The former made a far harder struggle for existence. It was started at Philadelphia, in 1879, by the Continent Publishing Co., in which the editor, Albion W. Tourgée, was understood to be a chief stockholder; was then transferred to New York under the proprietorship of Messrs. Fords, Howard, & Hulbert, and came to a sudden close, 1884.

PERKINS, CHARLES C.: b. Boston, 1823; graduated at Harvard; studied oil-painting under Ary Scheffer, and etching under Bracquemond and Lalanne. He is not a professional artist, but is prominently identified with many of the art clubs and museums of Boston and New York; delivers lectures on subjects connected with art, and has pub. *Tuscan Sculptors*, 1864; *Italian Sculptors*, 1867; *Raphael and Michel Angelo*, a biographical and critical essay, 1878, etc.

PÉRONNE, a fortified t. in the dept. of the Somme, France, on the Somme river, abt. 94 m. n. e. of Paris. It has manufactories of leather, flour, sugar, etc. It was bombarded and forced to capitulate during the Franco-Prussian war, 1870-71, and was almost destroyed, but has since been rebuilt. It contains buildings which date back to the middle ages. Pop. '81, 4,696.

*PERPETUITIES, LAW AGAINST. The provisions of law in relation to P. in the U. S. are generally the same as in England. It is recognized to be against the policy of the law to allow a person to tie up property for an unreasonably long time. The limitation is fixed by statute in each state, and is ordinarily expressed as being for two lives in being and 21 years afterward. In some instances the period of gestation is added.

PERRY, WILLIAM STEVENS, D.D., LL.D.: b. Providence, R. I., 1832; graduated at Harvard coll., 1854; ordained priest in the Prot. Epis. church, 1858; held several rectorships in New England, and was pres. of Hobart coll., 1876. He was consecrated bp. of Iowa, 1876. Bp. Perry is the author of many works; among these are: *The Connection of the Church of England with Early American Colonization*, *Questions on the Life and Labors of the Great Apostle*, and many historical collections of the American colonial church. In 1885 he pub. his great work on the history of the Epis. church.

*PERU. After the fall of Lima some desultory fighting was done until a treaty of peace was concluded in the fall of 1883, which was ratified and exchanged some months

later. P. ceded to Chili absolutely the province of Tarapaca, and for a term of 10 years the territories of Tacua and Arica; at the close of this term the people of these territories are to decide by popular vote whether they will return to P. or remain under Chilian rule. In either case the country to which they will be annexed agrees to pay the other an indemnity of \$10,000,000. Chili agreed to pay the creditors of P. 50 per cent of the net proceeds from the guano and nitrate of soda trade, until the debt should be paid or the products exhausted; and received an indemnity from P. to pay for the maintenance of an army of occupation stationed in P. previous to the ratification of the treaty. Gen. Miguel Iglesias was recognized as the *de facto* pres. of P. The war left the country in a shattered and bankrupt condition, with scarcely a remnant of its army and its once flourishing navy. No official returns of revenue and expenditure have been published by the govt. for some years.

PESSIMISM: roughly speaking, is the doctrine that the pains of life are largely in excess of its pleasures; that life is a burden instead of a privilege; that everything in nature is ordered for or tends to the worst. It is the opposite of optimism (a term of earlier coinage), and although the word is a recent one, and the school of philosophers who have built up a metaphysical system known by this title date from the commencement of the present century, the theory itself is almost as old as the race. In their view of the emptiness and weariness of this life, considered *per se*, the modern pessimists differ little from the writer of the *Book of Job*, or of *Ecclesiastes*, or from the author of *De Contemptu Mundi*, and the whole school of Christian ascetics, though these, unlike the pessimists, believe that the evil of this present world is vastly outweighed by the universal good and the eternal life. In their doctrine that the nearest approach to happiness lies in the annihilation of desire, they differ only in terminology from the Buddhists, who for 2,000 years have been aiming at Nirvâna; and even their terminology sometimes reveals a startling likeness. Wertherism in Germany, Renéism in France, Byronism in England—all are forms of P. But, technically speaking, P. originated with Schopenhauer, whose first book was published in 1819, although the term itself, as applied to his teachings, did not make its appearance until about 1865. Schopenhauer's avowed aim was to overthrow the optimistic theories of Leibnitz, to show that this was not only not the best possible world, but the worst. His works were at first neglected, in consequence of the superior popularity of the Hegelian philosophy, which he despised and reviled, but they eventually attracted a large body of disciples. The greatest of these is Hartmann, who, in his *Philosophy of the Unconscious* (1869), holds out the glorious hope that when humanity as a whole has acquired sufficient intelligence to recognize its own misery, it will destroy itself in a last despairing act of cosmic suicide. See OPTIMISM.

PETAU, DENYS; (better known by the Latinized *Dionysius Petavius*): 1583–1652; b. Orleans, France: became prof. of philosophy in his 19th year at Bourges; entered the Society of Jesus, 1605, and afterward taught rhetoric and theology in the colleges of the order at Reims, La Flèche, and Paris. He published numerous controversial and philosophical works, the chief being a treatise on chronology *De Doctrina Temporum*, 1627, which with his own abridgment *Rationarum Temporum*, has been frequently reprinted, and his great but unfinished work *De Theologicis Dogmatibus*, 5 vols., 1644–50, which earned for him the title of “Restorer of Dogmatic Theology.”

PETERKIN, GEORGE WILLIAM, D.D.: b. Md., 1841: graduated at the univ. of Virginia, 1860, and at the theol. sem. of Virginia, 1868; was ordained priest in the Prot. Epis. church, 1869. He was asst. minister at St. James' church, Richmond, Va., and rector of St. Stephen's church, Culpepper, Va., and the Memorial church, Baltimore. He was consecrated bp. of W. Va., 1878.

PETERS, WILHELM CARL HARTWIG: 1815–83; b. Coldenbittel, Schleswig. He became known as a naturalist first by his exploration of Mozambique, 1842, under the auspices of the Prussian government. He described his exploration in a work of 4 vols., 1852–68. From this work Bleek compiled his *Languages of Mozambique*. For many years he was connected with the medical dept. of the univ. of Berlin, and became prof. of zoology and director of the zoological collections, 1857.

PETRIFIED FORESTS. Near Holbrook, Arizona, are found in great abundance trees that have undergone siliceous petrification; 20 or 30 varieties, mostly palms, have been recognized. One of these petrified trees spans a chasm 100 ft. wide. Many perfect specimens are found 2 ft. in diameter. The Peabody Museum, in New Haven, has one. The coloring is very beautiful, and under the microscope the woody structure is clearly seen. A company has been formed, and is now working the material for commercial purposes. It can be gotten out in slabs 2 ft. wide. For mantels, tiling, etc., it is well adapted.

PFALZBURG: a town in German Lorraine, on the w. slopes of the Vosges, 8 m. n. w. of Zabern. The principality of P. was originally a part of Luxemburg, but after belonging successively to the bp. of Metz, the bp. of Strasburg, and the duke of Lorraine, it passed into the hands of the French, 1661. The town commanded the passes of the Vosges, and was strongly fortified by Vauban, 1681; but the defenses were razed by the Germans on their capture of the place after four months' siege, 1870. Pop. '80, 3,379, chiefly Rom. Catholics.

PHELPS, EDWARD J., LL.D.: b. Vt., abt. 1824: educated at Middlebury coll., Vt.; was appointed second controller of the treasury by Pres. Fillmore; practised law in New York, and Burlington, Vt. Originally a whig in politics, he has been an ardent dem. since before the civil war. He was elected pres. of the American Bar assoc., 1881, and was appointed Kent prof. of law at Yale coll., and in the same year was defeated as the dem. nominee for gov. of Vt., 1880. He was appointed minister plenipotentiary to the court of St. James by Pres. Cleveland, 1885.

PHELPS, JOHN SMITH: b. Simsbury, Conn., 1814. He graduated at Trinity coll., Conn.; adopted law as a profession, and settled in Springfield, Mo., 1837; was elected to the legislature, 1840, and to Congress, 1844, serving nine consecutive terms. He fought in the Union army, and was appointed military gov. of Ark., 1862. He was elected gov. of Mo. by the democrats, 1876.

PHELPS, MOSES STUART, PH.D.: 1849-83; b. Andover, Mass.; son of Prof. Austin P., and grandson of Prof. Moses Stuart: graduated at Yale coll., 1869; tutor at Yale, 1873-76; instructor in mental philosophy at Middlebury coll., 1876; went to Germany and studied at the univ. of Berlin, 1876-77, taking the degree of PH.D.; prof. of mental and moral philosophy at Smith coll., Northampton, Mass., from 1878 to the time of his death. His death, which occurred by accident during his summer vacation, was greatly lamented as cutting short a life of unusual intellectual promise.

***PHELPS, WILLIAM WALTER:** resigned his position as minister to Austria, 1882, and was elected from N. J. to the XLVIIIth congress; re-elected to the XLIXth. He has distinguished himself as an advocate of a protective tariff; and during the campaign of 1884 he was one of the staunchest supporters of James G. Blaine for president. He wrote a letter in defense of his candidate, which was printed as a campaign document.

PHILISTINISM: a cant term introduced into England by Carlyle, whose use has since been widely extended by Matthew Arnold. The allusion is to the ancient Philistines, the enemies of the children of light; hence P., in its modern application, means stolid opposition to the higher intelligence of the age, inaccessibility to ideas; plain, humdrum, respectable conventionalism. The German students first applied the term *Philister* to a townsman or to one who had not been trained in a univ.; it soon found a foothold in German literature, and was first imported into England in Carlyle's essay on Goethe. The term has now grown so hackneyed that the finer sort of people hesitate to use it, and its indiscriminate use has almost emptied it of meaning. Perhaps Leslie Stephen's definition of P. as "a term of contempt applied by prigs to the rest of their species" is the only one that is sufficiently comprehensive.

PHILOSOPHY, CONCORD SCHOOL OF. For many years Mr. A. Bronson Alcott had in mind the establishing of a school of philosophy, and in 1842 a philosophical library was bequeathed to him for this purpose by James Pierpont Greaves, of England. In 1879 arrangement was made for a school, meeting at Concord, a vill. in Middlesex co., Mass.; and its sessions were to last five weeks during mid-summer. The first session was held at Mr. Alcott's old residence, *Orchard House*. The succeeding sessions were held in a building erected for the purpose called *Hillside Chapel*, capable of seating about 140 persons. Here many persons of note delivered lectures; besides Alcott, Emerson, the Rev. W. H. Channing, of England, S. H. Emery, jr., the director of the school, Prof. Wm. T. Harris, Pres. Noah Porter of Yale coll., Dr. H. K. Jones, Mrs. Julia Ward Howe, and others. The audiences were principally composed of women. The idea of the school was to seek a surer basis for the truths by which we live and advance, and to apply practically to life what it found of good. Hegel, Plato, Schelling, the personality of God, recent thought concerning history, sociology, literature, and art were among the topics discussed. The school suffered a severe loss in the death of Emerson, 1882; and in 1883, owing to the illness of Mr. Alcott and to insufficient attendance, it practically lapsed; however, it met for two weeks to discuss Emerson, 1884; and discussed Goethe, 1885.

PHILOXENUS: B.C. 434-380; b. in the island of Cythera; d. Ephesus: the last of the dithyrambic poets of Greece. When his birthplace was conquered by the Athenians, B.C. 435, P. was sold as a slave, passed into the hands of the dithyrambic poet Melanippides, and afterward resided at the court of Dionysius, in Syracuse. He is said to have composed 24 dithyrambs and a lyric poem; but although some of these had great popularity, only insignificant fragments have survived.

***PHOTOGRAPHY.** The later improvements in the preparation of photographic materials have removed a great many of the impediments to the practice of the art; and now, in different parts of the country, many enthusiastic amateurs are taking good pictures, and are making improvements in the art itself. The great invention that has done more than all others, to popularize P., is what is known as the "dry process," which consists in using gelatine instead of collodion for coating the plates. Besides having the advantage of cheapness, the gelatinized sensitive plates can be bought from the manufacturer, and kept always on hand ready for use, and they do not need to be developed immediately, but can be put away for future convenience. Complete photographic outfits can now be bought; they are put up in very small space, and the artist or tourist can in a few minutes get a satisfactory picture of any pleasing bit of landscape, or other object that strikes his fancy. The "blue print" process has come into extensive use; paper is pre-

pared with a solution of oxalate of iron, and kept in the dark till used ; after exposure in the camera, it should be kept for a few minutes in the light ; it is then dipped in a bath containing a solution of red prussiate of potash, when the image will appear in blue tints.

*PICTURES : are protected by the copyright laws of the U. S. as in England. The law enumerates among other proper subjects of a copyright, any book, map, chart, engraving, cut, print, photograph, painting, drawing, chromo, etc., and the process is similar to that in case of copyright of a book. (See COPYRIGHT.)

The law further provides, however, that in the construction of this act, the words "engraving," "cut," and "print" shall be applied only to pictorial illustrations or to works connected with the fine arts ; any other prints or labels may be registered at the Patent office.

PIERCE, HENRY LILLIE : b. Stoughton, Mass., 1825 : was a member of the legislature, 1860-66 ; was mayor of Boston, 1873. He was elected as a repub. to the XLIII^d congress to fill a vacancy, and was re-elected to the XLIVth. He was again elected mayor of Boston, 1878.

PIERCE, HENRY NILES : D.D., LL.D. : b. Pawtucket, R. I., 1820 : graduated at Brown univ., Providence, 1842 ; ordained priest in the Prot. Epis. church, 1849 ; engaged in missionary work in the south and west ; was consecrated missionary bp. of Arkansas and Indian territory, 1870. He is the author of *The Agnostic*, and other poems.

PIERCE, LOVICK : 1785-1879 ; b. Halifax co., N. Car. ; d. Sparta, Ga. He became a Meth. Epis. minister, 1804. Subsequently he graduated in medicine in Philadelphia, but soon returned to the ministry. He was a chaplain in the war of 1812 ; a delegate to the Meth. gen. conf. of 1836, 1840, and 1844, and after the southern church was organized, 1846, he sat in its highest court. He was at the Louisville conf., 1874, together with his son, Rp. Pierce. In spite of his great age he preached until shortly before his death, and published during the previous year a series of essays in a church periodical.

PIÉROLA, NICOLÁS DE : called by some the "evil genius of Peru ;" came into prominence first in 1864 as the leader of the Peruvian rebellion against Spanish aggression ; was minister of the treasury under Pres. Balta, and took part in the unsuccessful revolutions of 1874 and 1876. In the Chili-Peruvian war of 1879 P. assumed the title of supreme chief, upon the flight of Pres. Prado, who had left the government in the incapable hands of Gen. La Puerta. Defeated in the battles of Chorrillos and Miraflores, he fled to the mountains—a provisional government under Señor Garcia Calderon taking the place of his dictatorship.

PIERSON, WILLIAM, M.D. : 1796-1882 ; b. and d. New Jersey : graduated at Princeton coll., 1816, and studied medicine in New York and at the univ. of Pennsylvania. He settled in Orange, N. J., where he practised for about 50 years ; was sec. of the state medical soc. for 30 years, and afterward pres. ; was a member of the state legislature, 1836-38, and was the first mayor of Orange. He held various positions of trust, and was at one time sheriff of his county.

PIKE, AUSTIN F. : b. Franklin, N. H., 1819 : was admitted to the bar, 1845 ; was in the N. H. legislature, 1850-52 ; in the state senate, 1857-58, and during the last year was pres. of the senate ; was chairman of the repub. state committee, 1858-60 ; was speaker of the N. H. house, 1865-66. He was elected as a repub. to the XLIII^d congress, 1873, and to the U. S. senate, 1883.

PILLSBURY, JOHN S. : b. N. H., abt. 1827 : removed to Minn., 1854, and settled at the Falls of St. Anthony. He was member of the Minn. legislature for more than 10 years, and at one time pres. of the board of regents of the state univ. In 1875 he was elected gov. (repub.) and held the office till 1882, Jan. 1.

PILSBURY, AMOS : b. Londonderry, N. H., 1805 : received a common school education ; at 18 years of age had served a four years' apprenticeship to the tanner's trade ; in 1824 became a guard in the N. H. state prison, of which his father, Moses P., was warden ; in 1827 became deputy warden, and in 1830 succeeded his father as warden of the Conn. state prison at Wethersfield. In 1845 he was invited to Albany, where, with a brief interval, he has since had charge of the Albany co. penitentiary, which he built, and afterward enlarged, at a total cost of less than \$100,000. A high authority in prison matters has said of him : "He is the most remarkable prison officer in America. His rule has been severe but just, and he has managed the prison finances without the cost of a penny to the public."

PINK EYE : a highly contagious fever, prevalent among horses ; thought to be due to the presence in the blood of a specific virus. Its period of incubation is about three days. Loss of appetite, stiff joints, and a generally dull appearance are the first symptoms. About the fifth day the eyelids become swollen and very red, and a discharge comes from the eyes ; the fever has now reached its crisis, and the temperature, which rises as high as 105°, begins to fall. At this stage the animal generally suffers from diarrhœa. The disease is not fatal unless the animal is old or in bad condition.

PINKERTON, ALLAN G. : 1819-84 ; b. Glasgow, Scotland ; d. Chicago. He served an apprenticeship to the cooper's trade in Scotland, and in 1842, becoming involved in

the Chartist outbreak in Birmingham, emigrated to the U. S., and settled in Ill., where, from a love of adventure, he secured the arrest of a band of counterfeiters, and was appointed deputy-sheriff. In 1852 he established a detective agency at Chicago. In the spring of 1861 he kept within reach of Mr. Lincoln on the way from Ill. to Washington, and during the civil war, under the disguise of "Major E. J. Allen," he superintended the secret-service division of the army. His personal exploits were material for romance. His specialty, if he had a specialty, for he was very versatile, was the detection of great bank and express robberies, and the running down of lawless bands. He wrote and published *Thirty Years a Detective*, *The Spy of the Rebellion*, *Professional Thieves and the Detective*, etc.

PIPE LINES. The first P. L. for transport of oil was laid by Samuel Van Syckle in 1865. The local lines carry oil from the wells to certain points, where it is pumped into the trunk lines, which now extend to New York, Philadelphia, Baltimore, Pittsburgh, and Cleveland, and are made of 6-inch pipe tested to a pressure of 2,000 lbs. At intervals of 25 m. are pumps to force the oil through the pipes; they are capable of raising a column of oil 1,000 ft. In 1884 the average number of barrels pumped through the P. L. daily was 64,784. The National transit co. control 90 per cent of all the P. L. See OIL WELLS AND OIL TRADE.

PIT DWELLERS OF YEZO: the aboriginal inhabitants of the island of Yezo, Japan, who have left indications of their presence in the form of pit-like depressions of a rectangular shape, around which flint arrows and fragments of earthenware are found. According to Japanese authorities, they were a race of dwarfs, and lived in huts built over these pits. They were driven out by the Ainos, who in their turn yielded at the advent of the Japanese. Their presumed descendants, or at least a race of people who dwell in huts built over similar holes, are now found in portions of the Kurile islands, and, more rarely, in Saghalin and Kamchatka.

PITTSTOWN: a tp. in Rensselaer co., N. Y., including the vills. of Johnsonville and Valley Falls; traversed by the Troy and Boston railroad. Pop. '80, 4,095.

PLAINFIELD: a tp. in Windham co., Conn., including vill. of Plainfield, where cotton goods are largely manufactured. Pop. '80, 4,021.

PLAINS: a tp. in Luzerne co., Penn., crossed by the North Branch of the Susquehanna river, the Lehigh Valley railroad, and the New Jersey Central railroad. The post-vill. of Plains has 3 churches. Coal mining is a leading industry. Pop. of tp. '80, 5,354.

PLAINS: a magisterial dist., Rockingham co., Va., containing Broadway t., with a pop., '80, of 323. Pop. of dist. '80, 5,529.

PLAISTED, HARRIS M.: b. Jefferson, N.H., 1828: graduated at Colby univ., 1853; at the Albany, N. Y., law school, 1855; and began practice at Bangor, Me., 1856. He fought as col. in the Union army, and was breveted major-gen.; was a member of the Maine legislature, 1867-8; and was state atty.-gen., 1873-75; was elected to congress as a repub., 1874; and was elected gov. on the "greenback" ticket, 1880.

PLANET, INTRA-MERCURIAL: a planet nearer than Mercury to the sun has long been supposed to exist, by reason of unexplained disturbances in the planetary orbits. Les Carbault reported its discovery 1859, Mar. 26, and in 1876 Weber said that he saw it on Apr. 4. At the request of Le Verrier search for it was made at Washington, 1876, Oct. 2, and in 1882 at the Watson solar observatory, designed for day observation—the only time when the supposed planet (Vulcan) would, according to calculation, be visible. The search was unsuccessful. Watson estimated its magnitude at $4\frac{1}{2}$ and its light at $\frac{1}{70}$ that of a star of the first order. See VULCAN.

***PLANETOIDS:** the following have been discovered since 1877, Feb. 5, when the 172d was found:

Name.	Date of Discovery.	Discoverer.
173.....	1877, Aug. 2	Borelly.
174.....	" Sept. 2	Watson.
175.....	" Oct. 1	Watson.
176 Idunna	" Oct. 14	Peters.
177.....	" Nov. 5	Paul Henry.
178.....	" Nov. 6	Palisa.
179.....	" Nov. 11	Watson.
180 Garumna.....	1878, Jan. 29	Perotin.
181 Eucharis.....	" Feb. 2	Cotterctot.
182 Elsbeth.....	" Feb. 7	Palisa.
183 Iseria.....	" Feb. 8	Palisa.
184 Deiopeia.....	" Feb. 28	Palisa.
185 Ennike	" Mar. 1	Peters.
186 Ccluta	" Apr. 6	Prosper Henry.
187 Lamberta.....	" Apr. 11	Coggin.
188 Menippe.....	" June 18	Peters.
189 Phthia.....	" Sept. 9	Peters.

Name.	Date of Discovery.	Discoverer.
190 Esmene.....	1878, Sept. 22	Peters.
191 Kolga	" Sept. 30	Peters.
192 Mansikaa	1879, Feb. 17	Palisa.
193 Ambrosia.....	" Feb. 28	Coggin.
194 Proene	" Mar. 21	Peters.
195 Euryeleia.....	" Apr. 19	Palisa.
196 Philomela.....	" May 14	Peters.
197 Arete.....	" May 21	Palisa.
198 Ampella.....	" June 13	Borelly.
199 Byblis.....	" July 9	Peters.
200 Dynamene.....	" July 27	Peters.
201 Penelope.....	" Aug. 7	Palisa.
202 Chryseis.....	" Sept. 1	Peters.
203 Pompeia.....	" Sept. 25	Peters.
204 Callisto.....	" Oct. 8	Palisa.
205.....	" Oct. 13	Palisa.
206 Hersilia	" Oct. 13	Peters.
207.....	" Oct. 17	Palisa.
208.....	" Oct. 21	Palisa.
209 Dido	" Oct. 22	Peters.
210.....	" Nov. 12	Palisa.
211.....	" Dec. 10	Palisa.
212.....	1880, Feb. 6	Palisa.
213 Silaea.....	" Feb. 17	Peters.
214.....	" Mar. 1	Palisa.
215 Oenone.....	" Apr. 7	Knorre.
216.....	" Apr. 10	Palisa.
217.....	" Aug. 30	Coggin.
218.....	" Sept. 4	Palisa.
219.....	" Sept. 30	Palisa.
220.....	1881, Feb. 23	Palisa.
221 Eos.....	1882, Jan. 18	Palisa.
222 Lucia.....	" Feb. 9	Palisa.
223 Rosa.....	" Mar. 10	Palisa.
224 Oceana	" Mar. 30	Palisa.
225 Henrietta	" Apr. 19	Palisa.
226 Weringia.....	" July 19	Palisa.
227 Philosophia.....	" Aug. 12	Prosper Henry.
228 Agathe	" Aug. 19	Palisa.
229 Adelina	" Aug. 22	Palisa.
230 Athamantis.....	" Sept. 3	L. de Ball.
231 Vindobonda	" Sept. 10	Palisa.
232 Russia	1883, Jan. 31	Palisa.
233.....	" May 11	Borelly.
234 Barbara.....	" Aug. 12	Peters.
235 Carolina.....	" Nov. 28	Palisa.
236 Honoria	1884, Apr. 26	Palisa.
237 Coelestine	" June 27	Palisa.
238 Hypatia.....	" July 1	Knorre.
239.....	" Aug. 18	Palisa.
240 Vanadis.....	" Aug. 27	Borelly.
241 Germania.....	" Sept. 12	Luther.
242 Kriemhild	" Sept. 22	Palisa.
243.....	" Sept. 29	Palisa.
244.....	" Oct. 14	Palisa.
245.....	" Oct. 27	Palisa.
246.....	1885, Mar. 14	Luther.

PLANTAMOUR, EMILE: 1815-82; b. and d. Geneva, Switzerland: graduated as doctor of philosophy at the univ. of Königsberg, Prussia, 1839. He became prof. of astronomy at the Geneva univ. and director of the observatory, member of the Geneva soc. of physics and of the British astronomical soc., and was chosen correspondent of the French institute, 1865. He was the author of a *Disquisition on the Methods of Determining the Orbits of Comets*; *Hypsometrical Measurements in the Alps*, 1860; *The Climate of Geneva*, 1863; *Experiments with the Reversion Pendulum*, 1866-72; and, together with Prof. Hirsh, he wrote a great work, in 5 vols., upon the *Exact Levels of Switzerland*, 1867-75.

PLATT, ORVILLE H.: b. Litchfield, Conn., 1834: was secretary of state of Conn., 1857-58; in state senate, 1861-62, and speaker of the house, 1869. He was elected as a repub. to the U. S. senate, 1879; re-elected, 1885.

PLATTSMOUTH: a city, cap. of Cass co., Neb., on the Missouri river, 22 m. directly s. of Omaha. The Burlington and Missouri River railroad passes through it. It has a national bank, 6 churches, 2 newspapers, and several manufactories. Pop. '80, 4,175.

*PLOW, PLOWING. Before the revolution there were but few plows in the colonies, and these mostly of the rough wooden sort. After the war great attention was given to improving agricultural implements. Thomas Jefferson experimented on the clumsy English bull-plow, 1788-93, and his son-in-law, Col. Randolph, invented the hill-side plow. In 1816 Jethro Wood of New York invented a cast-iron plow, much lighter and more easily managed than any previous implement of the kind. The shape of his mold-board has been but little improved, though subsequently it was made of steel, which greatly lessened the adhesion of the soil to its surface; and more recently the chilling process has been applied to it, increasing its durability. Great improvements have been made in lightening the weight and lessening the draft. The sulky plow has come much into use, with considerable advantages in lessening friction, and the labor of the plowman. Many varieties, adapted to various kinds of work, are in use, among them a light and serviceable modification of the double-furrow plow, described in the main article; a number of different forms of reversible hill-side plow, combination plow, and pulverizers; gang plows, which consist of two or more small plows, running side by side between wheels; and many others. But though American invention has done so much, this country is strangely behind in the use of the steam-plow, which has revolutionized plowing upon the large farms of England and Scotland, where there are now over 3,000 in use. They have been largely introduced also on the European continent, and in some countries of Asia, Africa, and South America. Some early attempts at steam-plowing were made in this country, which were failures, as were the early attempts in England. So much money was sunk in these abortive efforts that the idea of making steam-plowing practicable was abandoned. But as it has been practically demonstrated that with the later inventions of steam-plow, as described in the main article, not only can cheaper work be done upon large farms, but a deeper and more efficient cultivation be obtained, besides the saving of time and labor, it cannot be long before steam-plowing will come into general use in this country, especially upon the extensive western farms.

PLUMB, PRESTON B.: b. Delaware co., O., 1837. He learned the printing art, and removed to Kansas, 1856; was a member of the Leavenworth constitutional convention, 1859; was admitted to the bar, 1861; was in the state legislature, 1862. He entered the union army as second lieut. of the 11th Kansas infantry, and was promoted to lieut.-col. of that regiment. He was speaker of the Kansas house of representatives, 1867, and a member, 1868. He was sent as a repub. to the U. S. senate, 1877; and was re-elected, 1883.

PLYMOUTH: a borough in Luzerne co., Penn., on the Susquehanna river, and on the Lackawanna and Bloomsburg railroad. It contains 9 churches, a savings bank, a national bank, and 2 newspaper offices. Much coal is mined near here. Pop., mostly Welsh, Irish, and German, in '80, 6,065. In the early months of 1885, the place was ravaged by a peculiarly fatal form of typhoid fever, due to the pollution of its drinking-water.

*POLAR EXPEDITIONS. As nothing had been heard from the *Jeannette* expedition, the U. S. govt., in the summer of 1880, sent Capt. Hooper, in command of the *Corwin*, to look for it, and for several whaling ships in the polar seas, from which no tidings had come. Capt. Hooper returned, Oct. 12, having seen nothing of the missing vessels. In 1881 five expeditions were sent out by the U. S. The *Rodgers*, in charge of Lieut. Berry, was to find the *Jeannette*, and the whalers, *Mt. Wollaston* and *Vigilant*; the *Corwin*, under Capt. Hooper, and the *Alliance*, in charge of Commander Wadleigh, besides having other missions, were to aid in the search. In addition, two parties were sent to occupy the two international polar stations—one to Pt. Barrow and the other to Smith's sound. According to the agreement made at the International polar congress, held in 1880, Russia was to establish two stations; Norway, Sweden, Holland, Austria, and Denmark, one station each. The observations were to begin after 1881, Aug. 1, and to continue till 1883, Sept. 1. France and Germany sent parties to the south polar regions. There were to be meteorological, magnetic, electric, and pendulum observations. Lieut. Greely and party were landed at Lady Franklin bay, 1881, Aug. 11, and were to remain there till 1883. In the mean time news came from the *Jeannette* party; the ship had been crushed by ice, 1881, June 13, and part of the crew in two boats reached the mouth of the Lena river, made their way through northern Siberia to the Russian settlements, only 12 surviving the journey. In 1882 observations were being made at 15 of the polar stations. The relief expedition sent in 1882 to the Greely party failed to reach them on account of the ice, and again, in 1883, the expedition under Lieut. Garlington in the *Proteus* and *Yantic* failed. The *Proteus* was crushed by the ice, and after, with much difficulty, leaving 500 rations near Cape Sabine, Garlington and his men reached the *Yantic* and returned to St. John's, N. F. The Greely party having had no relief since they were sent out, their condition excited great anxiety and sympathy, and in 1884 three thoroughly equipped vessels were sent in search, finding and rescuing the starving remnant of the party—seven persons—June 22, near the mouth of Smith's sound. See GREELY, A. W.

*POLICE. In the U. S. the system of municipal P. is modelled after the English, the functions of these officers being limited to securing the person and property of law-abiding citizens. They are charged with the maintenance of public order, the suppression of crime, the investigation of offenses, the arrest of criminals, the collection of proof

against them, etc. But the duties of maintaining the safety of the state, of regulating the operations of trade and commerce, and of looking after the public health—all of which devolve upon the P. in many European countries, as in France, Germany, Austria, and Russia, are in this country delegated to other branches of the state and municipal government. While there are no general laws in the U. S. determining the duties and powers of the P., which even in their broad outlines are only a matter of state supervision, and in their details are regulated by local ordinances, nevertheless the system adopted throughout the country is essentially the same. A distinction is generally made between the rural P., which operates throughout the country districts, and the metropolitan P., which is constituted for large cities. Both these classes, indeed, have the same purposes, and are clothed with similar authority; but the duties of the latter are far more extensive and detailed. The P. system of New York may be taken as an example of the system established in all the larger cities. It is managed by four commissioners appointed by the mayor for a term of six years. They appoint all members of the force, from the superintendent down, and have the power of dismissal for cause shown. The superintendent is the chief executive officer. Immediately under him are four inspectors, one of whom is required to be at P. headquarters at night. For patrol service the city is divided into 34 preeincts, each having its own station-house, with quarters for the men, cells for prisoners, and lodgings for homeless applicants. The force of a preeinct consists of a capt., sergeants, roundsmen, and patrolmen. In the upper or suburban districts there are a number of mounted patrolmen. The duty of the roundsmen is to go the rounds and see that each patrolman is on his beat. All the police stations are connected by telegraphic wires with the central office, and the latter must at once be notified of any occurrence of special importance. The quota known as the 24th preeinct are assigned to harbor duty, and their headquarters are on a steam tug-boat provided for their use. The detective service (see DETECTIVES) has its headquarters at the central office, and is under command of an inspector. There are six police courts, for the summary trial of small offenses, or the preliminary hearing in graver cases. They are furnished with a squad of men, under command of a sergeant, who attend the courts, serving processes, etc.
