Abstract (reverse if necessary and identify by block number)

Naval Sea Systems Command (NAVSEA) initiated an investigation of the Tarawa class (LHA-1) superheater headers due to the reoccurrence of numerous cracks and leaks in the tube to header attachment welds.

A 3-dimensional solid finite element model was developed to simulate the superheater header geometry. ADINA, a finite element program for automatic dynamic incremental nonlinear analysis, is used to evaluate the stresses present in the header particularly the stresses that are present in the tube to header welds. The model that is used evaluates the stresses induced both pressure and thermal loadings. This is part of a continuing study of high pressure and high temperature boiler components.

I. INTRODUCTION

In recent years, the United States Navy has encountered problems with the superheater headers in the Combustion Engineering Company, type V2M, marine boilers that are fitted on the Tarawa class (LHA-1) ships. The problems encountered are numerous cracks and leaks that have developed in the tube to header attachment welds. This prompted Naval Sea Systems Command to begin an evaluation of these superheater headers in order to assess the cause of these failures and to generate corrective actions in order to minimize the down time of the ships and the cost of repairing these failures.

A 3-dimensional solid finite element model was developed using the ADINA program [Ref. 1: pp. 48-61] in order to perform a thermal stress analysis of the header in the region of the tube to header attachment welds.

This thesis will try to simulate, as close as can be determined, the actual conditions that the superheater headers are subjected to. This will include temperature dependent properties, combined loadings caused by boiler pressure coupled with a longitudinal temperature gradient and different initial temperatures of the header. The primary focus will be the induced stresses that are present in the tube to header attachment welds for 25° and 90° boiler loads.

II. DESCRIPTION OF THE PROBLEM

The Tarawa class (LHA-1) ships generate superheated steam for propulsion from two Combustion Engineering Company, type V2M, marine boilers. Each of these boilers are two drum, natural circulation, "D" type boilers fitted with an integral superheater, see Figure 1 on page 3. The boilers are rated at 628 psi with 904 degree F. superheater outlet conditions when operating at full power conditions.

The superheater is made up of 268 "U" shaped tubes that are inclined with the vertical and arranged such that there are 67 rows of tubes along the length of the header. The headers themselves are positioned such that they lie in a horizontal plane, see Figure 2 on page 4. The headers are 12.75 inch O.D. x 2.0 inch minimum wall thickness, 2.25 chrome pipe (ASME-SA-335-Grade P-22) and the tubes are 1.5 inch O.D. x 0.12 inch minimum wall thickness, seamless, 2.25 chrome tubing (MIL-T-16286, Class E) [Ref. 2: p. A-3]. The superheater is arranged such that once the steam has entered the superheater, it makes four passes before exiting (each pass consists of the steam flowing from the inlet-outlet header to the intermediate header or vice versa).

The tubes are lightly rolled into the tube holes of the header proper and then are seal welded internal to the header. These welds, referred to in this thesis as tube to header attachment welds, are the source of problems encountered that have prompted the investigation. The problems being linear defects that were discovered while performing magnetic particle inspections on the headers. The following description of the linear defects is a summary of the description given by Naval Sea Systems Command and those given by Lt. Doyle R. Kitchin [Ref. 1: p. 2]. The linear defects or cracks were oriented predominantly transverse to the longitudinal axis of the header; in other words, the cracks tended to propagate between tube to header attachment welds within the individual rows of tubes, but there were also a few exceptions where the crack propagated between tube to header attachment welds of adjacent rows. The majority of these linear defects were located in the inlet-outlet header as compared to the number of linear defects found in the intermediate header of the respective boiler. The linear defects found in the inlet-outlet header were concentrated in the first and the fourth passes (at the entrance and at the exit of the header). A more detailed description of the superheater geometry and the linear defects can be found in [Ref. 3: pp. 10 -15].

III. DESCRIPTION OF ADINA

ADINA, which stands for Automatic Dynamic Incremental Nonlinear Analysis, is a computer program that is designed to perform static and dynamic analysis in structural or solid mechanics, heat transfer, fluid flow, and other field problems that would lend themselves to a finite element analysis. ADINA uses a consistent set of units; forces are in pounds, stresses are in pounds per square inch, and displacements are in inches. The complete ADINA system consists of the programs ADINA for displacements and stress analysis, ADINA-F for the solution of fluid flow with heat transfer (ADINA-F was not used in this thesis and therefore it will not be discussed), ADINA-T for analysis of heat transfer in solids and structures and the solution of field problems, ADINA-IN for preparation and display of the input data and ADINA-PLOT for display of the calculated results [Ref. 4: p. 1]. The overall sequence of the ADINA system is shown in Figure 3 on page 6 which is taken from [Ref. 4: p. 2].

A. ADINA

The program ADINA [Ref. 4] is the central part of the ADINA system. ADINA is basically the problem solver of the ADINA system. ADINA performs the displacement and stress analysis for the given model. It is capable of generating a solution for static and dynamic, linear or nonlinear, problems in 1-dimension, 2-dimensions, or 3-dimensions.

ADINA has the capability of handling a varied selection of elements for different model geometries. ADINA will handle truss, 1-dimensional solid, 2-dimensional solid, 3-dimensional solid, isobeam, plate, shell, pipe, general spring, general mass stiffness, 2-dimensional and 3-dimensional fluid elements.

ADINA also has the capability of handling a wide variety of material types. It can handle elastic, orthotropic, thermo- elastic, concrete, plastic, thermo-plastic and fluid materials, just to name a few. These are easily programmed using simple commands.

ADINA allows the programmer to define contact surfaces. Contact surfaces are two or more surfaces that the programmer anticipates are in contact with each other or that could come into contact with each other during the solution of the problem.

ADINA will also perform a thermal stress analysis for a given model. ADINA uses the output form ADINA-T (which is discussed later) along with the proper material definition in order to perform these calculations.

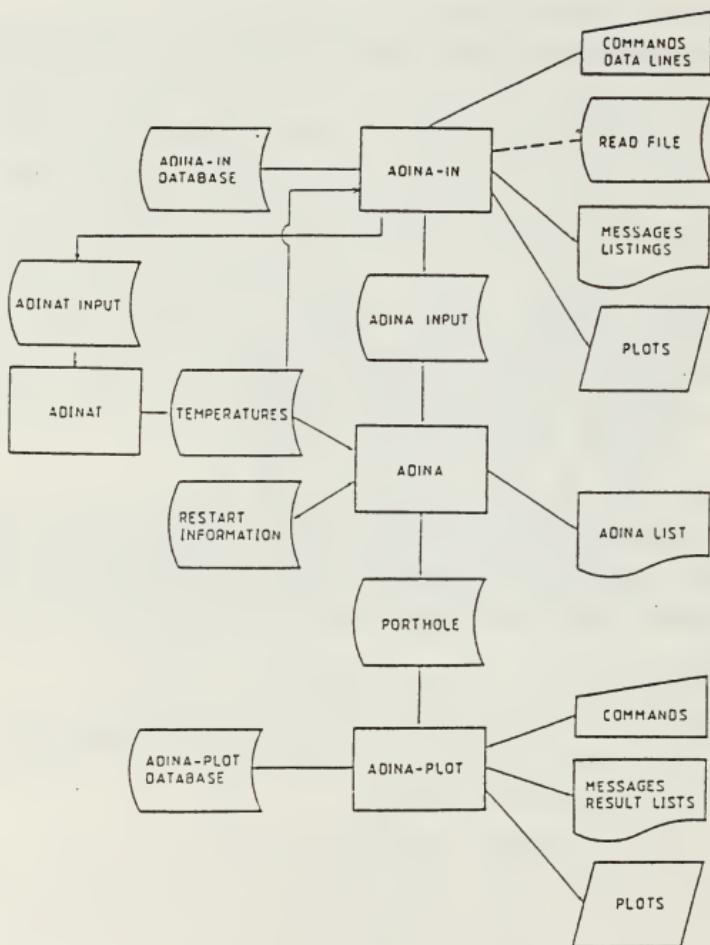

Figure 3. Sequence of execution of ADINA programs

Fracture mechanics, frequencies, mode shapes, and mode superpositions are other options that can be calculated from ADINA.

B. ADINA-IN

The preparation and checking of the input data for ADINA is done by the ADINA-IN portion of the ADINA system. ADINA-IN is the starting program for all models that are using the ADINA system. ADINA-IN can also be used to generate input data for the ADINA-T and ADINA-F programs. ADINA-IN can be used interactively or noninteractively (batch mode). The noninteractive option of ADINA-IN allows the programmer to define a large problem quite simply. This is done by writing an ADINA input file.

The ADINA input file is the file that contains all pertinent information about the model. This includes model coordinates, element types, material types, element loadings, type of analysis to be performed, contact surface definition, and boundary conditions. The model coordinates can be input in local or global coordinate systems using Cartesian, cylindrical, spherical or any combination of these. Meshes consisting of line, surface, or volume elements can be generated by the commands GLINE, GSURFACE, or GVOLUME respectively [Ref. 5: pp. 1-3]. These commands give the programmer the ability to define a minimal number of nodes in order to generate the model instead of having to define each nodal coordinate separately. ADINA-IN will automatically generate the rest of the nodes of the model based upon the type and number of nodes of the specified element that is used. ADINA-IN will also automatically number the rest of the nodes of the model.

The element loading can also be specified in the ADINA input file. The elements can be loaded in different ways; the LOADS ELEMENT command can be used to put pressure or distributed loads on the elements. The command LOADS TEMPERATURE or LOADS HEATFLUX can be used to describe the type of loading used in the heat transfer problem.

The type of material is also specified in the ADINA input file. Material types for the displacement, stress analysis or heat transfer problems are numerous, as mentioned previously. The versatility of the MATERIAL and the LOADS commands demonstrates how one input file for a given model can be used to solve a stress analysis, thermal stress analysis or heat transfer problem; it is just a matter of invoking the proper commands for the specific portion of the ADINA system that is to be used.

ADINA-IN also allows the programmer to take advantage of geometric symmetry in the given problem. If the geometry of the problem lends itself to that of a repeating section, ADINA-IN will allow the programmer to define the repeating section using the SUBSTRUCTURE command and then combine the same substructure numerous times using the REUSE command until the entire model is generated. There is one major disadvantage to using these commands and that is that only distributed or pressure loadings can be implemented in the problem.

ADINA-IN also has a graphics subroutine incorporated in it. The graphics standard used by ADINA-IN is GKS (Graphics Kernel System). This is a very useful tool to have because it allows the programmer to see what the model actually looks like at compilation time. In this way, the programmer can correct inaccuracies in the model prior to using another portion of the ADINA system. This graphics routine has the capability for hidden line removal which is very helpful when viewing a 3-dimensional model.

ADINA-IN will generate error messages as the errors are detected during the generation of the input data. In many cases, ADINA-IN takes corrective action in order to allow ADINA to be executed.

An optimization of the equation numbering is performed by ADINA-IN using the reverse Cuthill-McKee algorithm in order to reduce the bandwidth and profile of the stiffness and mass matrices [Ref. 5: pp. 1-5].

C. ADINA-T

ADINA-T, which stands for Automatic Dynamic Incremental Nonlinear Analysis of Temperatures, can be used for linear and nonlinear steady state or transient heat transfer problems to solve for the temperature distribution of a given model. ADINA-T is a compatible heat transfer analysis program to the stress analysis program ADINA. A specific feature of ADINA-T is that the same code can also be used to solve other field problems such as seepage, electric conduction, etc. [Ref. 6: pp. 1-2]. ADINA-T offers the programmer the ability to specify convection, radiation, temperatures, heatflux, initial conditions, or any combination of these as boundary conditions. ADINA-T offers the ability to utilize constant or temperature time dependent properties such as convection or conduction coefficients and if needed, phase changes can be incorporated into the model.

D. ADINA-PLOT

ADINA-PLOT [Ref. 7] is the portion of the ADINA system that is utilized for post-processing of resultant data from the ADINA program. ADINA-PLOT has the capacity to give the programmer graphics and display the results. The graphics standard used is the same as ADINA-IN, the Graphics Kernel System (GKS).

The graphics portion of ADINA-PLOT allows the programmer to see the undeformed model and the deformed model either as separate displays or on the same display. It also has the hidden line removal routine as does ADINA-IN but it must be kept in mind that hidden line removal is slow and is computationally expensive. ADINA-PLOT gives the programmer the ability to view the deformed and undeformed model in different colors; there is also a windowing feature that allows the programmer to zoom in on a particular part of the model.

The displaying of results can be accomplished in numerous ways. Results can be displayed in graphs, lists, scans or isobands. Graphs can be set up to show a comparison of any combination of results the programmer wishes. A listing of any of the results can be obtained and if the programmer wishes to see a listing of values that exceed a specified value, ADINA-PLOT will produce these using the scan feature. ADINA-PLOT will also produce plots of isobands in various colors, but presently, this is limited to 2-dimensional problems.

Further information about the ADINA system can be found in [Ref. 1].

IV. 3-DIMENSIONAL SOLID FINITE ELEMENT MODEL

The 3-dimensional model used in this thesis was developed by LCDR. Doyle R. Kitchin [Ref. 1: pp. 48-60]. The model was developed in order to study thermal stresses in the header. One tube row was chosen as the repeating section and this tube row was divided in half by passing a vertical plane through the tube row's longitudinal axis. The 3-dimensional model is shown in Figure 4 on page 11. The model consists of 288 elements and 1957 nodes. The element that was chosen for the model was the 20-node isoparametric solid element. Figure 5 on page 12 shows the 20-node isoparametric element. This element was chosen because it is able to approximate the curved geometry of the header. The following boundary conditions are imposed on the model. All nodes in the Y=0 plane were constrained to roll only within that plane. All of the nodes in the Z direction, from the origin, were fixed and the nodes in the positive X direction, from the origin, were constrained to roll only in the X direction.

The material of the header and tubes is considered to be 2.25 Chromium and 1.0 Molybdenum as discussed previously. An important assumption that must be understood is that the material used in the tube to header attachment weld is the same as the header and the tubes; it follows from this assumption that the weld properties are identical to those of the header and tubes.

Internal pressure applied to the header is assumed constant throughout the analysis. The internal pressure applied to the model is 700 psi, which is a worse case scenario of the operating conditions of the boiler [Ref. 3: p. 38].

A. PROGRAM SUPHTRTEMP.IN

Program SUPHTRTEMP.IN is a continuation from LCDR. Doyle R. Kitchin's model [Ref. 1: pp. 87-100]. In this program, the graphics portion for ADINA-IN was updated to the latest version of ADINA.

Program SUPHTRTEMP.IN is basically two programs incorporated into one ADINA input file. Program SUPHTRTEMP.IN is listed in Appendix A. The first portion of the program is to set up the data needed for ADINA-T in order to produce the temperature distribution of the header and the second portion of the program sets up the data needed by ADINA in order to produce the thermal stresses within the header. The procedure for executing Program SUPHTRTEMP.IN will be discussed later.

 XWIND 12.13
 YWIND -4.071
 YWIND 2.931

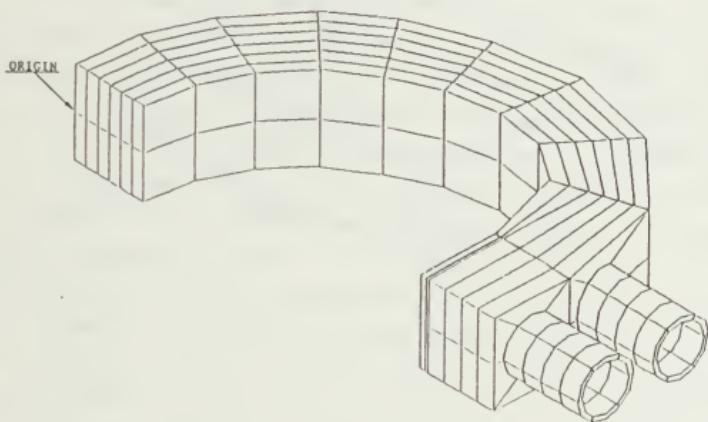

Figure 4. 3-Dimensional model of the repeating section

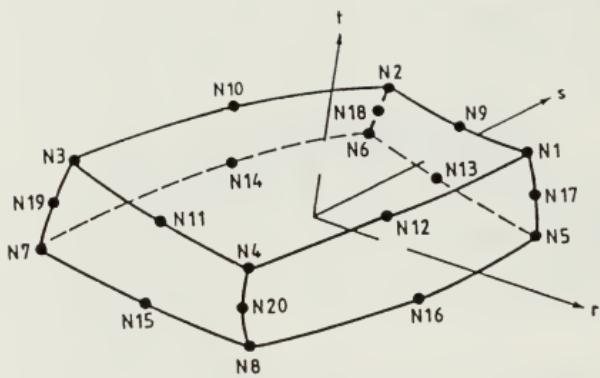

Figure 5. 20-node isoparametric element

The temperature portion of Program SUPHTRTEMP.IN is currently set up to perform a steady state analysis of the heat conduction equation [Ref. 6: pp. 3-5] in order to derive the temperature distribution of the header. This distribution is needed by ADINA for the thermal stress analysis. The thermal conductivity is not assumed to be constant during the solution of the temperature distribution; the values for the temperature dependence of thermal conductivity was taken from [Ref. 8: p. 652]. The reader is reminded that ADINA accepts temperature dependent thermal conductivity during the non linear part of the solution algorithm. The aspect of thermal conductivity being temperature dependent was introduced into the model to simulate the actual conditions that the header was subject to.

Four assumptions are made with respect to the temperature distribution of the header. First, the internal longitudinal temperature gradient of the header is assumed to be linear. This temperature gradient was derived by taking the difference between the inlet and outlet temperatures and dividing this by the distance between row 1 and row 67 of the header (the distance between row 1 and row 67 is 148.5 inches) [Ref. 2: Plan A-18]. The inlet temperature was taken to be 503 degrees F., which is the saturated steam temperature at 700 psi. The outlet temperature was taken from information provided by Naval Ship Systems Engineering Station, Philadelphia. Second, the longitudinal temperature gradient along the outside of the header was assumed to be linear. The same procedure was used to calculate the outside gradient applied to the model as the inside gradient discussed previously. The temperature data for the inlet and outlet regions of the outside of the header was also provided by Naval Ships Systems Engineering Station, Philadelphia. Third, the temperature gradient through the thickness of the header is assumed to be linear. Fourth, being that the tube thickness is relatively small compared to the header thickness, the tube is assumed to be at a constant temperature through the thickness. These assumptions were made in order to provide the boundary conditions for the solution of the heat conduction equation. The inner and outer temperature gradients provided the boundary conditions for the inner and outer surfaces of the model respectively. The thickness temperature gradient provides the boundary conditions for the edges of the model. These edge boundary conditions are derived by taking the difference between the inner and outer node temperatures of the respective edges. It should be noted that there are specified nodal temperatures at the midpoints of the model on both the inner and outer surfaces. At the two edges along the Y=0 plane, a value of heat flux equal to zero was imposed on the model unsuccessfully and therefore the linear temperature gradient assumption was assumed along these edges.

In actual practice, these boilers are kept on a 150 psi steam blanket (or close to this condition) when the boilers are secured. With this idea in mind, a 350 degree F. initial condition was placed on the header to simulate actual light off conditions of the boiler (350 degrees F. corresponds to a saturated steam temperature of 150 psi steam). This is an important concept in the conclusions of this thesis.

The second portion of Program SUPHTRTEMP.IN is set up to perform a static thermal stress analysis of the header. In this portion, the temperature distribution is used along with the internal pressure of the header in order to perform the thermal stress analysis. The two loading aspects, thermal and pressure, simulate the actual loading of the header. The only aspect of loading that is not incorporated into this model is the weight of the header; the reason that this condition was left out is discussed in the section that describes Program SUPHTR.IN. Pressure loading is only prescribed on the inner faces of the inner elements of the header in order to simulate the actual pressure loading. The thermo-elastic material selection was chosen for this model due to the fact that Young's Modulus and the linear coefficient of thermal expansion are both temperature dependent. It was felt that using this temperature dependency in the model would add some realism of the actual conditions that the header is subjected to. The data for how Young's Modulus varies with temperature for 2.25 Chromium and 1.0 Molybdenum was supplied by Naval Ship Systems Engineering Station, Philadelphia, but the data for how the linear coefficient of thermal expansion varied was taken from [Ref. 8: p. 653]. Contact surfaces are defined for the model due to the fact that the tube to header interface cannot be considered rigid. Even though the tube is welded to the header on the inner part of the header, the remaining length of the tube through the header is left free to movement. Contact surfaces are defined by ADINA as being surfaces that initially are in contact or that are anticipated to come into contact during the solution [Ref. 5: p. 5.19-2].

ADINA can use numerous types of convergence criteria. Normally by default, an energy convergence criteria [Ref. 5: p. 5.2-48] is used, but when contact surfaces are defined in a problem, convergence is also contingent upon the convergence of the contact surface forces [Ref. 5: p. 5.2-50]. For a small temperature change across the thickness of the header (10-20 degrees), the default contact surface force tolerance of 0.05 is satisfactory. If there is a large temperature change across the thickness of the header (80-100 degrees), the default contact surface force tolerance was too stringent. The program was running up to 90 or more hours on the VAX 2000 station trying to solve the problem. Therefore, it was decided to try to bracket the contact surface tolerance.

The values between 0.075 and 0.15 were found to yield 0.32 and 0.00 percent differences respectively when compared to the results of a tolerance of 0.1; the run time for these values were 30.7 and 22.9 hours respectively, a significant decrease as compared to the time at 0.05 tolerance. The tolerance of 0.075 was chosen to be used in the solution of the problem.

B. PROGRAM SUPHTRTEMP.PLOT

Program SUPHTRTEMP.PLOT is a program written in order to utilize ADINA-PLOT capabilities; a listing of Program SUPHTRTEMP.PLOT is in Appendix B. Program SUPHTRTEMP.PLOT is presently set up to give the user the normal and shear stress values for integration points of the elements that simulate the tube to header weld. Figure 6 on page 16 shows the tube to header arrangement as modeled. The tube to header weld is simulated as being the lower nodal points of the modeled tube, also as shown in Figure 6. The elements that model the lower tubes are elements 55 through 60 for the inner tube and elements 115 through 120 for the outer tube. Program SUPHTRTEMP.PLOT is also set up so that a file called SUPHTRTEMP.LIST is created that gives the stress values of the integration points for these elements. Along with these values, Program SUPHTRTEMP.PLOT will produce the undeformed header versus the deformed header superimposed upon each other in the same picture so an immediate comparison of the header before and after can be viewed.

C. PROGRAM SUPHTR.IN

The original direction of this thesis was to study the entire superheater inlet outlet header. Program SUPHTR.IN was the ADINA input file created to model the entire header; a listing of Program SUPHTR.IN is given in Appendix C. The use of the SUBSTRUCTURE and REUSE commands can be seen in the program. A main structure of the header was first defined. This consisted of defining the four corner nodal points of the repeating section in the Y=0 plane and then defining nodal points along the Z axis, also in the Y=0 plane, that would correspond to the corner points of the model spaced at a model's width apart. The main portion of the model is defined by the command SUBSTRUCTURE 0. The repeating section is defined by the command SUBSTRUCTURE 1. Now the REUSE command could be employed to link the model together to form the entire model (this program only models two repeating sections ~~linked~~ together). ADINA allows the programmer to utilize the REUSE command up to 100 times for a given substructure within the main structure [Ref. 5: p. 5.22-4].

ADINA ORIGINAL

XMIN -2.000
XMAX 0.
YMIN 0.
YMAX 2.250

Z
Y

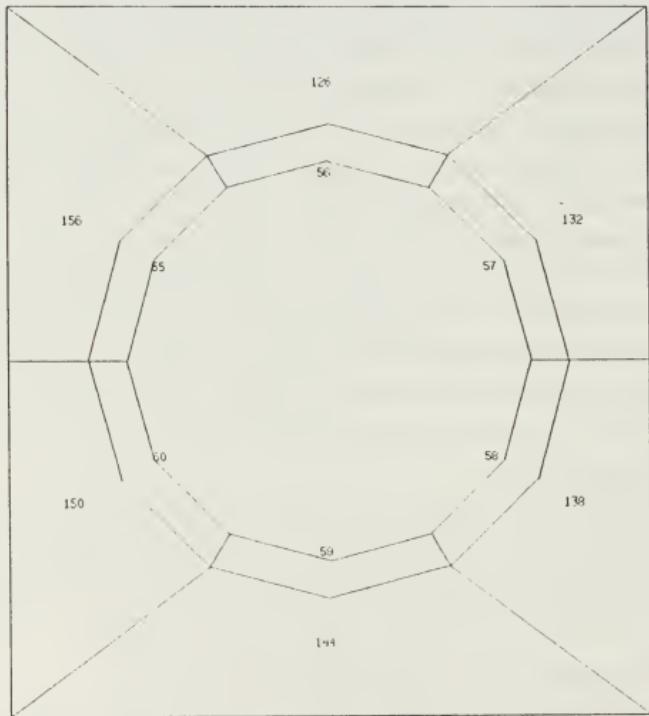

Figure 6. Tube to header arrangement

The program had to be abandoned due to the fact that ADINA is presently limited as to the types of problems that can be solved using the SUBSTRUCTURE and REUSE commands. Only problems using pressure or concentrated loadings can be solved using this technique. Problems using contact surfaces and thermal loads, as this thesis is involved with, can not be solved using the SUBSTRUCTURE and REUSE commands [Ref. 5: p. 5.22-2 and 5.22-3]. Therefore this thesis is restricted to evaluating specific regions of the inlet outlet header.

D. PROCEDURES FOR USING SUPHTRTEMP.IN AND SUPHTRTEMP.PLOT

These programs are set up to be used with the VAX/VMS operating system. It should be understood that any logical file name can be given to these files, but for the operation of ADINA, the ADINA input file must be named FILENAME.IN and the plot program must be named FILENAME.PLOT.

To run the problem, first the temperature distribution must be created. To do this, enter the editor with the ADINA input file SUPHTRTEMP.IN and place the corresponding nodal temperatures in the proper TIMEFUNCTION commands. Ensure that all data for ADINA is commented out (these areas can be found easily as there are instructions throughout Program SUPHTRTEMP.IN with the corresponding line numbers that tell which sections are needed for ADINA-T and ADINA). Also at the end of the file, there are two commands ADINA-T and ADINA. The command ADINA must be commented out in order to run ADINA-T. Exit the editor (saving this version of the input file) and at the system prompt, type @ADINAIN FILENAME. This runs ADINA-IN and will create a file named FILENAME.DAT. This is the data file that ADINA-T uses; again at the system prompt, type @ADINAT FILENAME. ADINA-T is now solving the temperature distribution. It is very important to note that all of the ADINA programs create numerous FOR*.DAT files during their respective operations. At the end of their respective runs, all of the FOR*.DAT file are automatically deleted. FOR056.DAT is the data file that contains the temperature distribution that is needed by ADINA to solve the thermal stress problem. The user should ensure that his/her ADINA-T command file is modified to rename FOR056.DAT to another name. I chose to modify my ADINA-T command file to rename FOR056.DAT to SUPHTRTEMP TEMP.

After ADINA-T is completed, if you look in your directory, you will see that there are the following files, FILENAME.IN, FILENAME.DAT, FILENAME.PLOT, FILENAME.OUT, FILENAME.PORHOLE, FILENAME.TEMP, and

FILENAME.RESTART. Delete from the directory FILENAME.DAT, FILENAME.OUT, FILENAME.PORTHOLE, and FILENAME.RESTART. Enter the editor again with the ADINA input file FILENAME.IN. Comment out all the sections that are used with ADINA-T and comment in the sections that are used in ADINA. Comment out the command ADINA-T and comment in the command ADINA at the end of the file. Exit the editor (saving this version of FILENAME.IN). At the system prompt, type @ADINAIN FILENAME. This is creating FILENAME.DAT that will be the data file used by ADINA. After this is finished and the prompt appears, rename FILENAME.TEMP to FOR056.DAT. Now you are ready for ADINA: at the system prompt, type @ADINA FILENAME. ADINA is now solving the problem.

When ADINA is finished and the system prompt appears, type @ADINAPLOT FILENAME. This will execute FILENAME.PLOT, which will read the file FILENAME.PORTHOLE; FILENAME.PORTHOLE contains all the data of the problem. The results of the problem will be displayed. FILENAME.PLOT will also create a file named FILENAME.LIST, which contains the thermal stresses of the simulated tube to header attachment weld nodes. There is also a file named FILENAME.OUT created. This file contains all of the model data, initial conditions of the model, final nodal displacements and final nodal stresses for all of the nodes for the entire model. The actual run time of the ADINA problem can also be found in FILENAME.OUT at the end of the file.

If you wish to create a graphics file of the model, set OPTION=0 in the WORKSTATION command of FILENAME.IN and FILENAME.PLOT. If the graphics are preferred on the screen, set OPTION=1 in the WORKSTATION command.

V. RESULTS

As previously discussed, the entire superheater header could not be modeled. Therefore, it was decided that a modeled section in the first pass and a modeled section in the fourth pass would be used. The modeled section of the first pass was taken to be row 1 and for the fourth pass row 67 was used. The selection of these two rows was based on the fact that the inlet and outlet steam temperatures for the superheater header can be readily determined. It was also decided that system behavior at two steam flows would be evaluated, 25 percent and 90 percent steam flows. These steam flows seemed to yield the two extremes with respect to the inner and outer temperature gradients and the temperature gradient through the thickness of the header. Therefore for the 25 percent steam flow condition, a model of row 1 and a model of row 67 were evaluated and similarly for the 90 percent steam flow. There was one other model run; this was row 1 for 25 percent steam flow with the header starting from a 0 degree F. initial condition and a comparison was made to the same model except that a 350 degree F. initial condition was imposed on the model.

It must be understood that the stress values that are represented in this thesis are not nodal point stresses. They are the respective element integration point stresses for the 3-dimensional isoparametric element.

It also needs to be stated that the temperature data from Naval Ship Systems Engineering, Philadelphia for the first and fourth passes of the inlet outlet header was not very detailed. The temperature data used in this thesis was for the worst case temperature readings from this information.

As the following discussion of integration point stresses for the simulated elements for the tube to header attachment weld continues, refer to Figure 6 on page 16 in order to have a perspective of the geometry and location of the elements for the inner tube of the header. The same geometry consists for the outer tube of the header but with different element numbers.

A. 25 PERCENT STEAM FLOW

An inner longitudinal temperature gradient of 2.356 degrees F. per inch and an outer longitudinal temperature gradient of 1.911 F. degrees per inch were imposed on the model. A linear 10 degree temperature gradient was imposed on the upstream edge of the model for row 1. The temperature gradient on the downstream edge of the model

for row 1 was also assumed to be linear except these temperatures were defined by the inner and outer edge values of the model once the longitudinal temperature gradients inside and outside the model were imposed. The temperature gradients imposed on the model for row 67 were determined the same way except for the temperature gradients on the edges. There was an 80 degree temperature gradient imposed on the downstream edge of the model and the upstream edge temperatures were determined in the same manner as the downstream edge of the model for row 1. The tubes were assumed to have a uniform temperature of 503 F. degrees for the row 1 model and 850 degrees F. for the row 67 model.

The model for row 1 was run for a 0 degree F. initial condition and for a 350 degree F. initial condition of the header. As can be seen from Appendix D and Appendix E, the integration point stress values for the respective elements were the same, but for the sake of simulating the 150 psi steam layup of the boilers, it was decided to use the 350 degree initial condition for the rest of the evaluations.

The most significant result that can be drawn from this data is the very high values of the normal stresses in the Y direction for the majority of the integration points for elements 56 and 59 of the inner tube. Values above 40,000 psi are considered significant by this author. The value of 40,000 psi was used because it seems to represent an average value of yield stress. For the given steam flow, normal stresses in the Y direction of $6.35807E+04$ and $6.28656E+04$ were encountered for elements 56 and 59 respectively for the row 1 model. Values of $8.56997E+04$ and $8.43748E+04$ were encountered for elements 56 and 59 respectively for the row 67 model. The rest of the elements simulating the weld had integration point stress values below 40,000 psi. The elements simulating the weld for the outer tube also were found to have integration point stress values below the 40,000 psi value. These values can be seen in Appendix E and Appendix F.

The deformed versus the undeformed header can be seen in Figure 7 on page 22 for the row 1 model and Figure 8 on page 23 for the row 67 model respectively. The undeformed header is represented by the solid lines and the deformed header is shown with dotted lines. It should be noted that both figures look exactly the same, but there are differences in nodal point displacements. These differences are too small to show any significant change in the figures.

B. 90 PERCENT STEAM FLOW

An inner longitudinal temperature gradient of 2.54 degrees F. per inch and an outer longitudinal temperature gradient of 2.0 degrees F. per inch were imposed on the model. A linear 20 degree temperature gradient was imposed on the upstream edge of the model for row 1 and a 100 degree temperature gradient was imposed on the downstream edge of the model for row 67. The same procedure was used for assigning temperatures for the downstream edge of the row 1 model and the upstream edge of the row 67 model as was done for the 25 percent steam flow case. The tubes were also assumed to have uniform temperatures of 503 degrees F. for the row 1 model and 880 degrees F. for the row 67 model.

It was found again that elements 56 and 59 of the inner tube had normal integration point stresses in the Y direction above the 40,000 psi value. This data can be seen in Appendix G for the row 1 model and Appendix H for the row 67 model. For the row 1 model, normal integration point stresses in the Y direction were as high as $6.12707E+04$ and $6.05892E+04$ for elements 56 and 59 respectively for the inner tube. For the row 67 model, the inner tube normal integration point stresses in the Y direction were as high as $8.39943E+04$ and $8.26567E+04$ for elements 56 and 59 respectively. As was the case for the 25 percent steam flow, the elements that simulated the weld for the outer tube were all found to have integration point stresses less than the 40,000 psi value.

The deformed versus the undeformed header can be seen in Figure 9 on page 24 for the row 1 model and Figure 10 on page 25 for the row 67 model. It should also be kept in mind that even though the figures look the same, there is a small difference in the nodal point displacements that are not able to be seen in these two figures.

VI. CONCLUSIONS

A. DISCUSSION OF THE RESULTS

The results have shown that there is definitely a problem region located in elements 56 and 59 of the simulated tube to header attachment weld for the inner tube, please refer to Figure 6 on page 16 to see these locations. It is believed the linear defects start within these elements. These boilers are operated in such a manner that steady state steaming is not always maintained. The steam flow rates are quite often varied in a cyclic way; by no means does the author intend that the cyclic pattern is repeated the same way each time. It is due to the cyclic steam flow rates and the high values of the stresses found in the simulated weld elements that leads to the idea that low cycle fatigue is present within these headers. It is also the author's belief that once the defect is initiated, that the stress distribution changes within the tube to header attachment weld thereby locating these high stress values at a different location where another defect can start.

The results also show that the temperature gradient across the thickness of the header along with the longitudinal temperature gradient effects the stress levels induced in the header. As can be seen, the integration point stresses are higher for the 25 percent steam flow when compared to the 90 percent steam flow, but in both cases, elements 56 and 59 of the inner tube do exhibit normal integration point stresses in the Y direction that are high.

It is also the author's belief that the 150 psi steam blanket placed on the idle boilers provides a type of stress relief to the tube to header attachment weld. This coupled with the redistribution of the stresses in the header, once a defect develops, could explain why it takes a period of time for numerous defects to appear.

As a final comment to the reader, one must keep in mind that the stress values presented in this thesis are stresses at the Gauss integration points within each element. These values do seem excessive until one remembers that the nodal point stresses are extrapolated from their neighboring integration point stresses. Until these extrapolated nodal point stresses are calculated and reviewed, it will be hard to determine whether the stresses in these headers are marginal or excessive. An extrapolation program was not developed in this investigation due to time limitations. Convergence studies have not been formally conducted in this investigation due to time limitations.

B. OPPORTUNITIES FOR FURTHER RESEARCH

The ADINA program is a versatile finite element program, but it does have some disadvantages. One such disadvantage is that if the programmer uses any material other than elastic, orthotropic or Mooney-Rivlin material, a nodal stress output table cannot be generated. All of the stresses that have been discussed in this thesis deal with stresses that are present at the Gauss integration points of the elements. The next step in this research would be to develop a 3-dimensional computer program that would extrapolate the nodal point stresses from the Gauss integration point stresses. To do this, the coordinates of the integration points needs to be known. Figure 11 on page 28 shows an example of integration point labeling used by ADINA for a 3-dimensional solid element. It should be kept in mind that this figure is not representative of the 20 node isoparametric element used in this thesis. Figure 12 on page 29 shows the coordinates of the Gauss integration point numbering system. The convention for the integration point numbering is as follows. The first integration of the element is the point with the most negative location of r, s and t and this is denoted by INR = 1, INS = 1, INT = 1. The next integration point is located by increasing t successively up to its maximum positive value, then increasing s one position in the positive direction and varying t from its maximum negative value to its maximum positive value, and so on [Ref. 4: pp. XIII-14 to XIII-17]. With the integration point coordinates and the integration point stresses for the elements, the nodal point stresses can be extrapolated.

A steady state analysis was performed in this thesis, but the transient temperature loading should be evaluated. In order to do the transient loading, or even a more accurate steady state analysis, better temperature data needs to be obtained along the entire length of the header so that less assumptions are made and more actual conditions can be incorporated into the model.

A defect should be modeled into the tube to header attachment weld and the stress redistribution of the header evaluated again. Another area of research could be the study of creep within the header. Further research should also incorporate a pressure gradient across the header in order to simulate the increase in steam flow rates.

This report has attempted to incorporate as much of the actual environment of the superheater header as was permissible in the given time allotted for this research. It is hoped that further investigations can be made in order to solve this problem and any other similar problems that may be encountered.
